Since the root VDOM is in virtual cluster 1 and the Eng_vdm VDOM is in virtual cluster 2 the result of this configuration will be that 620_ha_1 will process all root VDOM traffic and 620_ha_2 will process all Eng_vdm traffic. You make this happen by changing the cluster unit device priorities for each virtual cluster. You could use the following settings:

	Device Priority	
Host Name	**Virtual Cluster 1**	**Virtual Cluster 2**
620_ha_1	200	100
620_ha_2	100	200

Since the device priority is not synchronized you can edit the device priorities of each virtual cluster on each FortiGate unit separately. To do this:

- Log into the CLI and note the FortiGate unit you have actually logged into (for example, by checking the host name displayed in the CLI prompt).
- Change the virtual cluster 1 and 2 device priorities for this cluster unit.
- Then use the `execute ha manage` command to log into the other cluster unit CLI and set its virtual cluster 1 and 2 device priorities.

Enter the following commands from the 620_ha_1 cluster unit CLI:

```
config global
  config system ha
    set priority 200
      config secondary-vcluster
        set priority 100
      end
  end
end
```

Enter the following commands from the 620_ha_2 cluster unit CLI:

```
config global
  config system ha
    set priority 100
      config secondary-vcluster
        set priority 200
      end
  end
```

```
end
```

The cluster may renegotiate during this step resulting in a temporary loss of connection to the CLI and a temporary service interruption.

Since the device priority of Virtual Cluster 1 is highest for 620_ha_1 and since the root VDOM is in Virtual Cluster 1, all traffic for the root VDOM is processed by 620_ha_1.

Since the device priority of Virtual Cluster 2 is highest for 620_ha_2 and since the Eng_vdm VDOM is in Virtual Cluster 2, all traffic for the Eng_vdm VDOM is processed by 620_ha_2.

To verify the VDOM partitioning configuration

1 Log into the 620_ha_2 cluster unit CLI and enter the following command:

```
config global
  get system ha status
    Model: 620
    Mode: a-p
    Group: 0
    Debug: 0
    ses_pickup: disable
    Slave :100 620_ha_2         FG600B3908600825 0
    Master:200 620_ha_1         FG600B3908600705 1
    number of vcluster: 2
    vcluster 1: standby 169.254.0.2
    Slave :1 FG600B3908600825
    Master:0 FG600B3908600705
    vcluster 2: work 169.254.0.1
    Master:0 FG600B3908600825
    Slave :1 FG600B3908600705
```

The command output shows that 620_ha_1 is the primary unit for virtual cluster 1 (because the command output show the `Master` of virtual cluster 1 is the serial number of 620_ha_1) and that 620_ha_2 is the primary unit for virtual cluster 2.

If you enter the same command from the 620_ha_1 CLI the same information is displayed but in a different order. The command always displays the status of the cluster unit that you are logged into first.

```
config global
  get system ha status
    Model: 620
    Mode: a-p
    Group: 0
    Debug: 0
    ses_pickup: disable
    Master:200 620_ha_1         FG600B3908600705 1
    Slave :100 620_ha_2         FG600B3908600825 0
    number of vcluster: 2
    vcluster 1: work 169.254.0.2
    Master:0 FG600B3908600705
    Slave :1 FG600B3908600825
    vcluster 2: standby 169.254.0.1
    Slave :1 FG600B3908600705
    Master:0 FG600B3908600825
```

To test the VDOM partitioning configuration

You can do the following to confirm that traffic for the root VDOM is processed by 620_ha_1 and traffic for the Eng_vdm is processed by 620_ha_2. These steps assume the cluster is operating correctly.

1. Log into the CLI by connecting to port2 using IP address 10.11.101.100.

   You will log into 610_ha_1 because port2 is in the root VDOM and all traffic for this VDOM is processed by 610_ha_1. You can confirm that you have logged into 610_ha_1 by checking the host name in the CLI prompt. Also the `get system status` command displays the status of the 610_ha_1 cluster unit.
2. Log into the web-based manager or CLI by connecting to port6 using IP address 10.12.101.100.

   You will log into 610_ha_2 because port6 is in the Eng_vdm VDOM and all traffic for this VDOM is processed by 610_ha_2.
3. Add security policies to the root virtual domain that allow communication from the internal network to the Internet and connect to the Internet from the internal network.
4. Log into the web-based manager and go to *Config* > *System* > *HA* and select *View HA Statistics*.

   The statistics display shows more active sessions, total packets, network utilization, and total bytes for the 620_ha_1 unit.
5. Add security policies to the Eng_vdm virtual domain that allow communication from the engineering network to the Internet and connect to the Internet from the engineering network.
6. Log into the web-based manager and go to *Config* > *System* > *HA* and select *View HA Statistics*.

   The statistics display shows more active sessions, total packets, network utilization, and total bytes for the 620_ha_2 unit.

Example: inter-VDOM links in a virtual clustering configuration

In a virtual domain configuration you can use inter-VDOM links to route traffic between two virtual domains operating in a single FortiGate unit without using physical interfaces. Adding an inter-VDOM link has the affect of adding two interfaces to the FortiGate unit and routing traffic between the virtual domains using the inter-VDOM link interfaces.

In a virtual clustering configuration inter-VDOM links can only be made between virtual domains that are in the same virtual cluster. So, if you are planning on configuring inter-VDOM links in a virtual clustering configuration, you should make sure the virtual domains that you want to link are in the same virtual cluster.

For example, Table 114 and Table 115 show an example virtual clustering configuration where each virtual cluster contains three virtual domains. In this configuration you can configure inter-VDOM links between root and vdom_1 and between vdom_2 and vdom_3. But, you cannot configure inter-VDOM links between root and vdom_2 or between vdom_1 and vdom_3 (and so on).

Table 114: Virtual Cluster 1 configuration

Virtual Domains	Hostname	
	FortiGate_A	FortiGate_B
root vdom_1	**Priority** 200	**Priority** 100
	Role Primary	**Role** Subordinate

Table 115: Virtual Cluster 2 configuration

Virtual Domains	Hostname	
	FortiGate_A	FortiGate_B
vdom_2 vdom_3	**Priority** 100	**Priority** 200
	Role Subordinate	**Role** Primary

Configuring inter-VDOM links in a virtual clustering configuration

Configuring inter-VDOM links in a virtual clustering configuration is very similar to configuring inter-VDOM links for a standalone FortiGate unit. The main difference the `config system vdom-link` command includes the `vcluster` keyword. The default setting for `vcluster` is `vcluster1`. So you only have to use the `vcluster` keyword if you are added an inter-VDOM link to virtual cluster 2.

To add an inter-VDOM link to virtual cluster 1

This procedure describes how to create an inter-VDOM link to virtual cluster 1 that results in a link between the root and vdom_1 virtual domains.

Inter-VDOM links are also called internal point-to-point interfaces.

1 Add an inter-VDOM link called `vc1link`.

```
config global
  config system vdom-link
  edit vc1link
end
```

Adding the inter-VDOM link also adds two interfaces. In this example, these interfaces are called `vc1link0` and `vc1link1`. These interfaces appear in all CLI and web-based manager interface lists. These interfaces can only be added to virtual domains in virtual cluster 1.

2 Bind the `vc1link0` interface to the root virtual domain and bind the `vc1link1` interface to the vdom_1 virtual domain.

```
config system interface
  edit vc1link0
      set vdom root
  next
  edit vc1link1
    set vdom vdom_1
  end
```

To add an inter-VDOM link to virtual cluster 2

This procedure describes how to create an inter-VDOM link to virtual cluster 2 that results in a link between the vdom_2 and vdom_3 virtual domains.

3 Add an inter-VDOM link called `vc2link`.

```
config global
  config system vdom-link
    edit vc2link
      set vcluster vcluster2
    end
```

`Adding the inter-VDOM link also adds two interf`aces. In this example, these interfaces are called `vc2link0` and `vc2link1`. These interfaces appear in all CLI and web-based manager interface lists. These interfaces can only be added to virtual domains in virtual cluster 2.

4 Bind the `vc2link0` interface to the vdom_2 virtual domain and bind the `vc2link1` interface to the vdom_3 virtual domain.

```
config system interface
  edit vc2link0
    set vdom vdom_2
  next
  edit vc2link1
    set vdom vdom_3
  end
```

Troubleshooting virtual clustering

Troubleshooting virtual clusters is similar to troubleshooting any cluster (see "Troubleshooting HA clusters" on page 2083). This section describes a few testing and troubleshooting techniques for virtual clustering.

To test the VDOM partitioning configuration

You can do the following to confirm that traffic for different VDOMs will be distributed among both FortiGate units in the virtual cluster. These steps assume the cluster is otherwise operating correctly.

1 Log into the web-based manager or CLI using the IP addresses of interfaces in each VDOM.

Confirm that you have logged into the FortiGate unit that should be processing traffic for that VDOM by checking the HTML title displayed by your web browser or the CLI prompt. Both of these should include the host name of the cluster unit that you have logged into. Also on the system Dashboard, the System Information widget displays the serial number of the FortiGate unit that you logged into. From the CLI the `get system status` command displays the status of the cluster unit that you logged into.

2 To verify that the correct cluster unit is processing traffic for a VDOM:

- Add security policies to the VDOM that allow communication between the interfaces in the VDOM.
- Optionally enable traffic logging and other monitoring for that VDOM and these security policies.
- Start communication sessions that pass traffic through the VDOM.
- Log into the web-based manager and go to *Config* > *System* > *HA* and select *View HA Statistics*. Verify that the statistics display shows more active sessions, total packets, network utilization, and total bytes for the unit that should be processing all traffic for the VDOM.
- Optionally check traffic logging and the Top Sessions Widget for the FortiGate unit that should be processing traffic for that VDOM to verify that the traffic is being processed by this FortiGate unit.

Configuring and operating FortiGate full mesh HA

This chapter provides an introduction to full mesh HA and also contains general procedures and configuration examples that describe how to configure FortiGate full mesh HA.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameters.

This chapter contains the following sections:

Full mesh HA overview

When two or more FortiGate units are connected to a network in an HA cluster the reliability of the network is improved because the HA cluster replaces a single FortiGate unit as a single point of failure. With a cluster, a single FortiGate unit is replaced by a cluster of two or more FortiGate units.

However, even with a cluster, potential single points of failure remain. The interfaces of each cluster unit connect to a single switch and that switch provides a single connection to the network. If the switch fails or if the connection between the switch and the network fails service is interrupted to that network.

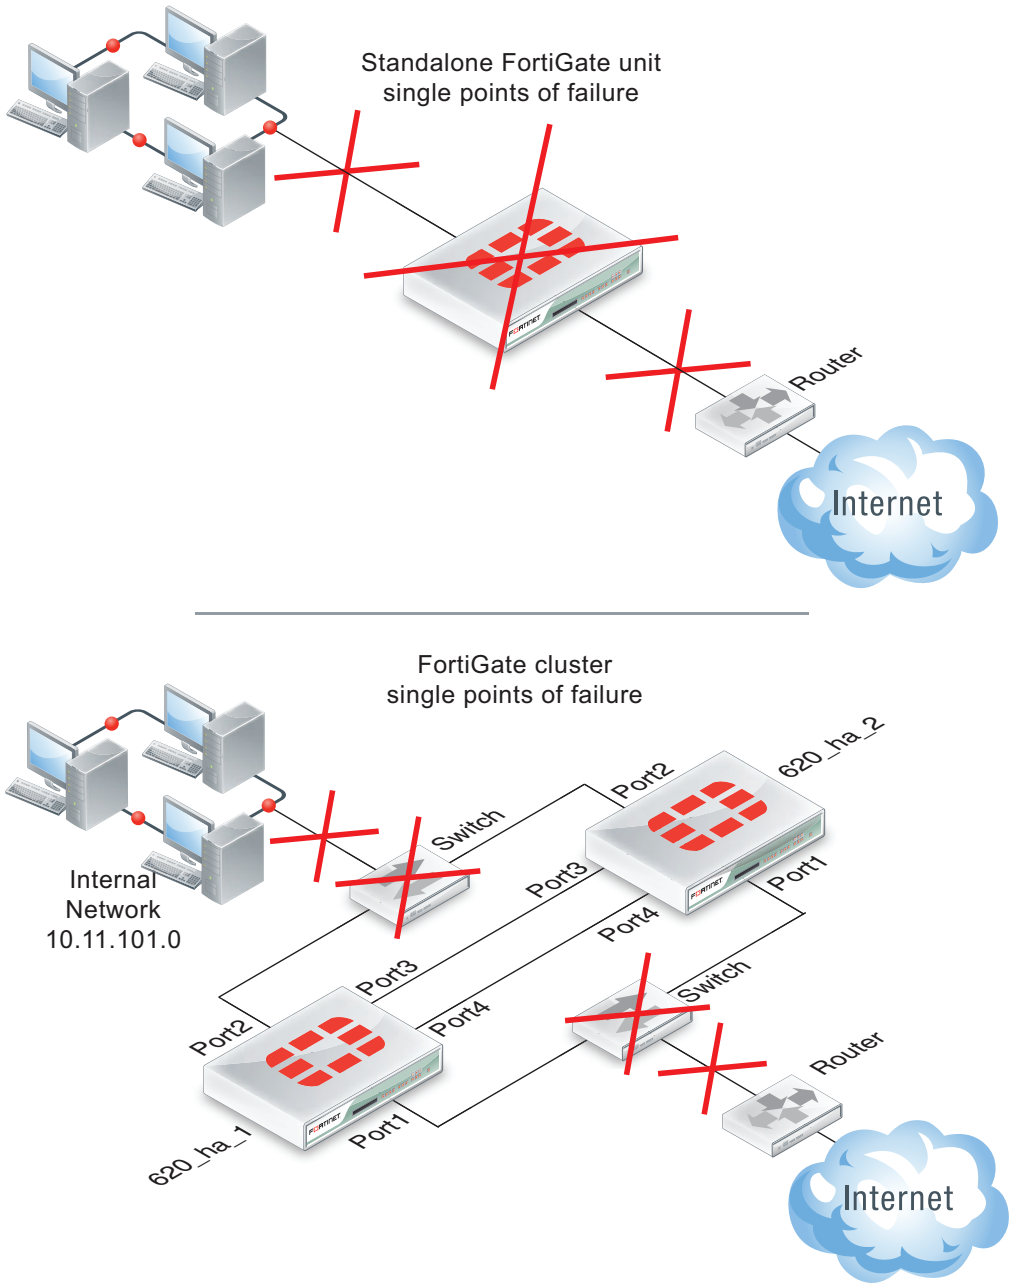
The HA cluster does improve the reliability of the network because switches are not as complex components as FortiGate units, so are less likely to fail. However, for even greater reliability, a configuration is required that includes redundant connections between the cluster the networks that it is connected to.

FortiGate models that support 802.3ad Aggregate or Redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster.

This redundant configuration can be achieved using FortiGate 802.3ad Aggregate or Redundant interfaces and a full mesh HA configuration. In a full mesh HA configuration, you connect an HA cluster consisting of two or more FortiGate units to the network using 802.3ad Aggregate or Redundant interfaces and redundant switches. Each 802.3ad Aggregate or Redundant interface is connected to two switches and both of these switches are connected to the network.

The resulting full mesh configuration, an example is shown in Figure 207, includes redundant connections between all network components. If any single component or any single connection fails, traffic automatically switches to the redundant component and connection and traffic flow resumes.

Figure 207: SIngle points of failure in a standalone and HA network configuration



Full mesh HA and redundant heartbeat interfaces

A full mesh HA configuration also includes redundant HA heartbeat interfaces. At least two heartbeat interfaces should be selected in the HA configuration and both sets of HA heartbeat interfaces should be connected. The HA heartbeat interfaces do not have to be configured as redundant interfaces because the FGCP handles failover between heartbeat interfaces.

Full mesh HA, redundant interfaces and 802.3ad aggregate interfaces

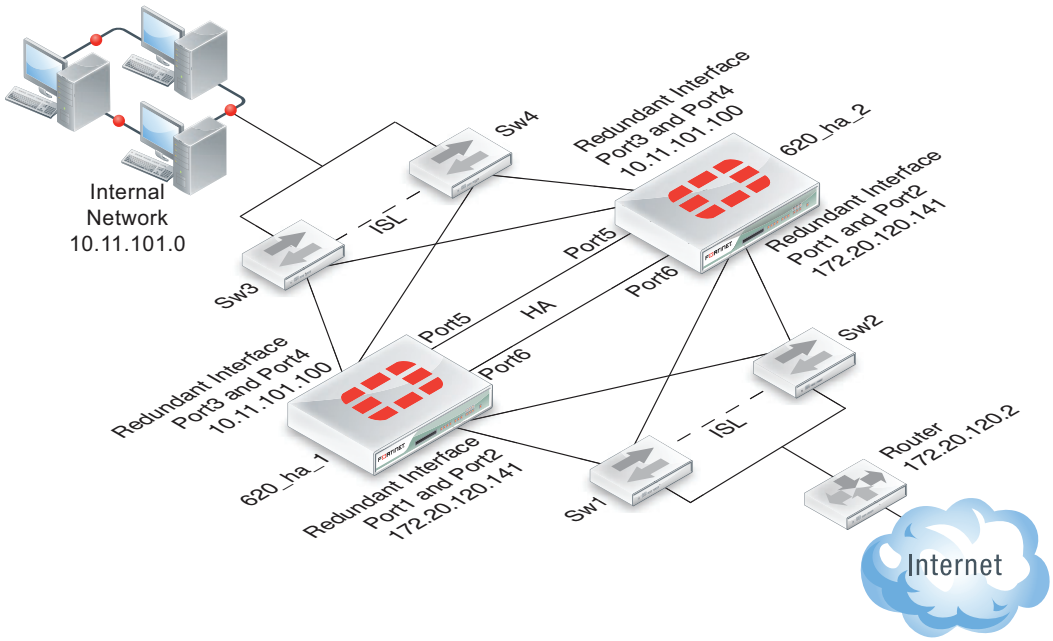
Full mesh HA is supported for both redundant interfaces and 802.3ad aggregate interfaces. In most cases you would simply use redundant interfaces. However, if your switches support 802.3ad aggregate interfaces and split multi-trunking you can use aggregate interfaces in place of redundant interfaces for full mesh HA. One advantage of using aggregate interfaces is that all of the physical interfaces in the aggregate interface can send and receive packets. As a result, using aggregate interfaces may increase the bandwidth capacity of the cluster.

Usually redundant and aggregate interfaces consist of two physical interfaces. However, you can add more than two physical interfaces to a redundant or aggregate interface. Adding more interfaces can increase redundancy protection. Adding more interfaces can also increase bandwidth capacity if you are using 802.3ad aggregate interfaces.

Example: full mesh HA configuration

Figure 207 shows a full mesh HA configuration with a cluster of two FortiGate-620b units. This section describes the FortiGate configuration settings and network components required for a full mesh HA configuration. This section also contains example steps for setting up this full mesh HA configuration. The procedures in this section describe one of many possible sequences of steps for configuring full mesh HA. As you become more experienced with FortiOS, HA, and full mesh HA you may choose to use a different sequence of configuration steps.

Figure 208: Full Mesh HA configuration



For simplicity these procedures assume that you are starting with two new FortiGate units set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

These procedures describe how to configure a cluster operating in NAT/Route mode because NAT/Route is the default FortiGate operating mode. However, the steps are the same if the cluster operates in Transparent mode. You can either switch the cluster units to operate in Transparent mode before beginning these procedures, or you can switch the cluster to operate in Transparent mode after HA is configured and the cluster is connected and operating.

FortiGate-620B full mesh HA configuration

The two FortiGate-620B units (620_ha_1 and 620_ha_2) can be operating in NAT/Route or Transparent mode. Aside from the standard HA settings, the FortiGate-620B configuration includes the following:

- The port5 and port6 interfaces configured as heartbeat interfaces. A full mesh HA configuration also includes redundant HA heartbeat interfaces.
- The port1 and port2 interfaces added to a redundant interface. Port1 is the active physical interface in this redundant interface. To make the port1 interface the active physical interface it should appear above the port2 interface in the redundant interface configuration.
- The port3 and port4 interfaces added to a redundant interface. Port3 is the active physical interface in this redundant interface. To make the port3 interface the active physical interface it should appear above the port4 interface in the redundant interface configuration.

Full mesh switch configuration

The following redundant switch configuration is required:

- Two redundant switches (Sw3 and Sw4) connected to the internal network. Establish an interswitch-link (ISL) between them.
- Two redundant switches (Sw1 and Sw2) connected to the Internet. Establish an interswitch-link (ISL) between them.

Full mesh network connections

Make the following physical network connections for 620_ha_1:

- Port1 to Sw1 (active)
- Port2 to Sw2 (inactive)
- Port3 to Sw3 (active)
- Port4 to Sw4 (inactive)

Make the following physical network connections for 620_ha_2:

- Port1 to Sw2 (active)
- Port2 to Sw1 (inactive)
- Port3 to Sw4 (active)
- Port4 to Sw3 (inactive)

How packets travel from the internal network through the full mesh cluster and to the Internet

If the cluster is operating in active-passive mode and 620_ha_2 is the primary unit, all packets take the following path from the internal network to the internet:

1. From the internal network to Sw4. Sw4 is the active connection to 620_ha_2; which is the primary unit. The primary unit receives all packets.

2 From Sw4 to the 620_ha_2 port3 interface. Active connection between Sw4 and 620_ha_2. Port3 is the active member of the redundant interface.
3 From 620_ha_2 port3 to 620_ha_2 port1. Active connection between 620_ha_2 and Sw2. Port1 is the active member of the redundant interface.
4 From Sw2 to the external router and the Internet.

Configuring FortiGate-620B units for HA operation - web-based manager

Each FortiGate-620B unit in the cluster must have the same HA configuration.

To configure the FortiGate-620B units for HA operation

1 Connect to the web-based manager of one of the FortiGate-620B units.
2 On the *System Information* dashboard widget, beside *Host Name* select *Change*.
3 Enter a new Host Name for this FortiGate unit.

New Name	620_ha_1

4 Go to *System* > *Config* > *HA* and change the following settings.

Mode	Active-Active	
Group Name	Rexample1.com	
Password	RHA_pass_1	
Heartbeat Interface		
	Enable	**Priority**
port5	Select	50
port6	Select	50

5 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

6 Power off the first FortiGate unit.

7 Repeat these steps for the second FortiGate unit.

Set the second FortiGate unit host name to:

New Name	620_ha_2

To connect the cluster to your network

1 Make the following physical network connections for 620_ha_1:
- Port1 to Sw1 (active)
- Port2 to Sw2 (inactive)
- Port3 to Sw3 (active)
- Port4 to Sw4 (inactive)

2 Make the following physical network connections for 620_ha_2:
- Port1 to Sw2 (active)
- Port2 to Sw1 (inactive)
- Port3 to Sw4 (active)
- Port4 to Sw3 (inactive)

3 Connect Sw3 and Sw4 to the internal network.

4 Connect Sw1 and Sw2 to the external router.

5 Enable ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.

6 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1 View the system dashboard.

The System Information dashboard widget shows the *Cluster Name* (Rexample1.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

2 Go to *System* > *Config* > *HA* to view the cluster members list.

The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGate units are not functioning as a cluster. See "Troubleshooting HA clusters" on page 2083 to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1 Log into the cluster web-based manager.

2 Go to *System* > *Admin* > *Administrators*.

3 For *admin*, select the *Change Password* icon

4 Enter and confirm a new password.

5 Select OK.

6 Go to *Router* > *Static* and temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.

7 Go to *System* > *Network* > *Interface* and select *Create New* and configure the redundant interface to connect to the Internet.

Name	Port1_Port2
Type	Redundant
Physical Interface Members	
Selected Interfaces	port1, port2
IP/Netmask	172.20.120.141/24

8 Select OK.

9 Select *Create New* and configure the redundant interface to connect to the internal network.

Name	Port3_Port4
Type	Redundant
Physical Interface Members	
Selected Interfaces	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

10 Select OK.

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Notice that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

11 Go to *Router* > *Static*.

12 Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

13 Select OK.

To configure HA port monitoring for the redundant interfaces

1 Go to *System* > *Config* > *HA*.

2 In the cluster members list, edit the primary unit.

3 Configure the following port monitoring for the redundant interfaces:

	Port Monitor
Port1_Port2	Select
Port3_Port4	Select

4 Select OK.

Configuring FortiGate-620B units for HA operation - CLI

Each FortiGate-620B unit in the cluster must have the same HA configuration. Use the following procedure to configure the FortiGate-620B units for HA operation.

To configure the FortiGate-620B units for HA operation

1. Connect to the CLI of one of the FortiGate-620B units.
2. Enter a new Host Name for this FortiGate unit.

```
config system global
  set hostname 620_ha_1
end
```

3. Configure HA settings.

```
config system ha
  set mode a-a
  set group-name Rexample1.com
  set password RHA_pass_1
  set hbdev port5 50 port6 50
```

```
end
```

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4 Power off the first FortiGate unit.

5 Repeat these steps for the second FortiGate unit.

Set the other FortiGate unit host name to:

```
config system global
  set hostname 620_ha_2
end
```

To connect the cluster to your network

1 Make the following physical network connections for 620_ha_1:
- Port1 to Sw1 (active)
- Port2 to Sw2 (inactive)
- Port3 to Sw3 (active)
- Port4 to Sw4 (inactive)

2 Make the following physical network connections for 620_ha_2:
- Port1 to Sw2 (active)
- Port2 to Sw1 (inactive)
- Port3 to Sw4 (active)
- Port4 to Sw3 (inactive)

3 Connect Sw3 and Sw4 to the internal network.

4 Connect Sw1 and Sw2 to the external router.

5 Enable ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.

6 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1 Log into the CLI.

2 Enter `get system status` to verify the HA status of the cluster unit that you logged into.

If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit.

If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit.

If the command output includes `Current HA mode: standalone` the cluster unit is not operating in HA mode.

3 Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
  Model: 620
  Mode: a-a
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:128 620_ha_2         FG600B3908600825 0
  Slave :128 620_ha_1         FG600B3908600705 1
  number of vcluster: 1
```

```
vcluster 1: work 169.254.0.1
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

4 Use the `execute ha manage` command to connect to the other cluster unit's CLI and use these commands to verify cluster status.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGate units are not functioning as a cluster. See "Troubleshooting HA clusters" on page 2083 to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings. Some steps use the CLI and some the web-based manager.

1 Log into the cluster CLI.

2 Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <password_str>
end
```

3 Temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.

```
config router static
  delete 1
end
```

4 Go to *System* > *Network* > *Interface* and select *Create New* to add the redundant interface to connect to the Internet.

5 Add the redundant interface to connect to the Internet.

```
config sysetem interface
  edit Port1_Port2
    set type redundant
    set member port1 port2
  end
```

6 Add the redundant interface to connect to the internal network.

```
config sysetem interface
  edit Port3_Port4
    set type redundant
    set member port3 port4
```

```
  end
```

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

7 Go to *Router* > *Static*.

8 Add the default route.

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device Port1_Port2
end
```

To configure HA port monitoring for the redundant interfaces

1 Enter the following command to configure port monitoring for the redundant interfaces:

```
config system ha
  set monitor Port1_Port2 Port3_Port4
end
```

Troubleshooting full mesh HA

Troubleshooting full mesh HA clusters is similar to troubleshooting any cluster (see "Troubleshooting HA clusters" on page 2083 or "Troubleshooting virtual clustering" on page 2109). The configuration and operation of a full mesh HA cluster is very similar to the configuration and operation of a standard cluster. The only differences relate to the configuration, connection, and operation of the redundant interfaces and redundant switches.

- Make sure the redundant interfaces and switches are connected correctly. With so many connections it is possible to make mistakes or for cables to become disconnected.
- Confirm that the configuration of the cluster unit 802.3ad Aggregate or Redundant interfaces is correct according to the configuration procedures in this chapter.
- In some configurations with some switch hardware, MAC-learning delays on the inter-switch links on the surrounding topologies may occur. The delays occur if the gratuitous ARP packets sent by the cluster after a failover are delayed by the switches before being sent across the inter-switch link. If this happens the surrounding topologies may be delayed in recognizing the failover and will keep sending packets to the MAC address of the failed primary unit resulting in lost traffic. Resolving this problem may require changing the configuration of the switch or replacing them with switch hardware that does not delay the gratuitous ARP packets.

Operating a cluster

With some exceptions, you can operate a cluster in much the same way as you operate a standalone FortiGate unit. This chapter describes those exceptions and also the similarities involved in operating a cluster instead of a standalone FortiGate unit.

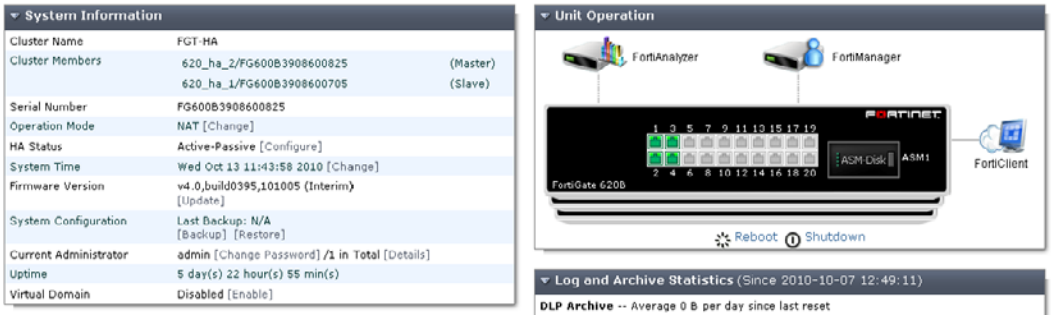
This chapter contains the following sections:

Operating a cluster

The configurations of all of the FortiGate units in a cluster are synchronized so that the cluster units can simulate a single FortiGate unit. Because of this synchronization, you manage the HA cluster instead of managing the individual cluster units. You manage the cluster by connecting to the web-based manager using any cluster interface configured for HTTPS or HTTP administrative access. You can also manage the cluster by connecting to the CLI using any cluster interface configured for SSH or telnet administrative access.

The cluster web-based manager dashboard displays the cluster name, the host name and serial number of each cluster member, and also shows the role of each unit in the cluster. The roles can be master (primary unit) and slave (subordinate units). The dashboard also displays a cluster unit front panel illustration.

Figure 209: Example cluster web-based manager dashboard



You can also go to *System* > *Config* > *HA* to view the cluster members list. This includes status information for each cluster unit. You can also use the cluster members list for a number of cluster management functions including changing the HA configuration of an operating cluster, changing the host name and device priority of a subordinate unit, and disconnecting a cluster unit from a cluster. See "Cluster members list" on page 2147.

You can use log messages to view information about the status of the cluster. See "Viewing and managing log messages for individual cluster units" on page 2136. You can use SNMP to manage the cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration information and receive traps.

You can configure a reserved management interface to manage individual cluster units. You can use this interface to access the web-based manager or CLI and to configure SNMP management for individual cluster units. See "Managing individual cluster units using a reserved management interface" on page 2129.

You can manage individual cluster units by using SSH, telnet, or the CLI console on the web-based manager dashboard to connect to the CLI of the cluster. From the CLI you can use the `execute ha manage` command to connect to the CLI of any unit in the cluster.

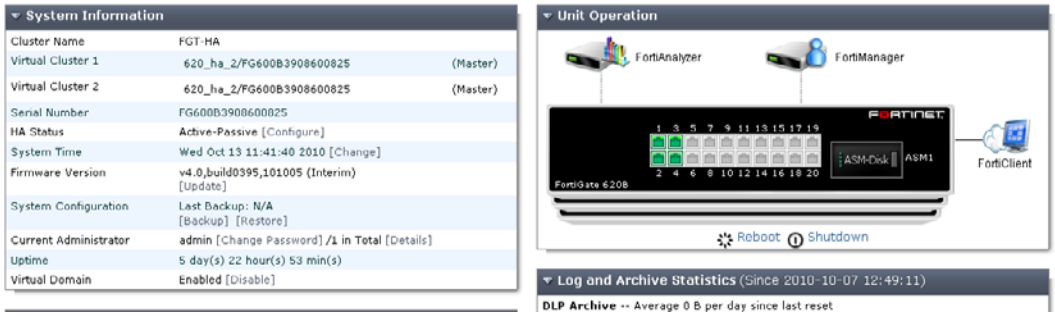
You can also manage individual cluster units by using a null-modem cable to connect to any cluster unit CLI. From there you can use the `execute ha manage` command to connect to the CLI of each unit in the cluster.

Operating a virtual cluster

Managing a virtual cluster is very similar to managing a cluster that does not contain multiple virtual domains. Most of the information in this chapter applies to managing both kinds of clusters. This section describes what is different when managing a virtual cluster.

If virtual domains are enabled, the cluster web-based manager dashboard displays the cluster name and the role of each cluster unit in virtual cluster 1 and virtual cluster 2.

Figure 210: Example virtual clustering web-based manager dashboard



The configuration and maintenance options that you have when you connect to a virtual cluster web-based manager or CLI depend on the virtual domain that you connect to and the administrator account that you use to connect.

If you connect to a cluster as the administrator of a virtual domain, you connect directly to the virtual domain. Since HA virtual clustering is a global configuration, virtual domain administrators cannot see HA configuration options. However, virtual domain administrators see the host name of the cluster unit that they are connecting to on the web browser title bar or CLI prompt. This host name is the host name of the primary unit for the virtual domain. Also, when viewing log messages by going to *Log & Report* > *Log Access* virtual domain administrator can select to view log messages for either of the cluster units.

If you connect to a virtual cluster as the admin administrator you connect to the global web-based manager or CLI. Even so, you are connecting to an interface and to the virtual domain that the interface has been added to. The virtual domain that you connect to does not make a difference for most configuration and maintenance operations. However, there are a few exceptions. You connect to the FortiGate unit that functions as the primary unit for the virtual domain. So the host name displayed on the web browser title bar and on the CLI is the host name of this primary unit.

Managing individual cluster units using a reserved management interface

You can provide direct management access to all cluster units by reserving a management interface as part of the HA configuration. Once this management interface is reserved, you can configure a different IP address, administrative access and other interface settings for this interface for each cluster unit. Then by connecting this interface of each cluster unit to your network you can manage each cluster unit separately from a different IP address. Configuration changes to the reserved management interface are not synchronized to other cluster units.

The reserved management interface provides direct management access to each cluster unit and gives each cluster unit a different identity on your network. This simplifies using external services, such as SNMP, to separately monitor and manage each cluster unit.

The reserved management interface is not assigned an HA virtual MAC address like other cluster interfaces. Instead the reserved management interface retains the permanent hardware address of the physical interface unless you change it using the `config system interface` command.

The reserved management interface and IP address should not be used for managing a cluster using FortiManager. To correctly manage a FortiGate HA cluster with FortiManager use the IP address of one of the cluster unit interfaces. If you use a reserved management interface, FortiManager will assume it is connected to a single FortiGate unit instead of a cluster.

If you enable SNMP administrative access for the reserved management interface you can use SNMP to monitor each cluster unit using the reserved management interface IP address. To monitor each cluster unit using SNMP, just add the IP address of each cluster unit's reserved management interface to the SNMP server configuration. You must also enable direct management of cluster members in the cluster SNMP configuration.

If you enable HTTPS or HTTP administrative access for the reserved management interfaces you can connect to the web-based manager of each cluster unit. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. From the subordinate units the web-based manager has the same features as the primary unit except that unit-specific information is displayed for the subordinate unit, for example:

- The *Dashboard System Information* widget displays the subordinate unit serial number but also displays the same information about the cluster as the primary unit
- On the Cluster members list (go to *System* > *Config* > *HA*) you can change the HA configuration of the subordinate unit that you are logged into. For the primary unit and other subordinate units you can change only the host name and device priority.
- Log Access displays the logs of the subordinate that you are logged into fist, You use the HA Cluster list to view the log messages of other cluster units including the primary unit.

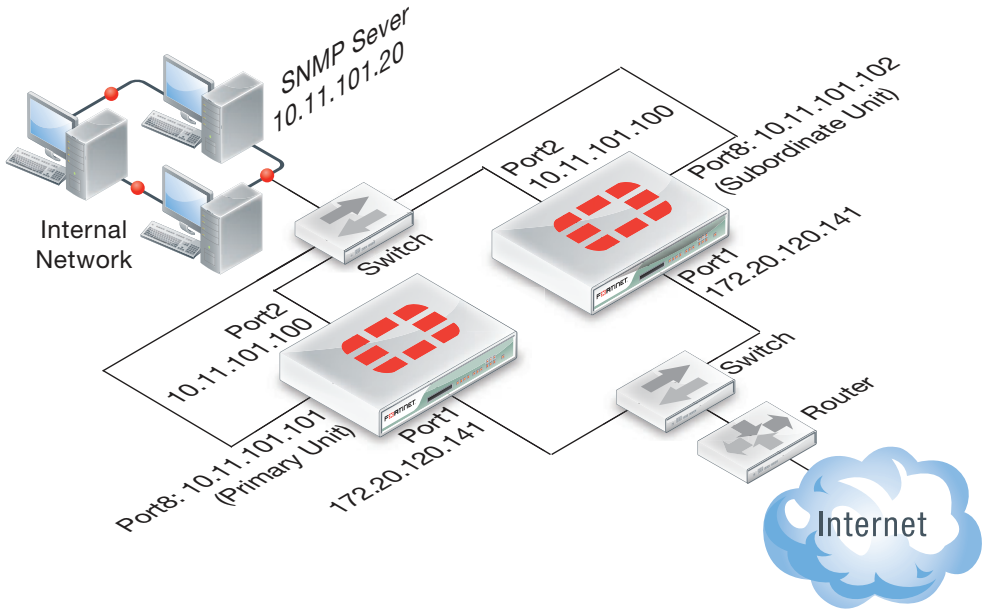
If you enable SSH or TELNET administrative access for the reserved management interfaces you can connect to the CLI of each cluster unit. The CLI prompt contains the host name of the cluster unit that you have connected to. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. You can also use the `execute ha manage` command to connect to other cluster unit CLIs.

The reserved management interface is available in NAT/Route and in Transparent mode. It is also available if the cluster is operating with multiple VDOMs. In Transparent mode you cannot normally add an IP address to an interface. However, you can add an IP address to the reserved management interface.

Configuring the reserved management interface and SNMP remote management of individual cluster units

This example describes how to configure SNMP remote management of individual cluster units using the HA reserved management interface. The configuration consists of two FortiGate-620B units already operating as a cluster. In the example, the port8 interface of each cluster unit is connected to the internal network using the switch and configured as the reserved management interface.

Figure 211: SNMP remote management of individual cluster units



To configure the reserved management interface - web-based manager

1 Go to *System* > *Config* > *HA*.

2 Edit the primary unit.

3 Select *Reserve Management Port for Cluster Member* and select port8.

4 Select OK.

To configure the reserved management interface - CLI

From the CLI you can also configure a default route that is only used by the reserved management interface.

1 Log into the CLI of any cluster unit.

2 Enter the following command to enable the reserved management interface, set port8 as the reserved interface, and add a default route of 10.11.101.100 for the reserved management interface.

```
config system ha
  set ha-mgmt-status enable
  set ha-mgmt-interface port8
  set ha-mgmt-interface-gateway 10.11.101.100
end
```

The reserved management interface default route is not synchronized to other cluster units.

To change the primary unit reserved management interface configuration - web-based manager

You can change the IP address of the primary unit reserved management interface from the primary unit web-based manager. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1 From a PC on the internal network, browse to http://10.11.101.100 and log into the cluster web-based manager.

This logs you into the primary unit web-based manager.

You can identify the primary unit from its serial number or host name that appears on the System Information dashboard widget.

2 Go to *System* > *Network* > *Interface* and edit the port8 interface as follows:

Alias	primary_reserved
IP/Netmask	10.11.101.101/24
Administrative Access	Ping, SSH, HTTPS, SNMP

3 Select OK.

You can now log into the primary unit web-based manager by browsing to https://10.11.101.101. You can also log into this primary unit CLI by using an SSH client to connect to 10.11.101.101.

To change subordinate unit reserved management interface configuration - CLI

At this point you cannot connect to the subordinate unit reserved management interface because it does not have an IP address. Instead, this procedure describes connecting to the primary unit CLI and using the `execute ha manage` command to connect to subordinate unit CLI to change the port8 interface. You can also use a serial connection to the cluster unit CLI. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1 Connect to the primary unit CLI and use the `execute ha manage` command to connect to a subordinate unit CLI.

You can identify the subordinate unit from is serial number or host name. The host name appears in the CLI prompt.

2 Enter the following command to change the port8 IP address to `10.11.101.102` and set management access to HTTPS, ping, SSH, and SNMP.

```
config system interface
  edit port8
    set ip 10.11.101.102/24
    set allowaccess https ping ssh snmp
end
```

You can now log into the subordinate unit web-based manager by browsing to https://10.11.101.102. You can also log into this subordinate unit CLI by using an SSH client to connect to 10.11.101.102.

To configure the cluster for SNMP management using the reserved management interfaces - CLI

This procedure describes how to configure the cluster to allow the SNMP server to get status information from the primary unit and the subordinate unit. The SNMP configuration is synchronized to all cluster units. To support using the reserved management interfaces, you must add at least one HA direct management host to an SNMP community. If your SNMP configuration includes SNMP users with user names and passwords you must also enable HA direct management for SNMP users.

1 Enter the following command to add an SNMP community called `Community` and add a host to the community for the reserved management interface of each cluster unit. The host includes the IP address of the SNMP server (10.11.101.20).

```
config system snmp community
    edit 1
      set name Community
      config hosts
        edit 1
          set ha-direct enable
          set ip 10.11.101.20
        end
end
```

2 Enter the following command to add an SNMP user for the reserved management interface.

```
config system snmp user
  edit 1
    set ha-direct enable
    set notify-hosts 10.11.101.20
  end
```

Configure other settings as required.

To get CPU, memory, and network usage of each cluster unit using the reserved management IP addresses

From the command line of an SNMP manager, you can use the following SNMP commands to get CPU, memory and network usage information for each cluster unit. In the examples, the community name is `Community`. The commands use the MIB field names and OIDs listed in Table 117 on page 2144.

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.101 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.101
   1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.101
   1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.101
   1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.102 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.102
   1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.102
   1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.102
   1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

The primary unit acts as a router for subordinate unit management traffic

HA uses routing and inter-VDOM links to route subordinate unit management traffic through the primary unit to the network. Similar to a standalone FortiGate unit, subordinate units may generate their own management traffic, including:

- DNS queries.
- FortiGuard Web Filtering rating requests.
- Log messages to be sent to a FortiAnalyzer unit, to a syslog server, or to the FortiGuard Analysis and Management Service.
- Log file uploads to a FortiAnalyzer unit.
- Quarantine file uploads to a FortiAnalyzer unit.
- SNMP traps.
- Communication with remote authentication servers (RADIUS, LDAP, TACACS+ and so on)

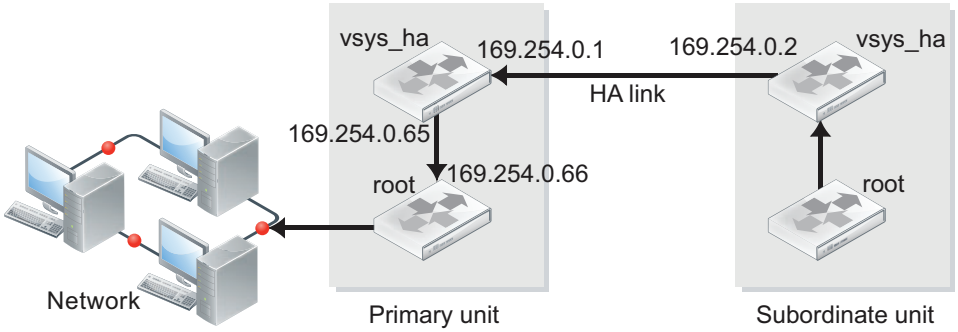
Subordinate units send this management traffic over the HA heartbeat link to the primary unit. The primary unit forwards the management traffic to its destination. The primary unit also routes replies back to the subordinate unit in the same way.

HA uses a hidden VDOM called vsys_ha for HA operations. The vsys_ha VDOM includes the HA heartbeat interfaces, and all communication over the HA heartbeat link goes through the vsys_ha VDOM. To provide communication from a subordinate unit to the network, HA adds hidden inter-VDOM links between the primary unit management VDOM and the primary unit vsys_ha VDOM. By default, root is the management VDOM.

Management traffic from the subordinate unit originates in the subordinate unit vsys_ha VDOM. The vsys_ha VDOM routes the management traffic over the HA heartbeat link to the primary unit vsys_ha VDOM. This management traffic is then routed to the primary unit management VDOM and from there out onto the network.

DNS queries and FortiGuard Web Filtering and Email Filter requests are still handled by the HA proxy so the primary unit and subordinate units share the same DNS query cache and the same FortiGuard Web Filtering and Email Filter cache. In a virtual clustering configuration, the cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering, Email Filtering, and DNS query cache.

Figure 212: Subordinate unit management traffic path



Cluster communication with RADIUS and LDAP servers

In an active-passive cluster, only the primary unit processes traffic, so the primary unit communicates with RADIUS or LDAP servers. In a cluster that is operating in active-active mode, subordinate units send RADIUS and LDAP requests to the primary unit over the HA heartbeat link and the primary units routes them to their destination. The primary unit relays the responses back to the subordinate unit.

Clusters and FortiGuard services

This section describes how various FortiGate HA clustering configurations communicate with the FDN.

In an operating cluster, the primary unit communicates directly with the FortiGuard Distribution Network (FDN). Subordinate units also communicate directly with the FDN but as described in "The primary unit acts as a router for subordinate unit management traffic" on page 2134, all communication between subordinate units and the FDN is routed through the primary unit.

You must register and licence all of the units in a cluster for all required FortiGuard services, both because all cluster units communicate with the FDN and because any cluster unit could potentially become the primary unit.

FortiGuard and active-passive clusters

For an active-passive cluster, only the primary unit processes traffic. Even so, all cluster units communicate with the FDN. Only the primary unit sends FortiGuard Web Filtering and Antispam requests to the FDN. All cluster units receive FortiGuard Antivirus, IPS, and application control updates from the FDN.

In an active-passive cluster the FortiGuard Web Filter and Email Filter caches are located on the primary unit in the same way as for a standalone FortiGate unit. The caches are not shared among cluster units so after a failover the new primary unit must build up new caches.

In an active-passive cluster all cluster units also communicate with the FortiGuard Analysis and Management Service (FAMS).

FortiGuard and active-active clusters

For an active-active cluster, both the primary unit and the subordinate units process traffic. Communication between the cluster units and the FDN is the same as for active-passive clusters with the following exception.

Because the subordinate units process traffic, they may also be making FortiGuard Web Filtering and Email Filter requests. The primary unit receives all such requests from the subordinate units and relays them to the FDN and then relays the FDN responses back to the subordinate units. The FortiGuard Web Filtering and Email Filtering URL caches are maintained on the primary unit. The primary unit caches are used for primary and subordinate unit requests.

FortiGuard and virtual clustering

For a virtual clustering configuration the management virtual domain of each cluster unit communicates with the FDN. The cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering and Email Filtering caches. All FortiGuard Web Filtering and Email Filtering requests are proxied by the management VDOM of the cluster unit that is the primary unit for the management virtual domain.

Clusters and logging

This section describes the log messages that provide information about how HA is functioning, how to view and manage logs for each unit in a cluster, and provides some example log messages that are recorded during specific cluster events.

You configure logging for a cluster in the same way as you configuring logging for a standalone FortiGate unit. Log configuration changes made to the cluster are synchronized to all cluster units.

All cluster units record log messages separately to the individual cluster unit's log disk, to the cluster unit's system memory, or both. You can view and manage log messages for each cluster unit from the cluster web-based manager Log Access page.

When remote logging is configured, all cluster units send log messages to remote FortiAnalyzer units or other remote servers as configured. HA uses routing and inter-VDOM links to route subordinate unit log traffic through the primary unit to the network. See "The primary unit acts as a router for subordinate unit management traffic" on page 2134.

When you configure a FortiAnalyzer unit to receive log messages from a FortiGate cluster, you should add a cluster to the FortiAnalyzer unit configuration so that the FortiAnalyzer unit can receive log messages from all cluster units.

Viewing and managing log messages for individual cluster units

This section describes how to view and manage log messages for an individual cluster unit.

To view HA cluster log messages

1 Log into the cluster web-based manager.

2 Go to *Log&Report* > *Log Access* and select Memory or Disk.

For each log display, the *HA Cluster* list displays the serial number of the cluster unit for which log messages are displayed. The serial numbers are displayed in order in the list.

3 Set *HA Cluster* to the serial number of one of the cluster units to display log messages for that unit.

You can view logs saved to memory or logs saved to the hard disk for the cluster unit.

About HA event log messages

HA event log messages always include the host name and serial number of the cluster unit that recorded the message. HA event log messages also include the HA state of the unit and also indicate when a cluster unit switches (or moves) from one HA state to another. Cluster units can operate in the HA states listed in Table 116:

Table 116: HA states

Hello	A FortiGate unit configured for HA operation has started up and is looking for other FortiGate units with which to form a cluster.
Work	In an active-passive cluster a cluster unit is operating as the primary unit. In an active-active cluster unit is operating as the primary unit or a subordinate unit.
Standby	In an active-passive cluster the cluster unit is operating as a subordinate unit.

HA log Event log messages also indicate the virtual cluster that the cluster unit is operating in as well as the member number of the unit in the cluster. If virtual domains are not enabled, all clusters unit are always operating in virtual cluster 1. If virtual domains are enabled, a cluster unit may be operating in virtual cluster 1 or virtual cluster 2. The member number indicates the position of the cluster unit in the cluster members list. Member 0 is the primary unit. Member 1 is the first subordinate unit, member 2 is the second subordinate unit, and so on.

The following log message indicates that the cluster unit with host name 5005_ha_2 and serial number FG5A253E06500088 has become the primary unit because it is operating in the work state as member 0.

```
2010-01-13 13:45:32 log_id=0105037892 type=event subtype=ha pri=notice
vd="root" msg="Virtual cluster's member state moved" vcluster=1
vcluster_state=work vcluster_member=0 hostname=5005_ha_2
sn=FG5A253E06500088
```

The following log message indicates that the cluster unit with host name 5005_ha_1 and serial number FG5A253E06500088 has become the first subordinate unit in an active-passive cluster because it is operating in the standby state as member 1.

```
2010-01-13 14:28:39 log_id=0105037892 type=event subtype=ha pri=notice
vd="root" msg="Virtual cluster's member state moved" vcluster=1
vcluster_state=standby vcluster_member=1 hostname=5005_ha_2
sn=FG5A253E06500088
```

The following log message indicates that the cluster unit with host name 5005_ha_1 and serial number FG5A253E07600124 has become the first subordinate unit in an active-active cluster because it is operating in the work state as member 1.

```
2010-01-13 14:23:58 log_id=0105037892 type=event subtype=ha pri=notice
vd="root" msg="Virtual cluster's member state moved" vcluster=1
vcluster_state=work vcluster_member=1 hostname=5005_ha_1
sn=FG5A253E07600124
```

The following log message indicates that the FortiGate unit was disconnected from a cluster. The message shows that the cluster unit was disconnected over the telnet link between cluster units and the HA mode was changed from active-active to standalone.

```
2010-01-13 13:45:09 log_id=0104032140 type=event subtype=admin vd=root
pri=notice user="FGT_ha_admin" ui=telnet(169.254.0.2) old=A-A new=standalone
msg="User FGT_ha_admin changed HA mode from A-A to standalone"
```

HA log messages

See the *FortiGate Log Message Reference* for a listing of and descriptions of the HA log messages.

Example log messages

This section displays some log message sequences when specific cluster events occur.

Unit changing to HA mode and becoming the primary unit

1. 2010-01-14 13:24:56 log_id=0104032140 type=event subtype=admin vd=root pri=notice user="admin" ui=GUI(10.21.101.100) old=standalone new=A-P msg="User admin changed HA mode from standalone to A-P"

   The administrator changed the HA mode to active-passive.

2. 2010-01-14 13:25:09 log_id=0105037899 type=event subtype=ha pri=notice vd="root" msg="HA device(interface) peerinfo" ha_role=slave devintfname=port4

   The the cluster unit received heartbeat packets at the port4 interface.

3. 2010-01-14 13:25:09 log_id=0105037894 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster detected member join" vcluster=1 ha_group=0

   The the cluster unit detected another unit that it could form a cluster with.

4. 2010-01-14 13:25:11 log_id=0105037892 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster's member state moved" vcluster=1 vcluster_state=work vcluster_member=0 hostname=5005_ha_1 sn=FG5A253E07600124

   The the cluster unit's state changed to work, meaning that the cluster unit became the primary unit.

Unit changing to HA mode and becoming a subordinate unit

1. 2010-01-13 14:57:04 log_id=0104032140 type=event subtype=admin vd=root pri=notice user="admin" ui=GUI(10.21.101.100) old=standalone new=A-P msg="User admin changed HA mode from standalone to A-P"

   The administrator changed the HA mode to active-passive.

2. 2010-01-13 14:57:07 log_id=0105037899 type=event subtype=ha pri=notice vd="root" msg="HA device(interface) peerinfo" ha_role=slave devintfname=port4

   The the cluster unit received heartbeat packets at the port4 interface.

3. 2010-01-13 14:57:07 log_id=0105037894 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster detected member join" vcluster=1 ha_group=0

   The the cluster unit detected another unit that it could form a cluster with.

4. 2010-01-13 14:57:09 log_id=0105037892 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster's member state moved" vcluster=1 vcluster_state=standby vcluster_member=1 hostname=5005_ha_1 sn=FG5A253E07600124

   The the cluster unit's state changed to standby, meaning that the cluster unit became a subordinate unit.

Primary unit fails (and is removed from cluster)

These messages are recorded by a subordinate unit (which becomes the primary unit).

1 2010-01-13 14:49:44 log_id=0105037901 type=event subtype=ha pri=critical vd="root" msg="Heartbeat device(interface) down" ha_role=slave hbdn_reason=neighbor info lost devintfname=port4

   The subordinate unit looses communication with the primary unit.

2 2010-01-13 14:50:00 log_id=0105037893 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster detected member dead" vcluster=1 ha_group=0

   The subordinate unit determines that the primary unit is no longer operating.

3 2010-01-13 14:50:02 log_id=0105037892 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster's member state moved" vcluster=1 vcluster_state=work vcluster_member=0 hostname=5005_ha_2 sn=FG5A253E06500088

   The subordinate unit negotiates to form a cluster and then begins to operate as the primary unit.

Subordinate unit fails (and is removed from cluster)

These messages are recorded by the primary unit.

1 2010-01-14 13:01:03 log_id=0105037901 type=event subtype=ha pri=critical vd="root" msg="Heartbeat device(interface) down" ha_role=master hbdn_reason=neighbor info lost devintfname=port4

   The primary unit looses contact with the subordinate unit.

2 2010-01-14 13:01:19 log_id=0105037893 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster detected member dead" vcluster=1 ha_group=0

   The primary unit determines that the subordinate unit is no longer operating.

3 2010-01-14 13:01:21 log_id=0105037892 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster's member state moved" vcluster=1 vcluster_state=work vcluster_member=0 hostname=5005_ha_1 sn=FG5A253E07600124

   The primary unit negotiates to form a cluster and then continues to operate as the primary unit.

New unit added to cluster

These messages are recorded by the primary unit.

1 2010-01-13 14:57:07 log_id=0105037899 type=event subtype=ha pri=notice vd="root" msg="HA device(interface) peerinfo" ha_role=master devintfname=port4

   The the cluster unit received heartbeat packets at the port4 interface.

2 2010-01-13 14:57:07 log_id=0105037894 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster detected member join" vcluster=1 ha_group=0

   The the cluster unit detected another unit that it could form a cluster with.

3 2010-01-13 14:57:09 log_id=0105037892 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster's member state moved" vcluster=1 vcluster_state=work vcluster_member=0 hostname=5005_ha_2 sn=FG5A253E06500088

   The primary unit negotiates to form a cluster with the new cluster unit and then continues to operate as the primary unit.

Unit removed from cluster

These log messages appear on the unit that was removed from the cluster.:

1. 2010-01-13 14:49:37 log_id=0104032121 type=event subtype=admin vd=root pri=notice user="admin" ui=GUI(10.21.101.100) intf="port1" field=access old="https+ping+ssh" new="https+ping+ssh+snmp+http+telnet" msg="User admin changed the access setting of interface port1 from GUI(10.21.101.100)"
2. 2010-01-13 14:49:37 log_id=0104032121 type=event subtype=admin vd=root pri=notice user="admin" ui=GUI(10.21.101.100) intf="port1" field=ip old=10.21.101.102:255.255.255.0 new=10.21.101.103:255.255.255.0 msg="User admin changed the ip setting of interface port1 from GUI(10.21.101.100)"
3. 2010-01-13 14:49:37 log_id=0104032140 type=event subtype=admin vd=root pri=notice user="admin" ui=GUI(10.21.101.100) old=A-P new=standalone msg="User admin changed HA mode from A-P to standalone"

Link failure of a monitored interface

These log messages, recorded by the primary unit, show the monitored port1 interface failed or was disconnected and the primary unit becoming a subordinate unit:

1. 2010-01-14 16:59:39 log_id=0100020099 type=event subtype=system vd=root pri=information action=interface-stat-change status=DOWN msg="Link monitor: Interface port1 was turned down"
2. 2010-01-14 16:59:39 log_id=0105037898 type=event subtype=ha pri=warning vd="root" msg="HA device(interface) fail" ha_role=master devintfname=port1
3. 2010-01-14 16:59:41 log_id=0105037892 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster's member state moved" vcluster=1 vcluster_state=standby vcluster_member=1 hostname=620_ha_1 sn=FG600B3908600705

Link failure of a monitored interface fixed

These log messages show the monitored port1 being reconnected and the cluster unit becoming the primary unit.

1. 2010-01-14 16:59:58 log_id=0100020099 type=event subtype=system vd=root pri=information action=interface-stat-change status=UP msg="Link monitor: Interface port1 was turned up"
2. 2010-01-14 16:59:58 log_id=0105037897 type=event subtype=ha pri=notice vd="root" msg="HA device(interface) ready" ha_role=slave devintfname=port1
3. 2010-01-14 17:00:00 log_id=0105037892 type=event subtype=ha pri=notice vd="root" msg="Virtual cluster's member state moved" vcluster=1 vcluster_state=work vcluster_member=0 hostname=620_ha_1 sn=FG600B3908600705

Configuration change synchronized from primary unit to subordinate unit

The following event log message is written by the primary unit when the admin administrator adds security policy with ID=3 by connecting to the web-based manager from a management PC with IP address 172.20.120.14 using HTTPS or HTTP:

2009-11-13 09:11:45 ***log_id=0104032126*** type=event subtype=admin vd=root pri=notice user="admin" ***ui=GUI(172.20.120.14)*** seq=1 sintf="external" dintf="internal" saddr="all" daddr="all" act=accept nat=no iptype=ipv4 schd="always" svr="ANY" log=no idbased=no msg="User admin added IPv4 firewall policy 3 from GUI(172.20.120.11)"

When incremental synchronization makes the same change to a subordinate unit the subordinate unit writes the following log message:

2009-11-13 09:11:45 ***log_id=0104032126*** type=event subtype=admin vd=root pri=notice user="admin" ***ui=ha_daemon seq=1*** sintf="external" dintf="internal" saddr="all" daddr="all" act=accept nat=no iptype=ipv4 schd="always" svr="ANY" log=no idbased=no msg="User admin added IPv4 firewall policy 3 from GUI(172.20.120.11)"

Notice that the two messages are identical (including the log IDs) except that on the subordinate unit the ui (user interface) is ha_daemon. ha_daemon is the name of the user interface used by the HA synchronization process to make incremental synchronization configuration changes.

Configuration change synchronized from subordinate unit to primary unit

The following event log message is written by a subordinate unit after the admin administrator logs into the subordinate unit CLI using the `execute ha manage` command and adds security policy 6.

2009-11-13 09:14:45 ***log_id=0104032126*** type=event subtype=admin vd=root pri=notice user="admin" ***ui=telnet(169.254.0.1)*** seq=6 sintf="external" dintf="internal" saddr="all" daddr="all" act=accept nat=no iptype=ipv4 schd="always" svr="ANY" log=no idbased=no msg="User admin added IPv4 firewall policy 6 from telnet(169.254.0.1)"

Notice the user interface is telnet(169.254.0.1). 169.254.0.1 is the IP address of the HA heartbeat interface of the primary unit. The log message shows that the `execute ha manage` command sets up a telnet session from the primary unit to the subordinate unit over the HA heartbeat link. Note that the IP address could be 169.254.0.2 if the cluster renegotiated.

When incremental synchronization makes the same change to the primary unit, the primary unit writes the following log message:

2009-11-13 09:14:45 ***log_id=0104032126*** type=event subtype=admin vd=root pri=notice user="admin" ***ui=ha_daemon*** seq=6 sintf="external" dintf="internal" saddr="all" daddr="all" act=accept nat=no iptype=ipv4 schd="always" svr="ANY" log=no idbased=no msg="User admin added IPv4 firewall policy 6 from ha_daemon"

Notice again that the messages are identical (including the log ID) except for the user interface.

Fortigate HA message "HA master heartbeat interface <intf_name> lost neighbor information"

The following HA log messages may be recorded by an operating cluster:

2009-02-16 11:06:34 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha pri=critical vd=root msg="HA slave heartbeat interface internal lost neighbor information"

2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha pri=notice vd=root msg="Virtual cluster 1 of group 0 detected new joined HA member"

2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha pri=notice vd=root msg="HA master heartbeat interface internal get peer information"

These log messages indicate that the cluster units could not connect to each other over the HA heartbeat link for the period of time that is given by hb-interval x hb-lost-threshold, which is 1.2 seconds with the default values.

To diagnose this problem

1. Check all heartbeat interface connections including cables and switches to make sure they are connected and operating normally.
2. Use the following commands to display the status of the heartbeat interfaces.

   ```
   get hardware nic <heartbeat_interface_name>
   diagnose hardware deviceinfo nic <heartbeat_interface_name>
   ```

   The status information may indicate the interface status and link status and also indicate if a large number of errors have been detected.
3. If the log message only appear during peak traffic times, increase the tolerance for missed HA heartbeat packets by using the following commands to increase the lost heartbeat threshold and heartbeat interval:

   ```
   config system ha
     set hb-lost-threshold 12
     set hb-interval 4
   end
   ```

   These settings multiply by 4 the loss detection interval. You can use higher values as well.
4. Optionally disable session-pickup to reduce the processing load on the heartbeat interfaces.
5. Instead of disabling session-pickup you can enable `session-pickup-delay` to reduce the number of sessions that are synchronized. With this option enabled only sessions that are active for more than 30 seconds are synchronized.

It may be useful to monitor CPU and memory usage to check for low memory and high CPU usage. You can configure event logging to monitor CPU and memory usage. You can also enable the CPU over usage and memory low SNMP events.

Once this monitoring is in place, try and determine if there have been any changes in the network or an increase of traffic recently that could be the cause. Check to see if the problem happens frequently and if so what the pattern is.

To monitor the CPU of the cluster units and troubleshoot further, use the following procedure and commands:

```
get system performance status
get sys performance top 2
diagnose sys top 2
```

These commands repeated at frequent intervals will show the activity of the CPU and the number of sessions.

Search the Fortinet Knowledge Base for articles about monitoring CPU and Memory usage.

If the problem persists, gather the following information (a console connection might be necessary if connectivity is lost) and provide it to Technical Support when opening a ticket:

- Debug log from the web-based manager: *System* > *Maintenance* > *Advanced* > *debug log*
- CLI command output:

  `diag sys top 2` (keep it running for 20 seconds)

```
get sys perf status (repeat this command multiple times to get good samples)
get sys ha status
diag sys ha status
diag sys ha dump all
diag sys ha dump 2
diag sys ha dump 3
diag netlink dev list
diag hardware dev nic <Heartbeat port Name>
execute log filter category event
execute log display
```

Clusters and SNMP

You can use SNMP to manage a cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration and status information and receive traps.

You configure SNMP for a cluster in the same way as configuring SNMP for a standalone FortiGate unit. SNMP configuration changes made to the cluster are shared by all cluster units.

Each cluster unit sends its own traps and SNMP manager systems can use SNMP get commands to query each cluster unit separately. To set SNMP get queries to each cluster unit you must create a special get command that includes the serial number of the cluster unit.

Alternatively you can use the HA reserved management interface feature to give each cluster unit a different management IP address. Then you can create an SNMP get command for each cluster unit that just includes the management IP address and does not have to include the serial number. See “Managing individual cluster units using a reserved management interface” on page 2129.

For a list of HA MIB fields and OIDs, see “Fortinet MIBs” on page 434.

SNMP get command syntax for the primary unit

Normally, to get configuration and status information for a standalone FortiGate unit or for a primary unit, an SNMP manager would use an SNMP get commands to get the information in a MIB field. The SNMP get command syntax would be similar to the following:

```
snmpget -v2c -c <community_name> <address_ipv4> {<OID> |
   <MIB_field>}
```

where:

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. The most commonly used community name is `public`.

`<address_ipv4>` is the IP address of the FortiGate interface that the SNMP manager connects to.

{<OID> | <MIB_field>} is the object identifier (OID) for the MIB field or the MIB field name itself. The HA MIB fields and OIDs are listed in Table 117.

Table 117: SNMP field names and OIDs

MIB field	OID	Description
fgHaSystemMode	.1.3.6.1.4.1.12356.101.13.1.1.0	HA mode (standalone, a-a, or a-p)
fgHaGroupId	.1.3.6.1.4.1.12356.101.13.1.2.0	The HA priority of the cluster unit. Default 128.
fgHaPriority	.1.3.6.1.4.1.12356.101.13.1.3.0	The HA priority of the cluster unit. Default 128.
fgHaOverride	.1.3.6.1.4.1.12356.101.13.1.4.0	Whether HA override is disabled or enabled for the cluster unit.
fgHaAutoSync	.1.3.6.1.4.1.12356.101.13.1.5.0	Whether automatic HA synchronization is disabled or enabled.
fgHaSchedule	.1.3.6.1.4.1.12356.101.13.1.6.0	The HA load balancing schedule. Set to none unless operating in a-p mode.
fgHaGroupName	.1.3.6.1.4.1.12356.101.13.1.7.0	The HA group name.
fgHaStatsIndex	.1.3.6.1.4.1.12356.101.13.2.1.1.1.1	The cluster index of the cluster unit. 1 for the primary unit, 2 to x for the subordinate units.
fgHaStatsSerial	.1.3.6.1.4.1.12356.101.13.2.1.1.2.1	The serial number of the cluster unit.
fgHaStatsCpuUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.3.1	The cluster unit's current CPU usage.
fgHaStatsMemUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.4.1	The cluster unit's current Memory usage.
fgHaStatsNetUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.5.1	The cluster unit's current Network bandwidth usage.
fgHaStatsSesCount	.1.3.6.1.4.1.12356.101.13.2.1.1.6.1	The cluster unit's current session count.
fgHaStatsPktCount	.1.3.6.1.4.1.12356.101.13.2.1.1.7.1	The cluster unit's current packet count.
fgHaStatsByteCount	.1.3.6.1.4.1.12356.101.13.2.1.1.8.1	The cluster unit's current byte count.
fgHaStatsIdsCount	.1.3.6.1.4.1.12356.101.13.2.1.1.9.1	The number of attacks reported by the IPS for the cluster unit.
fgHaStatsAvCount	.1.3.6.1.4.1.12356.101.13.2.1.1.10.1	The number of viruses reported by the antivirus system for the cluster unit.
fgHaStatsHostname	.1.3.6.1.4.1.12356.101.13.2.1.1.11.1	The hostname of the cluster unit.

To get the HA priority for the primary unit

The following SNMP get command gets the HA priority for the primary unit. The community name is `public`. The IP address of the cluster interface configured for SNMP management access is 10.10.10.1. The HA priority MIB field is fgHaPriority and the OID for this MIB field is 1.3.6.1.4.1.12356.101.13.1.3.0 The first command uses the MIB field name and the second uses the OID:

```
snmpget -v2c -c public 10.10.10.1 fgHaPriority
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.1.3.0
```

SNMP get command syntax for any cluster unit

To get configuration status information for a specific cluster unit (for the primary unit or for any subordinate unit), the SNMP manager must add the serial number of the cluster unit to the SNMP get command after the community name. The community name and the serial number are separated with a dash. The syntax for this SNMP get command would be:

```
snmpget -v2c -c <community_name>-<fgt_serial> <address_ipv4>
   {<OID> | <MIB_field>}
```

where:

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. All units in the cluster have the same community name. The most commonly used community name is `public`.

`<fgt_serial>` is the serial number of any cluster unit. For example, FGT4002803033172. You can specify the serial number of any cluster unit, including the primary unit, to get information for that unit.

`<address_ipv4>` is the IP address of the FortiGate interface that the SNMP manager connects to.

`{<OID> | <MIB_field>}` is the object identifier (OID) for the MIB field or the MIB field name itself. To find OIDs and MIB field names see "Fortinet MIBs" on page 434.

If the serial number matches the serial number of a subordinate unit, the SNMP get request is sent over the HA heartbeat link to the subordinate unit. After processing the request, the subordinate unit sends the reply back over the HA heartbeat link back to the primary unit. The primary unit then forwards the response back to the SNMP manager.

If the serial number matches the serial number of the primary unit, the SNMP get request is processed by the primary unit. You can actually add a serial number to the community name of any SNMP get request. But normally you only need to do this for getting information from a subordinate unit.

To get the CPU usage for a subordinate unit

The following SNMP get command gets the CPU usage for a subordinate unit in a FortiGate-5001SX cluster. The subordinate unit has serial number FG50012205400050. The community name is `public`. The IP address of the FortiGate interface is 10.10.10.1. The HA status table MIB field is fgHaStatsCpuUsage and the OID for this MIB field is 1.3.6.1.4.1.12356.101.13.2.1.1.3.1. The first command uses the MIB field name and the second uses the OID for this table:

```
snmpget -v2c -c public-FG50012205400050 10.10.10.1
   fgHaStatsCpuUsage
snmpget -v2c -c public-FG50012205400050 10.10.10.1
   1.3.6.1.4.1.12356.101.13.2.1.1.3.1
```

FortiGate SNMP recognizes the community name with syntax <community_name>-<fgt_serial>. When the primary unit receives an SNMP get request that includes the community name followed by serial number, the FGCP extracts the serial number from the request. Then the primary unit redirects the SNMP get request to the cluster unit with that serial number. If the serial number matches the serial number of the primary unit, the SNMP get is processed by the primary unit.

Getting serial numbers of cluster units

The following SNMP get commands use the MIB field name fgHaStatsSerial.<index> to get the serial number of each cluster unit. Where <index> is the cluster unit's cluster index and 1 is the cluster index of the primary unit, 2 is the cluster index of the first subordinate unit, and 3 is the cluster index of the second subordinate unit.

The OID for this MIB field is 1.3.6.1.4.1.12356.101.13.2.1.1.2.1. The community name is public. The IP address of the FortiGate interface is 10.10.10.1.

The first command uses the MIB field name and the second uses the OID for this table and gets the serial number of the primary unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.1
snmpget -v2c -c public 10.10.10.1
  1.3.6.1.4.1.12356.101.13.2.1.1.2.1
```

The second command uses the MIB field name and the second uses the OID for this table and gets the serial number of the first subordinate unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.2
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.2.2
```

SNMP get command syntax - reserved management interface enabled

To get configuration and status information for any cluster unit where you have enabled the HA reserved management interface feature and assigned IP addresses to the management interface of each cluster unit, an SNMP manager would use the following get command syntax:

```
snmpget -v2c -c <community_name> <mgt_address_ipv4> {<OID> |
   <MIB_field>}
```

where:

<community_name> is an SNMP community name added to the FortiGate configuration. You can add more than one community names to a FortiGate SNMP configuration. The most commonly used community name is public.

<mgt_address_ipv4> is the IP address of the FortiGate HA reserved management interface that the SNMP manager connects to.

{<OID> | <MIB_field>} is the object identifier (OID) for the MIB field or the MIB field name itself. To find OIDs and MIB field names see your FortiGate unit's online help.

See "To get CPU, memory, and network usage of each cluster unit using the reserved management IP addresses" on page 2133.

Clusters and file quarantine

You can configure file quarantine for a cluster in the same way as configuring file quarantine for a standalone FortiGate unit. Quarantine configuration changes made to the cluster are shared by all cluster units.

In an active-active cluster, both the primary unit and the subordinate units accept antivirus sessions and may quarantine files. In an active-passive cluster, only the primary unit quarantines files. Multiple cluster units in an active-passive cluster may have quarantined files if different cluster units have been the primary unit.

All cluster units quarantine files separately to their own hard disk. You can go to *Log&Report* > *Archive Access* > *Quarantine* to view and manage the quarantine file list for each cluster unit.

All cluster units can also quarantine files to a FortiAnalyzer unit. When you configure a FortiAnalyzer unit to receive quarantine files from a cluster, you should add each cluster unit to the FortiAnalyzer device configuration so that the FortiAnalyzer unit can receive quarantine files from all cluster units.

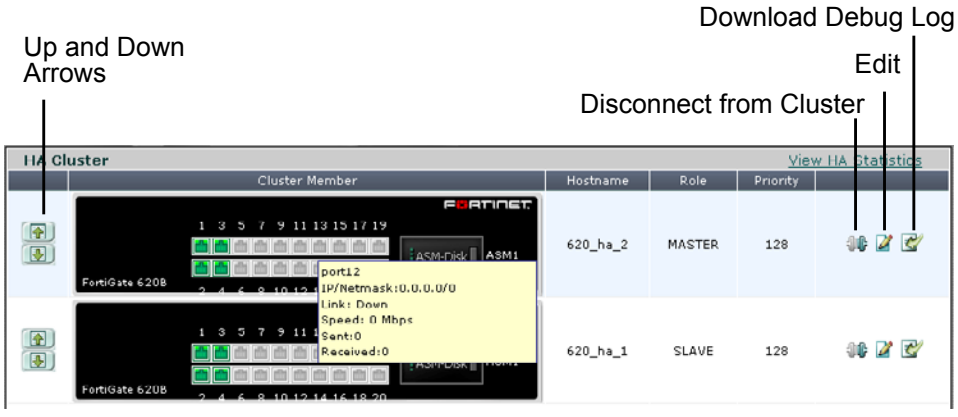
Cluster members list

Display the cluster members list to view the status of the FortiGate units in an operating cluster. To display the cluster members list, go to *System* > *Config* > *HA*.

From the cluster members list you can also:

- View HA statistics (see "Viewing HA statistics" on page 2150).
- View and optionally change the HA configuration of the operating cluster (see "Changing the HA configuration of an operating cluster" on page 2151).
- View and optionally change the host name and device priority of a subordinate unit (see "Changing the subordinate unit host name and device priority" on page 2152).
- Disconnect a cluster unit from a cluster (see "Disconnecting a cluster unit from a cluster" on page 2164).
- Download the Debug log for any cluster unit. You can send this debug log file to Fortinet Technical Support to help diagnose problems with the cluster or with individual cluster units.

Figure 213: Example cluster members list



View HA Statistics	Display the serial number, status, and monitor information for each cluster unit. See "Viewing HA statistics" on page 2150.
Up and down arrows	Change the order in which cluster members are listed. The operation of the cluster or of the units in the cluster are not affected. All that changes is the order in which cluster units are displayed on the cluster members list.

Cluster member	Illustrations of the front panels of the cluster units. If the network jack for an interface is shaded green, the interface is connected. Pause the mouse pointer over each illustration to view the cluster unit host name, serial number, and how long the unit has been operating (up time).[a] The list of monitored interfaces is also displayed.
Hostname	The host name of the FortiGate unit. The default host name of the FortiGate unit is the FortiGate unit serial number. • To change the primary unit host name, go to the system dashboard and select Change beside the current host name int System Information widget. • To change a subordinate unit host name, from the cluster members list select the edit icon for a subordinate unit.
Role	The status or role of the cluster unit in the cluster. • Role is MASTER for the primary (or master) unit • Role is SLAVE for all subordinate (or backup) cluster units
Priority	The device priority of the cluster unit. Each cluster unit can have a different device priority. During HA negotiation, the unit with the highest device priority becomes the primary unit. The device priority range is 0 to 255. The default device priority is 128.
Disconnect from cluster	Disconnect the cluster unit from the cluster. See “Disconnecting a cluster unit from a cluster” on page 2164.
Edit	Select Edit to change a cluster unit HA configuration. • For a primary unit, select Edit to change the cluster HA configuration. You can also change the device priority of the primary unit. • For a primary unit in a virtual cluster, select Edit to change the virtual cluster HA configuration. You can also change the virtual cluster 1 and virtual cluster 2 device priority of this cluster unit. • For a subordinate unit, select Edit to change the subordinate unit host name and device priority. See “Changing the subordinate unit host name and device priority” on page 2152. • For a subordinate unit in a virtual cluster, select Edit to change the subordinate unit host name. In addition you can change the device priority for the subordinate unit for the selected virtual cluster.
Download debug log	Download an encrypted debug log to a file. You can send this debug log file to Fortinet Technical Support to help diagnose problems with the cluster or with individual cluster units.

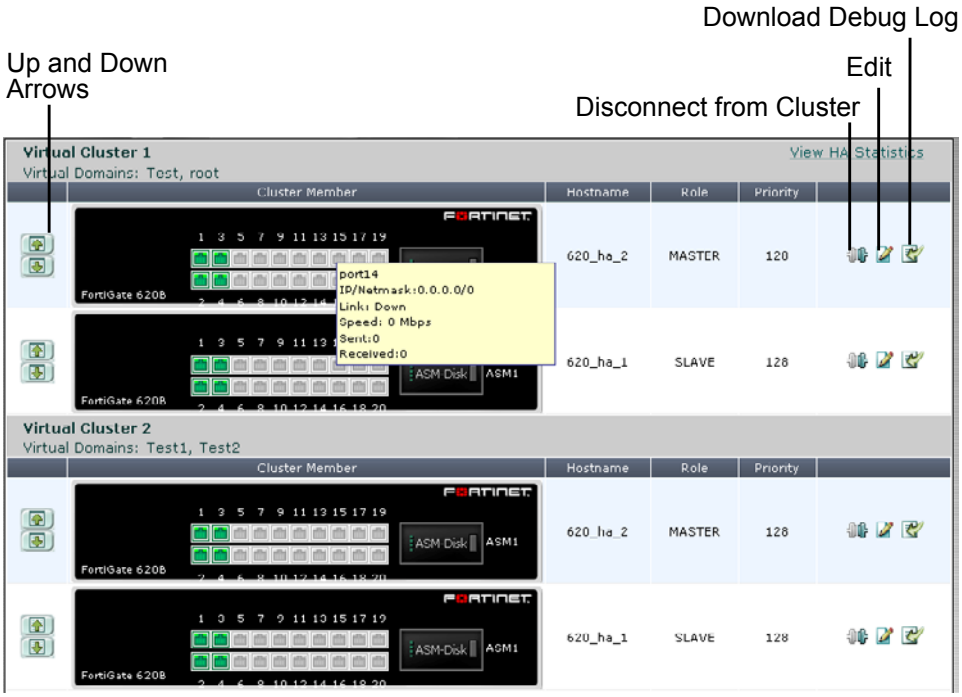
a.In this case, with the mouse position showing a pop-up, it would be worth showing the mouse cursor itself in the screen capture.

Virtual cluster members list

If virtual domains are enabled, you can display the cluster members list to view the status of the operating virtual clusters. The virtual cluster members list shows the status of both virtual clusters including the virtual domains added to each virtual cluster.

To display the virtual cluster members list for an operating cluster log in as the admin administrator, select Global Configuration and go to *System* > *Config* > *HA*.

Figure 214: Example FortiGate-5001SX virtual cluster members list



The fields and functions of the virtual cluster members list are the same as the fields and functions described in "Cluster members list" on page 2147 with the following exceptions.

- When you select the edit icon for a primary unit in a virtual cluster, you can change the virtual cluster 1 and virtual cluster 2 device priority of this cluster unit and you can edit the VDOM partitioning configuration of the cluster.
- When you select the edit icon for a subordinate unit in a virtual cluster, you can change the device priority for the subordinate unit for the selected virtual cluster.

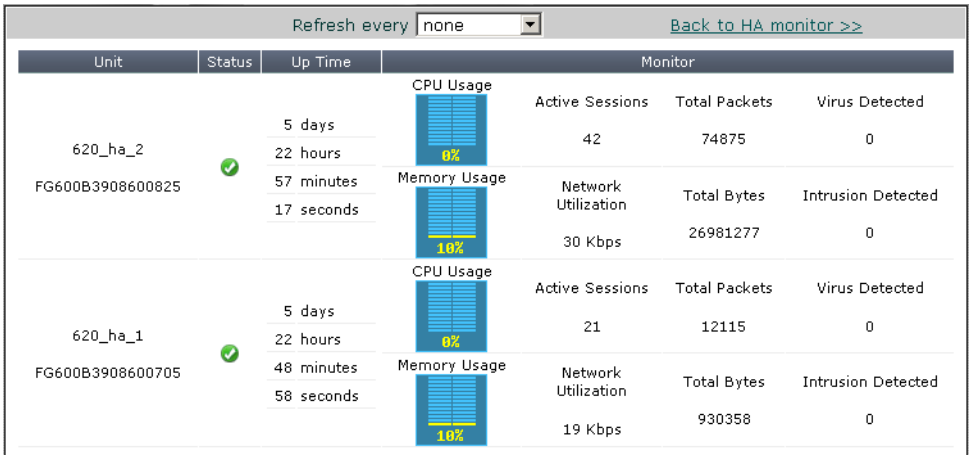
Also, the HA cluster members list changes depending on the cluster unit. For the virtual cluster described in the "Example: virtual clustering with two VDOMs and VDOM partitioning" on page 2093 if you connect to port5 using you are connecting to 620b_ha_2 (620b_ha_2 is displayed on the web browser title bar or in the CLI prompt).

If you connect to port1 you are connecting to 620b_ha_1 (620b_ha_2 is displayed on the web browser title bar or in the CLI prompt).

Viewing HA statistics

From the cluster members list you can select View HA statistics to display the serial number, status, and monitor information for each cluster unit. To view HA statistics, go to *System* > *Config* > *HA* and select View HA Statistics.

Figure 215: Example HA statistics (active-passive cluster)



Refresh every	Select to control how often the web-based manager updates the HA statistics display.
Back to HA monitor	Close the HA statistics list and return to the cluster members list.
Serial No.	Use the serial number ID to identify each FortiGate unit in the cluster. The cluster ID matches the FortiGate unit serial number.
Status	Indicates the status of each cluster unit. A green check mark indicates that the cluster unit is operating normally. A red X indicates that the cluster unit cannot communicate with the primary unit.
Up Time	The time in days, hours, minutes, and seconds since the cluster unit was last started.
Monitor	Displays system status information for each cluster unit.
CPU Usage	The current CPU status of each cluster unit. The web-based manager displays CPU usage for core processes only. CPU usage for management processes (for example, for HTTPS connections to the web-based manager) is excluded.
Memory Usage	The current memory status of each cluster unit. The web-based manager displays memory usage for core processes only. Memory usage for management processes (for example, for HTTPS connections to the web-based manager) is excluded.
Active Sessions	The number of communications sessions being processed by the cluster unit.
Total Packets	The number of packets that have been processed by the cluster unit since it last started up.
Virus Detected	The number of viruses detected by the cluster unit.

Network Utilization	The total network bandwidth being used by all of the cluster unit interfaces.
Total Bytes	The number of bytes that have been processed by the cluster unit since it last started up.
Intrusion Detected	The number of intrusions or attacks detected by Intrusion Protection running on the cluster unit.

Changing the HA configuration of an operating cluster

To change the configuration settings of an operating cluster, go to *System* > *Config* > *HA* to display the cluster members list. Select Edit for the master (or primary) unit in the cluster members list to display the HA configuration page for the cluster.

You can use the HA configuration page to check and fine tune the configuration of the cluster after the cluster is up and running. For example, if you connect or disconnect cluster interfaces you may want to change the Port Monitor configuration.

Any changes you make on this page, with the exception of changes to the device priority, are first made to the primary unit configuration and then synchronized to the subordinate units. Changing the device priority only affects the primary unit.

Changing the HA configuration of an operating virtual cluster

To change the configuration settings of the primary unit in a functioning cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to *System* > *Config* > *HA* to display the cluster members list. Select Edit for the master (or primary) unit in virtual cluster 1 or virtual cluster 2 to display the HA configuration page for the virtual cluster.

You can use the virtual cluster HA configuration page to check and fine tune the configuration of both virtual clusters after the cluster is up and running. For example, you may want to change the Port Monitor configuration for virtual cluster 1 and virtual cluster 2 so that each virtual cluster monitors its own interfaces.

You can also use this configuration page to move virtual domains between virtual cluster 1 and virtual cluster 2. Usually you would distribute virtual domains between the two virtual clusters to balance the amount of traffic being processed by each virtual cluster.

Any changes you make on this page, with the exception of changes to the device priorities, are first made to the primary unit configuration and then synchronized to the subordinate unit.

You can also adjust device priorities to configure the role of this cluster unit in the virtual cluster. For example, to distribute traffic to both cluster units in the virtual cluster configuration, you would want one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. You can create this configuration by setting the device priorities. The cluster unit with the highest device priority in virtual cluster 1 becomes the primary unit for virtual cluster 1. The cluster unit with the highest device priority in virtual cluster 2 becomes the primary unit in virtual cluster 2.

Changing the subordinate unit host name and device priority

To change the host name and device priority of a subordinate unit in an operating cluster, go to *System* > *Config* > *HA* to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

To change the host name and device priority of a subordinate unit in an operating cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to *System* > *Config* > *HA* to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

You can change the host name (Peer) and device priority (Priority) of this subordinate unit. These changes only affect the configuration of the subordinate unit.

The device priority is not synchronized among cluster members. In a functioning cluster you can change device priority to change the priority of any unit in the cluster. The next time the cluster negotiates, the cluster unit with the highest device priority becomes the primary unit.

The device priority range is 0 to 255. The default device priority is 128.

Upgrading cluster firmware

You can upgrade the FortiOS firmware running on an HA cluster in the same manner as upgrading the firmware running on a standalone FortiGate unit. During a normal firmware upgrade, the cluster upgrades the primary unit and all subordinate units to run the new firmware image. The firmware upgrade takes place without interrupting communication through the cluster.

Upgrading cluster firmware to a new major release (for example upgrading from 3.0 MRx to 4.0 MRx) is supported for clusters. Make sure you are taking an upgrade path described in the release notes. Even so you should back up your configuration and only perform such a firmware upgrade during a maintenance window.

To upgrade the firmware without interrupting communication through the cluster, the cluster goes through a series of steps that involve first upgrading the firmware running on the subordinate units, then making one of the subordinate units the primary unit, and finally upgrading the firmware on the former primary unit. These steps are transparent to the user and the network, but depending upon your HA configuration may result in the cluster selecting a new primary unit.

The following sequence describes in detail the steps the cluster goes through during a firmware upgrade and how different HA configuration settings may affect the outcome.

1. The administrator uploads a new firmware image from the web-based manager or CLI.
2. If the cluster is operating in active-active mode load balancing is turned off.
3. The cluster upgrades the firmware running on all of the subordinate units.
4. Once the subordinate units have been upgraded, a new primary unit is selected.

   This primary unit will be running the new upgraded firmware.

5 The cluster now upgrades the firmware of the former primary unit.

If the age of the new primary unit is more than 300 seconds (5 minutes) greater than the age of all other cluster units, the new primary unit continues to operate as the primary unit.

This is the intended behavior but does not usually occur because the age difference of the cluster units is usually less than the cluster age difference margin of 300 seconds. So instead, the cluster negotiates again to select a primary unit as described in "Primary unit selection" on page 2000.

You can keep the cluster from negotiating again by reducing the cluster age difference margin using the `ha-uptime-diff-margin` option. However, you should be cautious when reducing the age or other problems may occur. For information about the cluster age difference margin, see "Cluster age difference margin (grace period)" on page 2003). For more information about changing the cluster age margin, see "Changing the cluster age difference margin" on page 2003.

6 If the cluster is operating in active-active mode, load balancing is turned back on.

Changing how the cluster processes firmware upgrades

By default cluster firmware upgrades proceed as uninterruptable upgrades that do not interrupt traffic flow. If required, you can use the following CLI command to change how the cluster handles firmware upgrades. You might want to change this setting if you are finding uninterruptable upgrades take too much time.

```
config system ha
  set uninterruptable-upgrade disable
end
```

`uninterruptable-upgrade` is enabled by default. If you disable `uninterruptable-upgrade` the cluster still upgrades the firmware on all cluster units, but all cluster units are upgraded at once; which takes less time but interrupts communication through the cluster.

Synchronizing the firmware build running on a new cluster unit

If the firmware build running on a FortiGate unit that you add to a cluster is older than the cluster firmware build, you may be able to use the following steps to synchronize the firmware running on the new cluster unit.

This procedure describes re-installing the same firmware build on a cluster to force the cluster to upgrade all cluster units to the same firmware build.

Due to firmware upgrade and synchronization issues, in some cases this procedure may not work. In all cases it will work to install the same firmware build on the new unit as the one that the cluster is running before adding the new unit to the cluster.

To synchronize the firmware build running on a new cluster unit

1 Obtain a firmware image that is the same as build already running on the cluster.

2 Connect to the cluster using the web-based manager.

3 Go to *System* > *Dashboard* > *Status*.

4 Select *Update* beside *Firmware Version*.

You can also install a newer firmware build.

5 Select OK.

After the firmware image is uploaded to the cluster, the primary unit upgrades all cluster units to this firmware build.

Downgrading cluster firmware

For various reasons you may need to downgrade the firmware that a cluster is running. You can use the information in this section to downgrade the firmware version running on a cluster.

In most cases you can downgrade the firmware on an operating cluster using the same steps as for a firmware upgrade. A warning message appears during the downgrade but the downgrade usually works and after the downgrade the cluster continues operating normally with the older firmware image.

Downgrading between some firmware versions, especially if features have changed between the two versions, may not always work without the requirement to fix configuration issues after the downgrade.

Only perform firmware downgrades during maintenance windows and make sure you back up your cluster configuration before the downgrade.

If the firmware downgrade that you are planning may not work without configuration loss or other problems, you can use the following downgrade procedure to make sure your configuration is not lost after the downgrade.

To downgrade cluster firmware

This example shows how to downgrade the cluster shown in Figure 197 on page 2022. The cluster consists of two cluster units (620_ha_1 and 620_ha_2). The port1 and port2 interfaces are connected networks and the port3 and port4 interfaces are connected together for the HA heartbeat.

This example, describes separating each unit from the cluster and downgrading the firmware for the standalone FortiGate units. There are several ways you could disconnect units from the cluster. This example describes using the disconnect from cluster function described in "Disconnecting a cluster unit from a cluster" on page 2164.

1. Go to *System* > *Maintenance* > *Backup & Restore* and backup the cluster configuration.

   From the CLI use `execute backup config`.
2. Go to *System* > *Config* > *HA* and for 620_ha_1 select *Disconnect from cluster* icon.
3. Select the port2 interface and enter an IP address and netmask of 10.11.101.101/24 and select OK.

   From the CLI you can enter the following command (FG600B3908600705 is the serial number of the cluster unit) to be able to manage the standalone FortiGate unit by connecting to the port2 interface with IP address and netmask 10.11.101.101/24.

   ```
   execute ha disconnect FG600B3908600705 port2 10.11.101.101/24
   ```

   After 620_ha_1 is disconnected, 620_ha_2 continues processing traffic.
4. Connect to the 620_ha_1 web-based manager or CLI using IP address 10.11.101.101/24 and follow normal procedures to downgrade standalone FortiGate unit firmware.
5. When the downgrade is complete confirm that the configuration of 620_ha_1 is correct.
6. Set the HA mode of 620_ha_2 to Standalone and follow normal procedures to downgrade standalone FortiGate unit firmware.

   Network communication will be interrupted for a short time during the downgrade.
7. When the downgrade is complete confirm that the configuration of 620_ha_2 is correct.

8 Set the HA mode of 620_ha_2 to Active-Passive or the required HA mode.

9 Set the HA mode of 620_ha_1 to the same mode as 620_ha_2.

If you have not otherwise changed the HA settings of the cluster units and if the firmware downgrades have not affected the configurations the units should negotiate and form cluster running the downgraded firmware.

Backing up and restoring the cluster configuration

You can backup the configuration of the primary unit by logging into the web-based manager or CLI and following normal configuration backup procedures.

The following configuration settings are not synchronized to all cluster units:

- HA override and priority
- The interface configuration of the HA reserved management interface (`config system interface`)
- The HA reserved management interface default route (`ha-mgmt-interface-gateway`)
- The FortiGate unit host name.

To backup these configuration settings for each cluster unit you must log into each cluster unit and backup its configuration.

If you need to restore the configuration of the cluster including the configuration settings that are not synchronized you should first restore the configuration of the primary unit and then restore the configuration of each cluster unit. Alternatively you could log into each cluster unit and manually add the configuration settings that were not restored.

Monitoring cluster units for failover

If the primary unit in the cluster fails, the units in the cluster renegotiate to select a new primary unit. Failure of the primary unit results in the following:

- If SNMP is enabled, the new primary unit sends HA trap messages. The messages indicate a cluster status change, HA heartbeat failure, and HA member down. For more info about HA and SNMP, see “Clusters and SNMP” on page 2143.
- If event logging is enabled and HA activity event is selected, the new primary unit records log messages that show that the unit has become the primary unit. See “Example log messages” on page 2138 for some example message sequences when a failover occurs.
- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGate units. The failed primary unit no longer appears on the Cluster Members list.
- The host name and serial number of the primary unit changes. You can see these changes when you log into the web-based manager or CLI.
- The cluster info displayed on the dashboard, cluster members list or from the `get system ha status` command changes.

If a subordinate unit fails, the cluster continues to function normally. Failure of a subordinate unit results in the following:

- If event logging is enabled and HA activity event is selected, the primary unit records log messages that show that a subordinate has been removed from the cluster. See "Example log messages" on page 2138 for some example message sequences.
- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGate units. The failed unit no longer appears on the Cluster Members list.

Viewing cluster status from the CLI

Use the `get system ha status` command to display information about an HA cluster. The command displays general HA configuration settings. The command also displays information about how the cluster unit that you have logged into is operating in the cluster.

Usually you would log into the primary unit CLI using SSH or telnet. In this case the `get system ha status` command displays information about the primary unit first, and also displays the HA state of the primary unit (the primary unit operates in the work state). However, if you log into the primary unit and then use the `execute ha manage` command to log into a subordinate unit, (or if you use a console connection to log into a subordinate unit) the `get system status` command displays information about this subordinate unit first, and also displays the HA state of this subordinate unit. The state of a subordinate unit is work for an active-active cluster and standby for an active-passive cluster.

For a virtual cluster configuration, the `get system ha status` command displays information about how the cluster unit that you have logged into is operating in virtual cluster 1 and virtual cluster 2. For example, if you connect to the cluster unit that is the primary unit for virtual cluster 1 and the subordinate unit for virtual cluster 2, the output of the `get system ha status` command shows virtual cluster 1 in the work state and virtual cluster 2 in the standby state. The `get system ha status` command also displays additional information about virtual cluster 1 and virtual cluster 2.

The command display includes the following fields.

Fields	Description
`Model`	The FortiGate model number.
`Mode`	The HA mode of the cluster: a-a or a-p.
`Group`	The group ID of the cluster.
`Debug`	The debug status of the cluster.
`ses_pickup`	The status of session pickup: enable or disable.
`load balance`	The status of the `load-balance-all` keyword: enable or disable. Relevant to active-active clusters only.
`schedule`	The active-active load balancing schedule. Relevant to active-active clusters only.

Fields	Description
`Master` `Slave`	`Master` displays the device priority, host name, serial number, and cluster index of the primary (or master) unit. `Slave` displays the device priority, host name, serial number, and cluster index of the subordinate (or slave, or backup) unit or units. The list of cluster units changes depending on how you log into the CLI. Usually you would use SSH or telnet to log into the primary unit CLI. In this case the primary unit would be at the top the list followed by the other cluster units. If you use `execute ha manage` or a console connection to log into a subordinate unit CLI, and then enter `get system ha status` the subordinate unit that you have logged into appears at the top of the list of cluster units.
`number of vcluster`	The number of virtual clusters. If virtual domains are not enabled, the cluster has one virtual cluster. If virtual domains are enabled the cluster has two virtual clusters.

`vcluster 1`
`Master`
`Slave`
	The HA state (hello, work, or standby) and HA heartbeat IP address of the cluster unit that you have logged into in virtual cluster 1. If virtual domains are not enabled, `vcluster 1` displays information for the cluster. If virtual domains are enabled, `vcluster 1` displays information for virtual cluster 1.
	The HA heartbeat IP address is 169.254.0.2 if you are logged into the primary unit of virtual cluster 1 and 169.254.0.1 if you are logged into a subordinate unit of virtual cluster 1.
	`vcluster 1` also lists the primary unit (master) and subordinate units (slave) in virtual cluster 1. The list includes the cluster index and serial number of each cluster unit in virtual cluster 1. The cluster unit that you have logged into is at the top of the list.
	If virtual domains are not enabled and you connect to the primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the primary unit.
	If virtual domains are not enabled and you connect to a subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you have logged into.
	If virtual domains are enabled and you connect to the virtual cluster 1 primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the virtual cluster 1 primary unit.
	If virtual domains are enabled and you connect to the virtual cluster 1 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you are logged into.

Fields	Description
vcluster 2 Master Slave	vcluster 2 only appears if virtual domains are enabled. vcluster 2 displays the HA state (hello, work, or standby) and HA heartbeat IP address of the cluster unit that you have logged into in virtual cluster 2. The HA heartbeat IP address is 169.254.0.2 if you are logged into the primary unit of virtual cluster 2 and 169.254.0.1 if you are logged into a subordinate unit of virtual cluster 2. vcluster 2 also lists the primary unit (master) and subordinate units (slave) in virtual cluster 2. The list includes the cluster index and serial number of each cluster unit in virtual cluster 2. The cluster unit that you have logged into is at the top of the list. If you connect to the virtual cluster 2 primary unit CLI, the HA state of the cluster unit in virtual cluster 2 is work. The display lists the cluster units starting with the virtual cluster 2 primary unit. If you connect to the virtual cluster 2 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 2 is standby. The display lists the cluster units starting with the subordinate unit that you are logged into.

Examples

The following example shows get system ha status output for a cluster of two FortiGate-5001SX units operating in active-active mode. The cluster group ID, session pickup, load balance all, and the load balancing schedule are all set to the default values. The device priority of the primary unit is also set to the default value. The device priority of the subordinate unit has been reduced to 100. The host name of the primary unit is 5001_Slot_4. The host name of the subordinate unit in is 5001_Slot_3.

The command output was produced by connecting to the primary unit CLI (host name 5001_Slot_4).

```
Model: 5000
Mode: a-a
Group: 0
Debug: 0
ses_pickup: disable
load_balance: disable
schedule: round robin
Master:128 5001_Slot_4      FG50012204400045 1
Slave :100 5001_Slot_3      FG50012205400050 0
number of vcluster: 1
vcluster 1: work 169.254.0.2
Master:0 FG50012204400045
Slave :1 FG50012205400050
```

The following command output was produced by using execute HA manage 0 to log into the subordinate unit CLI of the cluster shown in the previous example. The host name of the subordinate unit is 5001_Slot_3.

```
Model: 5000
Mode: a-a
Group: 0
Debug: 0
```

```
ses_pickup: disable
load_balance: disable
schedule: round robin
Slave :100 5001_Slot_3      FG50012205400050 0
Master:128 5001_Slot_4      FG50012204400045 1
number of vcluster: 1

```

The following example shows `get system ha status` output for a cluster of three FortiGate-5001 units operating in active-passive mode. The cluster group ID is set to 20 and session pickup is enabled. Load balance all and the load balancing schedule are set to the default value. The device priority of the primary unit is set to 200. The device priorities of the subordinate units are set to 128 and 100. The host name of the primary unit is `5001_Slot_5`. The host names of the subordinate units are `5001_Slot_3` and `5001_Slot_4`.

```
Model: 5000
Mode: a-p
Group: 20
Debug: 0
ses_pickup: enable
load_balance: disable
schedule: round robin
Master:200 5001_Slot_5      FG50012206400112 0
Slave :100 5001_Slot_3      FG50012205400050 1
Slave :128 5001_Slot_4      FG50012204400045 2
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG50012206400112
Slave :1 FG50012204400045
Slave :2 FG50012205400050
```

The following example shows `get system ha status` output for a cluster of two FortiGate-5001 units with virtual clustering enabled. This command output was produced by logging into the primary unit for virtual cluster 1 (hostname: 5001_Slot_4, serial number FG50012204400045).

The virtual clustering output shows that the cluster unit with host name 5001_Slot_4 and serial number FG50012204400045 is operating as the primary unit for virtual cluster 1 and the subordinate unit for virtual cluster 2.

For virtual cluster 1 the cluster unit that you have logged into is operating in the work state and the serial number of the primary unit for virtual cluster 1 is FG50012204400045. For virtual cluster 2 the cluster unit that you have logged into is operating in the standby state and the serial number of the primary unit for virtual cluster 2 is FG50012205400050.

```

```

About the HA cluster index and the execute ha manage command

When a cluster starts up, the FortiGate Cluster Protocol (FGCP) assigns a cluster index and a HA heartbeat IP address to each cluster unit based on the serial number of the cluster unit. The FGCP selects the cluster unit with the highest serial number to become the primary unit. The FGCP assigns a cluster index of 0 and an HA heartbeat IP address of 169.254.0.1 to this unit. The FGCP assigns a cluster index of 1 and an HA heartbeat IP address of 169.254.0.2 to the cluster unit with the second highest serial number. If the cluster contains more units, the cluster unit with the third highest serial number is assigned a cluster index of 2 and an HA heartbeat IP address of 169.254.0.3, and so on. You can display the cluster index assigned to each cluster unit using the `get system ha status` command. Also when you use the `execute ha manage` command you select a cluster unit to log into by entering its cluster index.

The cluster index and HA heartbeat IP address only change if a unit leaves the cluster or if a new unit joins the cluster. When one of these events happens, the FGCP resets the cluster index and HA heartbeat IP address of each cluster unit according to serial number in the same way as when the cluster first starts up.

Each cluster unit keeps its assigned cluster index and HA heartbeat IP address even as the units take on different roles in the cluster. After the initial cluster index and HA heartbeat IP addresses are set according to serial number, the FGCP checks other primary unit selection criteria such as device priority and monitored interfaces. Checking these criteria could result in selecting a cluster unit without the highest serial number to operate as the primary unit.

Even if the cluster unit without the highest serial number now becomes the primary unit, the cluster indexes and HA heartbeat IP addresses assigned to the individual cluster units do not change. Instead the FGCP assigns a second cluster index, which could be called the operating cluster index, to reflect this role change. The operating cluster index is 0 for the primary unit and 1 and higher for the other units in the cluster. By default both sets of cluster indexes are the same. But if primary unit selection selects the cluster unit that does not have the highest serial number to be the primary unit then this cluster unit is assigned an operating cluster index of 0. The operating cluster index is used by the FGCP only. You can display the operating cluster index assigned to each cluster unit using the `get system ha status` command. There are no CLI commands that reference the operating cluster index.

Even though there are two cluster indexes there is only one HA heartbeat IP address and the HA heartbeat address is not affected by a change in the operating cluster index.

Using the execute ha manage command

When you use the CLI command `execute ha manage <index_integer>` to connect to the CLI of another cluster unit, the `<index_integer>` that you enter is the cluster index of the unit that you want to connect to.

Using get system ha status to display cluster indexes

You can display the cluster index assigned to each cluster unit using the CLI command `get system ha status`. The following example shows the information displayed by the `get system ha status` command for a cluster consisting of two FortiGate-5001SX units operating in active-passive HA mode with virtual domains not enabled and without virtual clustering.

```
get system ha status
Model: 5000
```

```
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 5001_slot_7 FG50012205400050 0
Slave :128 5001_slot_11 FG50012204400045 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG50012205400050
Slave :1 FG50012204400045
```

In this example, the cluster unit with serial number FG50012205400050 has the highest serial number and so has a cluster index of 0 and the cluster unit with serial number FG50012204400045 has a cluster index of 1. From the CLI of the primary (or master) unit of this cluster you can connect to the CLI of the subordinate (or slave) unit using the following command:

```
execute ha manage 1
```

This works because the cluster unit with serial number FG50012204400045 has a cluster index of 1.

The `get system ha status` command output shows two similar lists of indexes and serial numbers. The listing on the sixth and seventh lines of the command output are the cluster indexes assigned according to cluster unit serial number. These are the cluster indexes that you enter when using the `execute ha manage` command. The cluster indexes shown in the last two lines of the command output are the operating cluster indexes that reflect how the cluster units are actually operating in the cluster. In this example both sets of cluster indexes are the same.

The last three lines of the command output display the status of vcluster 1. In a cluster consisting of two cluster units operating without virtual domains enabled all clustering actually takes place in virtual cluster 1. HA is designed to work this way to support virtual clustering. If this cluster was operating with virtual domains enabled, adding virtual cluster 2 is similar to adding a new copy of virtual cluster 1. Virtual cluster 2 is visible in the `get system ha status` command output when you add virtual domains to virtual cluster 2.

The HA heartbeat IP address displayed on line 8 is the HA heartbeat IP address of the cluster unit that is actually operating as the primary unit. For a default configuration this IP address will always be 169.254.0.1 because the cluster unit with the highest serial number will be the primary unit. This IP address changes if the operating primary unit is not the primary unit with the highest serial number.

Example: actual and operating cluster indexes do not match

This example shows get system ha status command output for same cluster of two FortiGate-5001SX units. However, in this example the device priority of the cluster unit with the serial number FG50012204400045 is increased to 200. As a result the cluster unit with the lowest serial number becomes the primary unit. This means the actual and operating cluster indexes of the cluster units do not match.

```
get system ha status
Model: 5000
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 5001_slot_7 FG50012205400050 0
```

```
Slave :200 5001_slot_11 FG50012204400045 1
number of vcluster: 1
vcluster 1: work 169.254.0.2
Master:1 FG50012205400050
Slave :0 FG50012204400045
```

The actual cluster indexes have not changed but the operating cluster indexes have. Also, the HA heartbeat IP address displayed for vcluster 1 has changed to 169.254.0.2.

Virtual clustering example output

The `get system ha status` command output is the same if a cluster is operating with virtual clustering turned on but with all virtual domains in virtual cluster 1. The following `get system ha status` command output example shows the same cluster operating as a virtual cluster with virtual domains in virtual cluster 1 and added to virtual cluster 2. In this example the cluster unit with serial number FG50012204400045 is the primary unit for virtual cluster 1 and the cluster unit with serial number FG50012205400050 is the primary unit for virtual cluster 2.

```
get system ha status
Model: 5000
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 5001_slot_7 FG50012205400050 0
Slave :200 5001_slot_11 FG50012204400045 1
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master:1 FG50012205400050
Slave :0 FG50012204400045
vcluster 2: standby 169.254.0.1
Master:0 FG50012205400050
Slave :1 FG50012204400045
```

This example shows three sets of indexes. The indexes in lines six and seven are still used by the `execute ha manage` command. The indexes on lines ten and eleven are for the primary and subordinate units in virtual cluster 1 and the indexes on the last two lines are for virtual cluster 2.

Managing individual cluster units

The following procedure describes how to use SSH to log into the primary unit CLI and from there to use the `execute ha manage` command to connect to the CLI of any other unit in the cluster. The procedure is very similar if you use telnet, or the web-based manager dashboard CLI console.

You can use the `execute ha manage` command from the CLI of any cluster unit to log into the CLI of another the cluster unit. Usually you would use this command from the CLI of the primary unit to log into the CLI of a subordinate unit. However, if you have logged into a subordinate unit CLI, you can use this command to log into the primary unit CLI, or the CLI of another subordinate unit.

Using SSH or telnet or the web-based manager dashboard CLI console you can only log into the primary unit CLI. Using a direct console connection you can log into any cluster unit. In both cases you can use `execute ha manage` to connect to the CLI of other cluster units.

You log into the subordinate unit using the FGT_ha_admin administrator account. This built-in administrator account gives you read and write permission on the subordinate unit. Normally this built-in administrative account is not visible, however FGT_ha_admin does appear in event log messages.

1. Use SSH to connect to the cluster and log into the primary unit CLI.

   Connect to any cluster interface configured for SSH administrative access to log into the cluster.
2. Enter the following command followed by a space and type a question mark (`?`):

   ```
   execute ha manage
   ```

   The CLI displays a list of all the subordinate units in the cluster. Each cluster unit is numbered, starting at 1. The information displayed for each cluster unit includes the unit serial number and the host name of the unit.
3. Complete the command with the number of the subordinate unit to log into. For example, to log into subordinate unit 1, enter the following command:

   ```
   execute ha manage 1
   ```

   Press Enter to connect to and log into the CLI of the selected subordinate unit. If this subordinate unit has a different host name, the CLI prompt changes to this host name.

   You can use CLI commands to manage this subordinate unit. If you make changes to the configuration of any cluster unit (primary or subordinate unit) these changes are synchronized to all cluster units.
4. You can now use the `execute ha manage` command to connect to any other cluster unit (including the primary unit). You can also use the `exit` command to return to the primary unit CLI.

Disconnecting a cluster unit from a cluster

Use the following procedures to disconnect a cluster unit from a functioning cluster without disrupting the operation of the cluster. You can disconnect a cluster unit if you need to use the disconnected FortiGate unit for another purpose, such as to act as a standalone firewall.

You can use the following procedures for a standard cluster and for a virtual clustering configuration. To use the following procedures from a virtual cluster you must be logged in as the admin administrator and you must have selected Global Configuration.

When you disconnect a cluster unit you must assign an IP address and netmask to one of the interfaces of the disconnected unit. You can disconnect any unit from the cluster even the primary unit. After the unit is disconnected, the cluster responds as if the disconnected unit has failed. The cluster may renegotiate and may select a new primary unit.

When the cluster unit is disconnected the HA mode is changed to standalone. In addition, all interface IP addresses of the disconnected unit are set to 0.0.0.0 except for the interface that you configure.

Otherwise the configuration of the disconnected unit is not changed. The HA configuration of the disconnected unit is not changed either (except to change the HA mode to Standalone).

To disconnect a cluster unit from a cluster - web-based manager

1 Go to *System* > *Config* > *HA* to view the cluster members list.

2 Select the Disconnect from cluster icon for the cluster unit to disconnect from the cluster.

3 Select the interface that you want to configure. You also specify the IP address and netmask for this interface. When the FortiGate unit is disconnected, all management access options are enabled for this interface.

4 Specify an IP address and netmask for the interface. You can use this IP address to connect to the interface to configure the disconnected FortiGate unit.

5 Select OK.

The FortiGate unit is disconnected from the cluster and the cluster may renegotiate and select a new primary unit. The selected interface of the disconnected unit is configured with the specified IP address and netmask.

To disconnect a cluster unit from a cluster - CLI

1 Enter the following command to disconnect a cluster unit with serial number FGT5002803033050. The internal interface of the disconnected unit is set to IP address 1.1.1.1 and netmask 255.255.255.0.

```
execute ha disconnect FGT5002803033050 internal 1.1.1.1
  255.255.255.0
```

Adding a disconnected FortiGate unit back to its cluster

If you disconnect a FortiGate unit from a cluster, you can re-connect the disconnected FortiGate unit to the cluster by setting the HA mode of the disconnected unit to match the HA mode of the cluster. Usually the disconnected unit rejoins the cluster as a subordinate unit and the cluster automatically synchronizes its configuration.

You do not have to change the HA password on the disconnected unit unless the HA password has been changed after the unit was disconnected. Disconnecting a unit from a cluster does not change the HA password.

You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. You should also make sure that the HA `override` CLI option is not enabled on the disconnected unit. Otherwise, when the disconnected unit joins the cluster, the cluster will renegotiate and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units. This configuration change might disrupt the operation of the cluster.

The following procedure assumes that the disconnected FortiGate unit is correctly physically connected to your network and to the cluster but is not running in HA mode and not part of the cluster.

Before you start this procedure you should note the device priority of the primary unit.

To add a disconnected FortiGate unit back to its cluster - web-based manager

1 Log into the disconnected FortiGate unit.

If virtual domains are enabled, log in as the admin administrator and select Global Configuration.

2 Go to *System* > *Config* > *HA*.
3 Change Mode to match the mode of the cluster.
4 If required, change the group name and password to match the cluster.
5 Set the Device Priority lower than the device priority of the primary unit.
6 Select OK.

The disconnected FortiGate unit joins the cluster.

To add a disconnected FortiGate unit back to its cluster - CLI

1 Log into the CLI of the FortiGate unit to be added back to the cluster.
2 Enter the following command to access the global configuration and add the FortiGate unit back to a cluster operating in active-passive mode and set the device priority to 50 (a low number) so that this unit will not become the primary unit:

```
config global
  config system ha
    set mode a-p
    set priority 50
  end
end
```

You may have to also change the group name, group id and password. However if you have not changed these for the cluster or the FortiGate unit after it was disconnected from the cluster you should not have to adjust them now.

HA and failover protection

In FortiGate active-passive HA, the FortiGate Clustering Protocol (FGCP) provides failover protection. This means that an active-passive cluster can provide FortiGate services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiGate unit. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially in a mission-critical environment.

The FGCP supports three kinds of failover protection. Device failover automatically replaces a failed device and restarts traffic flow with minimal impact on the network. Link failover maintains traffic flow if a link fails. Session failover resumes communication sessions with minimal loss of data if a device or link failover occurs.

This chapter describes how FGCP failover protection works and provides detailed NAT/Route and Transparent mode packet flow descriptions.

This chapter contains the following sections:

About active-passive failover

To achieve failover protection in an active-passive cluster, one of the cluster units functions as the primary unit, while the rest of the cluster units are subordinate units, operating in an active stand-by mode. The cluster IP addresses and HA virtual MAC addresses are associated with the cluster interfaces of the primary unit. All traffic directed at the cluster is actually sent to and processed by the primary unit.

While the cluster is functioning, the primary unit functions as the FortiGate network security device for the networks that it is connected to. In addition, the primary unit and subordinate units use the HA heartbeat to keep in constant communication. The subordinate units report their status to the cluster unit and receive and store connection and state table updates.

Device failure

If the primary unit encounters a problem that is severe enough to cause it to fail, the remaining cluster units negotiate to select a new primary unit. This occurs because all of the subordinate units are constantly waiting to negotiate to become primary units. Only the heartbeat packets sent by the primary unit keep the subordinate units from becoming primary units. Each received heartbeat packet resets negotiation timers in the subordinate units. If this timer is allowed to run out because the subordinate units do not receive heartbeat packets from the primary unit, the subordinate units assume that the primary unit has failed, and negotiate to become primary units themselves.

Using the same FCGP negotiation process that occurs when the cluster starts up, after they determine that the primary unit has failed, the subordinate units negotiate amongst themselves to select a new primary unit. The subordinate unit that wins the negotiation becomes the new primary unit with the same MAC and IP addresses as the former primary unit. The new primary unit then sends gratuitous ARP packets out all of its interfaces to inform attached switches to send traffic to the new primary unit. Sessions then resume with the new primary unit.

Link failure

If a primary unit interface fails or is disconnected while a cluster is operation, a link failure occurs. When a link failure occurs the cluster units negotiate to select a new primary unit. Since the primary unit has not stopped operating, it participates in the negotiation. The link failure means that a new primary unit must be selected and the cluster unit with the link failure joins the cluster as a subordinate unit.

Just as for a device failover, the new primary unit sends gratuitous arp packets out all of its interfaces to inform attached switches to send traffic to it. Sessions then resume with the new primary unit.

If a subordinate unit experiences a device failure its status in the cluster does not change. However, in future negotiations a cluster unit with a link failure is unlikely to become the primary unit.

Session failover

If you enable session failover (also called session pickup) for the cluster, during cluster operation the primary unit informs the subordinate units of changes to the primary unit connection and state tables, keeping the subordinate units up-to-date with the traffic currently being processed by the cluster.

After a failover the new primary unit recognizes open sessions that were being handled by the cluster. The sessions continue to be processed by the new primary unit and are handled according to their last known state.

If you leave session pickup disabled, the cluster does not keep track of sessions and after a failover, active sessions have to be restarted or resumed.

Primary unit recovery

If a primary unit recovers after a device or link failure, it will operate as a subordinate unit, unless the `override` CLI keyword is enabled and its device priority is set higher than the unit priority of other cluster units (see "HA override" on page 2008).

About active-active failover

HA failover in a cluster running in active-active mode is similar to active-passive failover described above. Active-active subordinate units are constantly waiting to negotiate to become primary units and, if session failover is enabled, continuously receive connection state information from the primary unit. If the primary unit fails, or one of the primary unit interfaces fails, the cluster units use the same mechanisms to detect the failure and to negotiate to select a new primary unit. If session failover is enabled, the new primary unit also maintains communication sessions through the cluster using the shared connection state table.

Active-active HA load balances sessions among all cluster units. For session failover, the cluster must maintain all of these sessions. To load balance sessions, the functioning cluster uses a load balancing schedule to distribute sessions to all cluster units. The shared connection state table tracks the communication sessions being processed by all cluster units (not just the primary unit). After a failover, the new primary unit uses the load balancing schedule to re-distribute all of the communication sessions recorded in the shared connection state table among all of the remaining cluster units. The connections continue to be processed by the cluster, but possibly by a different cluster unit, and are handled according to their last known state.

Device failover

The FGCP provides transparent device failover. Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device.

In the case of FortiOS HA, the device is the primary unit. If the primary unit fails, device failover ensures that one of the subordinate units in the cluster automatically takes the place of the primary unit and can continue processing network traffic in the same way as the failed primary unit.

Device failover does not maintain communication sessions. After a device failover, communication sessions have to be restarted. To maintain communication sessions, you must enable session failover. See "Session failover (session pick-up)" on page 2205.

FortiGate HA device failover is supported by the HA heartbeat, virtual MAC addresses, configuration synchronization, route synchronization and IPsec VPN SA synchronization.

The HA heartbeat makes sure that the subordinate units detect a primary unit failure. If the primary unit fails to respond on time to HA heartbeat packets the subordinate units assume that the primary unit has failed and negotiate to select a new primary unit.

The new primary unit takes the place of the failed primary unit and continues functioning in the same way as the failed primary unit. For the new primary unit to continue functioning like the failed primary unit, the new primary unit must be able to reconnect to network devices and the new primary unit must have the same configuration as the failed primary unit.

FortiGate HA uses virtual MAC addresses to reconnect the new primary unit to network devices. The FGCP causes the new primary unit interfaces to acquire the same virtual MAC addresses as the failed primary unit. As a result, the new primary unit has the same network identity as the failed primary unit.

The new primary unit interfaces have different physical connections than the failed primary unit. Both the failed and the new primary unit interfaces are connected to the same switches, but the new primary unit interfaces are connected to different ports on these switches. To make sure that the switches send packets to the new primary unit, the new primary unit interfaces send gratuitous ARP packets to the connected switches. These gratuitous ARP packets notify the switches that the primary unit MAC and IP addresses are on different switch ports and cause the switches to send packets to the ports connected to the new primary unit. In this way, the new primary unit continues to receive packets that would otherwise have been sent to the failed primary unit.

Configuration synchronization means that the new primary unit always has the same configuration as the failed primary unit. As a result the new primary unit operates in exactly the same way as the failed primary unit. If configuration synchronization were not available the new primary unit may not process network traffic in the same way as the failed primary unit.

Route synchronization synchronizes the primary unit routing table to all subordinate units so that after a failover the new primary unit does not have to form a completely new routing table. IPsec VPN SA synchronization synchronizes IPsec VPN security associations (SAs) and other IPsec session data so that after a failover the new primary unit can resume IPsec tunnels without having to establish new SAs.

HA heartbeat and communication between cluster units

The HA heartbeat keeps cluster units communicating with each other. The heartbeat consists of hello packets that are sent at regular intervals by the heartbeat interface of all cluster units. These hello packets describe the state of the cluster unit and are used by other cluster units to keep all cluster units synchronized.

HA heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8890. The default time interval between HA heartbeats is 200 ms. The FGCP uses link-local IP4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

For best results, isolate the heartbeat devices from your user networks by connecting the heartbeat devices to a separate switch that is not connected to any network. If the cluster consists of two FortiGate units you can connect the heartbeat device interfaces directly using a crossover cable. Heartbeat packets contain sensitive information about the cluster configuration. Heartbeat packets may also use a considerable amount of network bandwidth. For these reasons, it is preferable to isolate heartbeat packets from your user networks.

On startup, a FortiGate unit configured for HA operation broadcasts HA heartbeat hello packets from its HA heartbeat interface to find other FortiGate units configured to operate in HA mode. If two or more FortiGate units operating in HA mode connect with each other, they compare HA configurations (HA mode, HA password, and HA group ID). If the HA configurations match, the units negotiate to form a cluster.

While the cluster is operating, the HA heartbeat confirms that all cluster units are functioning normally. The heartbeat also reports the state of all cluster units, including the communication sessions that they are processing.

Heartbeat interfaces

A heartbeat interface is an Ethernet network interface in a cluster that is used by the FGCP for HA heartbeat communications between cluster units.

To change the HA heartbeat configuration go to *System* > *Config* > *HA* and select the *FortiGate interfaces to use as HA heartbeat interfaces*.

From the CLI enter the following command to make port4 and port5 HA heartbeat interfaces and give both interfaces a heartbeat priority of 150:

```
config system ha
  set hbdev port4 150 port5 150
end
```

The following example shows how to change the default heartbeat interface configuration so that the port4 and port1 interfaces can be used for HA heartbeat communication and to give the port4 interface the highest heartbeat priority so that port4 is the preferred HA heartbeat interface.

```
config system ha
  set hbdev port4 100 port1 50
end
```

By default, for most FortiGate models two interfaces are configured to be heartbeat interfaces. You can change the heartbeat interface configuration as required. For example you can select additional or different heartbeat interfaces. You can also select only one heartbeat interface.

In addition to selecting the heartbeat interfaces, you also set the *Priority* for each heartbeat interface. In all cases, the heartbeat interface with the highest priority is used for all HA heartbeat communication. If the interface fails or becomes disconnected, the selected heartbeat interface that has the next highest priority handles all heartbeat communication.

If more than one heartbeat interface has the same priority, the heartbeat interface with the highest priority that is also highest in the heartbeat interface list is used for all HA heartbeat communication. If this interface fails or becomes disconnected, the selected heartbeat interface with the highest priority that is next highest in the list handles all heartbeat communication.

The default heartbeat interface configuration sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration if one or both of the default heartbeat interfaces are connected. You can select different heartbeat interfaces, select more heartbeat interfaces and change heartbeat priorities according to your requirements.

For the HA cluster to function correctly, you must select at least one heartbeat interface and this interface of all of the cluster units must be connected together. If heartbeat communication is interrupted and cannot failover to a second heartbeat interface, the cluster units will not be able to communicate with each other and more than one cluster unit may become a primary unit. As a result the cluster stops functioning normally because multiple devices on the network may be operating as primary units with the same IP and MAC addresses creating a kind if split brain scenario.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0. The higher the number the higher the priority.

In most cases you can maintain the default heartbeat interface configuration as long as you can connect the heartbeat interfaces together. Configuring HA heartbeat interfaces is the same for virtual clustering and for standard HA clustering.

You can enable heartbeat communications for physical interfaces, but not for VLAN subinterfaces, IPsec VPN interfaces, redundant interfaces, or for 802.3ad aggregate interfaces. You cannot select these types of interfaces in the heartbeat interface list.

Selecting more heartbeat interfaces increases reliability. If a heartbeat interface fails or is disconnected, the HA heartbeat fails over to the next heartbeat interface.

You can select up to 8 heartbeat interfaces. This limit only applies to FortiGate units with more than 8 physical interfaces.

HA heartbeat traffic can use a considerable amount of network bandwidth. If possible, enable HA heartbeat traffic on interfaces used only for HA heartbeat traffic or on interfaces connected to less busy networks.

Connecting HA heartbeat interfaces

For most FortiGate models if you do not change the heartbeat interface configuration, you can isolate the default heartbeat interfaces of all of the cluster units by connecting them all to the same switch. Use one switch per heartbeat interface. If the cluster consists of two units you can connect the heartbeat interfaces together using crossover cables. For an example of how to connect heartbeat interfaces, see "Connecting a FortiGate HA cluster" on page 1996.

HA heartbeat and data traffic are supported on the same cluster interface. In NAT/Route mode, if you decide to use heartbeat interfaces for processing network traffic or for a management connection, you can assign the interface any IP address. This IP address does not affect HA heartbeat traffic.

In Transparent mode, you can connect the heartbeat interface to your network and enable management access. You would then establish a management connection to the interface using the Transparent mode management IP address. This configuration does not affect HA heartbeat traffic.

Heartbeat interfaces and FortiGate switch interfaces

You can configure a FortiGate interface that contains an internal switch as an HA heartbeat interface. However this configuration is not recommended for two reasons:

- For security reasons and to save network bandwidth you should keep HA heartbeat traffic off of your internal network, and internal switch interfaces are usually intended to be connected to your internal network.
- Heartbeat packets may be lost if the switch interface is processing high volumes of traffic. Losing heartbeat packets may lead to unnecessary and repeated failovers.

Heartbeat packets and heartbeat interface selection

HA heartbeat hello packets are constantly sent by all of the enabled heartbeat interfaces. Using these hello packets, each cluster unit confirms that the other cluster units are still operating. The FGCP selects one of the heartbeat interfaces to be used for communication between the cluster units. The FGCP selects the heartbeat interface for heartbeat communication based on the linkfail states of the heartbeat interfaces, on the priority of the heartbeat interfaces, and on the interface index.

The FGCP checks the linkfail state of all heartbeat interfaces to determine which ones are connected. The FGCP selects one of these connected heartbeat interfaces to be the one used for heartbeat communication. The FGCP selects the connected heartbeat interface with the highest priority for heartbeat communication.

If more than one connected heartbeat interface has the highest priority the FGCP selects the heartbeat interface with the lowest interface index. The web-based manager lists the FortiGate unit interfaces in alphabetical order. This order corresponds to the interface index order with lowest index at the top and highest at the bottom. If more than one heartbeat interface has the highest priority, the FGCP selects the interface that is highest in the heartbeat interface list (or first in alphabetical order) for heartbeat communication.

If the interface that is processing heartbeat traffic fails or becomes disconnected, the FGCP uses the same criteria to select another heartbeat interface for heartbeat communication. If the original heartbeat interface is fixed or reconnected, the FGCP again selects this interface for heartbeat communication.

The HA heartbeat communicates cluster session information, synchronizes the cluster configuration, synchronizes the cluster routing table, and reports individual cluster member status. The HA heartbeat constantly communicates HA status information to make sure that the cluster is operating properly.

Interface index and display order

The web-based manager and CLI display interface names in alphanumeric order. For example, the sort order for a FortiGate unit with 10 interfaces (named port1 through port10) places port10 at the bottom of the list:

- port1
- port2 through 9
- port10

However, interfaces are indexed in hash map order, rather than purely by alphabetic order or purely by interface number value comparisons. As a result, the list is sorted primarily alphabetical by interface name (for example, base1 is before port1), then secondarily by index numbers:

- port1
- port10
- port2 through port9

HA heartbeat interface IP addresses

The FGCP uses link-local IP4 addresses (RFC 3927) in the 169.254.0.x range for HA heartbeat interface IP addresses and for inter-VDOM link interface IP addresses. When a cluster initially starts up, the primary unit heartbeat interface IP address is 169.254.0.1. Subordinate units are assigned heartbeat interface IP addresses in the range 169.254.0.2 to 169.254.0.63. HA inter-VDOM link interfaces on the primary unit are assigned IP addresses 169.254.0.65 and 169.254.0.66.

The ninth line of the following CLI command output shows the HA heartbeat interface IP address of the primary unit.

```
get system ha status
  Model: 620
  Mode: a-p
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:150 head_office_upper FG600B3908600825 1
  Slave :150 head_office_lower FG600B3908600705 0
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
```

```
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

You can also use the `execute traceroute` command from the subordinate unit CLI to display HA heartbeat IP addresses and the HA inter-VDOM link IP addresses. For example, use `execute ha manage 1` to connect to the subordinate unit CLI and then enter the following command to trace the route to an IP address on your network:

```
execute traceroute 172.20.20.10
   traceroute to 172.20.20.10 (172.20.20.10), 32 hops max, 72 byte packets
   1  169.254.0.1  0 ms  0 ms  0 ms
   2  169.254.0.66  0 ms  0 ms  0 ms
   3  172.20.20.10 0 ms  0 ms  0 ms
```

Both HA heartbeat and data traffic are supported on the same FortiGate interface. All heartbeat communication takes place on a separate VDOM called vsys_ha. Heartbeat traffic uses a virtual interface called port_ha in the vsys_ha VDOM. Data and heartbeat traffic use the same physical interface, but they're logically separated into separate VDOMs.

Heartbeat packet Ethertypes

Normal IP packets are 802.3 packets that have an Ethernet type (Ethertype) field value of 0x0800. Ethertype values other than 0x0800 are understood as level2 frames rather than IP packets.

By default, HA heartbeat packets use the following Ethertypes:

- HA heartbeat packets for NAT/Route mode clusters use Ethertype 0x8890. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ethertype of these packets using the `ha-eth-type` option of the `config system ha` command.
- HA heartbeat packets for Transparent mode clusters use Ethertype 0x8891. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ethertype of these packets using the `hc-eth-type` option of the `config system ha` command.
- HA telnet sessions between cluster units over HA heartbeat links use Ethertype 0x8893. The telnet sessions are used to synchronize the cluster configurations. Telnet sessions are also used when an administrator uses the `execute ha manage` command to connect from one cluster unit CLI to another. You can change the Ethertype of these packets using the `l2ep-eth-type` option of the `config system ha` command.

Because heartbeat packets are recognized as level2 frames, the switches and routers on your heartbeat network that connect to heartbeat interfaces must be configured to allow them. If level2 frames are dropped by these network devices, heartbeat traffic will not be allowed between the cluster units.

Some third-party network equipment may use packets with these Ethertypes for other purposes. For example, Cisco N5K/Nexus switches use Ethertype 0x8890 for some functions. When one of these switches receives Ethertype 0x8890 packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGate units connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8893, and 0x8891 to pass.

Alternatively, you can use the following CLI options to change the Ethertypes of the HA heartbeat packets:

```
config system ha
  set ha-eth-type <ha_ethertype_4-digit_hex
  set hc-eth-type <hc_ethertype_4-digit_ex>
  set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For example, use the following command to change the Ethertype of the HA heartbeat packets from 0x8890 to 0x8895 and to change the Ethertype of HA Telnet session packets from 0x8891 to 0x889f:

```
config system ha
  set ha-eth-type 8895
  set l2ep-eth-type 889f
end
```

Modifying heartbeat timing

In an HA cluster, if a cluster unit CPU becomes very busy, the cluster unit may not be able to send heartbeat packets on time. If heartbeat packets are not sent on time other units in the cluster may think that the cluster unit has failed and the cluster will experience a failover.

A cluster unit CPU may become very busy if the cluster is subject to a syn flood attack, if network traffic is very heavy, or for other similar reasons. You can use the following CLI commands to configure how the cluster times HA heartbeat packets:

```
config system ha
  set hb-interval <interval_integer>
  set hb-lost-threshold <threshold_integer>
  set helo-holddown <holddown_integer>
end
```

Changing the lost heartbeat threshold

The lost heartbeat threshold is the number of consecutive heartbeat packets that are not received from another cluster unit before assuming that the cluster unit has failed. The default value is 6, meaning that if the 6 heartbeat packets are not received from a cluster unit then that cluster unit is considered to have failed. The range is 1 to 60 packets.

If the primary unit does not receive a heartbeat packet from a subordinate unit before the heartbeat threshold expires, the primary unit assumes that the subordinate unit has failed.

If a subordinate unit does not receive a heartbeat packet from the primary unit before the heartbeat threshold expires, the subordinate unit assumes that the primary unit has failed. The subordinate unit then begins negotiating to become the new primary unit.

The lower the `hb-lost-threshold` the faster a cluster responds when a unit fails. However, sometimes heartbeat packets may not be sent because a cluster unit is very busy. This can lead to a false positive failure detection. To reduce these false positives you can increase the `hb-lost-threshold`.

Use the following CLI command to increase the lost heartbeat threshold to 12:

```
config system ha
```

```
  set hb-lost-threshold 12
end
```

Changing the heartbeat interval

The heartbeat interval is the time between sending HA heartbeat packets. The heartbeat interval range is 1 to 20 (100*ms). The heartbeat interval default is 2 (200 ms).

A heartbeat interval of 2 means the time between heartbeat packets is 200 ms. Changing the heartbeat interval to 5 changes the time between heartbeat packets to 500 ms (5 * 100ms = 500ms).

The HA heartbeat packets consume more bandwidth if the heartbeat interval is short. But if the heartbeat interval is very long, the cluster is not as sensitive to topology and other network changes.

Use the following CLI command to increase the heartbeat interval to 10:

```
config system ha
  set hb-interval 10
end
```

The heartbeat interval combines with the lost heartbeat threshold to set how long a cluster unit waits before assuming that another cluster unit has failed and is no longer sending heartbeat packets. By default, if a cluster unit does not receive a heartbeat packet from a cluster unit for 6 * 200 = 1200 milliseconds or 1.2 seconds the cluster unit assumes that the other cluster unit has failed.

You can increase both the heartbeat interval and the lost heartbeat threshold to reduce false positives. For example, increasing the heartbeat interval to 20 and the lost heartbeat threshold to 30 means a failure will be assumed if no heartbeat packets are received after 30 * 2000 milliseconds = 60,000 milliseconds, or 60 seconds.

Use the following CLI command to increase the heartbeat interval to 20 and the lost heartbeat threshold to 30:

```
config system ha
  set hb-lost-threshold 20
  set hb-interval 30
end
```

Changing the time to wait in the helo state

The hello state hold-down time is the number of seconds that a cluster unit waits before changing from hello state to work state. After a failure or when starting up, cluster units operate in the hello state to send and receive heartbeat packets so that all the cluster units can find each other and form a cluster. A cluster unit should change from the hello state to work state after it finds all of the other FortiGate units to form a cluster with. If for some reason all cluster units cannot find each other during the hello state then some cluster units may be joining the cluster after it has formed. This can cause disruptions to the cluster and affect how it operates.

One reason for a delay in all of the cluster units joining the cluster could be the cluster units are located at different sites of if for some other reason communication is delayed between the heartbeat interfaces.

If cluster units are joining your cluster after it has started up of if it takes a while for units to join the cluster you can increase the time that the cluster units wait in the helo state. The hello state hold-down time range is 5 to 300 seconds. The hello state hold-down time default is 20 seconds.

Use the following CLI command to increase the time to wait in the helo state to 1 minute (60 seconds):

```
config system ha
  set helo-holddown 60
end
```

Enabling or disabling HA heartbeat encryption and authentication

You can enable HA heartbeat encryption and authentication to encrypt and authenticate HA heartbeat packets. HA heartbeat packets should be encrypted and authenticated if the cluster interfaces that send HA heartbeat packets are also connected to your networks.

If HA heartbeat packets are not encrypted the cluster password and changes to the cluster configuration could be exposed and an attacker may be able to sniff HA packets to get cluster information. Enabling HA heartbeat message authentication prevents an attacker from creating false HA heartbeat messages. False HA heartbeat messages could affect the stability of the cluster.

HA heartbeat encryption and authentication are disabled by default. Enabling HA encryption and authentication could reduce cluster performance. Use the following CLI command to enable HA heartbeat encryption and authentication.

```
config system ha
  set authentication enable
  set encryption enable
end
```

HA authentication and encryption uses AES-128 for encryption and SHA1 for authentication.

Cluster virtual MAC addresses

When a cluster is operating, the FGCP assigns virtual MAC addresses to each primary unit interface. HA uses virtual MAC addresses so that if a failover occurs, the new primary unit interfaces will have the same virtual MAC addresses and IP addresses as the failed primary unit. As a result, most network equipment would identify the new primary unit as the exact same device as the failed primary unit.

If the MAC addresses changed after a failover, the network would take longer to recover because all attached network devices would have to learn the new MAC addresses before they could communicate with the cluster.

If a cluster is operating in NAT/Route mode, the FGCP assigns a different virtual MAC address to each primary unit interface. VLAN subinterfaces are assigned the same virtual MAC address as the physical interface that the VLAN subinterface is added to. Redundant interfaces or 802.3ad aggregate interfaces are assigned the virtual MAC address of the first interface in the redundant or aggregate list.

If a cluster is operating in Transparent mode, the FGCP assigns a virtual MAC address for the primary unit management IP address. Since you can connect to the management IP address from any interface, all of the FortiGate interfaces appear to have the same virtual MAC address.

A MAC address conflict can occur if two clusters are operating on the same network. See “Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain” on page 2182 for more information.

Subordinate unit MAC addresses do not change. You can verify this by connecting to the subordinate unit CLI and using the `get hardware interface nic` command to display the MAC addresses of each FortiGate interface.

When the new primary unit is selected after a failover, the primary unit sends gratuitous ARP packets to update the devices connected to the cluster interfaces (usually layer-2 switches) with the virtual MAC address. Gratuitous ARP packets configure connected network devices to associate the cluster virtual MAC addresses and cluster IP address with primary unit physical interfaces and with the layer-2 switch physical interfaces. This is sometimes called using gratuitous ARP packets (sometimes called GARP packets) to train the network. The gratuitous ARP packets sent from the primary unit are intended to make sure that the layer-2 switch forwarding databases (FDBs) are updated as quickly as possible.

Sending gratuitous ARP packets is not required for routers and hosts on the network because the new primary unit will have the same MAC and IP addresses as the failed primary unit. However, since the new primary unit interfaces are connected to different switch interfaces than the failed primary unit, many network switches will update their FDBs more quickly after a failover if the new primary unit sends gratuitous ARP packets.

Changing how the primary unit sends gratuitous ARP packets after a failover

When a failover occurs it is important that the devices connected to the primary unit update their FDBs as quickly as possible to reestablish traffic forwarding.

Depending on your network configuration, you may be able to change the number of gratuitous ARP packets and the time interval between ARP packets to reduce the cluster failover time.

You cannot disable sending gratuitous ARP packets, but you can use the following command to change the number of packets that are sent. For example, enter the following command to send 20 gratuitous ARP packets:

```
config system ha
  set arps 20
end
```

You can use this command to configure the primary unit to send from 1 to 60 ARP packets. Usually you would not change the default setting of 5. In some cases, however, you might want to reduce the number of gratuitous ARP packets. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending a higher number gratuitous ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully, you could reduce the number of gratuitous ARP packets that are sent to reduce the amount of traffic produced after a failover.

If failover is taking longer that expected, you may be able to reduce the failover time by increasing the number gratuitous ARP packets sent.

You can also use the following command to change the time interval in seconds between gratuitous ARP packets. For example, enter the following command to change the time between ARP packets to 3 seconds:

```
config system ha
  set arps-interval 3
end
```

The time interval can be in the range of 1 to 20 seconds. The default is 8 seconds between gratuitous ARP packets. Normally you would not need to change the time interval. However, you could decrease the time to be able send more packets in less time if your cluster takes a long time to failover.

There may also be a number of reasons to set the interval higher. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending gratuitous ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully you could increase the interval to reduce the amount of traffic produced after a failover.

For more information about gratuitous ARP packets see RFC 826 and RFC 3927.

How the virtual MAC address is determined

The virtual MAC address is determined based on following formula:

`00-09-0f-09-<group-id_hex>-<vcluster_integer><idx>`

where

`<group-id_hex>` is the HA Group ID for the cluster converted to hexadecimal. Table 118 lists the virtual MAC address set for each group ID.

Table 118: HA group ID in integer and hexadecimal format

Integer Group ID	Hexadecimal Group ID
0	00
1	01
2	02
3	03
4	04
...	...
10	0a
11	0b
...	...
63	3f

`<vcluster_integer>` is 0 for virtual cluster 1 and 2 for virtual cluster 2. If virtual domains are not enabled, HA sets the virtual cluster to 1 and by default all interfaces are in the root virtual domain. Including virtual cluster and virtual domain factors in the virtual MAC address formula means that the same formula can be used whether or not virtual domains and virtual clustering is enabled.

`<idx>` is the index number of the interface. Interfaces are numbered from 0 to x (where x is the number of interfaces). Interfaces are numbered according to their has map order. See “Interface index and display order” on page 2173. The first interface has an index of 0. The second interface in the list has an index of 1 and so on.

Only the `<idx>` part of the virtual MAC address is different for each interface. The `<vcluster_integer>` would be different for different interfaces if multiple VDOMs have been added.

Example virtual MAC addresses

An HA cluster with HA group ID unchanged (default=0) and virtual domains not enabled would have the following virtual MAC addresses for interfaces port1 to port12:

- port1 virtual MAC: `00-09-0f-09-00-00`
- port10 virtual MAC: `00-09-0f-09-00-01`
- port2 virtual MAC: `00-09-0f-09-00-02`
- port3 virtual MAC: `00-09-0f-09-00-03`
- port4 virtual MAC: `00-09-0f-09-00-04`
- port5 virtual MAC: `00-09-0f-09-00-05`
- port6 virtual MAC: `00-09-0f-09-00-06`
- port7 virtual MAC: `00-09-0f-09-00-07`
- port8 virtual MAC: `00-09-0f-09-00-08`
- port9 virtual MAC: `00-09-0f-09-00-09`
- port11 virtual MAC: `00-09-0f-09-00-0a`
- port12 virtual MAC: `00-09-0f-09-00-0b`

If the group ID is changed to 34 these virtual MAC addresses change to:

- port1 virtual MAC: `00-09-0f-09-22-00`
- port10 virtual MAC: `00-09-0f-09-22-01`
- port2 virtual MAC: `00-09-0f-09-22-02`
- port3 virtual MAC: `00-09-0f-09-22-03`
- port4 virtual MAC: `00-09-0f-09-22-04`
- port5 virtual MAC: `00-09-0f-09-22-05`
- port6 virtual MAC: `00-09-0f-09-22-06`
- port7 virtual MAC: `00-09-0f-09-22-07`
- port8 virtual MAC: `00-09-0f-09-22-08`
- port9 virtual MAC: `00-09-0f-09-22-09`
- port11 virtual MAC: `00-09-0f-09-22-0a`
- port12 virtual MAC: `00-09-0f-09-22-0b`

A cluster with virtual domains enabled where the HA group ID has been changed to 23, port5 and port 6 are in the root virtual domain (which is in virtual cluster1), and port7 and port8 are in the vdom_1 virtual domain (which is in virtual cluster 2) would have the following virtual MAC addresses:

port5 interface virtual MAC: `00-09-0f-09-23-05`

port6 interface virtual MAC: `00-09-0f-09-23-06`

port7 interface virtual MAC: `00-09-0f-09-23-27`

port8 interface virtual MAC: `00-09-0f-09-23-28`

Displaying the virtual MAC address

Every FortiGate unit physical interface has two MAC addresses: the current hardware address and the permanent hardware address. The permanent hardware address cannot be changed, it is the actual MAC address of the interface hardware. The current hardware address can be changed. The current hardware address is the address seen by the network. For a FortiGate unit not operating in HA, you can use the following command to change the current hardware address of the port1 interface:

```
config system interface
  edit port1
    set macaddr <mac_address>
  end
end
```

For an operating cluster, the current hardware address of each cluster unit interface is changed to the HA virtual MAC address by the FGCP. The `macaddr` option is not available for a functioning cluster. You cannot change an interface MAC address and you cannot view MAC addresses from the `system interface` CLI command.

You can use the `get hardware nic <interface_name_str>` command to display both MAC addresses for any FortiGate interface. This command displays hardware information for the specified interface. Depending on their hardware configuration, this command may display different information for different interfaces. You can use this command to display the current hardware address as `Current_HWaddr` and the permanent hardware address as `Permanent_HWaddr`. For some interfaces the current hardware address is displayed as `MAC`. The command displays a great deal of information about the interface so you may have to scroll the output to find the hardware addresses.

You can also use the `diagnose hardware deviceinfo nic <interface_str>` command to display both MAC addresses for any FortiGate interface.

Before HA configuration the current and permanent hardware addresses are the same. For example for one of the units in Cluster_1:

```
FGT60B3907503171 # get hardware nic internal
.
.
.
MAC: 02:09:0f:78:18:c9
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

During HA operation the current hardware address becomes the HA virtual MAC address, for example for the units in Cluster_1:

```
FGT60B3907503171 # get hardware nic internal
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

The following command output for Cluster_2 shows the same current hardware address for port1 as for the internal interface of Cluster_2, indicating a MAC address conflict.

```
FG300A2904500238 # get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 00:09:0F:85:40:FD
.
.
.
```

Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain

A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID.

This section describes a topology that can result in packet loss, how to determine if packets are being lost, and how to correct the problem by changing the HA Group ID.

Packet loss on a network can also be caused by IP address conflicts. Finding and fixing IP address conflicts can be difficult. However, if you are experiencing packet loss and your network contains two FortiGate HA clusters you can use the information in this article to eliminate one possible source of packet loss.

Changing the HA group ID to avoid MAC address conflicts

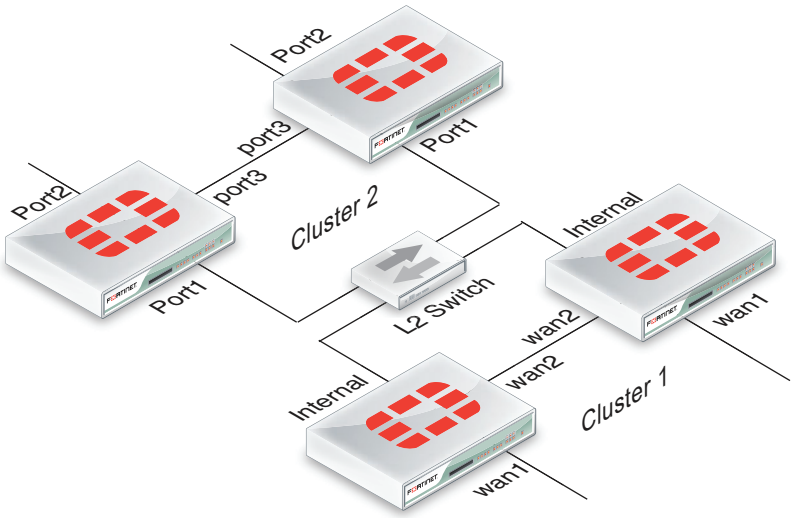
Change the Group ID to change the virtual MAC address of all cluster interfaces. You can change the Group ID from the FortiGate CLI using the following command:

```
config system ha
  set group-id <id_integer>
end
```

Example topology

The topology below shows two clusters. The Cluster_1 internal interfaces and the Cluster_2 port 1 interfaces are both connected to the same broadcast domain. In this topology the broadcast domain could be an internal network. Both clusters could also be connected to the Internet or to different networks.

Figure 216: Example HA topology with possible MAC address conflicts



Ping testing for packet loss

If the network is experiencing packet loss, it is possible that you will not notice a problem unless you are constantly pinging both HA clusters. During normal operation of the network you also might not notice packet loss because the loss rate may not be severe enough to timeout TCP sessions. Also many common types if TCP traffic, such as web browsing, may not be greatly affected by packet loss. However, packet loss can have a significant effect on real time protocols that deliver audio and video data.

To test for packet loss you can set up two constant ping sessions, one to each cluster. If packet loss is occurring the two ping sessions should show alternating replies and timeouts from each cluster.

Cluster_1	Cluster_2
reply	timeout
reply	timeout
reply	timeout
timeout	reply
timeout	reply
reply	timeout
reply	timeout
timeout	reply
timeout	reply
timeout	reply
timeout	reply

Viewing MAC address conflicts on attached switches

If two HA clusters with the same virtual MAC address are connected to the same broadcast domain (L2 switch or hub), the MAC address will conflict and bounce between the two clusters. This example Cisco switch MAC address table shows the MAC address flapping between different interfaces (1/0/1 and 1/0/4).

```
1    0009.0f09.0002    DYNAMIC     Gi1/0/1
1    0009.0f09.0002    DYNAMIC     Gi1/0/4
```

Synchronizing the configuration

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit.

The following settings are not synchronized between cluster units:

- HA override.
- HA device priority.
- The virtual cluster priority.
- The FortiGate unit host name.
- The HA priority setting for a ping server (or dead gateway detection) configuration.
- The system interface settings of the HA reserved management interface.
- The HA default route for the reserved management interface, set using the `ha-mgt-interface-gateway` option of the `config system ha` command.

The primary unit synchronizes all other configuration settings, including the other HA configuration settings.

Disabling automatic configuration synchronization

In some cases you may want to use the following command to disable automatic synchronization of the primary unit configuration to all cluster units.

```
config system ha
  set sync-config disable
end
```

When this option is disabled the cluster no longer synchronizes configuration changes. If a device failure occurs, the new primary unit may not have the same configuration as the failed primary unit. As a result, the new primary unit may process sessions differently or may not function on the network in the same way.

In most cases you should not disable automatic configuration synchronization. However, if you have disabled this feature you can use the `execute ha synchronize` command to manually synchronize a subordinate unit's configuration to that of the primary unit.

You must enter `execute ha synchronize` commands from the subordinate unit that you want to synchronize with the primary unit. Use the `execute ha manage` command to access a subordinate unit CLI. See "Viewing cluster status from the CLI" on page 2156.

For example, to access the first subordinate unit and force a synchronization at any time, even if automatic synchronization is disabled enter:

```
execute ha manage 0
execute ha synchronize start
```

You can use the following command to stop a synchronization that is in progress.

```
execute ha synchronize stop
```

You can use the following command to a synchronization all parts of the configuration:

```
execute ha synchronize all
```

Individual options are also available to synchronize parts of the configuration. For example, enter the following command to synchronize CA certificates:

```
execute ha synchronize ca
```

Incremental synchronization

When you log into the cluster web-based manager or CLI to make configuration changes, you are actually logging into the primary unit. All of your configuration changes are first made to the primary unit. Incremental synchronization then immediately synchronizes these changes to all of the subordinate units.

When you log into a subordinate unit CLI (for example using `execute ha manage`) all of the configuration changes that you make to the subordinate unit are also immediately synchronized to all cluster units, including the primary unit, using the same process.

Incremental synchronization also synchronizes other dynamic configuration information such as the DHCP server address lease database, routing table updates, IPsec SAs, MAC address tables, and so on. See "FortiGate HA compatibility with PPPoE and DHCP" on page 2012 for more information about DHCP server address lease synchronization and "Synchronizing routing table updates" on page 2191 for information about routing table updates.

Whenever a change is made to a cluster unit configuration, incremental synchronization sends the same configuration change to all other cluster units over the HA heartbeat link. An HA synchronization process running on the each cluster unit receives the configuration change and applies it to the cluster unit. The HA synchronization process makes the configuration change by entering a CLI command that appears to be entered by the administrator who made the configuration change in the first place.

Synchronization takes place silently, and no log messages are recorded about the synchronization activity. However, log messages can be recorded by the cluster units when the synchronization process enters CLI commands. You can see these log messages on the subordinate units if you enable event logging and set the minimum severity level to *Information* and then check the event log messages written by the cluster units when you make a configuration change. See "Configuration change synchronized from primary unit to subordinate unit" on page 2140.

You can also see these log messages on the primary unit if you make configuration changes from a subordinate unit. See "Configuration change synchronized from subordinate unit to primary unit" on page 2141.

Periodic synchronization

Incremental synchronization makes sure that as an administrator makes configuration changes, the configurations of all cluster units remain the same. However, a number of factors could cause one or more cluster units to go out of sync with the primary unit. For example, if you add a new unit to a functioning cluster, the configuration of this new unit will not match the configuration of the other cluster units. Its not practical to use incremental synchronization to change the configuration of the new unit.

Periodic synchronization is a mechanism that looks for synchronization problems and fixes them. Every minute the cluster compares the configuration file checksum of the primary unit with the configuration file checksums of each of the subordinate units. If all subordinate unit checksums are the same as the primary unit checksum, all cluster units are considered synchronized.

If one or more of the subordinate unit checksums is not the same as the primary unit checksum, the subordinate unit configuration is considered out of sync with the primary unit. The checksum of the out of sync subordinate unit is checked again every 15 seconds. This re-checking occurs in case the configurations are out of sync because an incremental configuration sequence has not completed. If the checksums do not match after 5 checks the subordinate unit that is out of sync retrieves the configuration from the primary unit. The subordinate unit then reloads its configuration and resumes operating as a subordinate unit with the same configuration as the primary unit.

The configuration of the subordinate unit is reset in this way because when a subordinate unit configuration gets out of sync with the primary unit configuration there is no efficient way to determine what the configuration differences are and to correct them. Resetting the subordinate unit configuration becomes the most efficient way to resynchronize the subordinate unit.

Synchronization requires that all cluster units run the same FortiOS firmware build. If some cluster units are running different firmware builds, then unstable cluster operation may occur and the cluster units may not be able to synchronize correctly.

Re-installing the firmware build running on the primary unit forces the primary unit to upgrade all cluster units to the same firmware build.

Console messages when configuration synchronization succeeds

When a cluster first forms, or when a new unit is added to a cluster as a subordinate unit, the following messages appear on the CLI console to indicate that the unit joined the cluster and had its configuring synchronized with the primary unit.

```
slave's configuration is not in sync with master's, sequence:0
slave's configuration is not in sync with master's, sequence:1
slave's configuration is not in sync with master's, sequence:2
slave's configuration is not in sync with master's, sequence:3
slave's configuration is not in sync with master's, sequence:4
slave starts to sync with master
logout all admin users
slave succeeded to sync with master
```

Console messages when configuration synchronization fails

If you connect to the console of a subordinate unit that is out of synchronization with the primary unit, messages similar to the following are displayed.

```
slave is not in sync with master, sequence:0. (type 0x3)
slave is not in sync with master, sequence:1. (type 0x3)
slave is not in sync with master, sequence:2. (type 0x3)
slave is not in sync with master, sequence:3. (type 0x3)
slave is not in sync with master, sequence:4. (type 0x3)
global compared not matched
```

If synchronization problems occur the console message sequence may be repeated over and over again. The messages all include a type value (in the example `type 0x3`). The type value can help Fortinet Support diagnose the synchronization problem.

Table 119: HA out of sync object messages and the configuration objects that they reference

Comparing checksums of cluster units

You can use the `diagnose sys ha showcsum` command to compare the configuration checksums of all cluster units. The output of this command shows checksums labelled `global` and `all` as well as checksums for each of the VDOMs including the `root` VDOM. The `get system ha-nonsync-csum` command can be used to display similar information; however, this command is intended to be used by FortiManager.

The primary unit and subordinate unit checksums should be the same. If they are not you can use the `execute ha synchronize` command to force a synchronization.

The following command output is for the primary unit of a cluster that does not have multiple VDOMs enabled:

```
diagnose sys ha showcsum
is_manage_master()=1, is_root_master()=1
debugzone
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following command output is for a subordinate unit of the same cluster:

```
diagnose sys ha showcsum
is_manage_master()=0, is_root_master()=0
debugzone
```

```
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following example shows using this command for the primary unit of a cluster with multiple VDOMs. Two VDOMs have been added named `test` and `Eng_vdm`.

From the primary unit:

```
config global
  diagnose sys ha showcsum
  is_manage_master()=1, is_root_master()=1
  debugzone
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
  root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
  Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
  all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53

  checksum
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
  root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
  Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
  all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53
```

From the subordinate unit:

```
config global
  diagnose sys ha showcsum
  is_manage_master()=0, is_root_master()=0
  debugzone
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
  root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
  Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
  all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53

  checksum
  global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
  test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
  root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
  Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
  all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53
```

How to diagnose HA out of sync messages

This section describes how to use the commands `diagnose sys ha showcsum` and `diagnose debug` to diagnose the cause of HA out of sync messages.

If HA synchronization is not successful, use the following procedures on each cluster unit to find the cause.

To determine why HA synchronization does not occur

1 Connect to each cluster unit CLI by connected to the console port.

2 Enter the following commands to enable debugging and display HA out of sync messages.

```
diagnose debug enable
diagnose debug console timestamp enable
diagnose debug application hatalk -1
diagnose debug application hasync -1
```

Collect the console output and compare the out of sync messages with the information in Table 119 on page 2187.

3 Enter the following commands to turn off debugging.

```
diagnose debug disable
diagnose debug reset
```

To determine what part of the configuration is causing the problem

If the previous procedure displays messages that include sync object 0x30 (for example, `HA_SYNC_SETTING_CONFIGURATION = 0x03`) there is a synchronization problem with the configuration. Use the following steps to determine the part of the configuration that is causing the problem.

If your cluster consists of two cluster units, use this procedure to capture the configuration checksums for each unit. If your cluster consists of more that two cluster units, repeat this procedure for all cluster units that returned messages that include 0x30 sync object messages.

1 Connect to each cluster unit CLI by connected to the console port.

2 Enter the following command to turn on terminal capture

```
diagnose debug enable
```

3 Enter the following command to stop HA synchronization.

```
execute ha sync stop
```

4 Enter the following command to display configuration checksums.

```
diagnose sys ha showcsum 1
```

5 Copy the output to a text file.

6 Repeat for all affected units.

7 Compare the text file from the primary unit with the text file from each cluster unit to find the checksums that do not match.

You can use a diff function to compare text files.

8 Repeat steps 4 to 7 for each checksum level:

```
diagnose sys ha showcsum 2
diagnose sys ha showcsum 3
diagnose sys ha showcsum 4
diagnose sys ha showcsum 5
diagnose sys ha showcsum 6
diagnose sys ha showcsum 7
diagnose sys ha showcsum 8
```

9 When the non-matching checksum is found, attempt to drill down further. This is possible for objects that have sub-components.

For example you can enter the following commands:

```
diagnose sys ha showcsum system.global
```

```
diagnose sys ha showcsum system.interface
```

Generally it is the first non-matching checksum in one of the levels that is the cause of the synchronization problem.

10 Attempt to can remove/change the part of the configuration that is causing the problem. You can do this by making configuration changes from the primary unit or subordinate unit CLI.

11 Enter the following commands to start HA configuration and stop debugging:

```
execute ha sync start
diagnose debug dis
diagnose debug reset
```

Synchronizing routing table updates

In a functioning cluster, the primary unit keeps all subordinate unit routing tables up to date and synchronized with the primary unit. After a failover, because of these routing table updates the new primary unit does not have to populate its routing table before being able to route traffic. After a failover the new primary unit rebuilds its routing table, but having the synchronized routes already available means the table is rebuilt much faster than if no route information was available.

This section describes how clusters handle dynamic routing failover and also describes how to use CLI commands to control the timing of routing table updates of the subordinate unit routing tables from the primary unit.

Configuring graceful restart for dynamic routing failover

When an HA failover occurs, neighbor routers will detect that the cluster has failed and remove it from the network until the routing topology stabilizes. During the time the routers may stop sending IP packets to the cluster and communications sessions that would normally be processed by the cluster may time out or be dropped. Also the new primary unit will not receive routing updates and so will not be able to build and maintain its routing database.

You can configure graceful restart (also called nonstop forwarding (NSF)) as described in RFC3623 (Graceful OSPF Restart) to solve the problem of dynamic routing failover. If graceful restart is enabled on neighbor routers, they will keep sending packets to the cluster following the HA failover instead of removing it from the network. The neighboring routers assume that the cluster is experiencing a graceful restart.

After the failover, the new primary unit can continue to process communication sessions using the synchronized routing data received from the failed primary unit before the failover. This gives the new primary unit time to update its routing table after the failover.

You can use the following commands to enable graceful restart or NSF on Cisco routers:

```
router ospf 1
  log-adjacency-changes
  nsf ietf helper strict-lsa-checking
```

If the cluster is running BGP, use the following command to enable graceful restart for BGP:

```
config router bgp
  set graceful-restart enable
end
```

You can also add BGP neighbors and configure the cluster unit to notify these neighbors that it supports graceful restart.

```
config router bgp
  config neighbor
    edit <neighbor_address_Ipv4>
      set capability-graceful-restart enable
    end
end
```

If the cluster is running OSPF, use the following command to enable graceful restart for OSFP:

```
config router ospf
  set restart-mode graceful-restart
end
```

To make sure the new primary unit keeps its synchronized routing data long enough to acquire new routing data, you should also increase the HA route time to live, route wait, and route hold values to 60 using the following CLI command:

```
config system ha
  set route-ttl 60
  set route-wait 60
  set route-hold 60
end
```

Controlling how the FGCP synchronizes routing updates

You can use the following commands to control some of the timing settings that the FGCP uses when synchronizing routing updates from the primary unit to subordinate units and maintaining routes on the primary unit after a failover.

```
config system ha
  set route-hold <hold_integer>
  set route-ttl <ttl_integer>
  set route-wait <wait_integer>
end
```

Change how long routes stay in a cluster unit routing table

Change the `route-ttl` time to control how long routes remain in a cluster unit routing table. The time to live range is 0 to 3600 seconds. The default time to live is 10 seconds.

The time to live controls how long routes remain active in a cluster unit routing table after the cluster unit becomes a primary unit. To maintain communication sessions after a cluster unit becomes a primary unit, routes remain active in the routing table for the route time to live while the new primary unit acquires new routes.

If `route-ttl` is set to 0 the primary unit must acquire all new routes before it can continue processing traffic. By default, `route-ttl` is set to 10 which may mean that only a few routes will remain in the routing table after a failover. Normally keeping `route-ttl` to 10 or reducing the value to 0 is acceptable because acquiring new routes usually occurs very quickly, especially if graceful restart is enabled, so only a minor delay is caused by acquiring new routes.

If the primary unit needs to acquire a very large number of routes, or if for other reasons, there is a delay in acquiring all routes, the primary unit may not be able to maintain all communication sessions.

You can increase the route time to live if you find that communication sessions are lost after a failover so that the primary unit can use synchronized routes that are already in the routing table, instead of waiting to acquire new routes.

Change the time between routing updates

Change the `route-hold` time to change the time that the primary unit waits between sending routing table updates to subordinate units. The route hold range is 0 to 3600 seconds. The default route hold time is 10 seconds.

To avoid flooding routing table updates to subordinate units, set `route-hold` to a relatively long time to prevent subsequent updates from occurring too quickly. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Increasing the time between updates means that this data exchange will not have to happen so often.

The `route-hold` time should be coordinated with the `route-wait` time.

Change the time the primary unit waits after receiving a routing update

Change the `route-wait` time to change how long the primary unit waits after receiving routing updates before sending the updates to the subordinate units. For quick routing table updates to occur, set route-wait to a relatively short time so that the primary unit does not hold routing table changes for too long before updating the subordinate units.

The `route-wait` range is 0 to 3600 seconds. The default `route-wait` is 0 seconds.

Normally, because the `route-wait` time is 0 seconds the primary unit sends routing table updates to the subordinate units every time its routing table changes.

Once a routing table update is sent, the primary unit waits the `route-hold` time before sending the next update.

Usually routing table updates are periodic and sporadic. Subordinate units should receive these changes as soon as possible so `route-wait` is set to 0 seconds. `route-hold` can be set to a relatively long time because normally the next route update would not occur for a while.

In some cases, routing table updates can occur in bursts. A large burst of routing table updates can occur if a router or a link on a network fails or changes. When a burst of routing table updates occurs, there is a potential that the primary unit could flood the subordinate units with routing table updates. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Setting `route-wait` to a longer time reduces the frequency of additional updates are and prevents flooding of routing table updates from occurring.

Synchronizing IPsec VPN SAs

The FGCP synchronizes IPsec security associations (SAs) between cluster members so that if a failover occurs, the cluster can resume IPsec sessions without having to establish new SAs. The result is improved failover performance because IPsec sessions are not interrupted to establish new SAs. Also, establishing a large number of SAs can reduce cluster performance.

The FGCP implements slightly different synchronization mechanisms for IKEv1 and IKEv2.

Synchronizing SAs for IKEv1

When an SA is synchronized to the subordinate units. the sequence number is set to the maximum sequence number. After a failover, all inbound traffic that connects with the new primary unit and uses the SA will be accepted without needing to re-key. However, first outbound packet to use the SA causes the sequence number to overflow and so causes the new primary unit to re-key the SA.

Please note the following:

- The cluster synchronizes all IPsec SAs.
- IPsec SAs are not synchronized until the IKE process has finished synchronizing the ISAKMP SAs. This is required in for dialup tunnels since it is the synchronizing of the ISAKMP SA that creates the dialup tunnel.
- A dialup interface is created as soon as the phase1 is complete. This ensures that the when HA synchronizes phase1 information the dialup name is included.
- If the IKE process re-starts for any reason it deletes any dialup tunnels that exist. This forces the peer to re-key them.
- IPsec SA deletion happens immediately. Routes associated with a dialup tunnel that is being deleted are cleaned up synchronously as part of the delete, rather than waiting for the SA hard-expiry.
- The FGCP does not sync the IPsec tunnel MTU from the primary unit to the subordinate units. This means that after HA failover if the first packet received by the FortiGate unit arrives after the HA route has been deleted and before the new route is added and the packet is larger than the default MTU of 1024 then the FortiGate unit sends back an ICMP fragmentation required. However, as soon as routing is re-established then the MTU will be corrected and traffic will flow.

Synchronizing SAs for IKEv2

Due to the way the IKEv2 protocol is designed the FGCP cannot use exactly the same solution that is used for synchronizing IKEv1 SAs, though it is similar.

For IKEv2, like IKEv1, the FGCP synchronizes IKE and ISAKMP SAs from the primary unit to the subordinate units. However, for IKEv2 the FGCP cannot actually use this IKE SA to send/receive IKE traffic because IKEv2 includes a sequence number in every IKE message and thus it would require synchronizing every message to the subordinate units to keep the sequence numbers on the subordinate units up to date.

After a failover when the new primary unit accepts incoming IKEv2 sessions, as in IKEv1, the primary unit uses the synchronized SA to decrypt the traffic before passing it through to its destination. For outgoing sessions, because the synchronized SA has an old sequence number, the primary unit negotiates a new SA. This is different from IKEv1 where the existing SA is re-keyed.

Normally for IKEv2 the new primary unit could just negotiate a CHILD_SA using the synchronized SA. However, because the sequence numbers are not up-to-date, as noted above, the synchronized SA cannot be used and the primary unit must instead negotiate a whole new SA.

Link failover

Link failover means that if a monitored interface fails, the cluster reorganizes to reestablish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic.

You configure monitored interfaces (also called interface monitoring or port monitoring) by selecting the interfaces to monitor as part of the cluster HA configuration.

You can monitor up to 16 interfaces. This limit only applies to FortiGate units with more than 16 physical interfaces. In a multiple VDOM configuration you can monitor up to 16 interfaces per virtual cluster.

The interfaces that you can monitor appear on the port monitor list. You can monitor all FortiGate interfaces including redundant interfaces and 802.3ad aggregate interfaces.

You cannot monitor the following types of interfaces (you cannot select the interfaces on the port monitor list):

- FortiGate interfaces that contain an internal switch.
- VLAN subinterfaces.
- IPsec VPN interfaces.
- Individual physical interfaces that have been added to a redundant or 802.3ad aggregate interface.
- FortiGate-5000 series backplane interfaces that have not been configured as network interfaces.

If you are configuring a virtual cluster you can create a different port monitor configuration for each virtual cluster. Usually for each virtual cluster you would monitor the interfaces that have been added to the virtual domains in each virtual cluster.

Wait until after the cluster is up and running to enable interface monitoring. You do not need to configure interface monitoring to get a cluster up and running and interface monitoring will cause failovers if for some reason during initial setup a monitored interface has become disconnected. You can always enable interface monitoring once you have verified that the cluster is connected and operating properly.

You should only monitor interfaces that are connected to networks, because a failover may occur if you monitor an unconnected interface.

To enable interface monitoring - web-based manager

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1 Connect to the cluster web-based manager.

2 Go to *System* > *Config* > *HA* and edit the primary unit (*Role* is *MASTER*).

3 Select the *Port Monitor* check boxes for the *port1* and *port2* interfaces and select *OK*.

The configuration change is synchronized to all cluster units.

To enable interface monitoring - CLI

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1 Connect to the cluster CLI.

2 Enter the following command to enable interface monitoring for port1 and port2.

```
configure system ha
  set monitor port1 port2
end
```

The following example shows how to enable monitoring for the external, internal, and DMZ interfaces.

```
config system ha
  set monitor external internal dmz
end
```

With interface monitoring enabled, during cluster operation, the cluster monitors each cluster unit to determine if the monitored interfaces are operating and connected. Each cluster unit can detect a failure of its network interface hardware. Cluster units can also detect if its network interfaces are disconnected from the switch they should be connected to.

Cluster units cannot determine if the switch that its interfaces are connected to is still connected to the network. However, you can use remote IP monitoring to make sure that the cluster unit can connect to downstream network devices. See "Remote link failover" on page 2200.

Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link between a network and the primary unit fails, to maintain communication with this network, the cluster must select a different primary unit; one that is still connected to the network. Unless another link failure has occurred, the new primary unit will have an active link to the network and will be able to maintain communication with it.

To support link failover, each cluster unit stores link state information for all monitored cluster units in a link state database. All cluster units keep this link state database up to date by sharing link state information with the other cluster units. If one of the monitored interfaces on one of the cluster units becomes disconnected or fails, this information is immediately shared with all cluster units.

If a monitored interface on the primary unit fails

If a monitored interface on the primary unit fails, the cluster renegotiates to select a new primary unit using the process described in "Primary unit selection" on page 2000. Because the cluster unit with the failed monitored interface has the lowest monitor priority, a different cluster unit becomes the primary unit. The new primary unit should have fewer link failures.

After the failover, the cluster resumes and maintains communication sessions in the same way as for a device failure. See "Device failover" on page 2169.

If a monitored interface on a subordinate unit fails

If a monitored interface on a subordinate unit fails, this information is shared with all cluster units. The cluster does not renegotiate. The subordinate unit with the failed monitored interface continues to function in the cluster.

In an active-passive cluster after a subordinate unit link failover, the subordinate unit continues to function normally as a subordinate unit in the cluster.

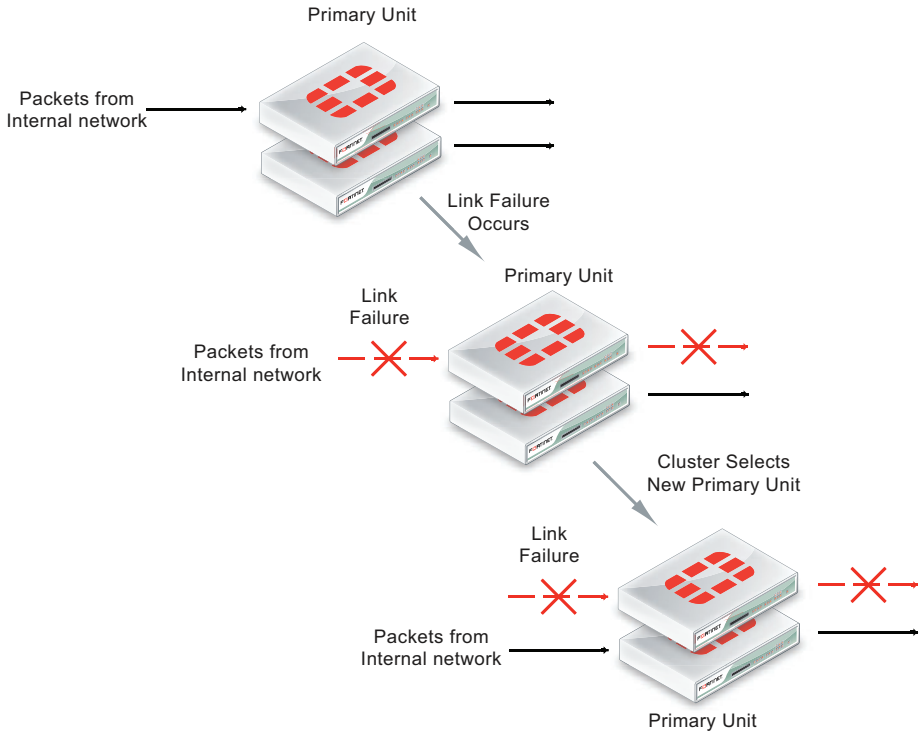
In an active-active cluster after a subordinate unit link failure:

- The subordinate unit with the failed monitored interface can continue processing connections between functioning interfaces. However, the primary unit stops sending sessions to a subordinate unit that use any failed monitored interfaces on the subordinate unit.
- If session pickup is enabled, all sessions being processed by the subordinate unit failed interface that can be are failed over to other cluster units. Sessions that cannot be failed over are lost and have to be restarted.
- If session pickup is not enabled all sessions being processed by the subordinate unit failed interface are lost.

How link failover maintains traffic flow

Monitoring an interface means that the interface is connected to a high priority network. As a high priority network, the cluster should maintain traffic flow to and from the network, even if a link failure occurs. Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link that the primary unit has to a high priority network fails, to maintain traffic flow to and from this network, the cluster must select a different primary unit. This new primary unit should have an active link to the high priority network.

Figure 217: A link failure causes a cluster to select a new primary unit



If a monitored interface on the primary unit fails, the cluster renegotiates and selects the cluster unit with the highest monitor priority to become the new primary unit. The cluster unit with the highest monitor priority is the cluster unit with the most monitored interfaces connected to networks.

After a link failover, the primary unit processes all traffic and all subordinate units, even the cluster unit with the link failure, share session and link status. In addition all configuration changes, routes, and IPsec SAs are synchronized to the cluster unit with the link failure.

In an active-active cluster, the primary unit load balances traffic to all the units in the cluster. The cluster unit with the link failure can process connections between its functioning interfaces (for, example if the cluster has connections to an internal, external, and DMZ network, the cluster unit with the link failure can still process connections between the external and DMZ networks).

If a monitored interface on a subordinate unit fails, the subordinate unit shares this information with all cluster units. The cluster does not renegotiate. The subordinate unit with the failed monitored interface continues to function in the cluster. In an active-active cluster, the subordinate unit can continue processing connections between functioning interfaces. The primary unit re-distributes traffic that was being processed by the failed interface of the subordinate unit to other cluster units. If session pickup is enabled, similar to a failover, some of these sessions continue while others must restart. See "Session failover (session pick-up)" on page 2205.

Recovery after a link failover

If you find and correct the problem that caused a link failure (for example, re-connect a disconnected network cable) the cluster updates its link state database and the cluster unit continues to operate as a subordinate unit. In an active-active cluster the primary unit will begin load balancing sessions to the now reconnected interface.

If the `override` CLI keyword is enabled on this cluster unit and its device priority is set higher that the unit priority of other cluster units the cluster will renegotiate when the link failure is repaired and the cluster unit with the highest device priority becomes the primary unit.

Testing link failover

You can test link failure by disconnecting the network cable from a monitored interface of a cluster unit. If you disconnect a cable from a primary unit monitored interface the cluster should renegotiate and select one of the other cluster units as the primary unit. You can also verify that traffic received by the disconnected interface continues to be processed by the cluster after the failover.

If you disconnect a cable from a subordinate unit interface the cluster will not renegotiate.

Updating MAC forwarding tables when a link failover occurs

When a FortiGate HA cluster is operating and a monitored interface fails on the primary unit, the primary unit usually becomes a subordinate unit and another cluster unit becomes the primary unit. After a link failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables (also called arp tables) of the switches connected to the cluster. This is normal link failover operation (for more information, see "Link failover" on page 2194).

Some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur if the switch does not detect the failure and does not clear its MAC forwarding table.

To make sure the switch detects the failover and clears its MAC forwarding tables, you can use the following command to cause a cluster unit with a monitored interface link failure to shut down all of its interfaces (except the heartbeat interfaces) for one second after the failover occurs. Usually this means the interfaces of the former primary unit are shut down. When this happens the switch should be able to detect this failure and clear its MAC forwarding tables of the MAC addresses of the former primary unit. Since the new primary unit has sent or will send gratuitous ARP packets the switch can then update its MAC forwarding tables to for the new primary unit.

```
config system ha
  set link-failed-signal enable
end
```

Multiple link failures

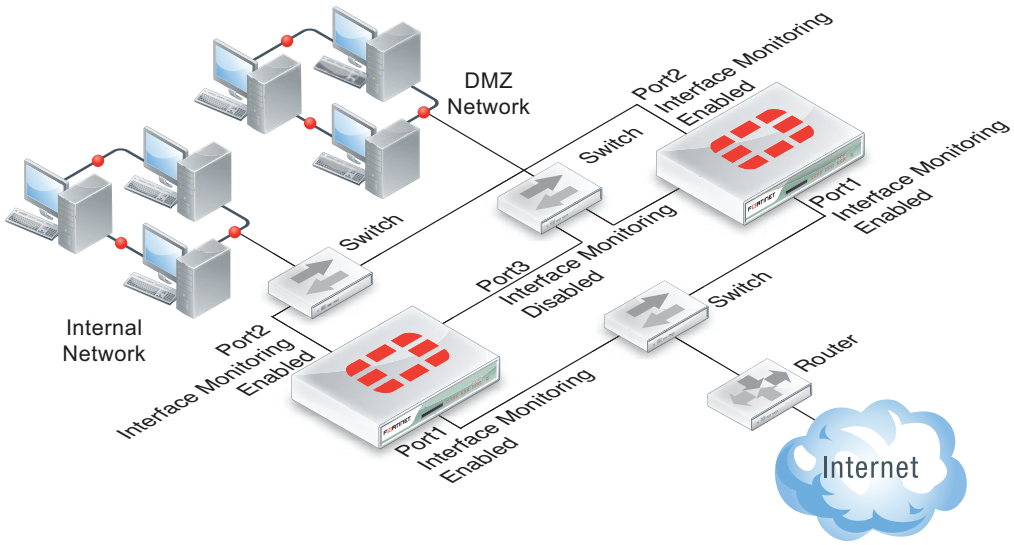
Every time a monitored interface fails, the cluster repeats the processes described above. If multiple monitored interfaces fail on more than one cluster unit, the cluster continues to negotiate to select a primary unit that can provide the most network connections.

Example link failover scenarios

For the following examples, assume a cluster configuration consisting of two FortiGate units (FGT_1 and FGT_2) connected to three networks: internal using port2, external using port1, and DMZ using port3. In the HA configuration, the device priority of FGT_1 is set higher than the unit priority of FGT_2.

The cluster processes traffic flowing between the internal and external networks, between the internal and DMZ networks, and between the external and DMZ networks. If there are no link failures, FGT1 becomes the primary unit because it has the highest device priority.

Figure 218: Sample link failover scenario topology



Example: the port1 link on FGT_1 fails

If the port1 link on FGT_1 fails, FGT_2 becomes primary unit because it has fewer interfaces with a link failure. If the cluster is operating in active-active mode, the cluster load balances traffic between the internal network (port2) and the DMZ network (port3). Traffic between the Internet (port1) and the internal network (port2) and between the Internet (port1) and the DMZ network (port3) is processed by the primary unit only.

Example: port2 on FGT_1 and port1 on FGT_2 fail

If port2 on FGT_1 and port1 on FGT_2 fail, then FGT_1 becomes the primary unit. After both of these link failures, both cluster units have the same monitor priority. So the cluster unit with the highest device priority (FGT_1) becomes the primary unit.

Only traffic between the Internet (port1) and DMZ (port3) networks can pass through the cluster and the traffic is handled by the primary unit only. No load balancing will occur if the cluster is operating in active-active mode.

Subsecond failover

HA link failover supports subsecond failover (that is a failover time of less than one second). Subsecond failover is available for interfaces that can issue a link failure system call when the interface goes down. When an interface experiences a link failure and sends the link failure system call, the FGCP receives the system call and initiates a link failover.

For interfaces that do not support subsecond failover, port monitoring regularly polls the connection status of monitored interfaces. When a check finds that an interface has gone down, port monitoring causes a link failover. Subsecond failover results in a link failure being detected sooner because the system doesn't have to wait for the next poll to find out about the failure.

Subsecond failover requires interfaces that support sending the link failure system call. This functionality is available for:

- Interfaces with network processors (NP2, NP4, etc.)
- Interfaces with content processors (CP4, CP5, CP6, etc.)
- Interfaces in Fortinet Mezzanine Cards that include network and content processors (FMC-XD2, FMC-XG2, etc.)
- Accelerated interface modules (FortiGate-ASM-FB4, ADM-FB8, ADM-XB2, ADM-XD4, RTM-XD2 etc).
- Interfaces in security processor modules (FortiGate-ASM-CE4, ASM-XE2, etc)

Subsecond failover can accelerate HA failover to reduce the link failover time to less than one second under ideal conditions. Actual failover performance may be vary depending on traffic patterns and network configuration. For example, some network devices may respond slowly to an HA failover.

No configuration changes are required to support subsecond failover. However, for best subsecond failover results, the recommended heartbeat interval is 100ms and the recommended lost heartbeat threshold is 5. (See "Changing the heartbeat interval" on page 2176)

```
config system ha
  set hb-lost-threshold 5
  set hb-interval 1
end
```

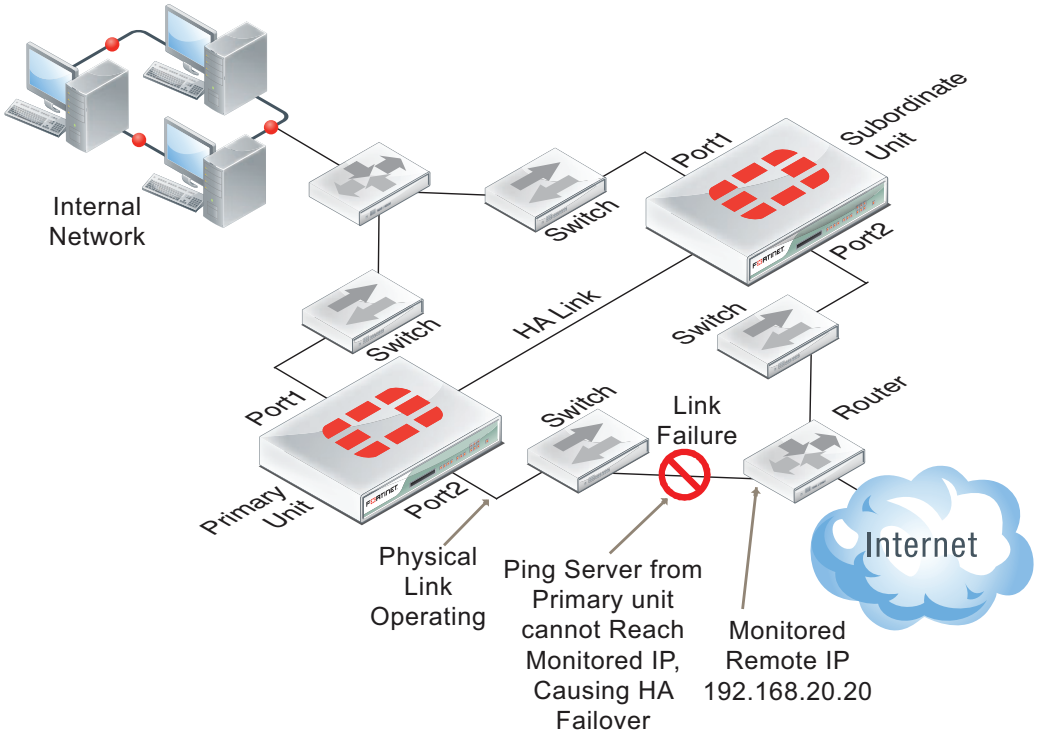
For information about how to reduce failover times, see "Failover performance" on page 2214.

Remote link failover

Remote link failover (also called remote IP monitoring) is similar to HA port monitoring and interface dead gateway detection. Port monitoring causes a cluster to failover if a monitored primary unit interface fails or is disconnected. Remote IP monitoring uses ping servers configured for FortiGate interfaces on the primary unit to test connectivity with IP addresses of network devices. Usually these would be IP addresses of network devices not directly connected to the cluster. For example, a downstream router. Remote IP monitoring causes a failover if one or more of these remote IP addresses does not respond to a ping server.

By being able to detect failures in network equipment not directly connected to the cluster, remote IP monitoring can be useful in a number of ways depending on your network configuration. For example, in a full mesh HA configuration, with remote IP monitoring, the cluster can detect failures in network equipment that is not directly connected to the cluster but that would interrupt traffic processed by the cluster if the equipment failed.

Figure 219: Example HA remote IP monitoring topology



In the simplified example topology shown in Figure 219, the switch connected directly to the primary unit is operating normally but the link on the other side of the switches fails. As a result traffic can no longer flow between the primary unit and the Internet.

To detect this failure you can create a remote IP monitoring configuration consisting of a ping server dead gateway detection configuration for port2 of the cluster. The primary unit tests connectivity to 192.168.20.20. If the ping server cannot connect to 192.268.20.20 the cluster to fails over and the subordinate unit becomes the new primary unit. The remote HA monitoring ping server on the new primary unit can connect to 192.168.20.20 so the failover maintains connectivity between the internal network and the Internet through the cluster.

To configure remote IP monitoring

1 Enter the following commands to configure HA remote monitoring for the example topology.

- Enter the `pingserver-monitor-interface` keyword to enable HA remote IP monitoring on port2.
- Leave the `pingserver-failover-threshold` set to the default value of 0. You can change this value if you do not want a failover to occur if only one ping server fails.
- Enter the `pingserver-flip-timeout` keyword to set the flip timeout to 120 minutes. After a failover, if HA remote IP monitoring on the new primary unit also causes a failover, the flip timeout prevents the failover from occurring until the timer runs out. Setting the `pingserver-flip-timeout` to 120 means that remote IP monitoring can only cause a failover every 120 minutes. This flip timeout is required to prevent repeating failovers if remote IP monitoring causes a failover from all cluster units because none of the cluster units can connect to the monitored IP addresses.

```
config system ha
  set pingserver-monitor-interface port2
  set pingserver-failover-threshold 0
  set pingserver-flip-timeout 120
end
```

2 Enter the following commands to add the ping server for the port2 interface and to set the HA remote IP monitoring priority for this ping server.

- Enter the `detectserver` keyword to add the ping server and set the ping server IP address to 192.168.20.20.
- Leave the `ha-priority` keyword set to the default value of 1. You only need to change this priority if you change the HA ping server failover threshold. The `ha-priority` setting is not synchronized among cluster units.
- Use the `interval` keyword to set the time between ping server pings and use the `failtime` keyword to set the number of times that the ping can fail before a failure is detected (the failover threshold). The following example reduces the failover threshold to 2 but keeps the ping interval at the default value of 5.

```
config router gwdetect
  edit port2
    set server 192.168.20.20
    set ha-priority 1
    set interval 5
    set failtime 2
  end
```

You can also do this from the web-based manager by going to *Router* > *Static* > *Settings*, selecting *Create New* to add a new dead gateway detection configuration, setting *Ping Server* to 192.168.20.20, *HA Priority* to 1, *Ping Interval* to 5, and *Failover Threshold* to 2.

Adding HA remote IP monitoring to multiple interfaces

You can enable HA remote IP monitoring on multiple interfaces by adding more interface names to the `pingserver-monitor-interface` keyword. If your FortiGate configuration includes VLAN interfaces, aggregate interfaces and other interface types, you can add the names of these interfaces to the `pingserver-monitor-interface` keyword to configure HA remote IP monitoring for these interfaces.

For example, enable remote IP monitoring for interfaces named port2, port20, and vlan_234:

```
config system ha
  set pingserver-monitor-interface port2 port20 vlan_234
  set pingserver-failover-threshold 10
  set pingserver-flip-timeout 120
end
```

Then configure ping servers for each of these interfaces. In the following example, default values are accepted for all settings other than the server IP address.

```
config router gwdetect
  edit port2
    set server 192.168.20.20
  next
  edit port20
    set server 192.168.20.30
  next
  edit vlan_234
    set server 172.20.12.10
  end
```

Changing the ping server failover threshold

By default the ping server failover threshold is 0 and the HA priority is 1 so any HA remote IP monitoring ping server failure causes a failover. If you have multiple ping servers you may want a failover to occur only if more than one of them has failed.

For example, you may have 3 ping servers configured on three interfaces but only want a failover to occur if two of the ping servers fail. To do this you must set the HA priorities of the ping servers and the HA ping server failover threshold so that the priority of one ping server is less thana the failover threshold but the added priorities of two ping servers is equal to or greater than the failover threshold. Failover occurs when the HA priority of all failed ping servers reaches or exceeds the threshold.

For example, set the failover threshold to 10 and monitor three interfaces:

```
config system ha
  set pingserver-monitor-interface port2 port20 vlan_234
  set pingserver-failover-threshold 10
  set pingserver-flip-timeout 120
end
```

Then set the HA priority of each ping server to 5.

```
config router gwdetect
  edit port2
    set server 192.168.20.20
    set ha-priority 5
  next
  edit port20
    set server 192.168.20.30
    set ha-priority 5
  next
  edit vlan_234
    set server 172.20.12.10
    set ha-priority 5
  end
```

If only one of the ping servers fails, the total ping server HA priority will be 5, which is lower than the failover threshold so a failover will not occur. If a second ping server fails, the total ping server HA priority of 10 will equal the failover threshold, causing a failover.

By adding multiple ping servers to the remote HA monitoring configuration and setting the HA priorities for each, you can fine tune remote IP monitoring. For example, if it is more important to maintain connections to some networks you can set the HA priorities higher for these ping servers. And if it is less important to maintain connections to other networks you can set the HA priorities lower for these ping servers. You can also adjust the failover threshold so that if the cluster cannot connect to one or two high priority IP addresses a failover occurs. But a failover will not occur if the cluster cannot connect to one or two low priority IP addresses.

Monitoring multiple IP addresses from one interface

You can add multiple IP addresses to a single ping server to use HA remote IP monitoring to monitor more than one IP address from a single interface. If you add multiple IP addresses, the ping will be sent to all of the addresses at the same time. The ping server only fails when no responses are received from any of the addresses.

```
config router gwdetect
  edit port2
    set server 192.168.20.20 192.168.20.30 172.20.12.10
  end
```

Flip timeout

The HA remote IP monitoring configuration also involves setting a flip timeout. The flip timeout is required to reduce the frequency of failovers if, after a failover, HA remote IP monitoring on the new primary unit also causes a failover. This can happen if the new primary unit cannot connect to one or more of the monitored remote IP addresses. The result could be that until you fix the network problem that blocks connections to the remote IP addresses, the cluster will experience repeated failovers. You can control how often the failovers occur by setting the flip timeout. The flip timeout stops HA remote IP monitoring from causing a failover until the primary unit has been operating for the duration of the flip timeout.

If you set the flip timeout to a relatively high number of minutes you can find and repair the network problem that prevented the cluster from connecting to the remote IP address without the cluster experiencing very many failovers. Even if it takes a while to detect the problem, repeated failovers at relatively long time intervals do not usually disrupt network traffic.

Detecting HA remote IP monitoring failovers

Just as with any HA failover, you can detect HA remote IP monitoring failovers by using SNMP to monitor for HA traps. You can also use alert email to receive notifications of HA status changes and monitor log messages for HA failover log messages. In addition, FortiGate units send the critical log message `Ping Server is down` when a ping server fails. The log message includes the name of the interface that the ping server has been added to.

Session failover (session pick-up)

Session failover means that a cluster maintains active network TCP and IPsec VPN sessions after a device or link failover. Session failover does not failover UDP, multicast, ICMP, or SSL VPN sessions. In some cases UDP sessions may be maintained after a failover.

FortiGate HA does not support session failover by default. To enable session failover go to *System* > *Config* > *HA* and select *Enable Session Pick-up*.

From the CLI enter:

```
config system ha
  set session-pickup enable
end
```

To support session failover, when *Enable Session Pick-up* is selected, the FGCP maintains an HA session table for most TCP communication sessions being processed by the cluster and synchronizes this session table with all cluster units. If a cluster unit fails, the HA session table information is available to the remaining cluster units and these cluster units use this session table to resume most of the TCP sessions that were being processed by the failed cluster unit without interruption.

You must enable session pickup for session failover protection. If you do not require session failover protection, leaving session pickup disabled may reduce HA CPU usage and reduce HA heartbeat network bandwidth usage.

If *Enable Session Pick-up* is not selected, the FGCP does not maintain an HA session table and most TCP sessions do not resume after a failover. After a device or link failover all sessions are briefly interrupted and must be restarted after the cluster renegotiates. Many protocols can successfully restart sessions without loss of data. Other protocols may experience data loss and some protocols may require sessions to be manually restarted.

Some sessions may resume after a failover whether or not enable session pick-up is selected:

- “Session failover and UDP, ICMP, multicast and broadcast packets” on page 2208
- “FortiOS Carrier GTP session failover” on page 2209
- “Active-active HA subordinate units sessions can resume after a failover” on page 2209.

Improving session synchronization performance

Two HA configuration options are available to reduce the performance impact of enabling session pickup. They include reducing the number of sessions that are synchronized by adding a session pickup delay and using more FortiGate interfaces for session synchronization.

Reducing the number of sessions that are synchronized

Enable the `session-pickup-delay` CLI option to reduce the number of sessions that are synchronized by synchronizing sessions only if they remain active for more than 30 seconds. Enabling this option could greatly reduce the number of sessions that are synchronized if a cluster typically processes very many short duration sessions, which is typical of most HTTP traffic for example.

Use the following command to enable a 30 second session pickup delay:

```
config system ha
  set session-pickup-delay enable
```

```
end
```

Enabling session pickup delay means that if a failover occurs more sessions may not be resumed after a failover. In most cases short duration sessions can be restarted with only a minor traffic interruption. However, if you notice too many sessions not resuming after a failover you might want to disable this setting.

Using multiple FortiGate interfaces for session synchronization

Using the `session-sync-dev` option you can select one or more FortiGate interfaces to use for synchronizing sessions as required for session pickup. Normally session synchronization occurs over the HA heartbeat link. Using this HA option means only the selected interfaces are used for session synchronization and not the HA heartbeat link. If you select more than one interface, session synchronization traffic is load balanced among the selected interfaces.

Moving sessions synchronization from the HA heartbeat interface reduces the bandwidth requirements of the HA heartbeat interface and may improve the efficiency and performance of the cluster, especially if the cluster is synchronizing a large number of sessions. Load balancing session synchronization among multiple interfaces can further improve performance and efficiency if the cluster is synchronizing a large number of sessions.

Use the following command to perform cluster session synchronization using the port10 and port12 interfaces.

```
config system ha
  set session-sync-dev port10 port12
end
```

Session synchronization packets use Ethertype 0x8892. The interfaces to use for session synchronization must be connected together either directly using the appropriate cable (possible if there are only two units in the cluster) or using switches. If one of the interfaces becomes disconnected the cluster uses the remaining interfaces for session synchronization. If all of the session synchronization interfaces become disconnected, session synchronization reverts back to using the HA heartbeat link. All session synchronization traffic is between the primary unit and each subordinate unit.

Since large amounts of session synchronization traffic can increase network congestion, it is recommended that you keep this traffic off of your network by using dedicated connections for it.

Session failover not supported for all sessions

Most of the features applied to sessions by FortiGate UTM functionality require the FortiGate unit to maintain very large amounts of internal state information for each session. The FGCP does not synchronize internal state information for the following UTM features, so the following types of sessions will not resume after a failover:

- Virus scanning of HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, and NNTP sessions,
- Web filtering and FortiGuard Web Filtering of HTTP and HTTPS sessions,
- Spam filtering of IMAP, IMAPS, POP3, POP3S, SMTP, and SMTPS sessions,
- DLP scanning of IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, SIP, SIMPLE, and SCCP sessions,

- DLP archiving of HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, SMTP, SMTPS, IM, NNTP, AIM, ICQ, MSN, Yahoo! IM, SIP, SIMPLE, and SCCP signal control sessions,

Active-active clusters can resume some of these sessions after a failover. See "Active-active HA subordinate units sessions can resume after a failover" on page 2209 for details.

If you use these features to protect most of the sessions that your cluster processes, enabling session failover may not actually provide significant session failover protection.

TCP sessions that are not being processed by these UTM features resume after a failover even if these sessions are accepted by security policies with UTM options configured. Only TCP sessions that are actually being processed by these UTM features do not resume after a failover. For example:

- TCP sessions that are not virus scanned, web filtered, spam filtered, content archived, or are not SIP, SIMPLE, or SCCP signal traffic resume after a failover, even if they are accepted by a security policy with UTM options enabled. For example, SNMP TCP sessions resume after a failover because FortiOS does not apply any UTM options to SNMP sessions.
- TCP sessions for a protocol for which UTM features have not been enabled resume after a failover even if they are accepted by a security policy with UTM features enabled. For example, if you have not enabled any antivirus or content archiving settings for FTP, FTP sessions resume after a failover.

The following UTM features do not affect TCP session failover:

- IPS does not affect session failover. Sessions being scanned by IPS resume after a failover. After a failover; however, IPS can only perform packet-based inspection of resumed sessions; reducing the number of vulnerabilities that IPS can detect. This limitation only applies to in-progress resumed sessions.
- Application control does not affect session failover. Sessions that are being monitored by application control resume after a failover.
- Logging enabled form UTM features does not affect session failover. UTM logging writes event log messages for UTM events; such as when a virus is found by antivirus scanning, when Web Filtering blocks a URL, and so on. Logging does not enable features that would prevent sessions from being failed over, logging just reports on the activities of enabled features.

If more than one UTM feature is applied to a TCP session, that session will not resume after a failover as long as one of the UTM features prevents session failover. For example:

- Sessions being scanned by IPS and also being virus scanned do not resume after a failover.
- Sessions that are being monitored by application control and that are being DLP archived or virus scanned will not resume after a failover.

SIP session failover

The FGCP supports SIP session failover (also called stateful failover) for active-passive HA. To support SIP session failover, create a standard HA configuration and select *Enable Session Pick-up* option.

SIP session failover replicates SIP states to all cluster units. If an HA failover occurs, all in-progress SIP calls (setup complete) and their RTP flows are maintained and the calls will continue after the failover with minimal or no interruption.

SIP calls being set up at the time of a failover may lose signaling messages. In most cases the SIP clients and servers should use message retransmission to complete the call setup after the failover has completed. As a result, SIP users may experience a delay if their calls are being set up when an HA a failover occurs. But in most cases the call setup should be able to continue after the failover.

Session failover and explicit web proxy, WCCP, and WAN optimization sessions

Similar to UTM sessions, the explicit web proxy, WCCP and WAN optimization features all require the FortiGate unit to maintain very large amounts of internal state information for each session. This information is not maintained and these sessions do not resume after a failover.

Session failover and SSL offloading and HTTP multiplexing

SSL offloading and HTTP multiplexing are both enabled from firewall virtual IPs and firewall load balancing. Similar to the features applied by UTM, SSL offloading and HTTP multiplexing requires the FortiGate unit to maintain very large amounts of internal state information for each session. Sessions accepted by security policies containing virtual IPs or virtual servers with SSL offloading or HTTP multiplexing enabled do not resume after a failover.

IPsec VPN and SSL VPN sessions

Session failover is supported for all IPsec VPN tunnels. To support IPsec VPN tunnel failover, when an IPsec VPN tunnel starts, the FGCP distributes the SA and related IPsec VPN tunnel data to all cluster units.

Session failover is not supported for SSL VPN tunnels.

PPTP and L2TP VPN sessions

PPTP and L2TP VPNs are supported in HA mode. For a cluster you can configure PPTP and L2TP settings and you can also add security policies to allow PPTP and L2TP pass through. However, the FGCP does not provide session failover for PPTP or L2TP. After a failover, all active PPTP and L2TP sessions are lost and must be restarted.

Session failover and UDP, ICMP, multicast and broadcast packets

The FGCP does not maintain a session table for UDP, ICMP, multicast, or broadcast packets. So the cluster does not specifically support failover of these packets.

Some UDP traffic can continue to flow through the cluster after a failover. This can happen if, after the failover, a UDP packet that is part of an already established communication stream matches a security policy. Then a new session will be created and traffic will flow. So after a short interruption, UDP sessions can appear to have failed over. However, this may not be reliable for the following reasons:

- UDP packets in the direction of the security policy must be received before reply packets can be accepted. For example, if a port1 -> port2 policy accepts UDP packets, UDP packets received at port2 destined for the network connected to port1 will not be accepted until the policy accepts UDP packets at port1 that are destined for the network connected to port2. So, if a user connects from an internal network to the Internet and starts receiving UDP packets from the Internet (for example streaming media), after a failover the user will not receive any more UDP packets until the user re-connects to the Internet site.

- UDP sessions accepted by NAT policies will not resume after a failover because NAT will usually give the new session a different source port. So only traffic for UDP protocols that can handle the source port changing during a session will continue to flow.

FortiOS Carrier GTP session failover

FortiOS Carrier HA supports GTP session failover. The primary unit synchronizes the GTP tunnel state to all cluster units after the GTP tunnel setup is completed. After the tunnel setup is completed, GTP sessions use UDP and HA does not synchronize UDP sessions to all cluster units. However, similar to other UDP sessions, after a failover, since the new primary unit will have the GTP tunnel state information, GTP UDP sessions using the same tunnel can continue to flow with some limitations.

The limitation on packets continuing to flow is that there has to be a security policy to accept the packets. For example, if the FortiOS Carrier unit has an internal to external security policy, GTP UDP sessions using an established tunnel that are received by the internal interface are accepted by the security policy and can continue to flow. However, GTP UDP packets for an established tunnel that are received at the external interface cannot flow until packets from the same tunnel are received at the internal interface.

If you have bi-directional policies that accept GTP UDP sessions then traffic in either direction that uses an established tunnel can continue to flow after a failover without interruption.

Active-active HA subordinate units sessions can resume after a failover

In an active-active cluster, subordinate units process sessions. After a failover, all cluster units that are still operating may be able to continue processing the sessions that they were processing before the failover. These sessions are maintained because after the failover the new primary unit uses the HA session table to continue to send session packets to the cluster units that were processing the sessions before the failover. Cluster units maintain their own information about the sessions that they are processing and this information is not affected by the failover. In this way, the cluster units that are still operating can continue processing their own sessions without loss of data.

The cluster keeps processing as many sessions as it can. But some sessions can be lost. Depending on what caused the failover, sessions can be lost in the following ways:

- A cluster unit fails (the primary unit or a subordinate unit). All sessions that were being processed by that cluster unit are lost.
- A link failure occurs. All sessions that were being processed through the network interface that failed are lost.

This mechanism for continuing sessions is not the same as session failover because:

- Only the sessions that can be are maintained.
- The sessions are maintained on the same cluster units and not re-distributed.
- Sessions that cannot be maintained are lost.

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended HA configuration for WAN optimization is active-passive mode. Also, when the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions. HA also does not support WAN optimization session failover.

In a cluster, the primary unit only stores web cache and byte cache databases. These databases are not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its web and byte caches. As well, the new primary unit cannot connect to a SAS partition that the failed primary unit used.

Rebuilding the byte caches can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGate units that it is participating with in WAN optimization tunnels.

Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time experienced by your network users may depend on how quickly the switches connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

Monitoring cluster units for failover

You can use logging and SNMP to monitor cluster units for failover. Both the primary and subordinate units can be configured to write log messages and send SNMP traps if a failover occurs. You can also log into the cluster web-based manager and CLI to determine if a failover has occurred. See “Monitoring cluster units for failover” on page 2155.

NAT/Route mode active-passive cluster packet flow

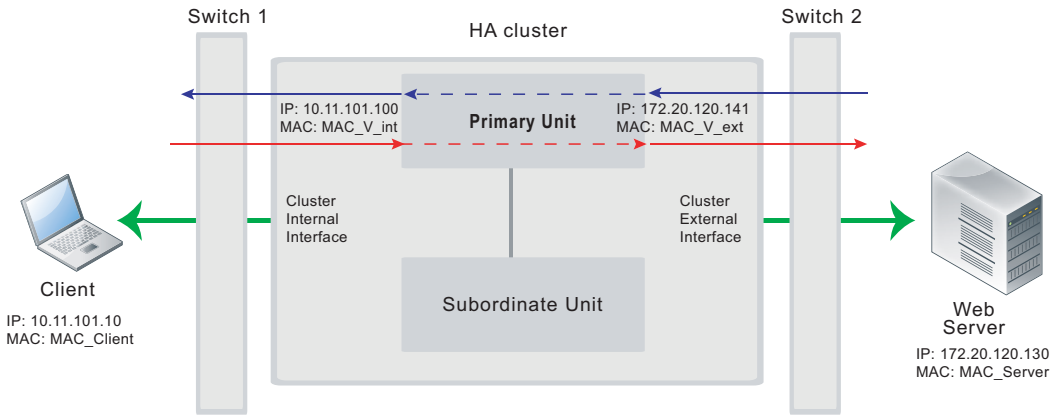
This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in NAT/Route mode. In the example, the NAT/Route mode cluster acts as the internet firewall for a client computer’s internal network. The client computer’s default route points at the IP address of the cluster internal interface. The client connects to a web server on the Internet. Internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In an active-passive cluster operating in NAT/Route mode, four MAC addresses are involved in communication between the client and the web server when the primary unit processes the connection:

- Internal virtual MAC address (MAC_V_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC_V_ext) assigned to the primary unit external interface,
- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),

In NAT/Route mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC_V_int) and the server only know the cluster external virtual MAC address (MAC_V_int). Cluster virtual MAC addresses are described in "Cluster virtual MAC addresses" on page 2177.

Figure 220: NAT/Route mode active-passive packet flow



Packet flow from client to web server

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.
4. The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC_V_int) which corresponds to its IP address of 10.11.101.100.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	172.20.120.130	MAC_V_int

6. The primary unit processes the packet.
7. The primary unit forwards the packet from its external interface to the web server.

	IP address	MAC address
Source	172.20.120.141	MAC_V_ext
Destination	172.20.120.130	MAC_Server

8. The primary unit continues to process packets in this way unless a failover occurs.

Packet flow from web server to client

1. When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.
2. The web server issues an ARP request to 172.20.120.141.
3. The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC_V_ext) which corresponds its IP address of 172.20.120.141.

4 The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5 The primary unit processes the packet.

6 The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_V_int
Destination	10.11.101.10	MAC_Client

7 The primary unit continues to process packets in this way unless a failover occurs.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1 If the primary unit fails the subordinate unit becomes the primary unit.

2 The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.

The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.

3 The new primary units sends gratuitous ARP packets from the internal interface to the 10.11.101.0 network to associate its internal IP address with the internal virtual MAC address.

4 The new primary units sends gratuitous ARP packets to the 172.20.120.0 to associate its external IP address with the external virtual MAC address.

5 Traffic sent to the cluster is now received and processed by the new primary unit.

If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

Transparent mode active-passive cluster packet flow

This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in Transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the Transparent mode cluster.

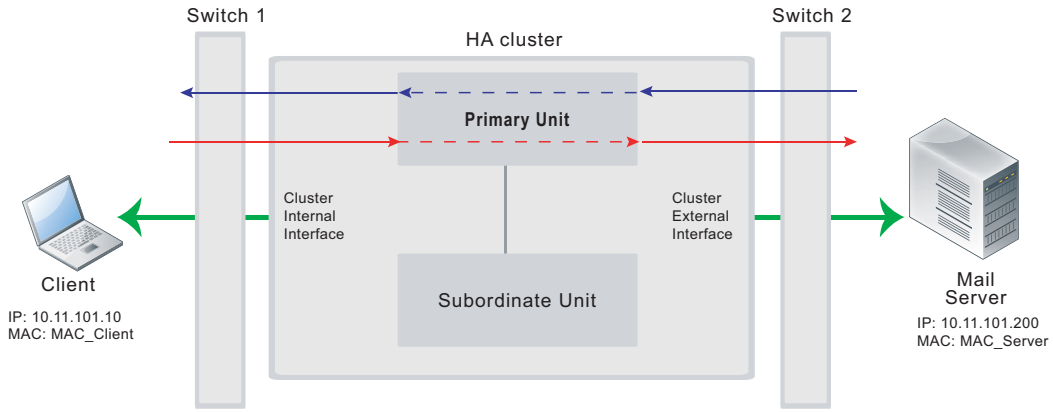
In an active-passive cluster operating in Transparent mode, two MAC addresses are involved in the communication between a client and a server when the primary unit processes a connection:

- Client MAC address (MAC_Client)
- Server MAC address (MAC_Server)

The HA virtual MAC addresses are not directly involved in communication between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and processed by the cluster.

The cluster's presence on the network is transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network segment connected to the cluster external interface with the HA virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the HA virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

Figure 221: Transparent mode active-passive packet flow



Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 110.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

6. The primary unit processes the packet.
7. The primary unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

8. The primary unit continues to process packets in this way unless a failover occurs.

Packet flow from mail server to client

1. To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.
2. The primary unit forwards the ARP request to the client computer.

3 The client computer responds with its MAC address (MAC_Client) which corresponds to its IP address of 192.168.20.10. The primary unit returns the ARP response to the mail server.

4 The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

5 The primary unit processes the packet.

6 The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

7 The primary unit continues to process packets in this way unless a failover occurs.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1 If the primary unit fails, the subordinate unit negotiates to become the primary unit.

2 The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.

3 The new primary units sends gratuitous ARP packets to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.

4 The new primary units sends gratuitous ARP packets to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.

5 Traffic sent to the cluster is now received and processed by the new primary unit.

If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

Failover performance

This section describes the designed device and link failover times for a FortiGate cluster and also shows results of a failover performance test.

Device failover performance

By design FGCP device failover time is 2 seconds for a two-member cluster with ideal network and traffic conditions. If subsecond failover is enabled the failover time can drop below 1 second.

All cluster units regularly receive HA heartbeat packets from all other cluster units over the HA heartbeat link. If any cluster unit does not receive a heartbeat packet from any other cluster unit for 2 seconds, the cluster unit that has not sent heartbeat packets is considered to have failed.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions. Typically if subsecond failover is not enabled you can expect a failover time of 9 to 15 seconds depending on the cluster and network configuration. The failover time can also be increased by more complex configurations and or configurations with network equipment that is slow to respond.

You can change the `hb-lost-threshold` to increase or decrease the device failover time. See "Modifying heartbeat timing" on page 2175 for information about using `hb-lost-threshold`, and other heartbeat timing settings.

Link failover performance

Link failover time is controlled by how long it takes for a cluster to synchronize the cluster link database. When a link failure occurs, the cluster unit that experienced the link failure uses HA heartbeat packets to broadcast the updated link database to all cluster units. When all cluster units have received the updated database the failover is complete.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions.

Reducing failover times

You can do the following to help reduce failover times:

- Keep the network configuration as simple as possible with as few as possible network connections to the cluster.
- If possible operate the cluster in Transparent mode.
- Use high-performance switches to that the switches failover to interfaces connected to the new primary unit as quickly as possible.
- Use accelerated FortiGate interfaces. In some cases accelerated interfaces will reduce failover times.
- Make sure the FortiGate unit sends multiple gratuitous arp packets after a failover. In some cases, sending more gratuitous arp packets will cause connected network equipment to recognize the failover sooner. To send 10 gratuitous arp packets:

```
config system ha
  set arps 10
end
```

- Reduce the time between gratuitous arp packets. This may also caused connected network equipment to recognize the failover sooner. To send 50 gratuitous arp packets with 1 second between each packet:

```
config system ha
  set arp 50
  set arps-interval 1
end
```

- Reduce the number of lost heartbeat packets and reduce the heartbeat interval timers to be able to more quickly detect a device failure. To set the lost heartbeat threshold to 3 packets and the heartbeat interval to 100 milliseconds:

```
config system ha
  set hb-interval 3
  set hb-lost-threshold 1
end
```

- Reduce the hello state hold down time to reduce the amount of the time the cluster waits before transitioning from the hello to the work state. To set the hello state hold down time to 5 seconds:

```
config system ha
  set helo-holddown 5
end
```

- Enable sending a link failed signal after a link failover to make sure that attached network equipment responds a quickly as possible to a link failure. To enable the link failed signal:

```
config system ha
  set link-failed-signal enable
end
```

HA and load balancing

FGCP active-active load balancing distributes network traffic among all of the units in a cluster. Load balancing can improve cluster performance because the processing load is shared among multiple cluster units.

This chapter describes how active-active load balancing works and provides detailed NAT/Route and Transparent mode packet flow descriptions.

This chapter contains the following sections:

Load balancing overview

In active-active HA, the FGCP uses unicast load balancing in which the primary unit is associated with the cluster HA virtual MAC address and cluster IP address. The primary unit is the only cluster unit to receive packets sent to the cluster.

An active-active HA cluster consists of a primary unit that processes communication sessions and one or more subordinate units that also process communication sessions. The primary unit receives all sessions and load balances sessions for security policies with UTM enabled to all cluster units. Because processing UTM sessions can be CPU and memory-intensive, load balancing UTM traffic may result in an active-active cluster having higher throughout than an active-passive cluster or a standalone FortiGate unit because resource-intensive UTM processing is distributed among all cluster units.

You can also enable the `load-balance-all` CLI keyword to have the primary unit load balance all TCP sessions. Load balancing TCP sessions is less likely to improve throughput because of extra overhead required for load balancing. So `load-balance-all` is disabled by default.

During active-active HA load balancing operation, when the primary unit receives the first packet of a UTM session (or a TCP session if `load-balance-all` is enabled) the primary unit uses the configured load balancing schedule to determine the cluster unit that will process the session. The primary unit stores the load balancing information for each active load balanced session in the cluster load balancing session table. Using the information in this table, the primary unit can then forward all of the remaining packets in each session to the appropriate cluster unit. The load balancing session table is synchronized among all cluster units.

UDP, ICMP, multicast, and broadcast sessions are never load balanced and are always processed by the primary unit. VoIP, IM, P2P, IPsec VPN, HTTPS, SSL VPN, HTTP multiplexing, SSL offloading, WAN optimization, explicit web proxy, and WCCP sessions are also always processed only by the primary unit.

In addition to load balancing, active-active HA also provides device and link failover protection similar to active-passive HA. If the primary unit fails, a subordinate unit becomes the primary unit and resumes operating the cluster. See "Device failover" on page 2169 and "Link failover" on page 2194 for more information.

Active-active HA provides session failover protection for all TCP sessions except UTM sessions. Active-active HA does not provide session failover for UTM sessions. Active-active HA also does not provide session failover for UDP, ICMP, multicast, and broadcast sessions. Protection profile sessions and all UDP, ICMP, multicast, and broadcast sessions are not failed over and must be restarted.

If a subordinate unit fails, the primary unit redistributes all TCP communications sessions among the remaining cluster units. Protection profile sessions that are in progress on the subordinate unit that failed are not failed over and must be restarted. All sessions being processed by the primary unit, including UDP, ICMP, multicast, and broadcast sessions, are not affected.

Because of the limitation of not supporting failover of UDP, ICMP, multicast, and broadcast sessions, active-active HA can be a less robust session failover solution than active-passive HA. See "Session failover (session pick-up)" on page 2205 more information about FortiGate session failover and its limitations.

Active-active HA does maintain as many UTM sessions as possible after a failover by continuing to process the UTM sessions that were being processed by the cluster units that are still operating. See "Active-active HA subordinate units sessions can resume after a failover" on page 2209 for more information. Active-passive HA does not support maintaining UTM sessions after a failover.

Load balancing schedules

The load balancing schedule controls how the primary unit distributes packets to all cluster units. You can select from the following load balancing schedules.

None	No load balancing. Select None when the cluster interfaces are connected to load balancing switches. If you select *None*, the Primary unit does not load balance traffic and the subordinate units process incoming traffic that does not come from the Primary unit. For all other load balancing schedules, all traffic is received first by the Primary unit, and then forwarded to the subordinate units. The subordinate units only receive and process packets sent from the primary unit.
Hub	Load balancing if the cluster interfaces are connected to a hub. Traffic is distributed to cluster units based on the source IP and destination IP of the packet.
Least-Connection	If the cluster units are connected using switches, select *Least Connection* to distribute network traffic to the cluster unit currently processing the fewest connections.
Round-Robin	If the cluster units are connected using switches, select Round-Robin to distribute network traffic to the next available cluster unit.
Weighted Round-Robin	Similar to round robin, but weighted values are assigned to each of the units in a cluster based on their capacity and on how many connections they are currently processing. For example, the primary unit should have a lower weighted value because it handles scheduling and forwards traffic. Weighted round robin distributes traffic more evenly because units that are not processing traffic will be more likely to receive new connections than units that are very busy.

Random	If the cluster units are connected using switches, select Random to randomly distribute traffic to cluster units.
IP	Load balancing according to IP address. If the cluster units are connected using switches, select *IP* to distribute traffic to units in a cluster based on the source IP and destination IP of the packet.
IP Port	Load balancing according to IP address and port. If the cluster units are connected using switches, select IP Port to distribute traffic to units in a cluster based on the source IP, source port, destination IP, and destination port of the packet.

Once a packet has been propagated to a subordinate unit, all packets are part of that same communication session are also propagated to that same subordinate unit. Traffic is distributed according to communication session, not just according to individual packet.

Any subordinate unit that receives a forwarded packet processes it, without applying load balancing. Note that subordinate units are still considered to be active, because they perform routing, virus scanning, and other FortiGate unit tasks on their share of the traffic. Active subordinate units also share their session and link status information with all cluster units. The only things that active members do not do is make load balancing decisions.

Even though the primary unit is responsible for the load balancing process, the primary unit still acts like a FortiGate unit in that it processes packets, performing, routing, firewall, virus scanning, and other FortiGate unit tasks on its share of the traffic. Depending on the load balancing schedule used, the primary unit may assign itself a smaller share of the total load.

Selecting which packets are load balanced

The primary unit processes all UDP and ICMP traffic. By default, the primary unit also processes all TCP traffic and load balances virus scanning traffic among all cluster units. You can change the default configuration so that the cluster load balances both TCP traffic and virus scanning traffic among all cluster units.

Load balancing increases network bandwidth usage and also increases the load on the primary unit CPU. Because of this, in some network environments, load balancing TCP traffic may not result in an overall cluster performance increase. However, in other network environments, TCP load balancing may improve cluster performance.

If the cluster is configured to load balance virus scanning sessions, the primary unit uses the load balancing schedule to distribute HTTP, FTP, SMTP, POP3, and IMAP packets to be virus scanned, among the primary unit and the subordinate units. Load balancing virus scanning traffic is much more likely to increase cluster performance. Virus scanning is processor intensive for the cluster unit that is performing the virus scanning. Distributing virus scanning over the cluster units significantly reduces the processing load on the primary unit. As a result overall cluster performance should improve. See “Load balancing UTM sessions and TCP sessions” on page 2221.

More about active-active failover

If a subordinate unit fails, the primary unit re-distributes the connections that the subordinate unit was processing among the remaining active cluster members. If the primary unit fails, the subordinate units negotiate to select a new primary unit. The new primary unit continues to distribute packets among the remaining active cluster units.

Failover works in a similar way if the cluster consists of only two units. If the primary unit fails the subordinate unit negotiates and becomes the new primary unit. If the subordinate unit fails, the primary unit processes all traffic. In both cases, the single remaining unit continues to function as a primary unit, maintaining the HA virtual MAC address for all of its interfaces.

HTTPS sessions, active-active load balancing, and proxy servers

To prevent HTTPS web filtering problems active-active HA does not load balance HTTPS sessions. The FortiGate unit identifies HTTPS sessions as all sessions received on the HTTPS TCP port. The default HTTPS port is 443. You can use the CLI command `config antivirus service` to configure the FortiGate unit to use a custom port for HTTPS sessions. If you change the HTTPS port using this CLI command, the FGCP stops load balancing all sessions that use the custom HTTPS port.

Normally you would not change the HTTPS port. However, if your network uses a proxy server for HTTPS traffic you may have to use the `config antivirus service` command to configure your cluster to use a custom HTTPS port. If your network uses a proxy server you might also use the same port for both HTTP and HTTPS traffic. In this case you would use `config antivirus service` to configure the FortiGate unit to use custom ports for both HTTP and HTTPS traffic.

Using the same port for HTTP and HTTPS traffic can cause problems with active-active clusters because active-active clusters always load balance HTTP traffic. If both HTTP and HTTPS use the same port, the active-active cluster cannot tell the difference between HTTP and HTTPS traffic and will load balance both HTTP and HTTPS traffic.

As mentioned above, load balancing HTTPS traffic may cause problems with HTTPS web filtering. To avoid this problem, you should configure your proxy server to use different ports for HTTP and HTTPS traffic. Then use the `config antivirus service` command to configure your cluster to also use different ports for HTTP and HTTPS.

Using FortiGate network processor interfaces to accelerate active-active HA performance

Many FortiGate models and FortiGate AMC modules include network processors that can provide hardware acceleration for active-active HA load balancing by offloading load balancing from the primary unit CPU. HA load balancing can be accelerated by NP1 network processors (called FA2 interfaces), NP2 network processors and NP4 network processors.

In some cases, performance of the primary unit can be reduced by active-active HA load balancing. Primary unit CPU cycles and bus bandwidth are required to receive, calculate load balancing schedules, and send balanced packets to the subordinate units. In very busy active-active clusters the primary unit may not be able to keep up with the processing load. This can result in lost traffic and can also cause the primary unit to delay sending heartbeat packets possibly reducing the stability and reliability of the active-active HA cluster.

Adding network processors to busy cluster unit interfaces increases load balancing performance by offloading load balancing to the network processors. The first packet of every new session is received by the primary unit and the primary unit uses its load balancing schedule to select the cluster unit that will process the new session. This information is passed back to the network processor and all subsequent packets of the same sessions are received by the primary unit interface network processor which sends the packet directly to a subordinate unit without using the primary unit CPU. Load balancing is effectively offloaded from the primary unit to the network processor resulting in a faster and more stable active-active cluster.

Using network processors to accelerate load balancing is especially useful if the `load-balance-all` option is enabled and the cluster is load balancing all TCP sessions because this could mean that the cluster is load balancing an excessive number of sessions.

To take advantage of network processor load balancing acceleration, connect the cluster unit interfaces with network processors to the busiest networks. Connect non-accelerated interfaces to less busy networks. No special FortiOS or HA configuration is required. Network processor acceleration of active-active HA load balancing is supported for any active-active HA configuration or active-active HA load balancing schedule.

Configuring load balancing settings

This section describes how to configure the following load balancing settings:

- Selecting a load balancing schedule
- Load balancing UTM sessions and TCP sessions
- Configuring weighted-round-robin weights

Selecting a load balancing schedule

You can select the load balancing schedule when initially configuring the cluster and you can change the load balancing schedule at any time while the cluster is operating without affecting cluster operation.

You can select a load balancing schedule from the CLI. Use the following command to select a load balancing schedule:

```
config system ha
  set schedule {hub | ip | ipport | leastconnection | none |
     random | round-robin | weight-round-robin}
end
```

Load balancing UTM sessions and TCP sessions

By default a FortiGate active-active cluster load balances UTM sessions among all cluster units. UTM processing applies protocol recognition, virus scanning, IPS, web filtering, email filtering, data leak prevention (DLP), application control, and VoIP content scanning and protection to HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, NNTP, SIP, SIMPLE, and SCCP sessions accepted by security policies. By load balancing this resource-intensive UTM processing among all cluster units, an active-active HA cluster may provide better UTM performance than a standalone FortiGate unit. Other features enabled in security policies such as Endpoint security, traffic shaping and authentication (identity-based policies) have no effect active-active load balancing.

All other sessions are processed by the primary unit. Using the CLI, you can configure the cluster to load balance TCP sessions among all cluster units in addition to UTM sessions. All UDP, ICMP, multicast, and broadcast sessions are never load balanced, but are always processed by the primary unit.

Use the following command to enable load balancing UTM and TCP sessions.

```
config system ha
  set load-balance-all enable
end
```

Enabling `load-balance-all` to load balance TCP sessions may not improve throughput because the cluster requires additional overhead to load balance sessions. The primary unit receives all sessions and load balances some TCP sessions to the subordinate units. Load balancing UTM sessions can improve performance because UTM session performance is limited by CPU performance. However, load balancing a non-UTM session usually requires about as much overhead as just processing it.

If your active-active cluster is processing TCP sessions and not performing UTM, you can enable `load-balance-all` and monitor network performance to see if it improves. If performance is not improved, you should change the HA mode to active-passive since active-active HA is not providing any benefit.

Configuring weighted-round-robin weights

You can configure weighted round-robin load balancing for a cluster and configure the static weights for each of the cluster units according to their priority in the cluster. When you set `schedule` to `weight-round-robin` you can use the `weight` option to set the static weight of each cluster unit. The static weight is set according to the priority of each unit in the cluster. A FortiGate HA cluster can contain up to four FortiGate units so you can set up to 4 static weights.

The priority of a cluster unit is determined by its device priority, the number of monitored interfaces that are functioning, its age in the cluster and its serial number. Priorities are used to select a primary unit and to set an order of all of the subordinate units. Thus the priority order of a cluster unit can change depending on configuration settings, link failures and so on. Since weights are also set using this priority order the weights are independent of specific cluster units but do depend on the role of the each unit in the cluster.

You can use the following command to display the priority order of units in a cluster. The following example displays the priority order for a cluster of 5 FortiGate-620B units:

```
get system ha status
  Model: 620

```

The cluster units are listed in priority order starting at the 6th output line. The primary unit always has the highest priority and is listed first followed by the subordinate units in priority order. The last 5 output lines list the cluster units in vcluster 1 and are not always in priority order. For more information about the get system ha status command, see “Viewing cluster status from the CLI” on page 2156.

The default static weight for each cluster unit is 40. This means that sessions are distributed evenly among all cluster units. You can use the `set weight` command to change the static weights of cluster units to distribute sessions to cluster units depending on their priority in the cluster. The weight can be between 0 and 255. Increase the weight to increase the number of connections processed by the cluster unit with that priority.

You set the weight for each unit separately. For the example cluster of 5 FortiGate-620B units you can set the weight for each unit as follows:

```
config system ha
  set mode a-a
  set schedule weight-roud-robin
  set weight 0 5
  set weight 1 10
  set weight 2 15
  set weight 3 20
  set weight 4 30
end
```

If you enter the `get` command to view the HA configuration the output for `weight` would be:

```
weight 5 10 15 20 30 40 40 40 40 40 40 40 40 40 40 40
```

This configuration has the following results if the output of the `get system ha status` command is that shown above:

- The first five connections are processed by the primary unit (host name head_office_cla, priority 0, weight 5). From the output of the
- The next 10 connections are processed by the first subordinate unit (host name head_office_clb, priority 1, weight 10)
- The next 15 connections are processed by the second subordinate unit (host name head_office_clc, priority 2, weight 15)
- The next 20 connections are processed by the third subordinate unit (host name head_office_cld, priority 3, weight 20)
- The next 30 connections are processed by the fourth subordinate unit (host name head_office_cle, priority 4, weight 30)

Dynamically optimizing weighted load balancing according to how busy cluster units are

In conjunction with using static weights to load balance sessions among cluster units you can configure a cluster to load balance sessions according to individual cluster unit CPU usage, memory usage, and number of UTM proxy sessions. If any of these system loading indicators increases above configured thresholds, weighted load balancing sends fewer new sessions to the busy unit until it recovers.

High CPU or memory usage indicates that a unit is under increased load and may not be able to process more sessions. UTM proxy use is also a good indicator of how busy a cluster unit is since processing high numbers of UTM proxy sessions can quickly reduce overall cluster unit performance.

For example, if you set a CPU usage high watermark, when a cluster unit's CPU usage reaches the high watermark threshold fewer sessions are sent to it. With fewer sessions to process the cluster unit's CPU usage should fall back to a low watermark threshold. When this happens the cluster resumes load balancing sessions to the cluster unit as normal.

You can set different high and low watermark thresholds for CPU usage and memory usage, and for the number of HTTP, FTP, IMAP, POP3, SMTP, or NNTP UTM proxy sessions. For each loading indicator you set a high watermark threshold a low watermark threshold and a weight. When you first enable this feature the weighted load balancing configuration is synchronized to all cluster units. Subsequent changes to the weighted load balancing configuration are not synchronized so you can configure different weights on each cluster unit.

If a cluster unit's CPU usage reaches the high watermark threshold fewer sessions are sent to it. With fewer sessions to process the cluster unit's CPU usage should fall back to the low watermark threshold. When this happens the cluster resumes sending sessions to at the previous rate.

The CPU usage, memory usage, and UTM proxy weights determine how the cluster load balances sessions when a high watermark threshold is reached and also affect how the cluster load balances sessions when multiple cluster units reach different high watermark thresholds at the same time. For example, you might be less concerned about a cluster unit reaching the memory usage high watermark threshold than reaching the CPU usage high watermark threshold. If this is the case you can set the weight lower for memory usage. Then, if one cluster unit reaches the CPU usage high watermark threshold and a second cluster unit reaches the memory usage high watermark threshold the cluster will load balance more sessions to the unit with high memory usage and fewer sessions to the cluster unit with high CPU usage. As a result, reaching the CPU usage high watermark will have a greater affect on how sessions are redistributed than reaching the memory usage high watermark.

When a high watermark threshold is reached, the corresponding weight is subtracted from the static weight of the cluster unit. The lower the weight the fewer the number of sessions that are load balanced to that unit. Subsequently when the low watermark threshold is reached, the static weight of the cluster returns to its configured value. For the weights to all be effective the weights assigned to the load indicators should usually be lower than or equal to the static weights assigned to the cluster units.

Use the following command to set thresholds and weights for CPU and memory usage and UTM proxy sessions:

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set cpu-threshold <weight> <low> <high>
  set memory-threshold <weight> <low> <high>
  set http-proxy-threshold <weight> <low> <high>
  set ftp-proxy-threshold <weight> <low> <high>
  set imap-proxy-threshold <weight> <low> <high>
  set nntp-proxy-threshold <weight> <low> <high>
  set pop3-proxy-threshold <weight> <low> <high>
  set smtp-proxy-threshold <weight> <low> <high>
end
```

For each option, the weight range is 0 to 255 and the default weight is 5. The low and high watermarks are a percent (0 to 100). The default low and high watermarks are 0 which means they are disabled. The high watermark must be greater than the low watermark.

For CPU and memory usage the low and high watermarks are compared with the percentage CPU and memory use of the cluster unit. For each of the UTM proxies the high and low watermarks are compared to a number that represents percent of the max number of proxy sessions being used by a proxy. This number is calculated using the formula:

```
proxy usage = (current sessions * 100) / max sessions
```

where:

`current sessions` is the number of active sessions for the proxy type.

`max sessions` is the session limit for the proxy type. The session limit depends on the FortiGate unit and its configuration.

You can use the following command to display the maximum and current number of sessions for a UTM proxy:

```
get test { ftpd | http | imap | nntp | pop3 | smtp} 4
```

You can use the following command to display the maximum number of session and the and current number of sessions for all of the proxies:

```
get test proxyworker 4
```

The command output includes lines similar to the following:

```
get test http 4
HTTP Common
Current Connections                5000/8032
```

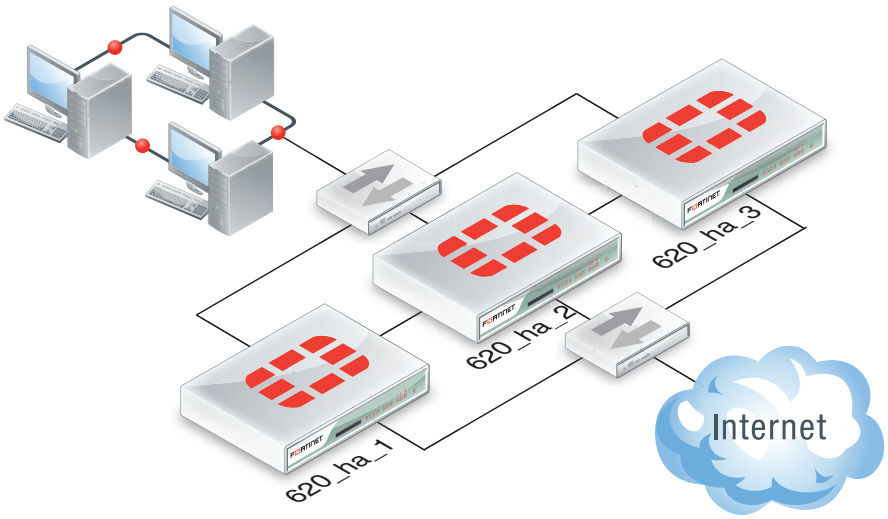
In the example, `5000` is the current number of proxy connections being used by HTTP and 8032 is the maximum number of proxy sessions allowed. For this example the proxy usage would be:

```
proxy usage = (5000 * 100) / 8032
proxy usage = 62%
```

Example weighted load balancing configuration

Consider a cluster of three FortiGate-620B units with host names 620_ha_1, 620_ha_2, and 620_ha_3 as shown in Figure 222. This example describes how to configure weighted load balancing settings for CPU and memory usage for the cluster and then to configure UTM proxy weights to send most HTTP and POP3 proxy sessions to different cluster units.

Figure 222: Example HA weighted load balancing configuration



Connect to the cluster CLI and use the following command to set the CPU usage threshold weight to 30, low watermark to 60, and high watermark to 80. This command also sets the memory usage threshold weight to 10, low watermark to 60, and high watermark to 90.

```
config system ha
  set mode a-a
  set schedule weight-round-robin
  set cpu-threshold 30 60 80
  set memory-threshold 10 60 90
end
```

The static weights for the cluster units remain at the default values of 40. Since this command changes the mode to `a-a` and the schedule to `weight-round-robin` for the first time, the weight settings are synchronized to all cluster units.

As a result of this configuration, if the CPU usage of any cluster unit (for example, 620_ha_1) reaches 80% the static weight for that cluster unit is reduced from 40 to 10 and only 10 of every 120 new sessions are load balanced to this cluster unit. If the memory usage of 620_ha_1 also reaches 90% the static weight further reduces to 0 and no new sessions are load balanced to 620_ha_1. Also, if the memory usage of 620_ha_2 reaches 90% the static weight of 620_ha_2 reduces to 30 and 30 of every 120 new sessions are load balanced to 620_ha_2.

Now that you have established the weight load balancing configuration for the entire cluster you can monitor the cluster to verify that processing gets distributed evenly to all cluster units. From the web-based manager you can go do *System* > *Config* > *HA* > *View HA Statistics* and see the CPU usage, active sessions, memory usage and other statistics for all of the cluster units. If you notice that one cluster unit is more or less busy than others you can adjust the dynamic weights separately for each cluster unit.

For example, in some active-active clusters the primary unit may tend to be busier than other cluster units because in addition to processing sessions the primary unit also receives all packets sent to the cluster and performs load balancing to distribute the sessions to other cluster units. To reduce the load on the primary unit you could reduce the CPU and memory usage high watermark thresholds for the primary unit so that fewer sessions are distributed to the primary unit. You could also reduce the primary unit's high watermark setting for the proxies to distribute more proxy sessions to other cluster units.

Note that this would only be useful if you are using device priorities and override settings to make sure the same unit always becomes the primary unit. See "Controlling primary unit selection using device priority and override" on page 2010.

If the example cluster is configured for 620_ha_2 to be the primary unit, connect to the 620_ha_2's CLI and enter the following command to set CPU usage, memory usage, and proxy usage high watermark thresholds lower.

```
config system ha
  set cpu-threshold 30 60 70
  set memory-threshold 30 60 70
  set http-proxy-threshold 30 60 70
  set ftp-proxy-threshold 30 60 70
  set imap-proxy-threshold 30 60 70
  set nntp-proxy-threshold 30 60 70
  set pop3-proxy-threshold 30 60 70
  set smtp-proxy-threshold 30 60 70
end
```

As a result, when any of these factors reaches 70% on the primary unit, fewer sessions will be processed by the primary unit, preventing the number of sessions being processed from rising.

NAT/Route mode active-active cluster packet flow

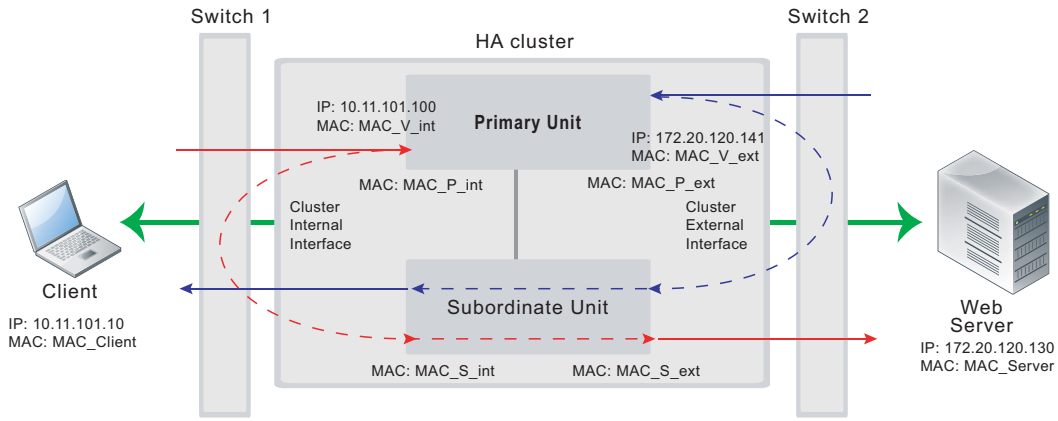
This section describes an example of how packets are load balanced and how failover occurs in an active-active HA cluster running in NAT/Route mode. In the example, the NAT/Route mode cluster acts as the internet firewall for a client computer's internal network. The client computer's default route points at the IP address of the cluster internal interface. The client connects to a web server on the Internet. Internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In NAT/Route mode, eight MAC addresses are involved in active-active communication between the client and the web server when the primary unit load balances packets to the subordinate unit:

- Internal virtual MAC address (MAC_V_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC_V_ext) assigned to the primary unit external interface,
- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),
- Primary unit original internal MAC address (MAC_P_int),
- Primary unit original external MAC address (MAC_P_ext),
- Subordinate unit internal MAC address (MAC_S_int),
- Subordinate unit external MAC address (MAC_S_ext).

In NAT/Route mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC_V_int) and the server only know the cluster external virtual MAC address (MAC_V_int). The cluster virtual MAC address is described in "Cluster virtual MAC addresses" on page 2177.

Figure 223: NAT/Route mode active-active packet flow



Packet flow from client to web server

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.

4 The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC_V_int) which corresponds to its IP address of 10.11.101.100.

5 The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	172.20.120.130	MAC_V_int

6 The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_P_int
Destination	172.20.120.130	MAC_S_int

7 The subordinate unit recognizes that the packet has been forwarded from the primary unit and processes it.

8 The subordinate unit forwards the packet from its external interface to the web server.

	IP address	MAC address
Source	172.20.120.141	MAC_S_ext
Destination	172.20.120.130	MAC_Server

9 The primary unit forwards further packets in the same session to the subordinate unit.

10 Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

Packet flow from web server to client

1 When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.

2 The web server issues an ARP request to 172.20.120.141.

3 The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC_V_ext) which corresponds its IP address of 172.20.120.141.

4 The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5 The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_P_ext
Destination	172.20.120.141	MAC_S_ext

6 The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.

7 The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_S_int
Destination	10.11.101.10	MAC_Client

8 The primary unit forwards further packets in the same session to the subordinate unit.

9 Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1 If the primary unit fails, the subordinate unit negotiates to become the primary unit.

2 The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.

The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.

3 The new primary units sends gratuitous ARP packets to the 10.10.101.0 network to associate its internal IP address with the internal virtual MAC address.

4 The new primary units sends gratuitous ARP packets to the 172.20.120.0 network to associate its external IP address with the external virtual MAC address.

5 Traffic sent to the cluster is now received and processed by the new primary unit.

If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

Transparent mode active-active cluster packet flow

This section describes and example of how packets are load balanced and how failover occurs in an active-active HA cluster running in Transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the Transparent mode cluster.

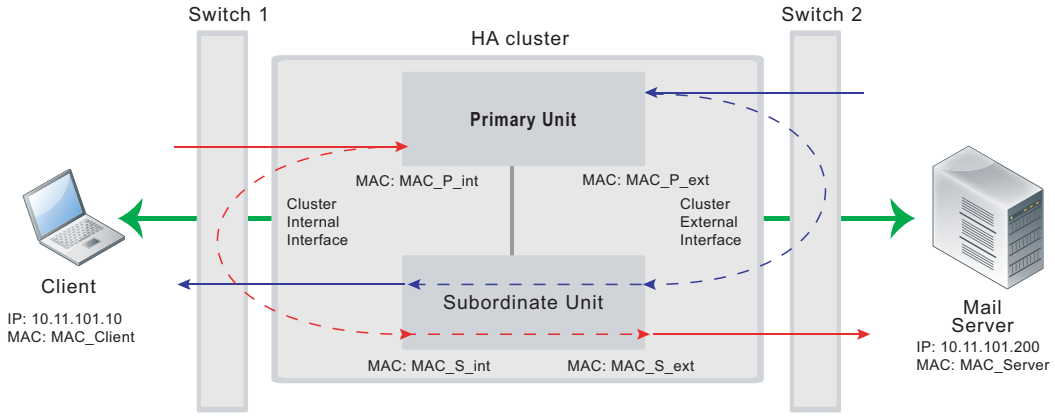
In Transparent mode, six MAC addresses are involved in active-active communication between a client and a server when the primary unit load balances packets to the subordinate unit:

- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),
- Primary unit original internal MAC address (MAC_P_int),
- Primary unit original external MAC address (MAC_P_ext),
- Subordinate unit internal MAC address (MAC_S_int),
- Subordinate unit external MAC address (MAC_S_ext).

The HA virtual MAC addresses are not directly involved in communicate between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and load balanced among cluster members.

The cluster's presence on the network and its load balancing are transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network segment connected to the cluster external interface with the external virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the internal virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

Figure 224: Transparent mode active-active packet flow



Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 10.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

6. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_P_int
Destination	10.11.101.200	MAC_S_int

7. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.

8 The subordinate unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
Source	10.11.101.10	MAC_S_ext
Destination	10.11.101.200	MAC_Server

9 The primary unit forwards further packets in the same session to the subordinate unit.

10 Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

Packet flow from mail server to client

1 To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.

2 The primary unit forwards the ARP request to the client computer.

3 The client computer responds with its MAC address (MAC_Client) which corresponds to its IP address of 10.11.101.10. The primary unit returns the ARP response to the mail server.

4 The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

5 The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_P_ext
Destination	10.11.101.10	MAC_S_ext

6 The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.

7 The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	10.11.101.200	MAC_S_int
Destination	10.11.101.10	MAC_Client

8 The primary unit forwards further packets in the same session to the subordinate unit.

9 Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1 If the primary unit fails the subordinate unit negotiates to become the primary unit.

2 The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.

3 The new primary units sends gratuitous ARP requests to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.

4 The new primary units sends gratuitous ARP requests to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.

5 Traffic sent to the cluster is now received and processed by the new primary unit.

If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

HA with third-party products

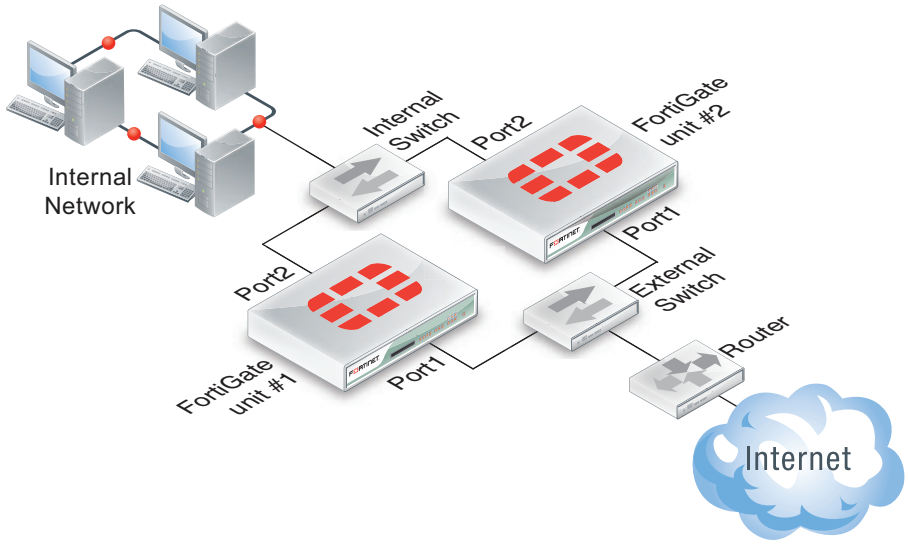
This chapter provides information about operating FortiGate clusters with third party products such as layer-2 and layer-3 switches. This chapter describes:

- Troubleshooting layer-2 switches
- Failover issues with layer-3 switches
- Changing spanning tree protocol settings for some switches
- Failover and attached network equipment
- Ethertype conflicts with third-party switches
- LACP, 802.3ad aggregation and third-party switches

Troubleshooting layer-2 switches

Issues may occur because of the way an HA cluster assigns MAC addresses to the primary unit. In a functioning HA cluster, all primary unit interfaces are assigned the same virtual MAC address. The last byte of the virtual MAC address is the hexadecimal equivalent of the group ID. See “Cluster virtual MAC addresses” on page 2177 for more information about the HA group ID and the cluster virtual MAC address.

Figure 225: Typical HA configuration, each interface connected to a different switch



Assigning the virtual MAC addresses in this way results in two restrictions when installing HA clusters:

- Two clusters with the same group ID cannot connect to the same switch and cannot be installed on the same network unless they are separated by a router.
- Two or more interfaces on the same primary unit cannot be connected to the same switch unless the traffic is separated using VLANs and unless the switch is VLAN-aware.

Forwarding delay on layer 2 switches

You must ensure that if there is a switch between the FortiGate HA cluster and the network its is protecting and the switch has a forwarding delay (even if spanning tree is disabled) when one of its interfaces is activated then the forwarding delay should be set as low as possible. For example, some versions of Cisco IOS have a forwarding delay of 15 seconds even when spanning tree is disabled. If left at this default value then TCP session pickup can fail because traffic is not forwarded through the switch on HA failover.

Failover issues with layer-3 switches

After a failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables of the switches connected to the cluster. If the cluster is connected using layer-2 switches, the MAC forwarding tables (also called arp tables) are refreshed by the gratuitous ARP packets and the switches start directing packets to the new primary unit.

In some configurations that use layer-3 switches, after a failover, the layer-3 switches may not successfully re-direct traffic to the new primary unit. The possible reason for this is that the layer-3 switch might keep a table of IP addresses and interfaces and may not update this table for a relatively long time after the failover (the table is not updated by the gratuitous ARP packets). Until the table is updated, the layer-3 switch keeps forwarding packets to the now failed cluster unit. As a result, traffic stops and the cluster does not function.

As of the release date of this document, Fortinet has not developed a workaround for this problem. One possible solution would be to clear the forwarding table on the layer-3 switch.

The `config system ha link-failed-signal` command described in "Updating MAC forwarding tables when a link failover occurs" on page 2198 can be used to resolve link failover issues similar to those described here.

Changing spanning tree protocol settings for some switches

Configuration changes may be required when you are running an active-active HA cluster that is connected to a switch that operates using the spanning tree protocol. For example, the following spanning tree parameters may need to be changed:

Maximum Age	The time that a bridge stores the spanning tree bridge control data unit (BPDU) before discarding it. A maximum age of 20 seconds means it may take 20 seconds before the switch changes a port to the listening state.
Forward Delay	The time that a connected port stays in listening and learning state. A forward delay of 15 seconds assumes a maximum network size of seven bridge hops, a maximum of three lost BPDUs and a hello-interval of 2 seconds.

For an active-active HA cluster to be compatible with the spanning tree algorithm, the FGCP requires that the sum of maximum age and forward delay should be less than 20 seconds. The maximum age and forward delay settings are designed to prevent layer 2 loops. If there is no possibility of layer 2 loops in the network, you could reduce the forward delay to the minimum value.

For some Dell 3348 switches the default maximum age is 20 seconds and the default forward delay is 15 seconds. In this configuration the switch cannot work with a FortiGate HA cluster. However, the switch and cluster are compatible if the maximum age is reduced to 10 seconds and the forward delay is reduced to 5 seconds.

Spanning Tree protocol (STP)

Spanning tree protocol is an IEEE 802.1 standard link management protocol that for media access control bridges. STP uses the spanning tree algorithm to provide path redundancy while preventing undesirable loops in a network that are created by multiple active paths between stations. Loops can be created if there are more than route between two hosts. To control path redundancy, STP creates a tree that spans all of the switches in an extended network. Using the information in the tree, the STP can force redundant paths into a standby, or blocked, state. The result is that only one active path is available at a time between any two network devices (preventing looping). Redundant links are used as backups if the initial link should fail. Without spanning tree in place, it is possible that two connections may be simultaneously live, which could result in an endless loop of traffic on the network.

Bridge Protocol Data Unit (BPDU)

BPDUs are spanning tree data messages exchanged across switches within an extended network. BPDU packets contain information on ports, addresses, priorities and costs and ensure that the data ends up where it was intended to go. BPDU messages are exchanged across bridges to detect loops in a network topology. The loops are then removed by shutting down selected bridge interfaces and placing redundant switch ports in a backup, or blocked, state.

Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time may depend on how quickly the switches connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

Ethertype conflicts with third-party switches

Some third-party network equipment may use packets with Ethertypes that are the same as the ethertypes used for HA heartbeat packets. For example, Cisco N5K/Nexus switches use Ethertype 0x8890 for some functions. When one of these switches receives Ethertype 0x8890 heartbeat packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGate units connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8893, and 0x8891 to pass.

You can also use the following CLI commands to change the Ethertypes of the HA heartbeat packets:

```
config system ha
  set ha-eth-type <ha_ethertype_4-digit_hex>
  set hc-eth-type <hc_ethertype_4-digit_hex>
  set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For more information, see "Heartbeat packet Ethertypes" on page 2174.

LACP, 802.3ad aggregation and third-party switches

If a cluster contains 802.3ad aggregated interfaces you should connect the cluster to switches that support configuring multiple Link Aggregation (LAG) groups.

The primary and subordinate unit interfaces have the same MAC address, so if you cannot configure multiple LAG groups a switch may place all interfaces with the same MAC address into the same LAG group; disrupting the operation of the cluster.

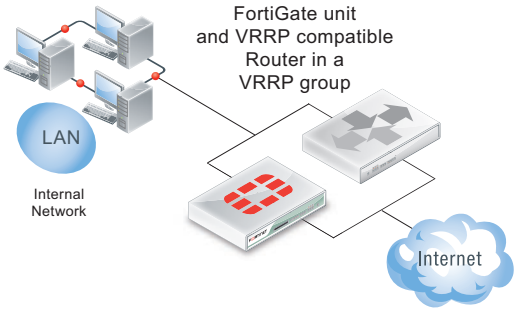
You can change the FortiGate configuration to prevent subordinate units from participating in LACP negotiation. For example, use the following command to do this for an aggregate interface named Port1_Port2:

```
config system interface
  edit Port1_Port2
    set lacp-ha-slave disable
  end
```

This configuration prevents the subordinate unit interfaces from sending or receiving packets. Resulting in the cluster not being able to operate in active-active mode. As well, failover may be slower because after a failover the new primary unit has to perform LACP negotiation before being able to process network traffic.

For more information, see "Example: HA and 802.3ad aggregated interfaces" on page 2057.

VRRP



A Virtual Router Redundancy Protocol (VRRP) configuration can be used as a high availability solution to make sure that a network maintains connectivity with the Internet (or with other networks) even if the default router for the network fails. Using VRRP, if a router or a FortiGate unit fails all traffic to this router transparently fails over to another router or FortiGate unit that takes over the role of the router or FortiGate unit that failed. If the failed router or FortiGate unit is restored, it will once again take over processing traffic for the network. VRRP is described by RFC 3768.

To configure VRRP you create a VRRP group that contains two or more routers. Some or all of these routers can be FortiGate units. You can include different FortiGate models in the same VRRP group. The group members are configured to be the master router and one or more backup routers of the VRRP group. The network directs all traffic to the master's IP address and MAC address. If the master fails, VRRP dynamically shifts packet forwarding to a backup router. VRRP provides this redundancy without user intervention or additional configuration to any of the devices on the network.

The VRRP redundancy scheme means that devices on the network keep a single IP address for the default gateway and this IP address maps to a well-known virtual MAC address. If the VRRP master fails, one of the backup units becomes the new master and acquires virtual IP and MAC addresses that match the addresses of the master. The network then automatically directs all traffic to the backup unit. VRRP uses the broadcast capabilities of Ethernet networks. A long as one of the routers in a VRRP group is running, ARP requests for the default gateway IP address always receive replies. Additionally, hosts can send packets outside their subnet without interruption.

FortiGate units support VRRP and can be quickly and easily integrated into a network that has already deployed a group of routers using VRRP. You can also create a new VRRP configuration consisting of a FortiGate unit acting as a VRRP master with one or more VRRP-compatible routers acting as backup routers. Some or all of those backup routers can be FortiGate units.

During normal operation the VRRP master unit sends VRRP advertisement messages to the backup units. A backup unit will not attempt to become a master unit while it is receiving these messages. When a FortiGate unit operating as a VRRP master fails, a backup unit takes its place and continues processing network traffic. The backup unit assumes the master unit has failed if it stops receiving the advertisement messages from the master unit. The backup unit with the highest priority becomes the new master unit after a short delay. During this delay the new master unit sends gratuitous ARPs to the network to map the virtual router IP address it its MAC address. As a result, all packets sent to the default route IP address are sent the new master unit. If the backup unit is a FortiGate unit, the network continues to benefit from FortiOS security features. If the backup unit is a router, after a failure traffic will continue to flow, but FortiOS security features will be unavailable until the FortiGate unit is back on line.

During a VRRP failover, as the backup unit starts to forward traffic it will not have session information for all of the failed over in-progress sessions. If the backup unit is operating as a normal FortiGate unit it will not be able to forward this traffic because of the lack of session information. To resolve this problem, immediately after a failover and for a short time as its taking over traffic processing, the backup unit operates with asymmetric routing enabled. This allows the backup unit to re-create all of the in-progress sessions and add them to the session table. While operating with asymmetric routing enabled, the backup unit cannot apply security functions. When the start-time ends the backup unit disables asymmetric routing and returns to normal operation including applying security functions.

Adding a VRRP virtual router to a FortiGate interface

Use the following command to add a VRRP virtual router to the port10 interface of a FortiGate unit. This VRRP virtual router has a virtual router ID of 200, uses IP address 10.31.101.200 and has a priority of 255. Since this is the highest priority this interface is configured to be the master of the VRRP group with ID number 200.

```
config system interface
  edit port10
    config vrrp
      edit 200
        set vrip 10.31.101.200
        set priority 255
      end
  end
```

VRRP virtual MAC address

The VRRP virtual MAC address (or virtual router MAC address) is a shared MAC address adopted by the VRRP master. If the master fails the same virtual MAC master fails over to the new master. As a result, all packets for VRRP routers can continue to use the same virtual MAC address. You must enable the VRRP virtual MAC address feature on all members of a VRRP group.

Each VRRP router is associated with its own virtual MAC address. The last part of the virtual MAC depends on the VRRP virtual router ID using the following format:

```
00-00-5E-00-01-<VRID_hex>
```

Where <VRID_hex> is the VRRP virtual router ID in hexadecimal format in internet standard bit-order. For more information about the format of the virtual MAC see RFC 3768.

Some examples:

- If the VRRP virtual router ID is 10 the virtual MAC would be 00-00-5E-00-01-05.
- If the VRRP virtual router ID is 200 the virtual MAC would be 00-00-5E-00-01-c8.

The VRRP virtual MAC address feature is disabled by default. Wen you enable the feature on a FortiGate interface, all of the VRRP routers added to that interface use their own VRRP virtual MAC address. Each virtual MAC address will be different because each virtual router has its own ID.

Use the following command to enable the VRRP virtual MAC address on the port2 interface:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
  end
```

```
end
```

The port2 interface will now accept packets sent to the MAC addresses of the VRRP virtual routers added to this interface.

Using the VRRP virtual MAC address can improve network efficiency especially on large and complex LANs because when a failover occurs devices on the LAN do not have to learn a new MAC address for the new VRRP router.

If the VRRP virtual MAC address feature is disabled, the VRRP group uses the MAC address of the master. In the case of a FortiGate VRRP virtual router this is the MAC address of the FortiGate interface that the VRRP virtual routers are added to. If a master fails, when the new master takes over it sends gratuitous ARPs to associate the VRRP virtual router IP address with the MAC address of the new master (or the interface of the FortiGate unit that has become the new master). If the VRRP virtual MAC address is enabled the new master uses the same MAC address as the old master.

Configuring VRRP

To configure VRRP you must configure two or more FortiGate interfaces or routers with the same virtual router ID and IP address. Then these FortiGate units or routers can automatically join the same VRRP group. You must also assign priorities to each of the FortiGate units or routers in the VRRP group. One of the FortiGate units or routers must have the highest priority to become the master. The other FortiGate units or routers in the group are assigned lower priorities and become backup units. All of the units in the VRRP group should have different priorities. If the master unit fails, VRRP automatically fails over to the remaining unit in the group with the highest priority.

You configure VRRP from the FortiGate CLI by adding a VRRP virtual router to a FortiGate interface. You can add VRRP virtual routers to multiple FortiGate interfaces and you can add more than one virtual router to the same interface.

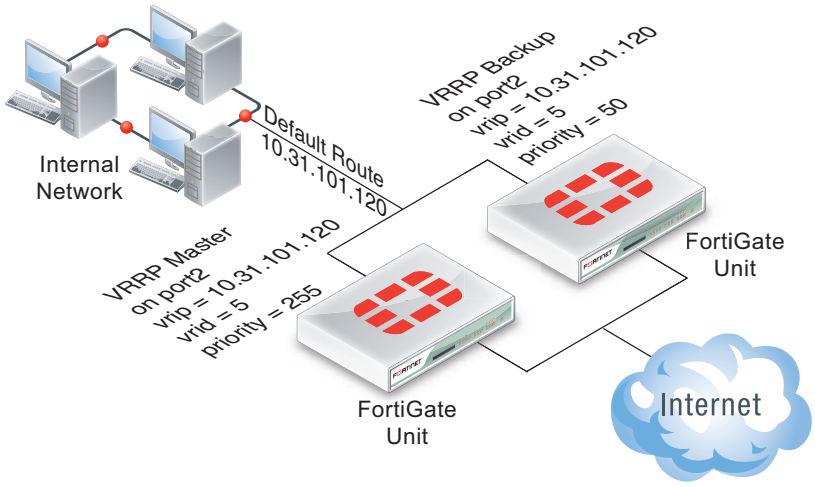
Example VRRP configuration: two FortiGate units in a VRRP group

This example includes a VRRP group consisting of two FortiGate units that connect an internal network to the Internet. As shown in Figure 226, the internal network's default route is 10.31.101.120.

The FortiGate port2 interfaces connect to the internal network. A VRRP virtual router is added to each FortiGate unit's port2 interface. The virtual router IP address is 10.31.101.120 (the internal network's default route) and the virtual router's ID is 5. The VRRP priority of the master unit is set to 255 and the VRRP priority of the backup unit is 50. The port2 interface of each FortiGate unit should have an IP address that is different from the virtual router IP address and the port2 interface IP addresses should be different from each other.

This example also includes enabling the VRRP virtual MAC address on both FortiGate unit port2 interfaces so that the VRRP group uses the VRRP virtual MAC address.

Figure 226: Example VRRP configuration with two FortiGate units



To configure the FortiGate units for VRRP

1 Select one of the FortiGate units to be the VRRP master and the other to be the backup unit.

2 From the master unit's CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
  edit port2
  set vrrp-virtual-mac enable
    config vrrp
      edit 5
        set vrip 10.31.101.120
        set priority 255
      end
  end
```

3 From the backup unit's CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
    config vrrp
      edit 5
        set vrip 10.31.101.120
        set priority 50
      end
  end
```

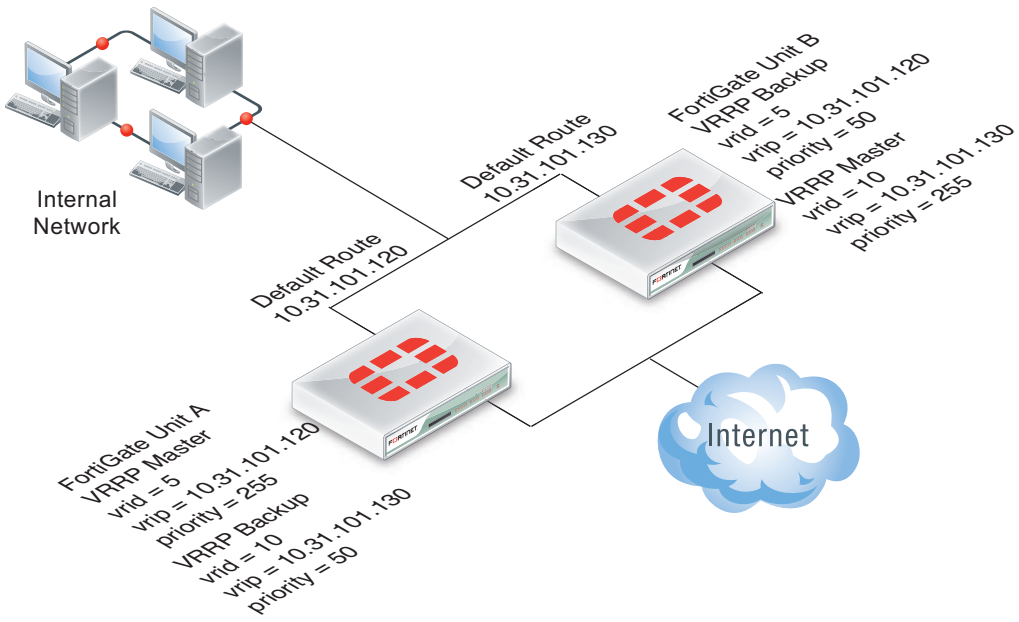
Example VRRP configuration: VRRP load balancing two FortiGate units and two VRRP groups

In this configuration two VRRP groups are involved. Each FortiGate unit participates in both of them. One FortiGate unit is the master of one group and the other FortiGate unit is the master of the other group. The network distributes traffic between two different default routes (10.31.101.120 and 10.31.101.130). One VRRP group is configured with one of the default route IP addresses and the other VRRP group get the other default route IP address. So during normal operation both FortiGate units are processing traffic and the VRRP groups are used to load balance the traffic between the two FortiGate units.

If one of the FortiGate units fails, the remaining FortiGate unit becomes the master of both VRRP groups. The network sends all traffic for both default routes to this FortiGate unit. The result is a configuration that under normal operation load balances traffic between two FortiGate units, but if one of the FortiGate units fails, all traffic fails over to the unit that is still operating.

This example also includes enabling the VRRP virtual MAC address on both FortiGate unit port2 interfaces so that the VRRP groups use their VRRP virtual MAC addresses.

Figure 227: Example VRRP configuration with two FortiGate units and two VRRP groups



To configure the FortiGate units

1 Log into the CLI of FortiGate unit A.

2 Enter the following command to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate unit A:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
    config vrrp
      edit 50 (32)
        set vrip 10.31.101.120
        set priority 255
```

```
    next
    edit 100 (64)
      set vrip 10.31.101.130
      set priority 50
    end
  end
```

3 Log into the CLI of FortiGate unit B.

4 Enter the following command to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate unit B:

```
config system interface
  edit port2
    set vrrp-virtual-mac enable
    config vrrp
      edit 50
        set vrip 10.31.101.120
        set priority 50
      next
      edit 100
        set vrip 10.31.101.130
        set priority 255
      end
  end
```

Optional VRRP configuration settings

In addition to the basic configuration settings, you can change to the VRRP configuration to:

- Adjust the virtual router advertisement message interval between 1 and 255 seconds using the `adv-interval` option.
- Adjust the startup time using the `start-time` option. The default start time is 3 seconds and the range is 1 to 255 seconds. The start time is the maximum time that the backup unit waits between receiving advertisement messages from the master unit. If the backup unit does not receive an advertisement message during this time it assumes the master has failed and becomes the new master unit. In some cases the advertisement messages may be delayed. For example, some switches with spanning tree enabled may delay some of the advertisement message packets. If you find that backup units are attempting to become master units without the master unit failing, you can extend the start time to make sure the backup units wait long enough for the advertisement messages.
- Enable or disable individual virtual router configurations using the `status` option. Normally virtual router configurations are enabled but you can temporarily disable one if its not required.
- Enable or disable preempt mode using the `preempt` option. In preempt mode a higher priority backup unit can preempt a lower priority master unit. This can happen if a master has failed, a backup unit has become the master unit, and the failed master is restarted. Since the restarted unit will have a higher priority, if preempt mode is enabled the restarted unit will replace the current master unit. Preempt mode is enabled by default.
- Monitor the route to a destination IP address using the `vrdst` option.

TCP session synchronization

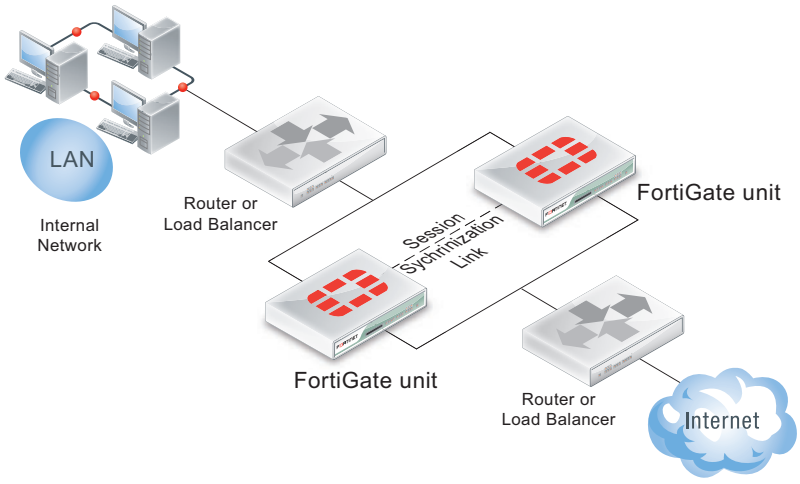
You can use the `config system session-sync` command to configure TCP session synchronization (also called standalone session synchronization) between two standalone FortiGate units. You can use this feature with external routers or load balancers configured to distribute or load balance TCP sessions between two peer FortiGate units. If one of the peers fails, session failover occurs and active TCP sessions fail over to the peer that is still operating. This failover occurs without any loss of data. As well, the external routers or load balancers will detect the failover and re-distribute all sessions to the peer that is still operating.

Standalone session synchronization between two standalone FortiGate units is also sometimes called TCP session synchronization or session synchronization between non-HA FortiGate units.

You cannot configure standalone session synchronization when HA is enabled.

Standalone session synchronization can be used instead of HA to provide TCP session synchronization between two peer FortiGate units. If the external load balancers direct all sessions to one peer the affect is similar to active-passive HA. If external load balancers or routers load balance traffic to both peers, the effect is similar to active-active HA. The load balancers should be configured so that all of the packets for any given session are processed by the same peer. This includes return packets.

Figure 228: Standalone session synchronization



By default, standalone session synchronization synchronizes all TCP sessions. You can optionally add filters to a configuration control which TCP sessions are synchronized. You can add filters to only synchronize packets from specified source and destination addresses, specified source and destination interfaces, and specified predefined firewall TCP services.

Unlike HA, standalone session synchronization does not include configuration synchronization. In fact, the configuration of the two peers is not identical because in most cases the peers would have different IP addresses. Also unlike HA, load balancing is done by external routers or load balancers. The FortiGate units only perform session synchronization and session failover.

Notes and limitations

Standalone session synchronization has the following limitations:

- Only TCP sessions accepted by security policies are synchronized. Due to their non-stateful nature, UDP and ICMP sessions don't need to be synchronized to naturally failover.
- Standalone session synchronization is a global configuration option. As a result you can only add one predefined firewall TCP service to a filter configuration. You cannot add custom services or service groups even if virtual domains are not enabled.
- You can only add one filter configuration to a given standalone session synchronization configuration. However, you can add multiple filters by adding multiple identical standalone session synchronization configurations, each one with a different filter configuration.
- Sessions accepted by security policies with UTM options configured are not synchronized.
- Sessions that include network address translation (NAT) applied by selecting NAT in security policies are not synchronized because the address translation binds to a FortiGate unit address and the peers have different IP addresses.
- Session synchronization is a CLI only configuration.
- Session synchronization is available for FortiGate units or virtual domains operating in NAT/Route or Transparent mode. NAT sessions are not synchronized in either mode. In NAT/Route mode, only sessions for route mode security policies are synchronized. In Transparent mode, only sessions for normal Transparent mode policies are synchronized.
- Session synchronization cannot be asymmetric. Session synchronization is stateful. So all of the packets of a given session must be processed on the same peer. This includes return packets. You must configure the load balancers so that they do not cause asymmetric routing.
- Session synchronization is supported for traffic on physical interfaces, VLAN interfaces, zones, and aggregate interfaces. Session synchronization has not been tested for inter-vdom links, accelerated interfaces (FA2 and NP2), between HA clusters, and for redundant interfaces.
- The names of the matching interfaces, including VLAN interfaces, aggregate interfaces and so on, must be the same on both peers.

Configuring session synchronization

You configure session synchronization for each virtual domain to be synchronized. If virtual domain configuration is not enabled, you configure session synchronization for the root virtual domain. When virtual domain configuration is enabled and you have added virtual domains you configure session synchronization for each virtual domain to be synchronized. You don’t have to synchronize all of the virtual domains.

You must configure session synchronization on both peers. The session synchronization configurations of each peer should compliment the other. In fact you can manage and configure both peers as separate FortiGate units. Using FortiManager, you can manage both peers as two separate FortiGate devices.

On each peer, configuring session synchronization consists of selecting the virtual domains to be synchronized using the `syncvd` field, selecting the virtual domain on the other peer that receives the synchronization packets using the `peervd` field, and setting IP address of the interface in the peer unit that receives the synchronization packets using the `peerip` field. The interface with the `peerip` must be in the `peervd` virtual domain.

The `syncvd` and `peervd` settings must be the same on both peers. However, the `peerip` settings will be different because the `peerip` setting on the first peer includes the IP address of an interface on the second peer. And the `peerip` setting on the second peer includes the IP address of an interface on the first peer.

Because session synchronization does not synchronize FortiGate configuration settings you must configure both peers separately. For session synchronization to work properly all session synchronized virtual domains must be added to both peers. The names of the matching interfaces in each virtual domain must also be the same; this includes the names of matching VLAN interfaces. Note that the index numbers of the matching interfaces and VLAN interfaces can be different. Also the VLAN IDs of the matching VLAN interfaces can be different.

As well, the session synchronized virtual domains should have the same security policies so that sessions can be resumed after a failover using the same security policies.

For a configuration example, see “Basic example configuration” on page 2246.

Configuring the session synchronization link

When session synchronization is operating, the peers share session information over an Ethernet link between the peers similar to an HA heartbeat link. Usually you would use the same interface on each peer for session synchronization. You should connect the session synchronization interfaces directly without using a switch or other networking equipment. If possible use a crossover cable for the session synchronization link. For FortiGate-5000 systems you can use a backplane interface as the session synchronization link.

You can use different interfaces on each peer for session synchronization links. Also, if you multiple sessions synchronization configurations, you can have multiple session synchronization links between the peers. In fact if you are synchronizing a lot of sessions, you may want to configure and connect multiple session synchronization links to distribute session synchronization traffic to these multiple links.

You cannot configure backup session synchronization links. Each configuration only includes one session synchronization link.

The session synchronization link should always be maintained. If session synchronization communication is interrupted and a failure occurs, sessions will not failover and data could be lost.

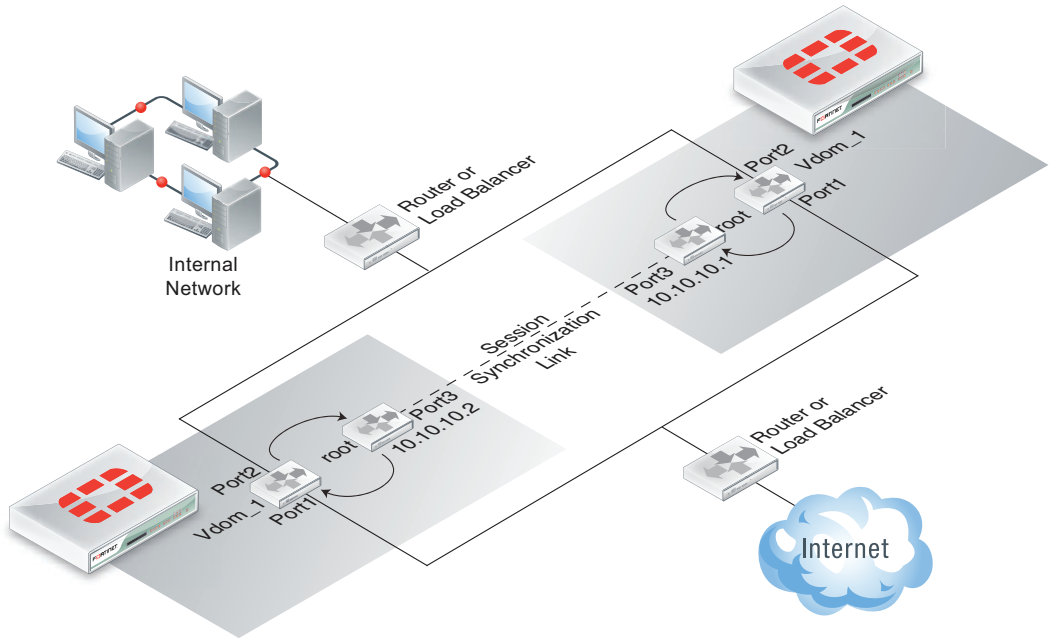
Session synchronization traffic can use a considerable amount of network bandwidth. If possible, session synchronization link interfaces should only be used for session synchronization traffic and not for data traffic.

Basic example configuration

The following configuration example shows how to configure a basic session synchronization configuration for two peer FortiGate units shown in Figure 229 on page 2246. The host names of peers are peer_1 and peer_2. Both peers are configured with two virtual domains: root and vdom_1. All sessions processed by vdom_1 are synchronized. The synchronization link interface is port3 which is in the root virtual domain. The IP address of port3 on peer_1 is 10.10.10.1. The IP address of port3 on peer_2 is 10.10.10.2.

Also on both peers, port1 and port2 are added to vdom_1. On peer_1 the IP address of port1 is set to 192.168.20.1 and the IP address of port2 is set to 172.110.20.1. On peer_2 the IP address of port1 is set to 192.168.20.2 and the IP address of port2 is set to 172.110.20.2.

Figure 229: Example standalone session synchronization network configuration



To configure standalone session synchronization

1 Configure the load balancer or router to send all sessions to peer_1.

2 Configure the load balancer or router to send all traffic to peer_2 if peer_1 fails.

3 Use normal FortiGate configuration steps on peer_1:

- Enable virtual domain configuration.
- Add the vdom_1 virtual domain.
- Add port1 and port2 to the vdom_1 virtual domain and configure these interfaces.
- Set the IP address of port1 to 192.168.20.1.
- Set the IP address of port2 to 172.110.20.1.
- Set the IP address of port3 to 10.10.10.1.
- Add route mode security policies between port1 and port2 to vdom_1.

4 Enter the following commands to configure session synchronization for peer_1

```
config system session-sync
```

```
  edit 1
    set peerip 10.10.10.2
    set peervd root
    set syncvd vdom_1
end
```

5 Use normal FortiGate configuration steps on peer_2:

- Enable virtual domain configuration.
- Add the vdom_1 virtual domain.
- Add port1 and port2 to the vdom_1 virtual domain and configure these interfaces.
- Set the IP address of port1 to 192.168.20.2.
- Set the IP address of port2 to 172.110.20.2.
- Set the IP address of port3 to 10.10.10.1.
- Add route mode security policies between port1 and port2 to vdom_1.

6 Enter the following commands to configure session synchronization for peer_1

```
config system session-sync
  edit 1
    set peerip 10.10.10.1
    set peervd root
    set syncvd vdom_1
end
```

To add a filter

You can add a filter to this basic configuration if you only want to synchronize some TCP sessions. For example you can enter the following commands on both FortiGate units to edit the standalone sessions configurations and add a filter so that only HTTP sessions are synchronized

```
config system session-sync
  edit 1
    config filter
      set service HTTP
    end
end
```

Chapter 13 Traffic Shaping

With the ever-increasing demands on network systems for a number of protocols from email, to HTTP traffic both internally and externally to the internet, voice over IP, FTP and so on, traffic slow downs become a reality. As such, important traffic may be dropped or slowed to an unusable speed. This can cause the halting or business traffic and revenues.

Traffic shaping attempts to normalize traffic peaks and bursts to prioritize certain flows over others. But there is a physical limitation to the amount of data which can be buffered and to the length of time.

FortiGate units can implement Quality of Service (QoS) by applying bandwidth limits and prioritization. Using traffic shaping, you can adjust how your FortiGate unit allocates resources to different traffic types to improve the performance and stability of latency sensitive or bandwidth intensive network applications.

This document discusses Quality of Service (QoS) and traffic shaping, describes FortiGate traffic shaping algorithms, and provides procedures and tips on how to configure traffic shaping on FortiGate units.

This FortiOS Handbook chapter contains the following chapters:

The purpose of traffic shaping describes traffic shaping theories and quality of service.

Traffic shaping methods describes the different methods of applying traffic shaping within FortiOS, and how to use TOS and Differentiated Services.

Examples provides some basic examples for the application of shapers.

Troubleshooting provides diagnose commands to use to troubleshoot traffic shapers to see if they are working correctly.

The purpose of traffic shaping

Traffic shaping, or traffic management, controls the bandwidth available and sets the priority of traffic processed by the policy to control the volume of traffic for a specific period (bandwidth throttling) or rate the traffic is sent (rate limiting).

Traffic shaping attempts to normalize traffic peaks and bursts to prioritize certain flows over others. But there is a physical limitation to the amount of data which can be buffered and to the length of time. Once these thresholds have been surpassed, frames and packets will be dropped, and sessions will be affected in other ways.

A basic traffic shaping approach is to prioritize certain traffic flows over other traffic whose potential discarding is less advantageous. This would mean that you accept sacrificing certain performance and stability on low-priority traffic, to increase or guarantee performance and stability to high-priority traffic.

If, for example, you are applying bandwidth limitations to certain flows, you must accept the fact that these sessions can be limited and therefore negatively impacted.

Note that traffic shaping is effective for normal IP traffic at normal traffic rates. Traffic shaping is not effective during periods when traffic exceeds the capacity of the FortiGate unit. Because packets must be received by the FortiGate unit before they are subject to traffic shaping, if the FortiGate unit cannot process all of the traffic it receives, then dropped packets, delays, and latency are likely to occur.

To ensure that traffic shaping is working at its best, make sure that the interface Ethernet statistics show no errors, collisions or buffer overruns.

Accelerated interfaces (NP2, NP4, CE) affect traffic shaping. For more information, see the *FortiGate Hardware* Guide.

Quality of Service

Quality of service (QoS) is the capability to adjust some quality aspects of your overall network traffic. This can include such techniques as priority-based queuing and traffic policing. Because bandwidth is finite and because some types of traffic are slow, jitter or packet loss sensitive, bandwidth intensive, or operation critical, QoS can be a useful tool for optimizing the performance of the various applications on your network.

Before implementing QoS, organizations should first identify the types of traffic that are important to the organization, the types of traffic that use high amounts of bandwidth, and the types of traffic that are sensitive to latency or packet loss.

For example, a company might want to guarantee sufficient bandwidth for revenue producing e-commerce traffic. They need to ensure that transactions can be completed and that clients do not experience service delays and interruptions. At the same time, the company may need to ensure low latency for voice over IP (VoIP) traffic used by sales and customer support, while traffic latency and bursts may be less critical to the success of other network applications such as long term, resumable file transfers. Many organizations discover that QoS is especially important for managing their voice and streaming multi-media traffic. These types of traffic can rapidly consume bandwidth and are sensitive to latency.

Discovering the needs and relative importance of each traffic type on your network will help you to design an appropriate overall approach, including how you will configure each available QoS component technique. Some organizations discover that they only need to configure bandwidth limits for some services. Other organizations determine that they need to fully configure interface and security policy bandwidth limits for all services, and prioritize queuing of critical services relative to traffic rate.

You can implement QoS on FortiGate units using the following techniques:

Traffic policing	Drops packets that do not conform to bandwidth limitations.
Traffic shaping	Ensures that the traffic may consume bandwidth at least at the guaranteed rate by assigning a greater priority queue if the guarantee is not being met. Also ensures that the traffic cannot consume bandwidth greater than the maximum at any given instant in time. Flows greater than the maximum rate are subject to traffic policing.
Queuing	Transmits packets in order of their assigned priority queue for that physical interface. All traffic in a higher priority traffic queue must be completely transmitted before traffic in lower priority queues will be transmitted.

When deciding how to configure QoS techniques, it can be helpful to know when FortiGate units employ each technique in the overall traffic processing flow, and the considerations that arise from those mechanisms.

Traffic policing

As traffic arrives (ingress) and departs (egress) on an interface, the FortiGate unit begins to process the traffic. In later phases of the network processing, such as enforcing maximum bandwidth use on sessions handled by a security policy, if the current rate for the destination interface or traffic regulated by that security policy is too high, the FortiGate unit may drop the packet. As a result, time spent on prior processing, such as web filtering, decryption or IPS, can be wasted on some packets that are not ultimately forwarded. This applies to VLAN interfaces as well has physical interfaces.

You can prevent this wasted effort on ingress by configuring the FortiGate unit to preemptively drop excess packets when they are received at the source interface, before most other traffic processing is performed:

```
config system interface
  edit <interface_name>
    set inbandwidth <rate_int>
  next
end
```

where `<rate_int>` is the bandwidth limit in Kb/s. Excess packets will be dropped. If `inbandwidth` is `0`, the rate is not limited.

A similar command is available that can be performed on egress as well using the CLI commands:

```
config system interface
  edit <interface_name>
    set outbandwidth <rate_int>
  next
end
```

As with ingress, setting the rate to 0 (zero) sets the rate to unlimited.

Rate limiting traffic accepted by the interface enables you to restrict incoming traffic to rates that, while no longer the full capacity of the interface, at the traffic shaping point in the processing are more likely to result in acceptable rates of outgoing traffic per destination interface or all security policies. This conserves FortiGate processing resources for those packets that are more likely to be viable completely to the point of egress.

Excessive traffic policing can degrade network performance rather than improve it. For details on factors you may want to consider when configuring traffic policing, see "Important considerations" on page 2258.

Bandwidth guarantee, limit, and priority interactions

After packet acceptance, the FortiGate unit classifies traffic and may apply traffic policing at additional points during processing. It may also apply additional QoS techniques, such as prioritization and traffic shaping. Traffic shaping consists of a mixture of traffic policing to enforce bandwidth limits, and priority queue adjustment to assist packets in achieving the guaranteed rate.

If you have configured prioritization, the FortiGate unit prioritizes egressing packets by distributing them among FIFO (first in, first out) queues associated with each possible priority number. Each physical interface has six priority queues. Virtual interfaces do not have their own queues, and instead use the priority queues of the physical interface to which they are bound.

Each physical interface's six queues are queue 0 to queue 5, where queue 0 is the highest priority queue. However, for the reasons described below, you may observe that your traffic uses only a subset of those six queues. Some traffic may always use a certain queue number. Some queuing may vary by the packet rate or mixture of services. Some queue numbers may be used only by through traffic for which you have configured traffic shaping in the security policy that applies to that traffic session. For example:

- Administrative access traffic will always use queue 0.
- Traffic matching security policies ***without*** traffic shaping may use queue 0, queue 1, or queue 2. Which queue will be used depends on the priority value you have configured for packets with that ToS (type of service) bit value, if you have configured ToS-based priorities.
- Traffic matching security policies ***with*** traffic shaping may use any queue. Which queue will be used depends on whether the packet rate is currently below the guaranteed bandwidth (queue 0), or above the guaranteed bandwidth. Packets at rates greater than the maximum bandwidth limit are dropped.
- If the global tos-based-priority is low (3), the priority in a traffic-shaper is medium (2) and a packet flows though a policy that refers to the shaper, the packet will be assigned the priority defined by the shaper, in this case medium (2).

Prioritization and traffic shaping behavior varies by your configuration, the service types and traffic volumes, and by whether the traffic is through traffic, or the traffic originates from or terminates at the FortiGate unit itself.

FortiGate traffic

Administrative access to the FortiGate through HTTPS or SSH, or IPsec tunnel negotiations, security policies do not apply, and therefore FortiGate units do not apply traffic shaping. Such traffic also uses the highest priority queue, queue 0. In other words:

packet priority = 0

Exceptions to this rule include traffic types that are connections related to a session governed by a security policy.

For example, if you have enabled scanning by FortiGuard antivirus, traffic from the sender technically terminates at the FortiGate proxy that scans that traffic type; the FortiGate unit initiates a second connection that transmits scanned content to its destination. Because the second connection's traffic is technically originating from the FortiGate proxy and therefore the FortiGate unit itself, it uses the highest priority queue, queue 0. However, this connection is logically associated with through traffic, and is therefore subject to possible bandwidth enforcement and guarantees in its governing security policy. In this way, it behaves partly like other through traffic.

Through traffic

For traffic passing through the FortiGate unit, the method a FortiGate unit uses to determine the priority queue varies by whether you have enabled Traffic Shaping. Packets may or may not use a priority queue directly or indirectly derived from the type of service (ToS) bit — sometimes used instead with differentiated services — in the packet's IP header.

If Traffic Shaping is not enabled in the security policy, the FortiGate unit neither limits nor guarantees bandwidth, and traffic for that session uses the priority queue determined directly by matching the ToS bit in its header with your configured values:

```
config system global
  set tos-based-priority {high | low | medium}
end
```

or, if you have configured a priority specifically for that TOS bit value:

```
config system tos-based-priority
  edit <id_int>
    set tos [0-15]
    set priority {high | low | medium}
  next
end
```

where `tos` is the value of the ToS bit in the packet's IP header, and `high` has a priority value of 0 and `low` is 2. Priority values configured in the second location will override the global ToS-based priority. In other words:

packet priority = ToS-based priority

For example, you might specify that packets with a ToS bit value of 2 should use queue 0, the highest priority queue:

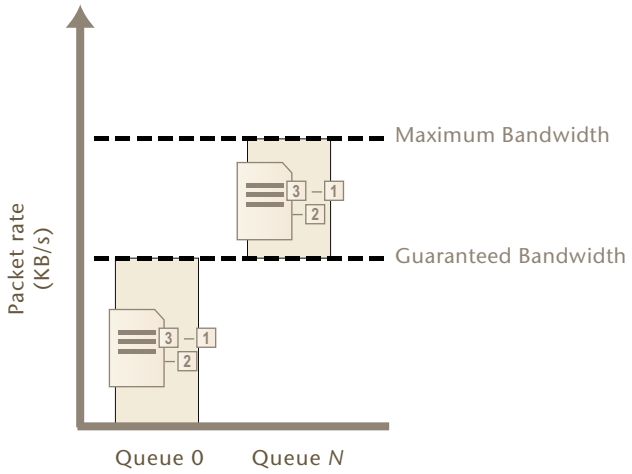
```
config system tos-based-priority
  edit 15
    set tos 2
    set priority high
  next
end
```

If Traffic Shaping is enabled in the security policy using shared traffic shapers, the FortiGate unit may instead or also subject packets to traffic policing, or priority queue increase in an effort to meet bandwidth guarantees configured in the shaper:

```
config firewall shaper traffic-shaper
  edit <shaper_name>
    ...
    set priority {high | medium | low}
    set maximum-bandwidth <rate>
    set guaranteed-bandwidth <rate>
end
```

where `high` has a priority value of 1 and `low` is 3, and `<rate>` is the bandwidth limit in kilobits per second.

Figure 230: Traffic queuing as packet rate increases



- If the current packet rate is less than Guaranteed Bandwidth, packets use priority queue 0. In other words:

  packet priority = 0

- If the current packet rate is greater than Guaranteed Bandwidth but less than Maximum Bandwidth, the FortiGate unit assigns a priority queue by adding the numerical value of the security policy-based priority, where the value of High is 1, and Low is 3, with the numerical value of the ToS-based priority, where `high` has a priority value of 0 and `low` is 2. Because the two values are added, depending on the your configured ToS-based priorities, packets in this category could use queues from queue 1 to queue 5. In other words:

  packet priority = ToS-based priority + security policy-based priority

  For example, if you have enabled Traffic Shaping in the security policy, and the security policy's Traffic Priority is Low (value 3), and the priority normally applied to packets with that ToS bit is `medium` (value 1), then packets have a total packet priority of 4, and use priority queue 4.

- If the current packet rate exceeds Maximum Bandwidth, excess packets are dropped.

Calculation and regulation of packet rates

Packet rates specified for Maximum Bandwidth or Guaranteed Bandwidth are:

```
rate = amount / time
```

where rate is expressed in kilobits per second (Kb/s).

Burst size at any given instant cannot exceed the amount configured in Maximum Bandwidth. Packets in excess are dropped. Packets deduct from the amount of bandwidth available to subsequent packets and available bandwidth regenerates at a fixed rate. As a result, bandwidth available to a given packet may be less than the configured rate, down to a minimum of 0 Kb/s.

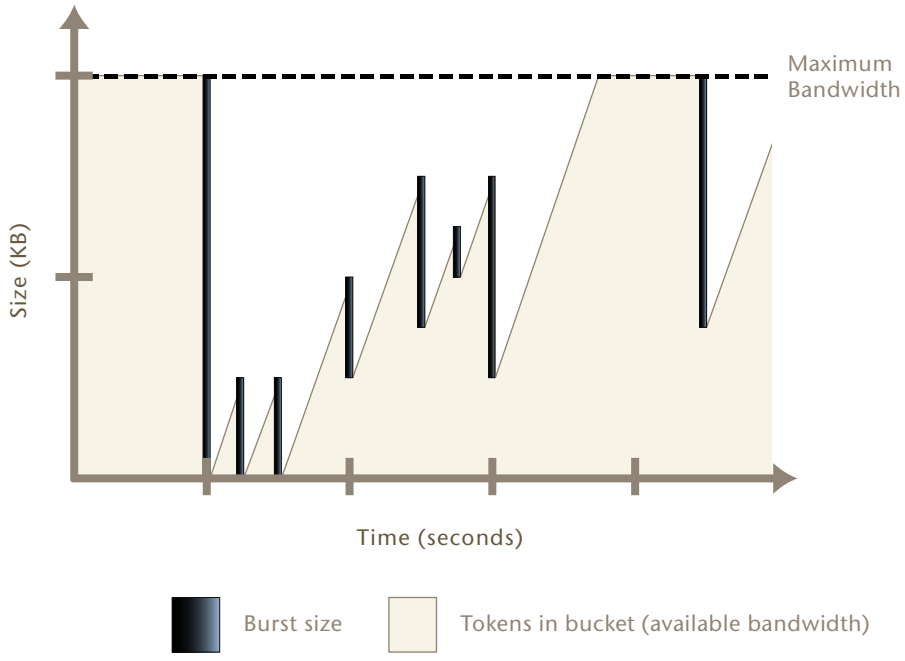
Rate calculation and behavior can alternatively be described using the token bucket metaphor, where:

- a traffic flow has an associated bucket, which represents burst size bounds, and is the size of your configured bandwidth limit
- the bucket receives tokens, which represent available bandwidth, at the fixed configured rate
- as time passes, tokens are added to the bucket, up to the capacity of the bucket; excess tokens are discarded
- when a packet arrives, the packet must deduct bandwidth tokens from the bucket equal to its packet size in order to egress
- packets cannot egress if there are insufficient tokens to pay for its egress; these nonconforming packets are dropped

Bursts are not redistributed over a longer interval, so bursts are propagated rather than smoothed, although their peak size is limited.

Maximum burst size is the capacity of the bucket (the configured bandwidth limit); actual size varies by the current number of tokens in the bucket, which may be less than bucket capacity, due to deductions from previous packets and the fixed rate at which tokens accumulate. A depleted bucket refills at the rate of your configured bandwidth limit. Bursts cannot borrow tokens from other time intervals. This behavior is illustrated in Figure 231 on page 2256.

Figure 231: Bursts and bandwidth limits over time



By limiting traffic peaks and token regeneration in this way, the available bandwidth at a given moment may be less than bucket capacity, but your limit on the total amount per time interval is ensured. That is, total bandwidth use during each interval of 1 second is at most the integral of your configured rate.

You may observe that external clients, such as FTP or BitTorrent clients, initially report rates between Maximum Bandwidth and twice that of Maximum Bandwidth, depending on the size of their initial burst. This is notably so when a connection is initiated following a period of no network activity.The apparent discrepancy in rates is caused by a difference of perspective when delimiting time intervals. A burst from the client may initially consume all tokens in the bucket, and before the end of 1 second, as the bucket regenerates, be allowed to consume almost another bucket's worth of bandwidth. From the perspective of the client, this constitutes one time interval. From the perspective of the FortiGate unit, however, the bucket cannot accumulate tokens while full; therefore, the time interval for token regeneration begins ***after*** the initial burst, and does not contain the burst. These different points of reference result in an initial discrepancy equal to the size of the burst — the client's rate contains it, but the FortiGate unit's rate does not. If the connection is sustained to its limit and time progresses over an increasing number of intervals, however, this discrepancy decreases in importance relative to the bandwidth total, and the client's reported rate will eventually approach that of the FortiGate unit's configured rate limit.

For example, your Maximum Bandwidth might be 50 Kb/s and there has been no network activity for one or more seconds. The bucket is full. A burst from an FTP client immediately consumes 50 Kb. Because the bucket completely regenerates over 1 second, by the time almost another 1 second has elapsed from the initial burst, traffic can consume another 49.999 Kb, for a total of 99.999 Kb between the two points in time. From the vantage point of an external FTP client regulated by this bandwidth limit, it therefore initially appears that the bandwidth limit is 99.999 Kb/s, almost twice the configured limit of 50 Kb/s. However, bucket capacity only regenerates at your configured rate of 50 Kb/s, and so the connection can only consume a maximum of 50 Kb during each second thereafter. The result is that as bandwidth consumption is averaged over an increasing number of time intervals, each of which are limited to 50 Kb/s, the effects of the first interval's doubled bandwidth size diminishes proportionately, and the client's reported rate eventually approach your configured rate limit. This effect is illustrated in Table 120 on page 2257.

Table 120: Effects of a 50 Kb/s limit on client reported rates

Total size transferred (Kb)	Time (s)	Rate reported by client (Kb/s)
99.999 (50 + 49.999)	1	99.999
149.999	2	74.999
199.999	3	66.666
249.999	4	62.499
299.999	5	59.998
349.999	6	58.333
...	...	...

Guaranteed Bandwidth can also be described using a token bucket metaphor. However, because this feature attempts to achieve or exceed a rate rather than limit it, the FortiGate unit does not discard non-conforming packets, as it does for Maximum Bandwidth; instead, when the flow does not achieve the rate, the FortiGate unit increases the packets' priority queue, in an effort to increase the rate.

Guaranteed and maximum bandwidth rates apply to the bidirectional total for all sessions controlled by the security policy. For example, an FTP connection may entail two separate connections for the data and control portion of the session; some packets may be reply traffic rather than initiating traffic. All packets for both connections are counted when calculating the packet rate for comparison with the guaranteed and maximum bandwidth rate.

Important considerations

In essence, by implementing QoS, you trade some performance and/or stability from traffic X by discarding packets or introducing latency in order to improve performance and stability of traffic Y. The best traffic shaping configuration for your network will appropriately balance the needs of each traffic flow by considering not only the needs of your particular organization, but also the resiliency and other characteristics of each particular service.

For example, you may find that web browsing traffic is both more resistant to interruptions or latency and less business critical than UDP or VoIP traffic, and so you might implement less restrictive QoS measures on UDP or VoIP traffic than on HTTP traffic.

An appropriate QoS configuration will also take into account the physical limits of your network devices, and the interactions of the aforementioned QoS mechanisms, described in "Bandwidth guarantee, limit, and priority interactions" on page 2253.

You may choose to configure QoS differently based upon the hardware limits of your network and FortiGate unit. Traffic shaping may be less beneficial in extremely high-volume situations where traffic exceeds a network interface's or your FortiGate model's overall physical capacity. A FortiGate unit must have sufficient resources, such as memory and processing power, to process all traffic it receives, and to process it at the required rate; if it does not have this capacity, then dropped packets and increased latency are likely to occur. For example, if the total amount of memory available for queuing on a physical interface is frequently exceeded by your network's typical packet rates, frames and packets must be dropped. In such a situation, you might choose to implement QoS using a higher model FortiGate unit, or to configure an incoming bandwidth limit on each interface.

Incorrect traffic shaping configurations can actually further degrade certain network flows, because excessive discarding of packets or increased latency beyond points that can be gracefully handled by that protocol can create additional overhead at upper layers of the network, which may be attempting to recover from these errors. For example, a configuration might be too restrictive on the bandwidth accepted by an interface, and may therefore drop too many packets, resulting in the inability to complete or maintain a SIP call.

To optimize traffic shaping performance, first ensure that the network interface's Ethernet statistics are clean of errors, collisions, or buffer overruns. To check the interface, enter the following diagnose command to see the traffic statistics:

```
diagnose hardware deviceinfo nic <port_name>
```

If these are not clean, adjust FortiGate unit and settings of routers or other network devices that are connected to the FortiGate unit. For additional information, see "Troubleshooting" on page 2285.

Once Ethernet statistics are clean, you may want to use only some of the available FortiGate QoS techniques, or configure them differently, based upon the nature of FortiGate QoS mechanisms described in "Bandwidth guarantee, limit, and priority interactions" on page 2253. Configuration considerations include:

- For maximum bandwidth limits, ensure that bandwidth limits at the source interface and/or the security policy are not too low, which can cause the FortiGate unit to discard an excessive number of packets.
- For prioritization, consider the ratios of how packets are distributed between available queues, and which queue is used by which types of services. If you assign most packets to the same priority queue, it negates the effects of configuring prioritization. If you assign many high bandwidth services to high priority queues, lower priority queues may be starved for bandwidth and experience increased or indefinite latency. For example, you may want to prioritize a latency-sensitive service such as SIP over a bandwidth-intensive service such as FTP. Consider also that bandwidth guarantees can affect the queue distribution, assigning packets to queue 0 instead of their typical queue in high-volume situations.
- You may or may not want to guarantee bandwidth, because it causes the FortiGate unit to assign packets to queue 0 if the guaranteed packet rate is not currently being met. Comparing queuing behavior for lower-bandwidth and higher-bandwidth situations, this would mean that effects of prioritization only become visible as traffic volumes rise and exceed their guarantees. Because of this, you might want only some services to use bandwidth guarantees, to avoid the possibility that in high-volume situations all traffic uses the same queue, thereby negating the effects of configuring prioritization.
- For prioritization, configure prioritization for all through traffic. You may want to configure prioritization by either ToS-based priority or security policy priority, but not both. This simplifies analysis and troubleshooting.

  Traffic subject to both security policy and ToS-based priorities will use a combined priority from both of those parts of the configuration, while traffic subject to only one of the prioritization methods will use only that priority. If you configure both methods, or if you configure either method for only a subset of your traffic, packets for which a combined priority applies will frequently receive a lower priority queue than packets for which you have only configured one priority method, or for which you have not configured prioritization.

  For example, if both ToS-based priority and security policy priority both dictate that a packet should receive a "medium" priority, in the absence of bandwidth guarantees, a packet will use queue 3, while if only ToS-based priority had been configured, the packet would have used queue 1, and if only security policy-based priority had been configured, the packet would have used queue 2. If no prioritization had been configured at all, the packet would have used queue 0.

For example alternative QoS implementations that illustrate these considerations, see "Examples" on page 2277

Traffic shaping methods

In FortiOS, there are three types of traffic shaping configuration. Each has a specific function, and all can be used together in varying configurations. Policy shaping enables you to define the maximum bandwidth and guaranteed bandwidth set for a security policy. Per-IP shaping enables you to define traffic control on a more granular level. Application traffic shaping goes further, enabling traffic controls on specific applications or application groupings.

This chapter describes the types of traffic shapers and how to configure them in the web-based manager and the CLI.

Traffic shaping options

When configuring traffic shaping for your network, there are three different methods to control the flow of network traffic to ensure that the desired traffic gets through while also limiting the bandwidth that users use for other less important or bandwidth consuming traffic. The three shaping options are:

- shared policy shaping - bandwidth management by security policies
- per-IP shaping - bandwidth management by user IP addresses
- application control shaping - bandwidth management by application

Shared policy shaping and per IP shaping are enabled within the security policy, while the application control shaping is configured in *UTM Profiles* > *Application Control* and enabled in the security policy by selecting *UTM Profiles* and selecting the application control profile from the drop-down list.

The FortiGate unit offers three different traffic shaping options, all of which can be enabled at the same time within the same security policy. Generally speaking, the hierarchy for shapers in FortiOS is:

- Application Control shaper
- Security policy shaper
- Per-IP shaper

With this hierarchy, if an application control list has a traffic shaper defined, it will have precedence always over any other security policy shaper. For example, with the example above creating an application control for Facebook, the shaper defined for Facebook will supersede any security policy enabled traffic shapers. While the Facebook application may reach its maximum bandwidth, the user can still have the bandwidth room available from the shared shaper and, if enabled, the per-IP shaper.

Equally, any security policy shared shaper will have precedence over any per-IP shaper. However, traffic that exceeds any of these shapers will be dropped. For example, the policy shaper will take effect first, however, if the per-IP shaper limit is reached first, then traffic for that user will be dropped even if the shared shaper limit for the policy has not been exceeded.

Shared policy shaping

Traffic shaping by security policy enables you to control the maximum and/or guaranteed throughput for a selected security policy. When configuring a shaper, you can select to apply the bandwidth shaping per policy or for all policies. Depending on your selection, the FortiGate unit will apply the shaping rules differently.

Per policy

When selecting a shaper to be per policy, the FortiGate unit will apply the shaping rules defined to each security policy individually.

For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. Three of these have the shaper enabled. Each security policy has the same maximum bandwidth of 1000 Kb/s.

Per policy traffic shaping is compatible with client/server (active-passive) transparent mode WAN optimization rules. Traffic shaping is ignored for peer-to-peer WAN optimization and for client/server WAN optimization not operating in transparent mode.

All policies

When selecting a shaper to be for all policies - *For All Policies Using This Shaper* - the FortiGate unit applies the shaping rules to all policies using the same shaper. For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. All four have the shaper enabled. Each security policy must share the defined 1000 Kb/s, and is set on a first come, first served basis. For example, if policy 1 uses 800 Kb/s, the remaining three must share 200 Kb/s. As policy 1 uses less bandwidth, it is opened up to the other policies to use as required. Once used, any other policies will encounter latency until free bandwidth opens from a policy currently in use.

Maximum and guaranteed bandwidth

The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the shaper.

The guaranteed bandwidth ensures there is a consistent reserved bandwidth available for a given service or user. When setting the guaranteed bandwidth, ensure that the value is significantly less than the bandwidth capacity of the interface, otherwise no other traffic will pass through the interface or very little an potentially causing unwanted latency.

Setting Maximum Bandwidth to 0 (zero) provides unlimited bandwidth.

Traffic priority

Select a Traffic Priority of high, medium or low, so the FortiGate unit manages the relative priorities of different types of traffic. For example, a policy for connecting to a secure web server needed to support e-commerce traffic should be assigned a high traffic priority. Less important services should be assigned a low priority. The firewall provides bandwidth to low-priority connections only when bandwidth is not needed for high-priority connections.

Be sure to enable traffic shaping on all security policies. If you do not apply any traffic shaping rule to a policy, the policy is set to high priority by default.

Distribute security policies over all three priority queues.

VLAN, VDOM and virtual interfaces

Policy-based traffic shaping does not use queues directly. It shapes the traffic and if the packet is allowed by the security policy, then a priority is assigned. That priority controls what queue the packet will be put in upon egress. VLANs, VDOMs, aggregate ports and other virtual devices do not have queues and as such, traffic is sent directly to the underlying physical device where it is queued and affected by the physical ports.

This is also the case with IPsec connections.

Shared traffic shaper configuration settings

To configure a shared traffic shaper go to *Firewall Objects* > *Traffic Shaper* > *Shared* and select *Create New*.

Name	Enter a name for the traffic shaper.
Apply Shaper	When selecting a shaper to be *Per Policy*, the FortiGate unit will apply the shaping rules defined to each security policy individually. For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. Three of these have the shaper enabled. Each security policy has the same maximum bandwidth of 1000 Kb/s. Per policy traffic shaping is compatible with client/server (active-passive) transparent mode WAN optimization rules. Traffic shaping is ignored for peer-to-peer WAN optimization and for client/server WAN optimization not operating in transparent mode. When selecting a shaper to be for all policies - *For All Policies Using This Shaper* - the FortiGate unit applies the shaping rules to all policies using the same shaper. For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. All four have the shaper enabled. Each security policy must share the defined 1000 Kb/s, and is set on a first come, first served basis. For example, if policy 1 uses 800 Kb/s, the remaining three must share 200 Kb/s. As policy 1 uses less bandwidth, it is opened up to the other policies to use as required. Once used, any other policies will encounter latency until free bandwidth opens from a policy currently in use
Traffic Priority	Select level of importance *Priority* so the FortiGate unit manages the relative priorities of different types of traffic. For example, a policy for connecting to a secure web server needed to support e-commerce traffic should be assigned a high traffic priority. Less important services should be assigned a low priority. If you do not apply any traffic shaping priority, the priority is set to high priority by default.

Maximum Bandwidth	The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the shaper. Setting Maximum Bandwidth to 0 (zero) provides unlimited bandwidth
Guaranteed Bandwidth	The guaranteed bandwidth ensures there is a consistent reserved bandwidth available for a given service or user. When setting the guaranteed bandwidth, ensure that the value is significantly less than the bandwidth capacity of the interface, otherwise no other traffic will pass through the interface or very little an potentially causing unwanted latency. Setting Guaranteed Bandwidth to 0 (zero) provides unlimited bandwidth.
DSCP	Enter the number for the DSCP value. You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet. For more information, see "Differentiated Services".

Example

The following steps creates a Per Policy traffic shaper called "Throughput" with a maximum traffic amount of 720,000 Kb/s, and a guaranteed traffic of 150,000 Kb/s with a high traffic priority.

To create the shared shaper - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaper* > *Shared* and select *Create New*.
2. Enter the *Name* `Throughput`.
3. Select *Per Policy*.
4. Select the *Maximum Bandwidth* check box and enter the value `120000`.
5. Select the *Guaranteed Bandwidth* check box and enter the value `150000`.
6. Set the *Traffic Priority* to *High*.
7. Select *OK*.

To create the shared shaper - CLI

```
config firewall shaper traffic-shaper
  edit Throughput
    set per-policy enable
    set maximum-bandwidth 720000
    set guaranteed-bandwidth 150000
    set priority high
end
```

Per-IP shaping

Traffic shaping by IP enables you to apply traffic shaping to all source IP addresses in the security policy. As well as controlling the maximum bandwidth users of a selected policy, you can also define the maximum number of concurrent sessions.

Per-IP traffic shaping enables you limit the behavior of every member of a policy to avoid one user from using all the available bandwidth - it now is shared within a group equally. Using a per-IP shaper avoids having to create multiple policies for every user you want to apply a shaper

Per-IP traffic shaping is not supported over NP2 interfaces.

Per-IP traffic shaping configuration settings

To configure per-IP traffic shaping go to *Firewall Objects* > *Traffic Shaper* > *Per-IP*. and select *Create New*.

Name	Enter a name for the per-IP traffic shaper.
Maximum Bandwidth	The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the shaper. Setting Maximum Bandwidth to 0 (zero) provides unlimited bandwidth.
Maximum Concurrent Connections	Enter the maximum allowed concurrent connection.
Forward DSCP Reverse DSCP	Enter the number for the DSCP value. You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet. For more information, see “Differentiated Services”.

Example

The following steps creates a Per-IP traffic shaper called “Accounting” with a maximum traffic amount of 720,000 Kb/s, and the number of concurrent sessions of 200.

To create the shared shaper - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaper* > *Per-IP*.
2. Select *Create New*.
3. Enter the *Name* `Accounting`.
4. Select the *Maximum Bandwidth* check box and enter the value `720000`.

5 Select the *Maximum Concurrent Sessions* check box and enter the value `200`.

6 Select *OK*.

To create the shared shaper - CLI

```
config firewall shaper per-ip-shaper
  edit Accounting
    set max-bandwidth 720000
    set max-concurrent-sessions 200
end
```

Application control shaping

Traffic shaping is also possible for specific applications for both shared and per IP shaping. Through the *UTM Profiles* > *Application Control* feature, you can configure a specific application's maximum bandwidth. When configuring the application control features, if the application is set to pass, you can set the traffic shaping options. The shapers available are those set up in the *Firewall Objects* > *Traffic Shaping* menu.

For more information on configuring application control shapers, see the *UTM Guide*.

Example

This example sets the traffic shaping definition for Facebook to a medium priority, a default traffic shaper.

To add traffic shaping for Facebook - web-based manager

1 Go to *UTM Objects* > *Application Control* > *Application Sensor*.

2 Select the *Create New* "Plus" icon in the upper right corner of the screen to create a new application group, and enter the name `Web`.

3 Select *OK*.

4 Select *Create New*.

5 Select *Web* from the *Category* drop-down list.

6 Select *Facebook* from the *Application* drop-down list.

7 Select *Monitor* for the *Action*.

8 Select *Traffic Shaping* and select medium-priority from the drop-down list.

9 Select *OK*.

To add traffic shaping for Facebook - CLI

```
config application list
  edit web
    config entries
      edit 1
        set category 12
        set application 15832
        set action pass
        set shaper medium-priority
      end
  end
end
```

Enabling in the security policy

All traffic shapers are enabled within a security policy, including the Application Control shapers. As such, the shapers are in effect after any DoS sensor policies, and before any routing or packet scanning occurs.

To enable traffic shaping - web-based manager

1 Go to *Policy* > *Policy* > *Policy*.
2 Select *Create New* or select an existing policy and select *Edit*.
3 Select *Traffic Shaping*.
4 Select the shaping option and select the shaper from the drop-down list.
5 Select *OK*.

To enable traffic shaping - CLI

```
config firewall policy
  edit <policy_number>
    ...
    set traffic-shaper <shaper_name>
    set per-ip-shaper <shaper_name>
end
```

Reverse direction traffic shaping

The shaper you select for the security policy (shared shaper) will affect the traffic in the direction defined in the policy. For example, if the source port is port 1 and the destination is port 3, the shaping affects the flow in this direction only. By selecting *Reverse Direction Traffic Shaping*, you can define the traffic shaper for the policy in the opposite direction. In this example, from port 3 to port 1.

To add a reverse shaper

1 Go to *Policy* > *Policy* > *Policy*.
2 Select *Traffic Shaping*.
3 Select *Shared Traffic Shaper Reverse Direction* and select the shaper from the list.
4 Select *OK*.

Setting the reverse direction only

There may be instances where you only need to have the traffic shaping for incoming connections. That is, the “reverse” direction to the typical traffic shaper. Using the CLI, you can enable a reverse-only shaper from the your configured list of shapers.

To add a reverse shaper - web-based manager

1 Go to *Policy* > *Policy* > *Policy*.
2 Select *Traffic Shaping*.
3 Select *Shared Traffic Shaper Reverse Direction* and select the shaper from the list.
4 Select *OK*.

To configure a reverse-only shaper - CLI

```
config firewall policy
  edit <policy_number>
```

```
    ...
    set traffic-shaper-reverse <shaper_name>
end
```

Application control shaper

Application control shapers are in effect within the application control profile. Within the security policy options, select *UTM* then *Application Control* and select the application from the list.

Type of Service priority

Type of service (ToS) is an 8-bit field in the IP header that enables you to determine how the IP datagram should be delivered, using criteria of Delay, Throughput, Priority, Reliability, and Cost. Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority ToS is 0, the highest is 7 when bits 3, 4, and 5 are all set to 1. There are 4 other bits that are seldom used or reserved that are not included here.

Together these bits are the tos variable of the `tos-based-priority` command. The router tries to match the ToS of the datagram to the ToS on one of the possible routes to the destination. If there is no match, the datagram is sent over a zero ToS route. Using increased quality may increase the cost of delivery because better performance may consume limited network resources.

Each bit represents the priority as per RFC 1349:

- 1000 - minimize delay
- 0100 - maximize throughput
- 0010 - maximize reliability
- 0001 - minimize monetary cost

The TOS value is set in the CLI using the commands:

```
config system tos-based-priority
  edit <sequence_number>
    set tos [0-15]
    set priority [high | medium | low]
end
```

Where `tos` is the value of the type of service bit in the IP datagram header with a value between 0 and 15, and `priority` is the priority of this type of service priority. These priority levels conform to the firewall traffic shaping priorities, as defined in RFC 1349.

For example, if you want to configure the FortiGate unit so that reliability is the first priority, set the tos value to 4.

```
config system tos-based-priority
  edit 1
    set tos 4
    set priority high
```

end

For a list of ToS values and their DSCP equivalents see “Tos and DSCP mapping” on page 2275.

Example

```
config system tos-based-priority
  edit 1
    set tos 1
    set priority low
  next
  edit 4
    set tos 4
    set priority medium
  next
  edit 6
    set tos 6
    set priority high
  next
end
```

TOS in FortiOS

Traffic shaping and TOS follow the following sequence:

1. The CLI command `tos-based-priority` acts as a `tos-to-priority` mapping. FortiOS maps the TOS to a priority when it receives a packet.
2. Traffic shaping settings adjust the packet's priority according the traffic.
3. Deliver the packet based on its priority.

Differentiated Services

Differentiated Services describes a set of end-to-end Quality of Service (QoS) capabilities. End-to-end QoS is the ability of a network to deliver service required by specific network traffic from one end of the network to another. By configuring differentiated services, you configure your network to deliver particular levels of service for different packets based on the QoS specified by each packet.

Differentiated Services (also called DiffServ) is defined by RFC 2474 and 2475 as enhancements to IP networking to enable scalable service discrimination in the IP network without the need for per-flow state and signaling at every hop. Routers that can understand differentiated services sort IP traffic into classes by inspecting the DS field in IPv4 header or the Traffic Class field in the IPv6 header.

You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet.

If the differentiated services feature is not enabled, the FortiGate unit treats traffic as if the DSCP value is set to the default (00), and will not change IP packets' DSCP field. DSCP values are also not applied to traffic if the traffic originates from a FortiGate unit itself.

The FortiGate unit applies the DSCP value and IPsec encryption to the differentiated services (formerly TOS) field in the first word of the IP header. The typical first word of an IP header, with the default DSCP value, is 4500:

- 4 for IPv4
- 5 for a length of five words
- 00 for the default DSCP value

You can change the packet's DSCP field for traffic initiating a session (forward) or for reply traffic (reverse) and enable each direction separately and configure it in the security policy.

Changes to DSCP values in a security policy effect new sessions. If traffic must use the new DSCP values immediately, clear all existing sessions.

DSCP is enabled using the CLI command:

```
config firewall policy
  edit <policy_number>
    ...
    set diffserv-forward enable
    set diffservcode-forward <binary_integer>
    set diffserv-reverse enable
    set diffservcode-rev <binary_integer>
end
```

For more information on the different DCSP commands, see the examples below and the *CLI Reference*.

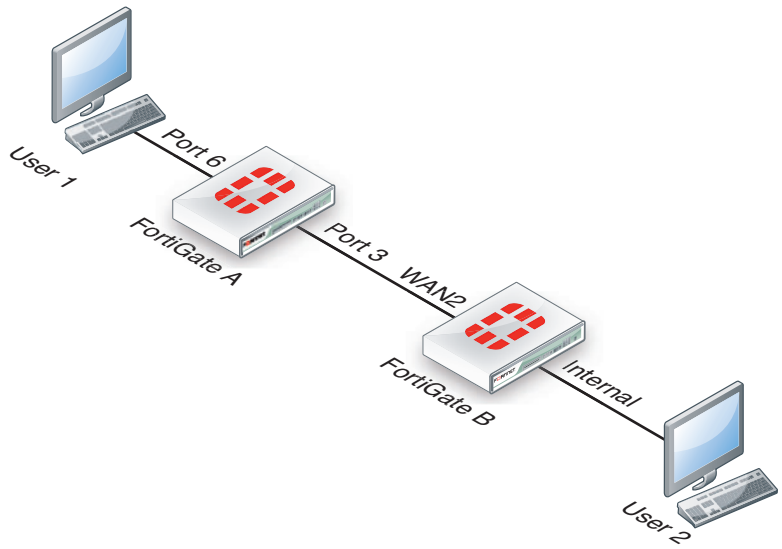
If you only set `diffserv-forward` and `diffserv-reverse` without setting the corresponding `diffvercode` values, the FortiGate unit will reset the bits to zero.

For a list of DSCP values and their ToS equivalents see "Tos and DSCP mapping" on page 2275.

DSCP values can also be defined within a shared shaper as a single value, and per-IP shaper for forward and reverse directions.

DSCP examples

For all the following DSCP examples, the FortiGate and client PC configuration is the following diagram and used firewall-based DSCP configurations.



Example

In this example, an ICMP ping is executed between User 1and FortiGate B, through a FortiGate unit. DSCP is disabled on FortiGate B, and FortiGate A contains the following configuration:

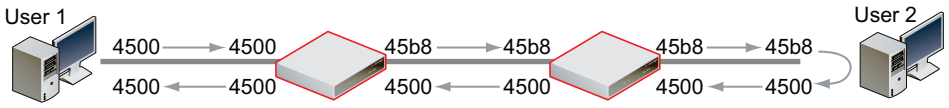
```
config firewall policy
  edit 2
    set srcintf port6
    set dstintf port3
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-forward enable
    set diffservcode-forward 101110
end
```

As a result, FortiGate A changes the DSCP field for outgoing traffic, but not to its reply traffic. The binary DSCP values used map to the following hexadecimal

TOS field values, which are observable by a sniffer (also known as a packet tracer):

- DSCP 000000 is TOS field 0x00
- DSCP 101110 is TOS field 0xb8, the recommended DSCP value for expedited forwarding (EF)

If you performed an ICMP ping between User 1 and User 2, the following output illustrates the IP headers for the request and the reply by sniffers on each of FortiGate unit's network interfaces. The right-most two digits of each IP header are the TOS field, which contains the DSCP value.



Example

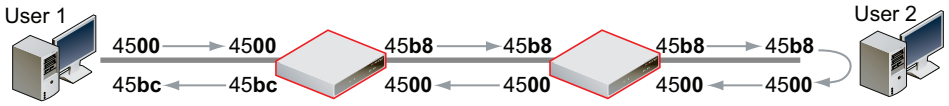
In this example, an ICMP ping is executed between User 1 and FortiGate B, through FortiGate A. DSCP is disabled on FortiGate B, and FortiGate A contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf port6
    set dstintf port3
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY"
    set diffserv-forward enable
    set diffserv-rev enable
    set diffservcode-forward 101110
    set diffservcode-rev 101111
end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic. The binary DSCP values in map to the following hexadecimal TOS field values, which are observable by a sniffer (also known as a packet tracer):

- DSCP 000000 is TOS field 0x**00**
- DSCP 101110 is TOS field 0x**b8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0x**bc**

If you performed an ICMP ping between User 1 and User 2, the output below illustrates the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and FortiGate B's network interfaces. The right-most two digits of each IP header are the TOS field, which contains the DSCP value.



Example

In this example, an ICMP ping is executed between User 1 and FortiGate B, through FortiGate A. DSCP is enabled for both traffic directions on FortiGate A, and enabled only for reply traffic on FortiGate B. FortiGate A contains the following configuration:

```
config firewall policy
  edit 2
```

```
    set srcintf port6
    set dstintf port3
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-forward enable
    set diffserv-rev enable
    set diffservcode-forward 101110
    set diffservcode-rev 101111
end
```

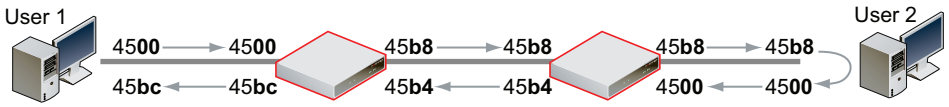
FortiGate B contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf wan2
    set dstintf internal
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-rev enable
    set diffservcode-rev 101101
end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic, and FortiGate B changes the DSCP field only for reply traffic. The binary DSCP values in this configuration map to the following hexadecimal TOS field values:

- DSCP 000000 is TOS field 0**x00**
- DSCP 101101 is TOS field 0**xb4**
- DSCP 101110 is TOS field 0**xb8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0**xbc**

If you performed an ICMP ping between User 1 and User 2, the output below illustrates the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and FortiGate B's network interfaces. The right-most two digits of each IP header are the TOS field, which contains the DSCP value.



Example

In this example, HTTPS and DNS traffic is sent from User 1 to FortiGate B, through FortiGate A. DSCP is enabled for both traffic directions on FortiGate A, and enabled only for reply traffic on FortiGate B. FortiGate A contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf port6
    set dstintf port3
```

```
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-forward enable
    set diffserv-rev enable
    set diffservcode-forward 101110
    set diffservcode-rev 101111
end
```

FortiGate B contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf wan2
    set dstintf internal
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-rev enable
    set diffservcode-rev 101101
end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic, but FortiGate B changes the DSCP field only for reply traffic which passes through its internal interface. Since the example traffic does not pass through the internal interface, FortiGate B does not mark the packets. The binary DSCP values in this configuration map to the following hexadecimal TOS field values:

- DSCP 000000 is TOS field 0**x00**
- DSCP 101101 is TOS field 0**xb4**, which is configured on FortiGate B but not observed by the sniffer because the example traffic originates from the FortiGate unit itself, and therefore does not match that security policy.
- DSCP 101110 is TOS field 0**xb8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0**xbc**

If you sent HTTPS or DNS traffic from User 1 to FortiGate B, the following would illustrate the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and FortiGate B's network interfaces. The right-most two digits of each IP header are the TOS field, which contains the DSCP value.

Tos and DSCP mapping

The table below lists the mapping of DSCP and ToS hexidecimal values for each service for QoS.

Table 121: ToS to DSCP mappings

Service Class	DSCP Bits	DSCP Value	ToS Value	ToS Hexidecimal
Network Control	111000	56-63	224	0xE0
Internetwork Control	110000	48-55	192	0xC0
Critical - Voice Data (RTP)	101110	46	184	0xB8
	101000	40	160	0xA0
Flash Override Video Data	100010	34	136	0x88
	100100	36	144	0x90
	100110	38	152	0x98
	100000	32	128	0x80
Flash Voice Control	011010	26	104	0x68
	011100	28	112	0x70
	011110	30	120	0x78
	011000	24	96	0x60
Immediate Deterministic (SNA)	010010	18	72	0x48
	010100	20	80	0x50
	010110	22	88	0x58
	010000	16	64	0x40
Priority Controlled Load	001010	10	40	0x28
	001100	12	48	0x30
	001110	14	56	0x38
	001000	8	32	0x20
Routine - Best Effort	000000	0	0	0x00
Routine - Penalty Box	000010	2	8	0x08

Traffic Shaper Monitor

You can view statistical information about traffic shapers and their bandwidth from *Firewall Objects* > *Monitor* > *Traffic Shaper Monitor*.

Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Report By	Select to display dropped packets or current bandwidth. The bar chart changes its name so that you know what current information is being displayed.
Traffic Shaper Usage Dropped packets	The bar chart displays the packets that were dropped by traffic shaper.
Traffic Shaper Usage Current Bandwidth	The bar chart displays the current bandwidth of traffic shapers.

Examples

While it is possible to configure QoS using a combination of security policies and in ToS-based priorities, and to distribute traffic over all six of the possible queues for each physical interface, the results of those configurations can be more difficult to analyze due to their complexity. In those cases, prioritization behavior can vary by several factors, including traffic volume, ToS (type of service) or differentiated services markings, and correlation of session to a security policy.

The following simple examples illustrate QoS configurations using either prioritization by security policy, or prioritization by ToS bit, but not both. The examples also assume you are not configuring traffic shaping for interfaces that receive hardware acceleration from network processing units (NPU).

QoS using priority from security policies

Configurations implementing QoS using the priority values defined in security policies are capable of applying bandwidth limits and guarantees.

In addition to configuring traffic shaping, you may also choose to limit bandwidth accepted by each interface. This can be useful in scenarios where bandwidth being received on source interfaces frequently exceeds the maximum bandwidth limit defined in the security policy. In this case, rather than wasting processing power on packets that will only be dropped later in the processing to enforce those limits, you may choose to preemptively police the traffic.

Note that if you implement QoS using security policies rather than ToS bit, the FortiGate unit applies QoS to all packets controlled by the policy. Control is less granular than prioritization by ToS bit, but has the benefits of correlating quality of service to a security policy, enabling you to distribute traffic over up to four of the possible 6 priority queues (queue 0 to queue 3), not requiring other devices in your network to set or respect the ToS bit, and of enabling you to configure bandwidth limits and guarantees.

In this example, we limit the bandwidth accepted by each source interface, limit the bandwidth used by sessions controlled by the security policy, and then configure prioritized queuing on the destination interface based upon the priority in the security policy, subject to alternative assignment to queue 0 when necessary to achieve the guaranteed packet rate.

To limit bandwidth accepted by an interface

In the CLI, enter the following commands:

```
config system interface
  edit <name_str>
    set inbandwidth <rate_int>
  next
end
```

where `<rate_int>` is the bandwidth limit in Kb/s. Excess packets will be dropped.

To configure bandwidth guarantees, limits, and priorities

1 Go to *Firewall Objects* > *Traffic Shaper* > *Shared*, and select *Create New*.
2 Enter a name for the shaper.
3 Enter the *Guaranteed Bandwidth*, if any.

   Bandwidth guarantees affect prioritization. While packet rates are less than this rate, they use priority queue 0. If this is not the effect you intend, consider entering a small guaranteed rate, or enter 0 to effectively disable bandwidth guarantees.
4 Enter Maximum Bandwidth.

   Packets greater than this rate will be discarded.
5 Select the *Traffic Priority*.

   High has a priority value of 1, while Low is 3. While the current packet rate is below Guaranteed Bandwidth, the FortiGate unit will disregard this setting, and instead use priority queue 0.
6 Select *OK*.

Sample configuration

This sample configuration limits ingressing bandwidth to 500 Kb/s. It also applies separate traffic shapers to FTP and HTTP traffic. In addition to the interface bandwidth limit, HTTP traffic is subject to a security policy bandwidth limit of 200 Kb/s.

All egressing FTP traffic greater than 10 Kb/s is subject to a low priority queue (queue 3), while all egressing HTTP traffic greater than 100 Kb/s is subject to a medium priority queue (queue 2). That is, unless FTP traffic rates are lower than their guaranteed rate, and web traffic rates are greater than their guaranteed rate, FTP traffic is lower priority than web traffic.

Traffic less than these guaranteed bandwidth rates use the highest priority queue (queue 0).

Set the inbandwidth limits. This setting is only available in the CLI:

```
config system interface
  edit wan1
    set inbandwidth 500
  next
end
```

Create the traffic shapers or FTP and HTTP.

To configure the shapers - web-based manager

1 Go to *Firewall Objects* > *Traffic Shaper* > *Shared*, and select *Create New*.
2 Enter FTP for the name of the shaper.
3 Enter the *Guaranteed Bandwidth*, of 10 Kbps.
4 Enter Maximum Bandwidth of 500 Kbps.
5 Select the *Traffic Priority* of *Low*.
6 Select *OK*.
7 Select Create New.
8 Enter HTTP for the name of the shaper.
9 Enter the *Guaranteed Bandwidth*, of 100 Kbps.
10 Enter Maximum Bandwidth of 200 Kbps.

11 Select the *Traffic Priority* of *Medium*.

12 Select *OK*.

To configure the shapers - CLI

```
config firewall shaper traffic-shaper
  edit FTP
    set maximum-bandwidth 500
    set guaranteed-bandwidth 10
    set per-policy enable
    set priority low
    end
  next
  edit HTTP
    set maximum-bandwidth 200
    set guaranteed-bandwidth 100
    set per-policy enable
    set priority medium
end
```

QoS using priority from ToS or differentiated services

Configurations implementing QoS using the priority values defined in either global or specific ToS bit values are not capable of applying bandwidth limits and guarantees, but are capable of prioritizing traffic at per-packet levels, rather than uniformly to all services matched by the security policy.

In addition to configuring traffic prioritization, you may also choose to limit bandwidth being received by each interface. This can sometimes be useful in scenarios where you want to limit traffic levels, but do not want to configure traffic shaping within a security policy. This has the benefit of policing traffic at a point before the FortiGate unit performs most processing.

Note that if you implement QoS using ToS octet rather than security policies, the FortiGate unit applies QoS on a packet by packet basis, and priorities may be different for packets and services controlled by the same security policy. This is more granular control than prioritization by security policies, but has the drawbacks that quality of service is may not be uniform for multiple services controlled by the same security policy, packets will only use up to three of the six possible queues (queue 0 to queue 2), and bandwidth cannot be guaranteed. Other devices in your network must also be able to set or preserve ToS bits.

In this example, we limit the bandwidth accepted by each source interface, and then configure prioritized queuing on the destination interface based upon the value of the ToS bit located in the IP header of each accepted packet.

To limit bandwidth accepted by an interface, in the CLI, enter the following commands:

```
config system interface
  edit <name_str>
  set inbandwidth <rate_int>
  next
end
```

where `<rate_int>` is the bandwidth limit in Kb/s. Excess packets will be dropped.

To configure priorities, in the CLI, configure the global priority value using the following commands:

```
config system global
  set tos-based-priority {high | low | medium}
end
```

where `high` has a priority value of 0 and `low` is 2.

If you want to prioritize some ToS bit values differently than the global ToS-based priority, configure the priority for packets with that ToS bit value using the following commands:

```
config system tos-based-priority
  edit <id_int>
    set tos [0-15]
    set priority {high | low | medium}
  next
end
```

where and `tos` is the value of the ToS bit in the packet's IP header, and `high` has a priority value of 0 and `low` is 2. Priority values configured in this location will override the global ToS-based priority.

Sample configuration

This sample configuration limits ingressing bandwidth to 500 Kb/s. It also queues egressing traffic based upon the ToS bit in the IP header of ingressing packets.

Unless specified for the packet's ToS bit value, packets use the low priority queue (queue 2). For ToS bit values 4 and 15, the priorities are specified as medium (value 1) and high (value 0), respectively.

```
config system interface
  edit wan1
    set inbandwidth 500
  next
end
config system global
  set tos-based-priority low
end
config system tos-based-priority
  edit 4
    set tos 4
    set priority medium
  next
  edit 15
    set tos 15
    set priority high
  next
end
```

Example setup for VoIP

In this example, there are three traffic shaping requirements for a network:

- Voice over IP (VoIP) requires a guaranteed, high-priority for bandwidth for telephone communications.
- FTP bursts must be contained so as not to consume any available bandwidth. As such this traffic needs to be throttled to a smaller amount.
- A consistent bandwidth requirement is needed for all other email and web-based traffic.

To enable this requirement, you need to create three separate shapers and three security policies for each traffic type.

For this example, the actual values are not actual values, they are used for the simplicity of the example.

Creating the traffic shapers

First create the traffic shapers that define the maximum and guaranteed bandwidth. The shared shapers will be used, some with per-policy and some all policies as shown in the table, to better control traffic.

VoIP shaper

The VoIP functionary is a key component to the business as a communication tool and as such requires a guaranteed bandwidth.

To create a VoIP shaper - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaping* > *Shared*.
2. Enter the *Name* `voip`.
3. Select *Per Policy*.
4. Enter the *Maximum Bandwidth* of `1000` Kb/s
5. Enter the *Guaranteed Bandwidth* of `800` Kb/s.
6. Select a *Traffic Priority* of *High*.
7. Select *OK*.

To create a VoIP shaper - CLI

```
config firewall shaper traffic-shaper
  edit voip
    set maximum-bandwidth 1000
    set guaranteed-bandwidth 800
    set per-policy enable
    set priority high
end
```

This ensures that whatever number of policies use this shaper, the defined bandwidth will always be the same. At the same time, the bandwidth is continually guaranteed at 800 Kb/s but if available can be as much as 1000 Kb/s. Setting the priority to high ensures that the FortiGate unit always considers VoIP traffic as the most important.

FTP shaper

The FTP shaper sets the maximum bandwidth to use to avoid sudden spikes by sudden uploading or downloading of large files, and interfering with other more important traffic.

To create a FTP shaper - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaping* > *Shared*.
2. Enter the *Name* `ftp`.
3. Select *For all Policies Using This Shaper*.
4. Enter the *Maximum Bandwidth* of `200` Kb/s

5 Enter the *Guaranteed Bandwidth* of `200` Kb/s.

6 Select a *Traffic Priority* of *Low*.

7 Select *OK*.

To create a FTP shaper - CLI

```
config firewall shaper traffic-shaper
  edit ftp
    set maximum-bandwidth 200
    set guaranteed-bandwidth 200
    set priority low
end
```

For this shaper, the maximum and guaranteed bandwidth are set low and to the same value. In this case, the bandwidth is restricted to a specific amount. By also setting the traffic priority low ensures more important traffic will be able to pass before FTP traffic.

Regular traffic shaper

The regular shaper sets the maximum bandwidth and guaranteed bandwidth for everyday business traffic such as web and email traffic.

To create a regular shaper - web-based manager

1 Go to *Firewall Objects* > *Traffic Shaping* > *Shared*.

2 Enter the *Name* `daily_traffic`.

3 Select *Per Policy*.

4 Enter the *Maximum Bandwidth* of `600` Kb/s

5 Enter the *Guaranteed Bandwidth* of `600` Kb/s.

6 Select a *Traffic Priority* of *Medium*.

7 Select *OK*.

To create a regular shaper - CLI

```
config firewall shaper traffic-shaper
  edit daily_traffic
    set maximum-bandwidth 600
    set guaranteed-bandwidth 600
    set per-policy enable
    set priority medium
end
```

For this shaper, the maximum and guaranteed bandwidth are set to a moderate value of 600 Kb/s. It is also set for per policy, which ensures each security policy for day-to-day business traffic has the same distribution of bandwidth.

Creating security policies

To employ the shaper, create security policies that use the shapers within the policies. Create a separate policy for each service and enable traffic shaping. For example, a policy for FTP traffic, a policy for SIP and so on.

For the following steps the VoIP traffic shaper is enabled as well as the reverse direction option. This ensures that return traffic for a VoIP call has the same guaranteed bandwidth as the outgoing call.

To enable traffic shaping in the security policy - web-based manager

1 Go to *Policy* > *Policy* > *Policy* and select *Create New*.

2 Enter the following and select:

Source interface/Zone	Internal
Source address	All
Destination interface/Zone	WAN1
Destination address	All
Schedule	always
Service	SIP
Action	ACCEPT

3 Select *Traffic Shaping*.

4 From the drop-down list, select the voip shaper created in the previous steps.

5 Select *Reverse Direction Traffic Shaping*.

6 Select *OK*.

To enable traffic shaping in the security policy - CLI

```
config firewall policy
  edit 6
    set srcintf internal
    set scraddr all
    set dstintf wan1
    set dstaddr all
    set action accept
    set schedule always
    set service sip
    set traffic-shaper voip
    set reverse-traffic-shaper voip
end
```

Troubleshooting

This chapter outlines some troubleshooting tips and steps to diagnose the shapers and whether they are working correctly. These diagnose commands include:

- `diagnose system tos-based-priority`
- `diagnose firewall shaper traffic-shaper`
- `diagnose firewall per-ip-shaper`
- `diagnose debug flow`

Interface diagnosis

To optimize traffic shaping performance, first ensure that the network interface's Ethernet statistics are clean of errors, collisions, or buffer overruns.To check the interface, enter the following diagnose command to see the traffic statistics:

```
diagnose hardware deviceinfo nic <port_name>
```

Shaper diagnose commands

There are specific diagnose commands you can use to verify the configuration and flow of traffic, including packet loss due to the employed shaper.

All of these diagnose troubleshooting commands are supported in both IPv4 and IPv6.

TOS command

Use the following command to list command to view information of the TOS lists and traffic.

```
diagnose system tos-based-priority
```

This example displays the priority value currently correlated with each possible TOS bit value. Priority values are displayed in order of their corresponding TOS bit values, which can range between 0 and 15, from lowest TOS bit value to highest.

For example, if you have not configured TOS-based priorities, the following appears...

```
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
```

...reflecting that all packets are currently using the same default priority, high (value 0).

If you have configured a TOS-based priority of `low` (value 2) for packets with a ToS bit value of 3, the following appears...

```
0 0 0 2 0 0 0 0 0 0 0 0 0 0 0 0
```

...reflecting that most packets are using the default priority value, except those with a ToS bit value of 3.

Shared shaper

To view information for the shared traffic shaper for security policies enter the command

```
diagnose firewall shaper traffic-shaper list
```

The resultant output displays the information on all available shapers. The more shapers available the longer the list. For example:

```
name Throughput
maximum-bandwidth 1200000 Kb/sec
guaranteed-bandwidth 50000 Kb/sec
current-bandwidth 0 B/sec
priority 1
packets dropped 0
```

Additional commands include:

`diagnose firewall shaper traffic-shaper state` - provides the total number of traffic shapers on the FortiGate unit.

`diagnose firewall shaper traffic-shaper stats` - provides summary statistics on the shapers. Sample output looks like the following:

```
shapers 9 ipv4 0 ipv6 0 drops 0
```

Per-IP shaper

To view information for the per-IP shaper for security policies enter the command

```
diagnose firewall shaper per-ip-shaper list
```

The resultant output displays the information on all available per-IP shapers. The more shapers available the longer the list. For example:

```
name accounting_group
maximum-bandwidth 200000 Kb/sec
maximum-concurrent-session 55
packet dropped 0
```

Additional commands include:

`diagnose firewall shaper per-ip-shaper state` - provides the total number of per-ip shapers on the FortiGate unit.

`diagnose firewall shaper per-ip-shaper stats` - provides summary statistics on the shapers. Sample output looks like the following:

```
memory allocated 3 packet dropped: 0
```

You can also clear the per-ip statistical data to begin a fresh diagnoses using:

```
diagnose firewall shaper per-ip-shaper clear
```

Packet loss with statistics on shapers

For each shaper there are counters that allow to verify if packets have been discarded. To view this information, in the CLI, enter the command diagnose firewall shaper.

The results will look similar to the following output:

```
diagnose firewall shaper traffic-shaper list

name limit_GB_25_MB_50_LQ
maximum-bandwidth 50 Kb/sec
guaranteed-bandwidth 25 Kb/sec
current-bandwidth 51 Kb/sec
priority 3
dropped 1291985
```

The diagnose command output is different if the shapers are configured either per-policy or shared between policies.

For per-IP the output would be:

```
diagnose firewall shaper per-ip-shaper list

name accounting_group
maximum-bandwidth 200000 Kb/sec
maximum-concurrent-session 55
packet dropped 3264220
```

Packet lost with the debug flow

When using the debug flow diagnostic command, there is a specific message information that a packet has exceed the shaper limits and therefor discarded:

```
diagnose debug flow show console enable
diagnose debug flow filter addr 10.143.0.5
diagnose debug flow trace start 1000

id=20085 trace_id=11 msg="vd-root received a packet(proto=17,
10.141.0.11:3735->10.143.0.5:5001) from port5."
id=20085 trace_id=11 msg="Find an existing session, id-0000eabc,
original direction"
id=20085 trace_id=11 msg="exceeded shaper limit, drop"
```

Session list details with dual traffic shaper

When a Security Policy has a different traffic shaper for each direction, it is reflected in the session list output from the CLI:

```
diagnose system session list

session info: proto=6 proto_state=02 expire=115 timeout=3600
flags=00000000 sock
flag=00000000 sockport=0 av_idx=0 use=4

```

Additional Information

- Packets discarded by the shaper impact flow-control mechanisms like TCP. For more accurate testing results prefer UDP protocol.
- Traffic shaping accuracy is optimum for security policies without a protection profile where no FortiGate content inspection is processed.
- Do not oversubscribe an outbandwith throughput. For example, sum[guaranteed BW] < outbandwith. For accuracy in bandwidth calculation, it is required to set the “outbandwidth” parameter on the interfaces. For more information see “Bandwidth guarantee, limit, and priority interactions” on page 2253.
- The FortiGate unit is not prioritizing traffic based on the DSCP marking configured in the security policy. However, TOS based prioritizing can be made at ingress. For more information see “Differentiated Services” on page 2269.

Chapter 14 FortiOS Carrier

This FortiOS Handbook chapter contains the following sections:

Overview of FortiOS Carrier features provides an overview of the three major topics for FortiOS Carrier — Dynamic Profiles, MMS, and GTP.

Carrier web-based manager settings describes the web-based manager interface of FortiOS Carrier specific features.

MMS UTM features describes FortiOS UTM features as they apply to MMS including MMS virus scanning, MMS file filtering, MMS content-based Antispam protection, and MMS DLP archiving.

Message flood protection describes setting thresholds to protect your MMS servers from receiving too many messages from the same sender.

Duplicate message protection describes setting thresholds to protect your MMS servers from receiving the same message from more than one sender.

MMS Replacement messages describes customizing MMS replacement messages.

Configuring GTP on FortiOS Carrier explains configuration of the more basic FortiOS Carrier GTP features.

GTP message type filtering explains this feature, and how to configure it on FortiOS Carrier.

GTP identity filtering explains this feature, and how to configure it on FortiOS Carrier.

Troubleshooting provides answer to common FortiOS Carrier GTP issues.

Overview of FortiOS Carrier features

FortiOS Carrier specific features include Multimedia messaging service (MMS) protection, and GPRS Tunneling Protocol (GTP) protection.

This section includes:

Overview

FortiOS Carrier provides all the features found on FortiGate units plus added features specific to carrier networks. These features include:

MMS

MMS is a standard for sending messages that include multimedia content between mobile phones. MMS is also popular as a method of delivering news and entertainment content including videos, pictures, and text. Carrier networks include four different MMS types of messages — MM1, MM3, MM4, and MM7. See "MMS background" on page 2292.

GTP

The GPRS Tunneling Protocol (GTP) runs on GPRS carrier networks. GPRS is a GSM packet radio standard. It provides more efficient usage of the radio interface so that mobile devices can share the same radio channel. FortiOS supports GTPv1 release 7.15.0 and GTPv1 release 8.12.0.

GPRS provides direct connections to the Internet (TCP/IP) and X.25 networks for point-to-point services (connection-less/connection oriented) and point-to-multipoint services (broadcast).

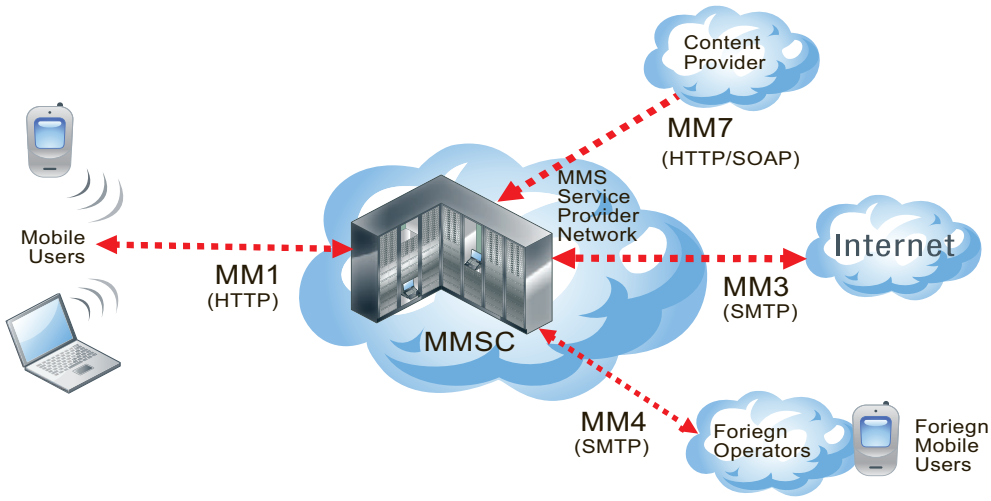
GPRS currently supports data rates from 9.6 kbps to more than 100 kbps, and it is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based) that converts the message from radio to wired, and sends the message to the carrier network and eventually the Internet (wired carrier network). See "GTP basic concepts" on page 2305.

MMS background

MMS is a common method for mobile users to send and receive multimedia content. A Carrier network supports MMS across its network. This makes up the MMS Service Provider Network (MSPN).

Messages can be sent or received between the MMSC and a number of other services including the Internet, content providers, or other carriers. Each of these different service connections uses different MMS formats including MM1 and MM7 MMS messages (essentially HTTP format), and MM3 and MM4 messages (SMTP formatted). These different formats reflect the different purposes and content for each type of MMS message.

Figure 232: MMS content interfaces



MMS content interfaces

MMS messages are sent from devices and servers to other devices and servers using MMS content interfaces

There are eight interfaces defined for the MMS standard, referred to as MM1 through MM8. The most important of these interfaces for the transfer of data is the MM1 interface, as this defines how mobile users communicate from the mobile network to the Multimedia Message Service Center (MMSC). MMS content to be monitored and controlled comes from these mobile users and is going to the provider network.

Other MMS content interfaces that connect a service provider network to other external sources can pose threats as well. MM3 handles communication between the Internet and the MMSC and is a possible source of viruses and other content problems from the Internet. MM4 handles communication between different content provider MMSCs. Filtering MM4 content protects the service provider network from content sent from foreign service providers and their subscribers. Finally MM7 is used for communication between content providers and the MMSC. Filtering MM3 content can also keep harmful content off of the service provider network.

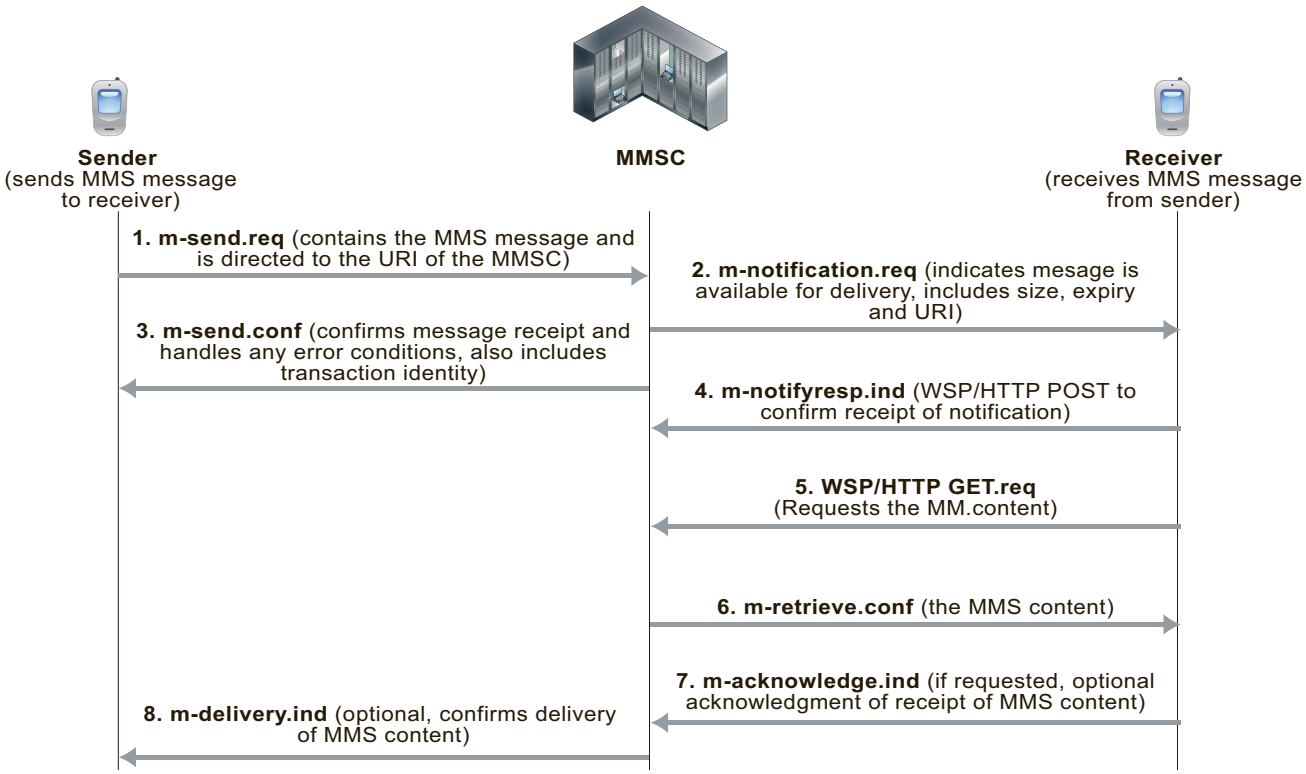
Table 122: MMS content interfaces that

Type	Transaction	Similar to
MM 1	Handset to MMSC	HTTP
MM 3	Between MMSC and Internet	SMTP
MM 4	Between Operator MMSCs	SMTP
MM 7	Content Providers to MMSC	HTTP and SOAP

How MMS content interfaces are applied

As shown in Figure 233, the sender's mobile device encodes the MMS content in a form similar to MIME email message (MMS MIME content formats are defined by the MMS Message Encapsulation specification). The encoded message is then forwarded to the service provider's MMSC. Communication between the sending device and the MMSC uses the MM1 content interface. The MM1 content interface establishes a connection and sends an MM1 send request (`m-send.req`) message that contains the MMS message. The MMSC processes this request and sends back an MM1 send confirmation (`m-send.conf`) HTTP response indicating the status of the message — accepted or an error occurred, for example.

Figure 233: MM1 transactions between senders and receivers and the MMSC

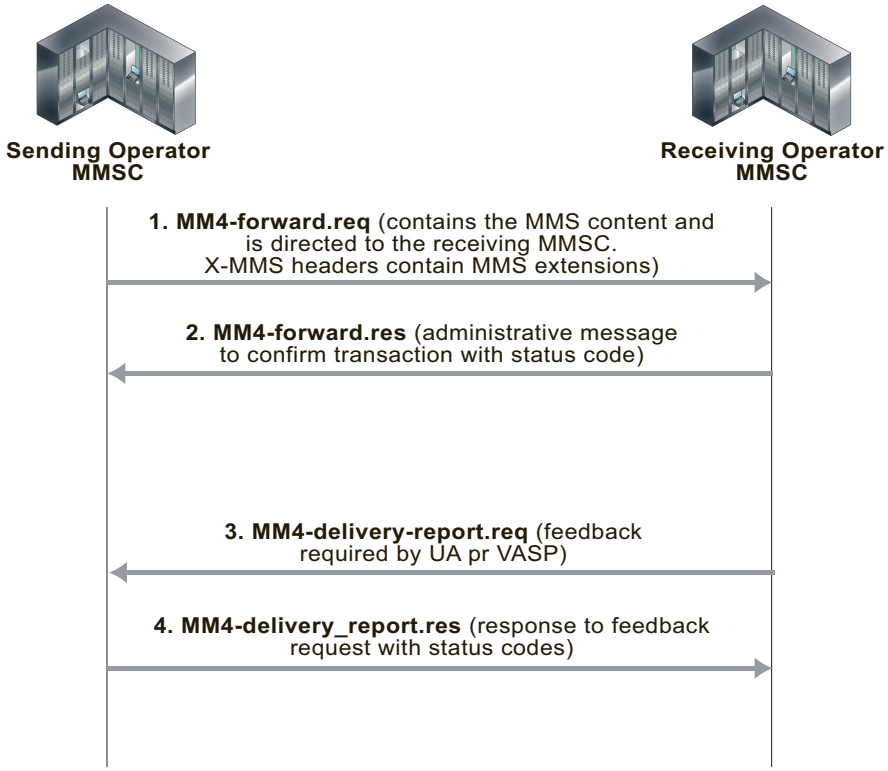


If the recipient is on another carrier, the MMSC forwards the message to the recipient's carrier. This forwarding uses the MM4 content interface for forwarding content between operator MMSCs (see Figure 234).

Before the MMSC can forward the message to the final recipient, it must first determine if the receiver's handset can receive MMS messages using the MM1 content interface. If the recipient can use the MM1 content interface, the content is extracted and sent to a temporary storage server with an HTTP front-end.

To retrieve the message, the receiver's handset establishes a connection with the MMSC. An HTTP get request is then sent from the recipient to the MMSC. This message contains the URL where the content of the message is stored. The MMSC responds with a retrieve confirmation (`m-retrieve.conf`) HTTP response that contains the message.

Figure 234: MM4 messages sent between operator MMSCs



This causes the receiver's handset to retrieve the content from the embedded URL. Several messages are exchanged to indicate status of the delivery attempt. Before delivering content, some MMSCs also include a content adaptation service that attempts to modify the multimedia content into a format suitable for the recipient's handset.

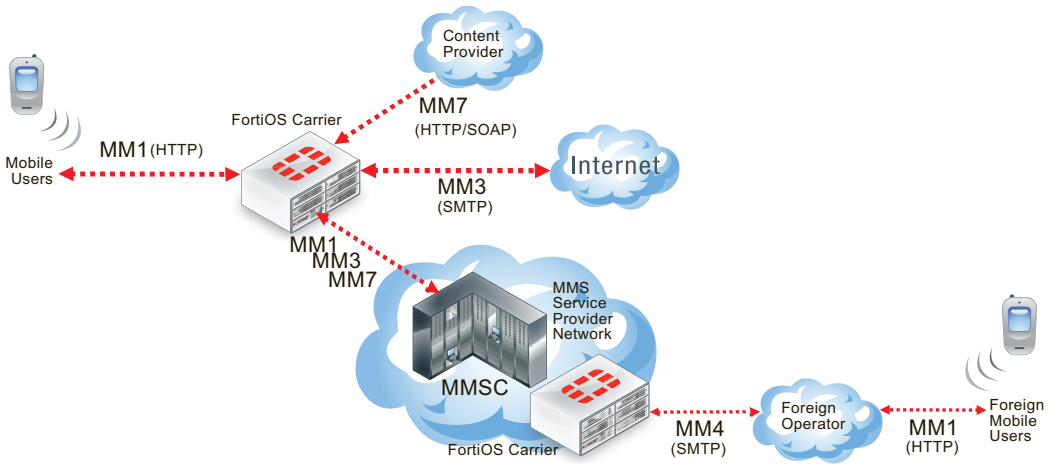
If the receiver's handset is not MM1 capable, the message can be delivered to a web based service and the receiver can view the content from a normal Internet browser. The URL for the content can be sent to the receiver in an SMS text message. Using this method, non-MM1 capable recipients can still receive MMS content.

Email and web-based gateways from MMSC to the Internet use the MM3 content interface. On the receiving side, the content servers can typically receive service requests both from WAP and normal HTTP browsers, so delivery via the web is simple. For sending from external sources to handsets, most carriers allow MIME encoded message to be sent to the receiver's phone number with a special domain.

How FortiOS Carrier processes MMS messages

MMS messages can be vectors for propagating undesirable content such as spam and viruses. FortiOS Carrier can scan MMS messages sent using the MM1, MM3, MM4, and MM7 content interfaces. You can configure FortiOS Carrier to scan MMS messages for spam and viruses by configuring and adding MMS protection profiles and adding the MMS protection profiles to security policies. You can also use MMS protection profiles to apply content blocking, carrier end point filtering, MMS address translation, sending MMS notifications, DLP archiving of MMS messages, and logging of MMS message activity.

Figure 235: FortiOS Carrier MMS processing



FortiOS Carrier can send MMS messages to senders informing those senders that their devices are infected. FortiOS Carrier can also send MMS notifications to administrators to inform them of suspicious activity on their networks.

For message floods and duplicate messages, FortiOS Carrier does not send notifications to message senders but does send notifications to administrators and sends messages to sender handsets to complete MM1 and MM4 sessions.

Where MMS messaging uses the TCP/IP set of protocols, SMS text messaging uses the Signaling System Number 7 (SS7) set of protocols, which is not supported by FortiOS.

FortiOS Carrier and MMS content scanning

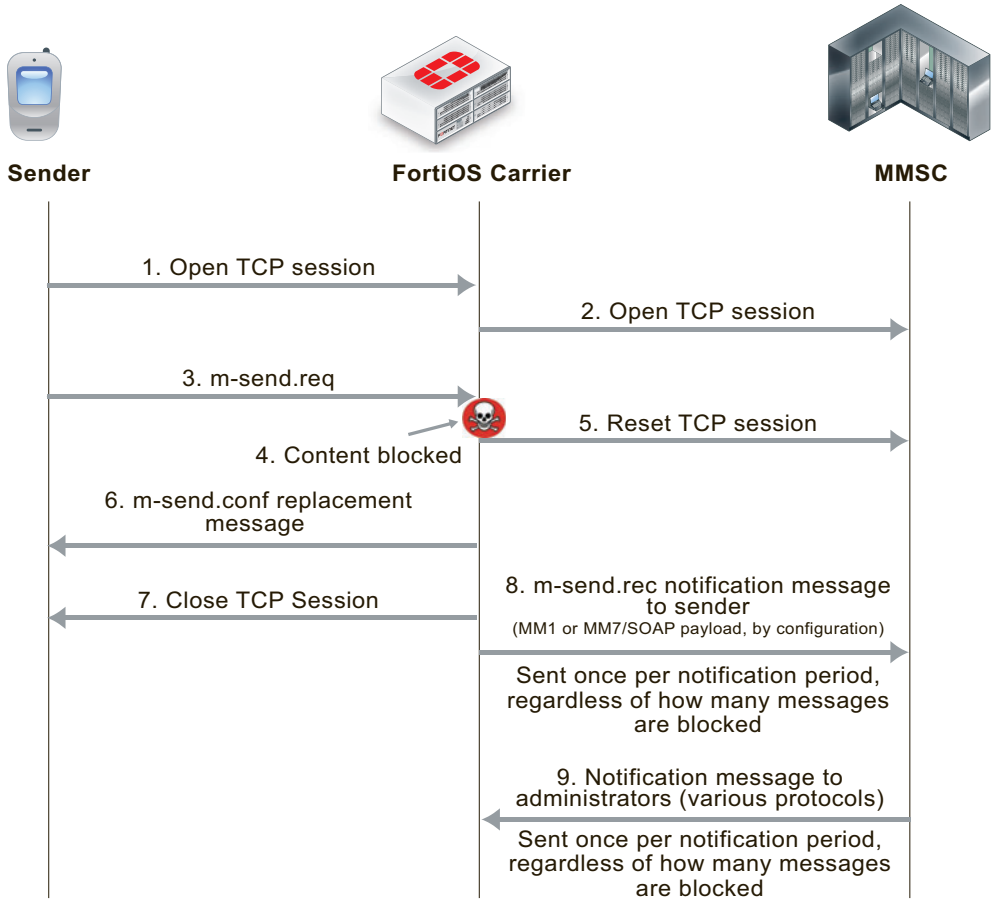
The following applies to MMS content scanning, including virus scanning, file filtering, content spam filtering, carrier end point filtering, and MMS content checksum filtering MMS.

MM1 Content Scanning

During MM1 content scanning a message is first transmitted from the sender, establishing a connection with the MMSC. FortiOS Carrier intercepts this connection and acts as the endpoint. FortiOS Carrier then establishes its own connection to the MMSC. Once connected, the client transmits its `m-send.req` HTTP post request to FortiOS Carrier which scans it according to the MMS protection profile settings. If the content is clean, the message is forwarded to the MMSC. The MMSC returns `m-send.conf` HTTP response through FortiOS Carrier to the sender.

If FortiOS Carrier blocks the message (for example because a virus was found (see Figure 236), FortiOS Carrier resets the connection to the MMSC and sends `m-send.conf` HTTP response back to the sender. The response message can be customized using replacement messages. Replacement messages are available for the different kinds of MMS scanning that the FortiOS Carrier unit can perform. FortiOS Carrier then terminates the connection. Sending back an `m-send.conf` message prevents the sender from trying to send the message again.

Figure 236: MM1 MMS scanning of message sent by sender (blocking m.send.req messages)



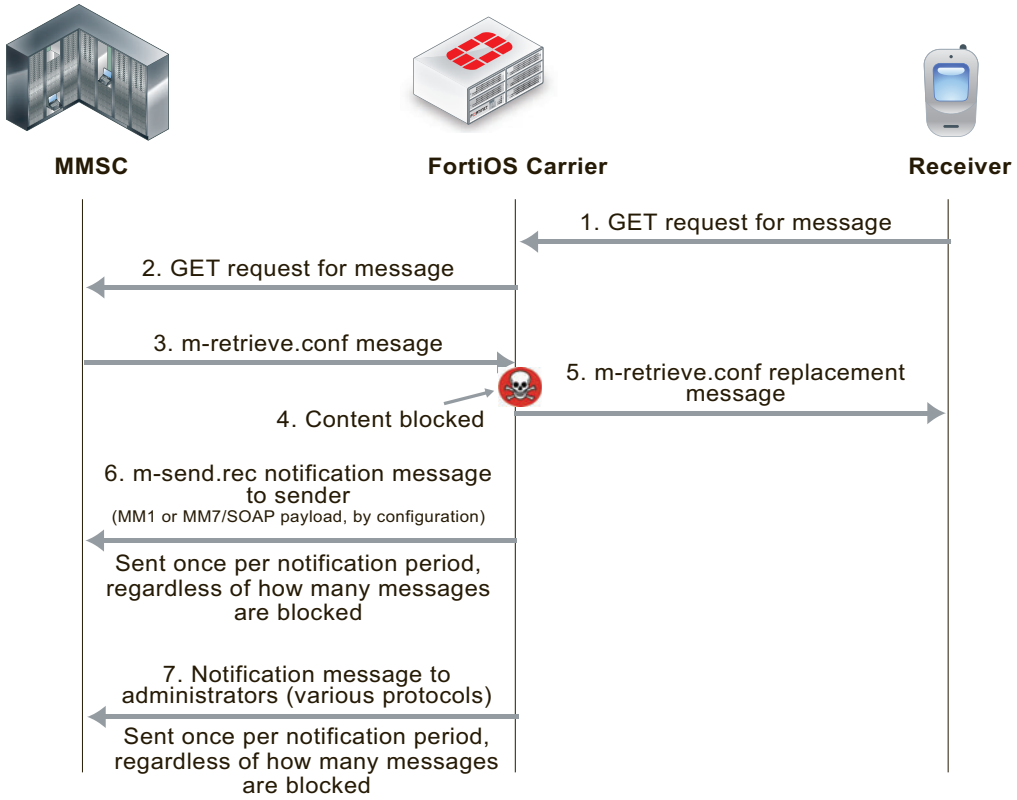
FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the sender to notify them of blocked messages.

Filtering message retrieval

Filtering message retrieval works in a similar way (see Figure 237). FortiOS Carrier intercepts the connection to the MMSC, and the m-retrieve.conf HTTP response from the MMSC is scanned according to the MMS content scanning settings. If the content is clean, the response is forwarded back to the client. If the content is blocked, FortiOS Carrier drops the connection to the MMSC. It then builds an m-retrieve.conf message from the associated replacement message and transmits this back to the client.

FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the receiver to notify them of blocked messages.

Figure 237: MM1 MMS scanning of messages received by receiver (blocking m.retrieve.conf messages)



Filtering MM3 and MM4 messages works in an similar way (see Figure 238 and Figure 239). FortiOS Carrier intercepts connections to the MMSC, and scans messages as configured. When messages are blocked, FortiOS Carrier closes sessions as required, sends confirmation messages to the sender, notifies administrators, and notifies senders and receivers of messages.

Figure 238: MM3 MMS scanning of messages sent from a sender on the Internet to an MMSC

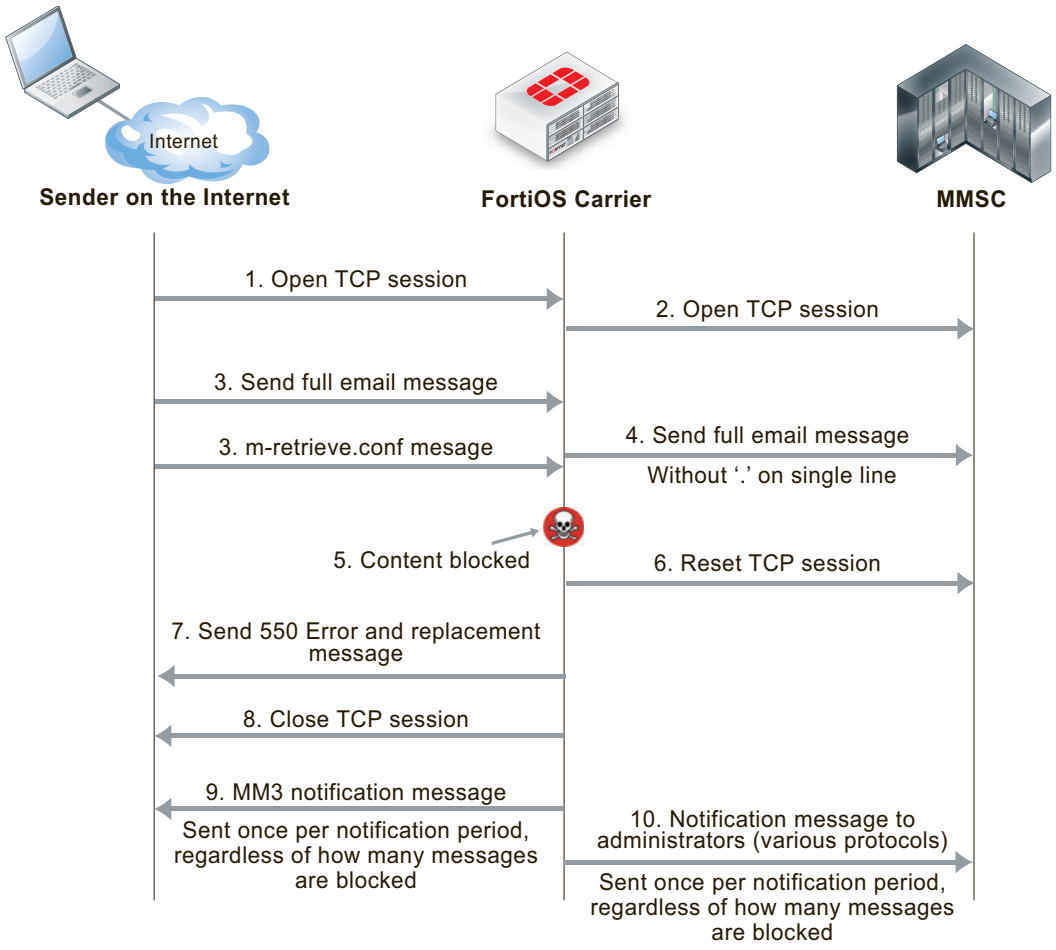


Figure 239: MM4 MMS scanning of messages sent between operator MMSCs

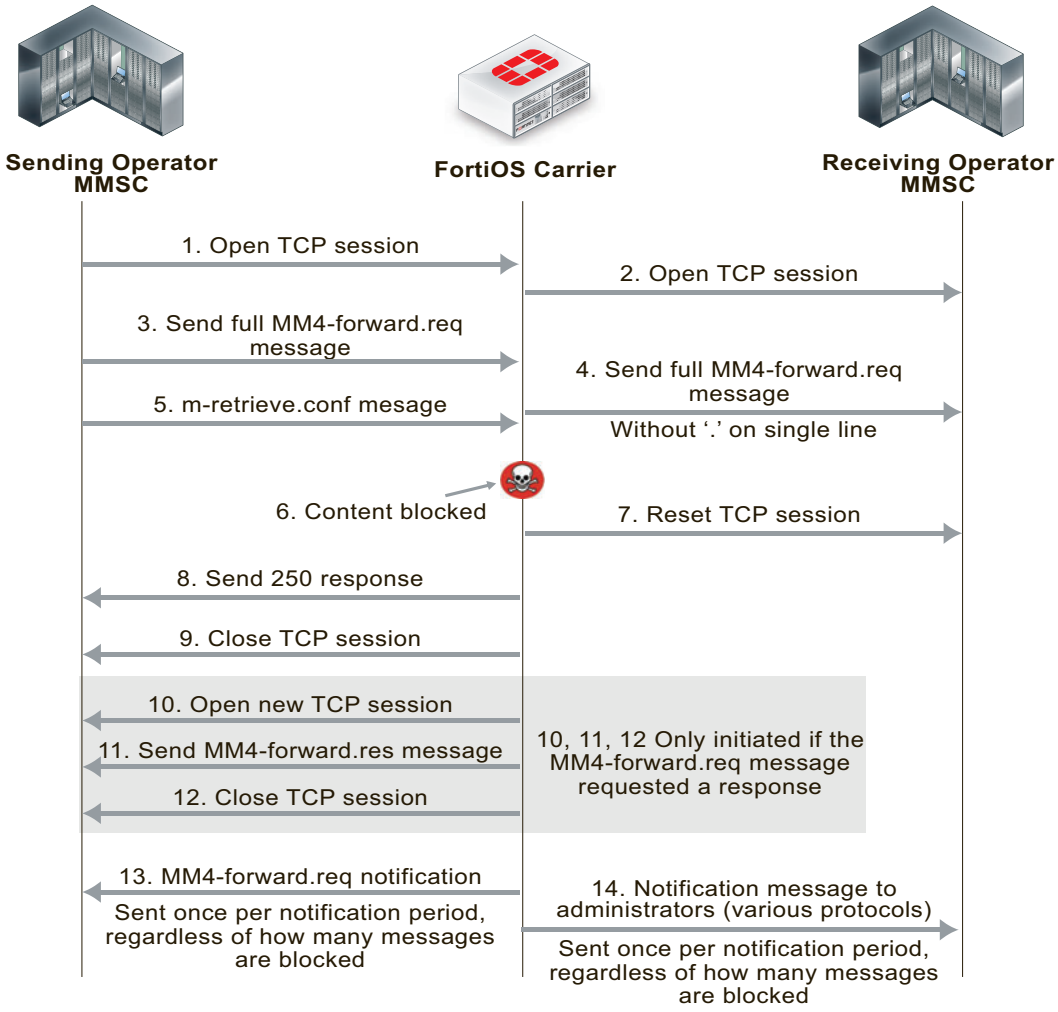

Figure 240: MM7 MMS scanning of messages sent between a VASP and an MMSC

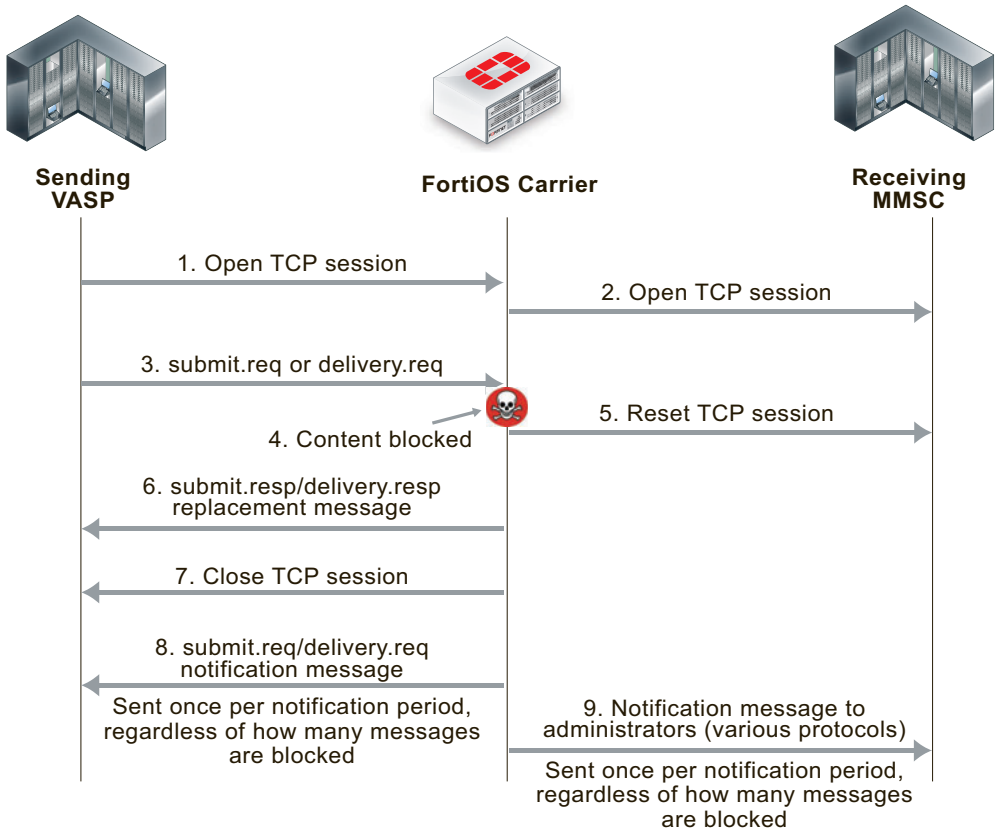

FortiOS Carrier and MMS duplicate messages and message floods

FortiOS Carrier detects duplicate messages and message floods for the MM1 and MM4 interfaces. How FortiOS Carrier detects and responds to duplicate messages and message floods is different from how FortiOS Carrier detects and responds to viruses and other MMS scanning protection measures.

For message floods and duplicate messages, if the sender is an attacker they can gain useful information about message flood and duplicate message thresholds if they receive notifications about floods or duplicate messages. Plus, duplicate messages and message floods are usually a result of a large amount of messaging activity and filtering of these messages is designed to reduce the amount of unwanted messaging traffic. Adding to the traffic by sending notifications to senders and receivers could result in an increase in message traffic.

You can create up to three thresholds for detecting duplicate messages and message floods. For each threshold you can configure the FortiOS Carrier unit to respond by logging the activity, archiving or quarantining the messages, notifying administrators of the activity, and by blocking the messages. In many cases you may only want to configure blocking for higher activity thresholds, and to just monitor and send administrator notifications at lower activity thresholds.

When a block threshold is reached for MM1 messages, FortiOS Carrier sends m-send.conf or m-retrieve.conf messages to the originator of the activity. These messages are sent to end the MM1 sessions, otherwise the originator would continue to re-send the blocked message. When a block threshold is reached for MM4, FortiOS Carrier sends a `MM4-forward.res` message to close the MM4 session. An MM4 message is sent only if initiated by the originating `MM4-forward.req` message.

Figure 241: MM1 message flood and duplicate message blocking of sent messages

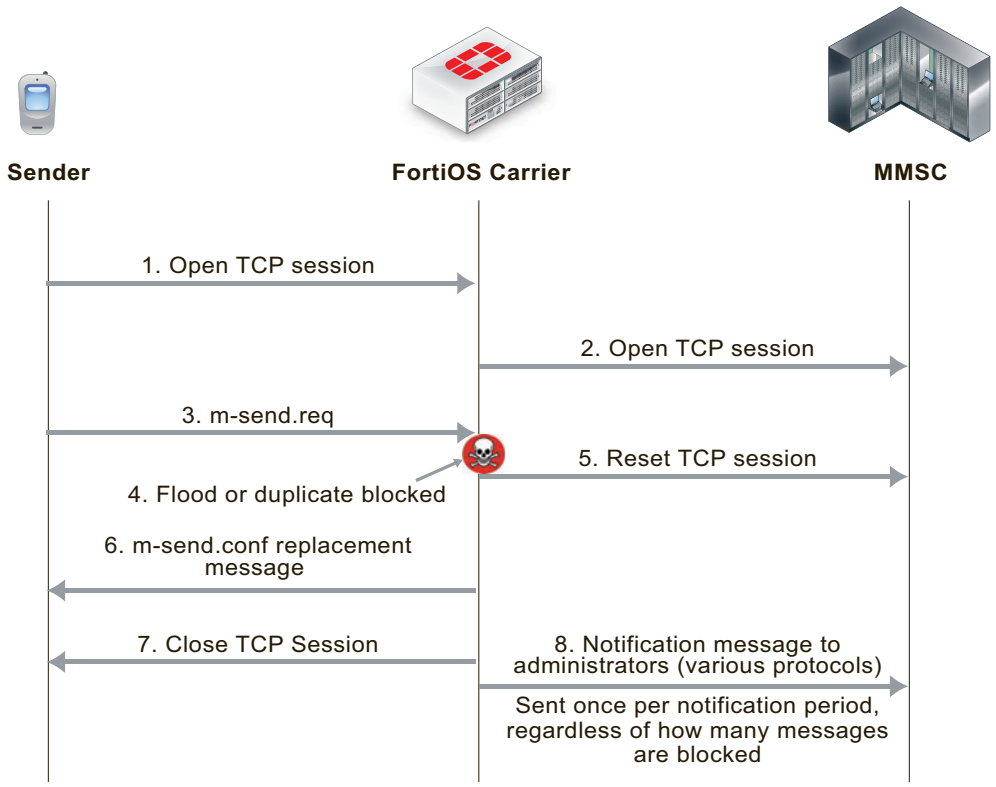

Figure 242: MM1 message flood and duplicate message blocking of received messages

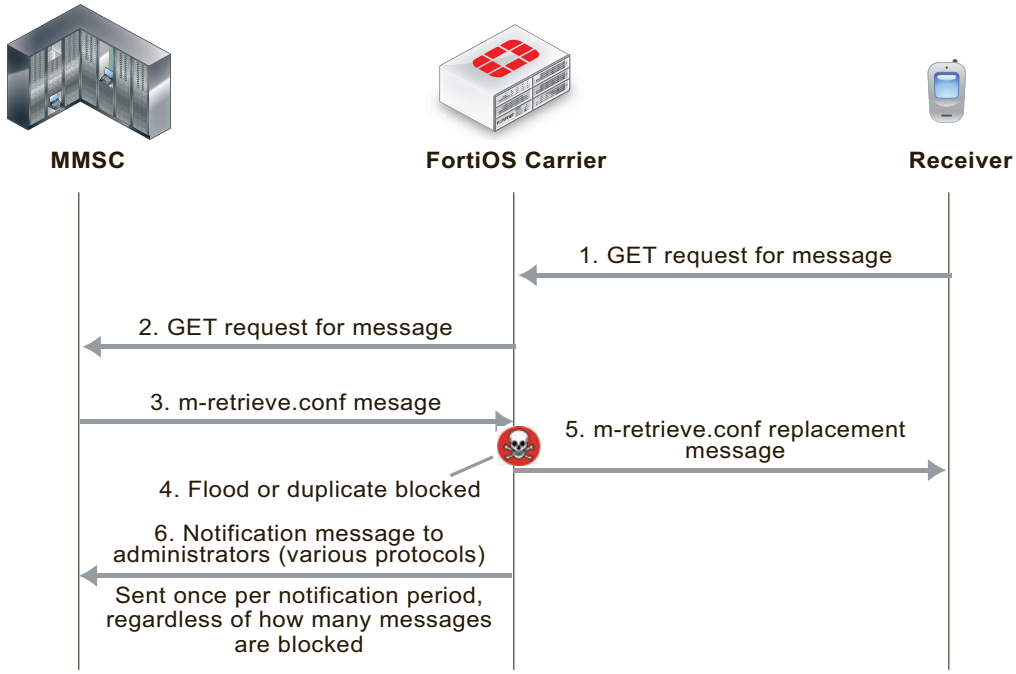

Figure 243: MM4 message flood and duplicate message blocking

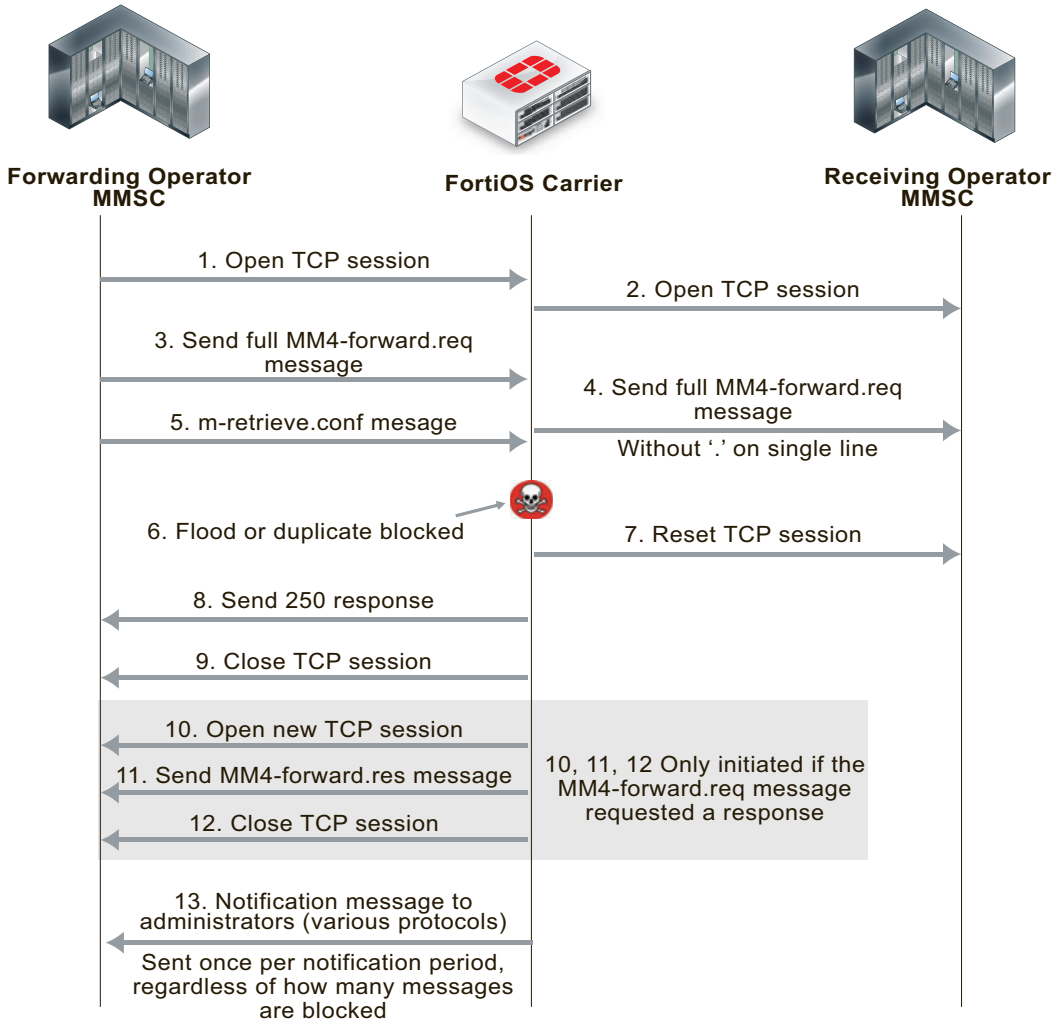

MMS protection profiles

An MMS protection profile is a group of settings that you can apply to an MMS session matched by a security policy.

MMS protection profiles are easy to configure and can be used by more than one security policy. You can configure a single MMS protection profile for the different traffic types handled by a set of security policies that require identical protection levels and types. This eliminates the need to repeatedly configure those same MMS protection profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need only moderate protection. You would configure two separate MMS protection profiles to provide the different levels of protection: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS Protection Profile, you need to add it to a security policy to apply the profile to MMS traffic.

See "MMS UTM features" on page 2353.

Bypassing MMS protection profile filtering based on user's carrier end points

You can use carrier end point filtering to exempt MMS sessions from MMS protection profile filtering. Carrier end point filtering matches carrier end points in MMS sessions with carrier end point patterns. If you add a carrier end point pattern to a filter list and set the action to exempt from all scanning, all messages from matching carrier end points bypass MMS protection profile filtering. See "Bypassing message flood protection based on user's carrier end points" on page 2380.

Applying MMS protection profiles to MMS traffic

To apply an MMS protection profile you must first create the MMS protection profile and then add the MMS protection profile to a security policy by enabling the UTM option. The MMS protection profile then applies to the traffic accepted by that security policy.

MMS protection profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS protection profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS protection profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS protection profile.

To add an MMS protection profile to a security policy

1. Go to *UTM Profiles* > *Carrier* > *MMS Profile*.
2. Select *Create New* to add an MMS protection profile.
3. Configure and save the new MMS protection profile.
4. Go to *Policy*.
5. Select *Create New* to add a security policy, or select an existing policy and *Edit* to add the MMS profile.
6. Configure the security policy as required.
7. Enable *UTM*.
8. Select *Enable MMS Profile*, and select the MMS profile to add to the security policy.
9. Select *OK*.

GTP basic concepts

GPRS currently supports data rates from 9.6kbps to more than 100 kbps, and is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based), and the base station unit sends the message to the carrier network and eventually the Internet (wired carrier network).

The network system then either sends the message back to a base station and to the destination mobile unit, or forwards the message to the proper carrier's network where it gets routed to the mobile unit.

This sections includes:

- PDP Context
- GPRS security

PDP Context

The packet data protocol (PDP) context is a connection between a mobile station and the end address that goes through the SGSN and GGSN. It includes identifying information about the mobile customer used by each server or device to properly forward the call data to the next hop in the carrier network, typically using a GTP tunnel between the SGSN and GGSN.

When a mobile customer has an active voice or data connection open, both the SGSN and GGSN have the PDP context information for that customer and session.

When a mobile phone wants to communicate with an address on an external packet network, either an IP or X.25 address, the mobile station that phone is connected to opens a PDP context through the SGSN and GGSN to the end address. Before any traffic is sent, the PDP context must first be activated.

The information included in the PDP context includes the customer's IP address, the IMSI number of the mobile handset, and the tunnel endpoint ID for both the SGSN and GGSN. The ID is a unique number, much like a session ID on a TCP/IP firewall. All this information ensures a uniquely identifiable connection is made.

Since one mobile device may have multiple connections open at one time, such as data connections to different Internet services and voice connections to different locations, there may be more than one PDP context with the same IP address making the extra identifying information required.

The end point that the mobile phone is connecting to only knows about the GGSN — the rest of the GPRS connection is masked by the GGSN.

Along the PDP context path, communication is accomplished in using three different protocols.

- The connection between the Mobile Station and SGSN uses the SM protocol.
- Between SGSN and GGSN GTP is used.
- Between GGSN and the end point either IP or X.25 is used.

FortiOS Carrier is concerned with the SGSN to GGSN part of the PDP context — the part that uses GTP.

For more about PDP context, see "Tunnel Management Messages" on page 2409.

Creating a PDP context

While FortiOS Carrier is concerned mostly with the SGSN to GGSN part of the PDP Context, knowing the steps involved in creating a PDP context helps understand the role each device, protocol, and message type plays.

Both mobile stations and GGSNs can create PDP contexts.

A Mobile Station creates a PDP context

1. The Mobile Station (MS) sends a `PDP activation request` message to the SGSN including the MS PDP address, and APN.
2. Optionally, security functions may be performed to authenticate the MS.
3. The SGSN determines the GGSN address by using the APN identifier.
4. The SGSN creates a downlink GTP tunnel to send IP packets between the GGSN and SGSN.
5. The GGSN creates an entry in its PDP context table to deliver IP packets between the SGSN and the external packet switching network.
6. The GGSN creates an uplink GTP tunnel to route IP-PDU from SGSN to GGSN.

7 The GGSN then sends back to the SGSN the result of the PDP context creation and if necessary the MS PDP address.

8 The SGSN sends an `Activate PDP context accept` message to the MS by returning negotiated the PDP context information and if necessary the MS PDP address.

9 Now traffic can pass from the MS to the external network end point.

A GGSN creates a PDP context

1 The network receives an IP packet from an external network.

2 The GGSN checks if the PDP Context has already been created.

3 If not, the GGSN sends a `PDU notification request` to the SGSN in order to initiate a PDP context activation.

4 The GGSN retrieves the IP address of the appropriate SGSN address by interrogating the HLR from the IMSI identifier of the MS.

5 The SGSN sends to the MS a request to activate the indicated PDP context.

6 The PDP context activation procedure follows the one initiated by the MS. See "A Mobile Station creates a PDP context" on page 2306.

7 When the PDP context is activated, the IP packet can be sent from the GGSN to the MS.

Terminating a PDP context

A PDP context remains open until it is terminated. To terminate the PDP context an MS sends a `Deactivate PDP context` message to the SGSN, which then sends a `Delete PDP Context` message to the GGSN. When the SGSN receives a PDP context deletion acknowledgment from the GGSN, the SGSN confirms to the MS the PDP context deactivation. The PDP can be terminated by the SGSN or GGSN as well with a slight variation of the order of the messages passed.

When the PDP Context is terminated, the tunnel it was using is deleted as well. If this is not completed in a timely manner, it is possible for someone else to start using the tunnel before it is deleted. This hijacking will result in the original customer being overbilled for the extra usage. Anti-overbilling helps prevent this. See "Configuring Anti-overbilling in FortiOS Carrier" on page 2405.

GPRS security

The GPRS network has some built-in security in the form of GPRS authentication. However this is minimal, and is not sufficient for carrier network security needs. A GTP firewall, such as FortiOS Carrier, is required to secure the Gi, Gn, and Gp interfaces.

GPRS authentication

GPRS authentication is handled by the SGSN to prevent unauthorized GPRS calls from reaching the GSM network beyond the SGSN (the base station system, and mobile station). Authentication is accomplished using some of the customer's information with a random number and uses two algorithms to create ciphers that then allow authentication for that customer.

User identity confidentiality ensures that customer information stays between the mobile station and the SGSN — no identifying information goes past the SGSN. Past that point other numbers are used to identify the customer and their connection on the network.

Periodically the SGSN may request identity information from the mobile station to compare to what is on record. This specifically looks at the IMEI number.

Call confidentiality is achieved through the use of a cipher, similar to the GPRS authentication described earlier. The cipher is applied between the mobile station and the SGSN. Essentially a cipher mask is XORd with each outgoing frame, and the receiving side XORs with its own cipher to result in the original frame and data.

Parts of a GTPv1 network

A sample GTP network consists of the end handset sender, the sender's mobile station, the carrier's network including the SGSN and GGSN, the receiver's mobile station, and the receiver handset.

When a handset moves from one mobile station and SGSN to another, the handset's connection to the Internet is preserved because the tunnel the handset has to the Internet using GTP tracks the user's location and information. For example, the handset could move from one cell to another, or between countries.

The parts of a GPRS network can be separated into the following groups according to the roles of the devices:

- Radio access to the GPRS network is accomplished by mobile phones and mobile stations (MS). See "Radio access" on page 2309.
- Transport the GPRS packets across the GPRS network is accomplished by SGSNs and GGSNs, both local and remote, by delivering packets to the external services. See "Transport" on page 2309.
- Billing and records are handled by CDF, CFR, HLR, and VLR devices. See "Billing and records" on page 2310.

GPRS networks also rely on access points and PDP contexts as central parts of the communication structure. These are not actual devices, but they are still critical .

For more information on APN, see "Access Point Number (APN)" on page 2418. For more information on PDP Context, see "PDP Context" on page 2306.

These devices, their roles, neighboring devices, the interfaces and protocols they use are outlined in the following table. These devices and their connections can be viewed in the "Packet flow through the GPRS network" on page 2312.

Figure 244: Carrier network showing the interfaces used (GTPv1)

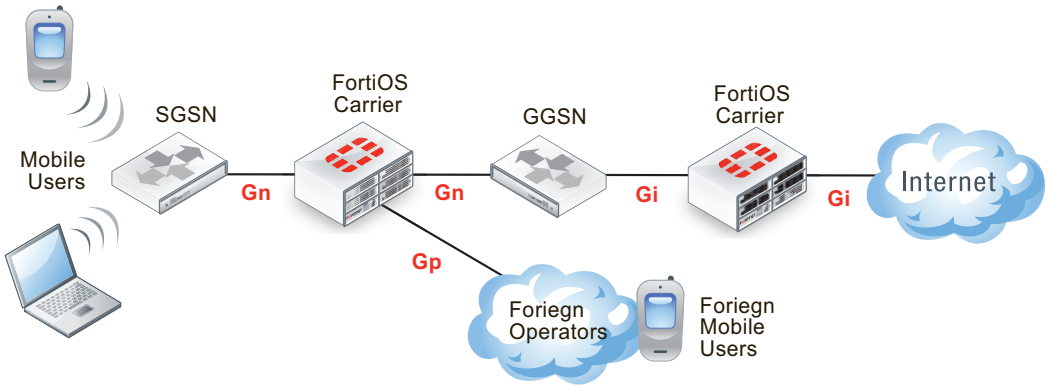

Table 123: Devices on a GTPv1 network

Device role	Neighboring Devices	Interfaces used	Protocols used

Table 123: Devices on a GTPv1 network

Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	
Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay
SGSN (local)	**MS, SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR**	Ga, Gb, Gn, Gp, Gz	IP, Frame Relay, GTP, GTP'
SGSN (remote)	**SGSN (local)**	Gn	GTP
GGSN (local)	SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gi, Gn, Gp, Gz	IP, GTP, GTP'
GGSN (remote)	SGSN (local), WAP gateway, Internet, other external services	Gi, Gp	IP, GTPv1
CDR, CFR	SGSN (local), GGSN (local)	Ga, Gz	GTP'
HLR, VLR	SGSN (local), GGSN (local)	Ga, Gz	GTP'

Radio access

For a mobile phone to access the GPRS core network, it must first connect to a mobile station. This is a cellular tower that is connected to the carrier network.

How the mobile phone connects to the mobile station (MS) is determined by what Radio Access Technologies (RATs) are supported by the MS.

Transport

Transport protocols move data along the carrier network between radio access and the Internet or other carrier networks.

FortiOS Carrier should be present where information enters the Carrier network, to ensure the information entering is correct and not malicious. This means a FortiOS Carrier unit intercepts the data coming from the SGSN or foreign networks destined for the SSGN or GGSN onto the network, and after the GGSN as the data is leaving the network.

GTP

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their network via tunneling. This tunneling allows users to move between SGSNs and still maintain connection to the Internet through the GGSN.

GTP has three versions version 0, 1, and 2. GTP1 and GTP2 are supported by FortiOS Carrier. The only GTP commands that are common to all forms of GTP are the echo request/response commands that allow GSNs to verify up to once every 60 seconds that neighboring GSNs are alive.

GGSN

The Gateway GPRS Support Node (GGSN) connects the GPRS network on one side via the SGSN to outside networks such as the Internet. These outside networks are called packet data networks (PDNs). The GGSN acts as an edge router between the two different networks — the GGSN forwards incoming packets from the external PDN to the addressed SGSN and the GGSN also forwards outgoing packets to the external PDN. the GGSN also converts the packets from the GPRS packets with SGSN to the external packets, such as IP or X.25.

SGSN

The Serving GPRS Support Node (SGSN) connects the GPRS network to GTPv1 compatible mobile stations, and mobile units (such as UTRAN and ETRAN) on one side and to the gateway node (GGSN), which leads to external networks, on the other side. Each SGSN has a geographical area, and mobile phones in that area connect to the GPRS network through this SGSN. The SGSN also maintains a location register that contains customer's location and user profiles until they connect through a different SGSN at which time the customer information is moved to the new SGSN. This information is used for packet routing and transfer, mobility management also known as location management, logical link management, and authentication and billing functions.

MME

MME essentially fills the role of the SGSN in a GTPv1 network — it is how the mobile stations gain access to the Carrier network. GTPv2 supports different mobile stations than GTPv1, so MME handles the GTPv2 MSes and SGSN handles the GTPv1 MSes

Billing and records

A major part of the GPRS network is devoted to billing. Customer billing requires enough information to identify the customer, and then billing specific information such as connection locations and times, as well as amount of data transferred. A modified form of GTP called GTP' is used for billing. The home location records and visitor location records store information about customers that is critical to billing.

GTP' (GTP prime)

GTP is used to handle tunnels of user traffic between SGSNs and GGSNs. However for billing purposes, other devices that are not supported by GTP are required. GTP' (GTP prime) is a modified form of GTP and is used to communicate with these devices such as the Charging Data Function (CDF) that communicates billing information to the Charging Gateway Function (CGF). In most cases, GTP' transports user records from many individual network elements, such as the GGSNs, to a centralised computer which then delivers the charging data more conveniently to the network operator's billing center, often through the CGF. The core network sends charging information to the CGF, typically including PDP context activation times and the quantity of data which the end user has transferred.

GTP' is used by the Ga and Gz interfaces to transfer billing information. GTP' uses registered UDP/TCP port 3386. GTP' defines a different header, additional messages, field values, as well as a synchronisation protocol to avoid losing or duplicating CDRs on CGF or SGSN/GGSN failure. Transferred CDRs are encoded in ASN.1.

HLR

The Home Location Register (HLR) is a central database that contains details of each mobile phone subscriber that is authorized to use the GSM core network. There can be several logical, and physical, HLRs per public land mobile network (PLMN), though one international mobile subscriber identity (IMSI)/MSISDN pair can be associated with only one logical HLR (which can span several physical nodes) at a time. The HLRs store details of every SIM card issued by the mobile phone operator. Each SIM has a unique identifier called an IMSI which is the primary key to each HLR record.

VLR

The Visitor Location Register (VLR) is a database which stores information about all the mobile devices that are currently under the jurisdiction of the Mobile Switching Center which it serves. Of all the information the VLR stores about each Mobile Station, the most important is the current Location Area Identity (LAI). This information is vital in the call setup process.

Whenever an MSC detects a new MS in its network, in addition to creating a new record in the VLR, it also updates the HLR of the mobile subscriber, informing it of the new location of that MS.

For more information on GTP‘, see “GTP-U and Charging Management Messages” on page 2410.

GPRS network common interfaces

There are interfaces for each connection on the GPRS network. An interface is an established standard form of communication between two devices. Consider a TCP/IP network. In addition to the transport protocol (TCP) there are other protocols on that network that describe how devices can expect communications to be organized, just like GPRS interfaces.

Interfaces between devices on the network

There are a series of interfaces that define how different devices on the carrier network communicate with each other. There interfaces are called Ga to Gz, and each one defines how a specific pair of devices will communicate. For example Gb is the interface between the base station and the SGSN, and Gn is one possible interface between the SGSN and GGSN.

The SGSN and GGSN keep track of the CDR information and forward it to the Charging Data Function (CDF) using the Gr interface between the SGSN and home location register (HLR), Gs interface between the SGSN and MSC (VLR), Gx interface between the GGSN and the Charging Rules Function (CRF), Gy between the GGSN and online charging system (OCS), and finally Gz which is the off-line (CDR-based) charging interface between the GSN and the CG that uses GTP'.

Each of these interfaces on the GPRS network is has a name in the format of `Gx` where `x` is a letter of the alphabet that determines what part of the network the interface is used in. It is common for network diagrams of GPRS networks to include the interface name on connections between devices. See “Packet flow through the GPRS network” on page 2312.

Tip: The FortiOS Carrier unit only provides protection on the Gn, Gp, and Gi interfaces.

Table 124: GPRS network interfaces, their roles, and billing

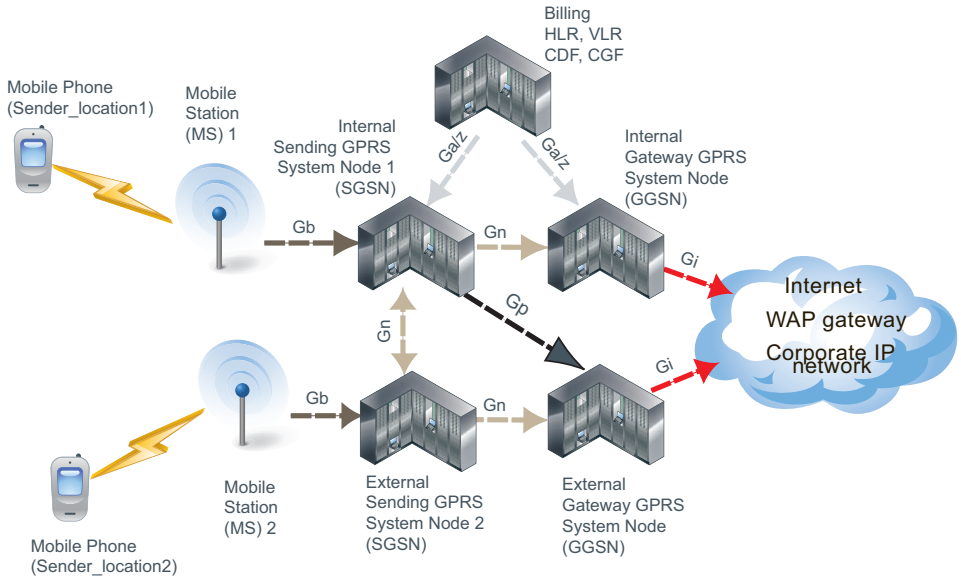
Name	Device connections that use this interface	Traffic Protocol used	Its role or how it affects billing
Ga	CDR and GSN (SGSNs and GGSNs)	GTP‘ - GTP modified to include CDR role	CDR have the accounting records, that are compiled in the GSN and then sent to the Charging Gateway (CG)
Gb	MS and SGSN	Frame Relay or IP	When an IP address moves to a new MS, the old MS may continue to use and bill that IP address.
Gi	GGSN and public data networks (PDNs)	IP based	This is the connection to the Internet. If the GTP tunnel is deleted without notifying the Gi interface, the connection may remain open incurring additional charges. FortiOS Carrier adds this interface to a firewall. See “Anti-overbilling with FortiOS Carrier” on page 2406.
Gn	SGSN and external SGSNs and internal GGSNs	GTP	When the GTP tunnel is deleted, need to inform other interfaces immediately to prevent misuse of connections remaining open. FortiOS Carrier adds this interface to a firewall.
Gp	Internal SGSN and external GGSNs	GTP	
Gz	GSN (SGSN and GGSN) and the charging gateway (CG)	GTP‘	Used for the offline charging interface. Ga is used for online charging.

Corporate customers may have a direct connection to the Gi interface for higher security. The Gi interface is normally an IP network, though a tunnelling protocol such as GRE or IPsec may be used instead.

Packet flow through the GPRS network

To better understand the GPRS network, we will follow the path data takes for a normal connection. For this example a call placed from a mobile phone involves accessing services on the Internet.

Figure 245: Sample GPRS network topology



1. A mobile phone places a call using a mobile station (MS). This connection between the mobile phone and the MS is a radio connection using one of the radio access technologies. See "Radio Access Technology (RAT) type" on page 2418.
2. The MS connects to a GPRS System Node (GSN) specifically a Sending GSN. This connection uses the Gb interface and typically uses IP address or Frame Relay.
3. The SGSN checks the mobile phone information located in the home location register (HLR) or visitor location register (VLR) to ensure there is subscriber information for that phone. If this mobile phone is from another network, it uses the VLR and updates its home carrier's information with its current location and information. This connection involves the Ga or Gz interfaces, and uses the GTP' protocol for communication.
4. The SGSN checks to make sure the phone did not transfer this connection from a different MS. If it did, the connection has already been established (along with the billing) and is handed off to this SGSN. If the call is being handed over from another SGSN, it will use the Gn interface between the two SGSNs.
5. The SGSN sends GTP messages to the local external Gateway GSN (GGSN) to create a GTP tunnel for this PDP context to access the Internet. It is possible that a remote GGSN has access to a service, such as a WAP gateway, that the local GGSN is missing. In this situation, the local SGSN uses the Gp interface to connect to the remote GGSN. Both the Gn and Gp interfaces use GTP.
6. The both the local and remote GGSNs connect to external services outside the GPRS network. These services can include a WAP gateway, a corporate IP network directly connected to the GPRS network, or the Internet. The connection from the GGSN to the external services uses the Gi interface.

Carrier web-based manager settings

The Carrier menu provides settings for configuring FortiOS Carrier features within the UTM menu. These features include MMS and GTP profiles.

In *UTM Profiles* > *Carrier*, you can configure profiles and settings for MMS and GTP. In the Carrier menu, you can configure an MMS profile and then apply it to a security policy. You can also configure GTP profiles and apply those to security policies as well.

This topic includes the following:

MMS profiles

Since MMS profiles can be used by more than one security policy, you can configure one profile for the traffic types handled by a set of security policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

If the security policy requires authentication, do not select the MMS profile in the security policy. This type of profile is specific to the authenticating user group. For details on configuring the profile associated with the user group, see User Groups in the *User Authentication guide*.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you might configure two separate protection profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS profile, you can then apply the profile to MMS traffic by applying it to a security policy.

MMS profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS profile.

The MMS Profile page contains options for each of the following:

- MMS scanning

- MMS Bulk Email Filtering Detection
- MMS Address Translation
- MMS Notifications
- DLP Archive
- Logging

MMS profile configuration settings

The following are MMS profile configuration settings in *UTM Profiles* > *Carrier* > *MMS Profile*.

MMS Profile page Lists each individual MMS profile that you created. On this page, you can edit, delete or create an MMS profile.	
Create New	Creates a new MMS profile. When you select *Create New*, you are automatically redirected to the New MMS Profile page.
Edit	Modifies settings within an MMS profile. When you select *Edit*, you are automatically redirected to the Edit MMS Profile.
Delete	Removes an MMS profile from the list on the MMS Profile page. To remove multiple MMS profiles from within the list, on the MMS Profile page, in each of the rows of the profiles you want removed, select the check box and then select *Delete*. To remove all MMS profiles from the list, on the MMS Profile page, select the check box in the check box column, and then select *Delete*.
Name	The name of the MMS profile.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM Profiles* > *Antivirus* > *Profile*), 1 appears in *Ref.* To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

New MMS Profile page	
Provides settings for configuring an MMS profile. This page also provides settings for configuring DLP archives and logging.	
Profile Name	Enter a name for the profile.
Comments	Enter a description about the profile. This is optional.
MMS Scanning	Configure MMS Scanning options. See "MMS scanning options" on page 2317.
MMS Bulk Email Filtering Detection	Configure MMS Bulk Email options. See "MMS bulk email filtering options" on page 2319.
MMS Address Translation	Configure MMS Address Translation options. See "MMS Address Translation options" on page 2322
MMS Notifications	Configure MMS Notification options. "MMS Notifications" on page 2324.
DLP Archive	Configure DLP archive option. See "DLP Archive options" on page 2326
Logging	Configure logging options. See "Logging" on page 2327.

MMS scanning options

You can configure MMS scanning protection profile options to apply virus scanning, file filtering, content filtering, carrier end point blocking, and other scanning to MMS messages transmitted using the MM1, MM3, MM4 and MM7 protocols.

The following are the MMS Scanning options that are available within an MMS profile. You can create an MMS profile in *UTM Profiles* > *Carrier* > *MMS Profile* or edit an existing one. You must expand MMS Scanning to access the following options.

MMS Scanning section of the New MMS Profile page	
Monitor Only	Select to cause the unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Select this option to be able to report on viruses and other problems in MMS traffic without affecting users. **Tip:** Select *Remove Blocked* if you want the unit to actually remove content intercepted by MMS scanning options.
Virus Scan	Select to scan attachments in MMS traffic for viruses. Since MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configuration also applies to MM1 and MM7 scanning. MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configuration also applies to MM3 and MM4 scanning.
Scan MM1 message retrieval	Select to scan message retrievals that use MM1. If you enable *Virus Scan* for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.

File Filter	Select to apply antivirus file filtering to MMS traffic. Select a file filter list to apply.
Quarantine	Select to quarantine the selected MMS traffic
Remove Blocked	Select to remove blocked content from each protocol and replace it with the replacement message. Select *Constant* if the unit is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message. **Tip:** If you only want to monitor blocked content, select *Monitor Only*.
Content Filter	Select to filter messages based on matching the content of the message with the words or patterns in the selected web content filter list. For information about adding a web content filter list, see the *FortiGate CLI Reference*.
Carrier Endpoint Block	Select to add *Carrier End Point Filtering* in this MMS profile. Select the carrier end point filter list to apply it to the profile. For information about carrier end point filtering, see "Carrier Endpoint Filter Lists" on page 2334.
MMS Content Checksum	Select to add MMS Content Checksum in this MMS profile. Select the MMS content checksum list to apply it to the profile.
Pass Fragmented Messages	Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.
Comfort Clients	Select client comforting for MM1 and MM7 sessions. Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.
Comfort Servers	Select server comforting for each protocol. Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for the unit to buffer and scan large POST requests from slow clients.
Interval (1-900 seconds)	Enter the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.
Amount (1-10240 bytes)	The number of bytes sent by client or server comforting at each interval.

Oversized MMS Message		Select *Block* or *Pass* for files and email messages exceeding configured thresholds for each protocol. The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.
	Threshold (1KB - 800 MB)	Enter the oversized file threshold and select KB or MB. If a file is larger than the threshold the file is passed or blocked depending on the *Oversized MMS Message* setting. The web-based manager displays the allowed threshold range. The threshold maximum is 10% of the unit's RAM.

MMS bulk email filtering options

You can use the MMS bulk email filtering options to detect and filter MM1 and MM4 message floods and duplicate messages. You can configure three thresholds that define a flood of message activity and three thresholds that define excessive duplicate messages. The configuration of each threshold includes the response actions for the threshold.

The configurable thresholds for each of the flood and duplicate sensors and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

You can also add MSISDN to the bulk email filtering configuration and select a subset of the bulk email filtering options to applied to these individual MSISDNs.

You must first select MM1 and/or MM4 to detect excessive message duplicates. If excessive message duplicates are detected, the unit will perform the *Duplicate Message Action* for the specified duration.

You can configure three duplicate message thresholds and enable them with separate values and actions. They are labeled Duplicate Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Duplicate Threshold 1 and Duplicate Threshold 2, but you cannot disable Duplicate Threshold 1 and enable Duplicate Threshold 2.

When traffic accepted by a security policy that contains an MMS profile with duplicate message configured receives MM1 or MM4 duplicate messages that match a threshold configured in the MMS protection profile, the unit performs the duplicate message action configured for the matching threshold.

You can configure three message flood thresholds and enable them with separate values and actions. They are labeled Flood Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

When traffic accepted by a security policy that contains an MMS protection profile with message flooding configured experiences MM1 or MM4 message flooding that matches a threshold configured in the MMS profile, the unit performs the message flood action configured for the matching threshold.

MMS Bulk Email Filtering Detection section of the New MMS Profile page ***This section of the New MMS Profile page contains numerous sections where you can configure specific settings for flood threshold, duplicate threshold and recipient MSISDNs.***		
Message Flood section of the new MMS Profile page The message flood settings for each flood threshold. Expand each to configure settings for a threshold.		
Flood Threshold 1		Expand to reveal the flood threshold settings for Flood Threshold 1. The settings for Flood Threshold 1 are the same for Flood Threshold 2 and 3.
	Enable	Select to apply Flood Threshold 1 to the MSISDN exception.
	Message Flood Window	Enter the period of time during which a message flood will be detected if the *Message Flood Limit* is exceeded. The message flood window can be 1 to 2880 minutes (48 hours).
	Message Flood Limit	Enter the number of messages which signifies a message flood if exceeded within the *Message Flood Window*.
	Message Flood Block Time	Enter the amount of time during which the unit performs the *Message Flood Action* after a message flood is detected.
	Message Flood Action	Select one or more actions that the unit is to perform when a message flood is detected.
Flood Threshold 2 **Flood Threshold 3**		Expand to configure settings for Flood Threshold 2 or 3 respectively.
Duplicate Message section of the new MMS Profile page ***The duplicate message threshold settings. Expand each to configure settings for a threshold.***		
MM1 Retrieve Duplicate Enable		Select to scan MM1 `mm1-retr` messages for duplicates. By default, `mm1-retr` messages are not scanned for duplicates as they may often be the same without necessarily being bulk or spam.
	Enable	Select to enable the selected duplicate message threshold and to make the rest of the options available for configuration.
	Duplicate Message Window	Enter the period of time during which excessive message duplicates will be detected if the Duplicate message Limit it exceeded. The duplicate message window can be 1 to 2880 minutes (48 hours).
	Duplicate Message Limit	Enter the number of messages which signifies excessive message duplicates if exceeded within the Duplicate Message Window.

	Duplicate Message Block Time	Enter the amount of time during which the unit will perform the Duplicate Message Action after a message flood is detected.
	Duplicate Message Action	Select one or more actions that the unit is to perform when excessive message duplication is detected.
Duplicate Threshold 2 **Duplicate Threshold 3**		Expand to configure settings for Duplicate Threshold 2 or 3 respectively.
Recipient MSISDN section of the New MMS Profile page The recipient Mobile Subscriber Integrated Services Digital Network Number (MSISDN) settings for each recipient MSISDN. When you select *Create New*, you are automatically redirected to the New MSISDN page. You need to save the profile before you can add MSISDNs.		
Recipient MSISDN		The recipient MSISDN.
Flood Threshold 1		Check to enable Flood Threshold 1 settings for this MSISDN.
Flood Threshold 2		Check to enable Flood Threshold 2 settings for this MSISDN.
Flood Threshold 3		Check to enable Flood Threshold 3 settings for this MSISDN.
Duplicate Threshold 1		Check to enable Duplicate Threshold 1 settings for this MSISDN.
Duplicate Threshold 2		Check to enable Duplicate Threshold 2 settings for this MSISDN.
Duplicate Threshold 3		Check to enable Duplicate Threshold 3 settings for this MSISDN.
Edit		Modifies the settings of a Recipient MSISDN in the Recipient MSISDN list. When you select *Edit*, you are automatically redirected to the New MSISDN page.
Delete		Removes a Recipient MSISDN in the Recipient MSISDN list within the Recipient MSISDN section of the page.
New MSISDN page		
Create New		Creates a new Recipient MSISDN. When you select *Create New*, you are automatically redirected to the New MSISDN page.
Recipient MSISDN		Enter a name for the recipient MSISDN.
Flood Threshold 1		Select to apply Flood Threshold 1 to the MSISDN exception.
Flood Threshold 2		Select to apply Flood Threshold 2 to the MSISDN exception.
Flood Threshold 3		Select to apply Flood Threshold 3 to the MSISDN exception.
Duplicate Threshold 1		Select to apply Duplicate Threshold 1 to the MSISDN exception.

Duplicate Threshold 2	Select to apply Duplicate Threshold 2 to the MSISDN exception.
Duplicate Threshold 3	Select to apply Duplicate Threshold 3 to the MSISDN exception.

MMS Address Translation options

The sender's carrier end point is used to provide logging and reporting details to the mobile operator and to identify the sender of infected content.

When MMS messages are transmitted, the *From* field may or may not contain the sender's address. When the address is not included, the sender information will not be present in the logs and the unit will not be able to notify the user if the message is blocked unless the sender's address is made available elsewhere in the request.

The unit can extract the sender's address from an extended HTTP header field in the HTTP request. This field must be added to the HTTP request before it is received by the unit. If this field is present, it will be used instead of the sender's address in the MMS message for logging and notification. If this header field is present when a message is retrieved, it will be used instead of the *To* address in the message. If this header field is not present the content of the *To* header field is used instead.

Alternatively, the unit can extract the sender's address from a cookie.

You can configure MMS address translation to extract the sender's carrier end point so that it can be added to log and notification messages. You can configure MMS address translation settings to extract carrier end points from HTTP header fields or from cookies. You can also configure MMS address translation to add an end point prefix to the extracted carrier end points. For more information, see Dynamic Profiles and End Points in the *User Authentication guide*.

MMS Address Translation section of the New MMS Profile page	
Sender Address Source	Select to extract the sender's address from the *HTTP Header Field* or a *Cookie*. You must also specify the identifier that contains the carrier end point.

Sender Address Identifier		Enter the sender address identifier that includes the carrier end point. The default identifier is `x-up-calling-line-id`.
		If the *Sender Address Source* is *HTTP Header Field*, the address and its identifier in the HTTP request header takes the format:
		`<Sender Address Identifier>: <MSISDN_value>`
		Where the `<MSISDN_value>` is the carrier end point. For example, the HTTP header might contain:
		`x-up-calling-line-id: 6044301297`
		where `x-up-calling-line-id` would be the Sender Address Identifier.
		If the *Sender Address Source* is Cookie, the address and its identifier in the HTTP request header's `Cookie` field takes the format of attribute-value pairs:
		`Cookie: id=<cookie-id>; <Sender Address Identifier>=<MSISDN Value>`
		For example, the HTTP request headers might contain:
		`Cookie: id=0123jf!a;x-up-calling-line-id=6044301297`
		where `x-up-calling-line-id` would be the *Sender Address Identifier*.

Convert Sender Address From / To HEX		Select to convert the sender address from ASCII to hexadecimal or from hexadecimal to ASCII. This is required by some applications.
Add Carrier Endpoint Prefix for Logging / Notification		Select the following to enable adding endpoint prefixes for logging and notification.
	Enable	Select to enable adding the country code to the extracted carrier end point, such as the MSISDN, for logging and notification purposes. You can limit the number length for the test numbers used for internal monitoring without a country code.
	Prefix	Enter a carrier end point prefix to be added to all carrier end points. Use the prefix to add extra information to the carrier end point in the log entry.
	Minimum Length	Enter the minimum length of the country code information being added. If this and Maximum Length are set to zero (`0`), length is not limited.
	Maximum Length	Enter the maximum length of the country code information being added. If this and Minimum Length are set to zero (`0`), length is not limited.

MMS Notifications

MMS notifications are messages that a unit sends when an MMS profile matches content in an MM1, MM3, MM4 or MM7 session. For example, the MMS profile detects a virus or uses content blocking to block a web page, text message or email. You can send notifications to the sender of the message using same protocol and the addressing headers in the original message. You can also configure MMS notifications to send notification messages to another destination (such as a system administrator) using the MM1, MM3, MM4 or MM7 protocol.

You need to enable one or more *Notification Types* or you can add an *Antivirus Notification List* to enable sending notifications,.

You can also use MMS notifications options to configure how often notifications are sent. The unit sends notification messages immediately for the first event, then at a configurable interval if events continue to occur. If the interval does not coincide with the window of time during which notices may be sent, the unit waits to send the notice in the next available window. Subsequent notices contain a count of the number of events that have occurred since the previous notification.

There are separate notifications for each notification type, including virus events. Virus event notifications include the virus name. Up to three viruses are tracked for each user at a time. If a fourth virus is found, one of the existing tracked viruses is removed from the list.

The notifications are MM1 `m-send-req` messages sent from the unit directly to the MMSC for delivery to the client. The host name of the MMSC, the URL to which `m-send-req` messages are sent, and the port must be specified.

MMS Notification section of the New MMS Profile page	
Antivirus Notification List	Optionally select an antivirus notification list to select a list of virus names to send notifications for. The unit sends a notification message whenever a virus name or prefix in the antivirus notification list matches the name of a virus detected in a session scanned by the MMS protection profile. Select *Disabled* if you do not want to use a notification list. To create an antivirus notification list, see "Notification List" on page 2329. Instead of selecting a notification list you can configure the *Virus Scan Notification Type* to send notifications for all viruses.
Message Protocol	In each column, select the protocol used to send notification messages. You can use a different protocol to send the notification message than the protocol on which the violation was sent. The MMS Notifications options change depending on the message protocol that you select. If you select a different message protocol, you must also enter the User Domain. If selecting MM7 you must also enter the Message Type.
Message Type	Select the MM7 message type to use if sending notifications using MM7. Options include deliver.REQ and submit.REQ

Detect Server Details	Select to use the information in the headers of the original message to set the address of the notification message. If you do not select this option, you can enter the required addressing information manually. You cannot select *Detect Server Details* if you are sending notification messages using a different message protocol. If you select *Detect Server Details*, you cannot change the *Port* where the notification is being sent.
Hostname	Enter the FQDN or the IP address of the server where the notifications will be sent.
URL	Enter the URL of the server. For example if the notification is going to www.example.com/home/alerts, the URL is /home/alerts. This option is available only when *Message Protocol* is *mm1* or *mm7*.
Port	Enter the port number of the server. You cannot change the *Port* if *Detect Server Details* is enabled.
Username	Enter the user name required for sending messages using this server (optional). This option is available only when *Message Protocol* is *mm7*.
Password	Enter the password required for sending messages using this server (optional). This option is available only when *Message Protocol* is *mm7*.
VASP ID	Enter the value-added-service-provider (VASP) ID to be used when sending a notification message. If a VAS is not offered by the mobile provider, it is offered by a third party or a VAS provider or content provider (CP). This option is available only when *Message Protocol* is *mm7*.
VAS ID	Enter the value-added-service (VAS) ID to be used when sending a notification message. A VAS is generally any service beyond voice calls and fax. This option is available only when *Message Protocol* is *mm7*.
All Notification Types	In each column, select notification for all MMS event types for that MMS protocol, then enter the amount of time and select the time unit for notice intervals. Alternatively, expand *All Notification Types*, and then select notification for individual MMS event types for each MMS protocol. Then enter the amount of time and select the time unit for notice intervals. Not all event types are available for all MMS protocols.
Content Filter	In each column, select to notify when messages are blocked by the content filter, then enter the amount of time and select the time unit for notice intervals.

	File Block	In each column, select to notify when messages are blocked by file block, then enter the amount of time and select the time unit for notice intervals.
	Carrier Endpoint Block	In each column, select to notify when messages are blocked, then enter the amount of time and select the time unit for notice intervals.
	Flood	In each column, select to notify when message flood events occur, then enter the amount of time and select the time unit for notice intervals.
	Duplicate	In each column, select to notify when duplicate message events occur, then enter the amount of time and select the time unit for notice intervals.
	MMS Content Checksum	In each column, select to notify when the content within an MMS message is scanned and banned because of the checksum value that was matched.
	Virus Scan	In each column, select to notify when the content within an MMS message is scanned for viruses.
Notifications Per Second Limit		For each MMS protocol, enter the number of notifications to send per second. If you enter zero `(0)`, the notification rate is not limited.
Day of Week		For each MMS protocol, select the days of the week the unit is allowed to send notifications.
Window Start Time		For each MMS protocol, select the time of day to begin the message alert window. By default, the message window starts at 00:00. You can change this if you want to start the message window later in the day. When configured, notification outside this window will not be sent.
Window Duration		For each MMS protocol, select the time of day at which to end the message alert window. By default, the message window ends at 00:24. You can change this if you want to end the message window earlier in the day. When configured, notification outside this window will not be sent

DLP Archive options

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. In addition to the MMS profile's DLP archive options, you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select *DLP archiving* for carrier end point patterns in a *Carrier End Point List* and select the *Carrier End Point Block* option in the *MMS Scanning* section of an MMS Profile

The unit only allows one sixteenth of its memory for transferring content archive files. For example, for units with 128MB RAM, only 8MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

DLP Archive section of the New MMS Profile page	
Display DLP meta-information on the system dashboard	Select each required protocol to display the content archive summary in the Log and Archive Statistics dashboard widget on the System Dashboard.
Archive to FortiAnalyzer/FortiGuard	Select the type of archiving that you want for the protocol (MM1, MM3, MM4, and MM7). You can choose from Full, Summary or None. **None —** Do not send content archives. **Summary —** Send content archive metadata only. Includes information such as date and time, source and destination, request and response size, and scan result. **Full —** Send content archive both metadata and copies of files or messages. In some cases, FortiOS Carrier may not archive content, or may make only a partial content archive, regardless of your selected option. This behavior varies by prerequisites for each protocol. This option is available only if a FortiAnalyzer unit or FortiGuard Analysis and Management Service is configured.

Logging

You can enable logging in an MMS profile to write event log messages when the MMS profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS profile logging options to write an event log message every time a virus is detected.

You must first configure how the unit stores log messages so that you can then record these logs messages. For more information, see the *FortiOS Handbook Logging and Reporting chapter*.

Logging section of the New MMS Profile page		
MMS-Antivirus		If antivirus settings are enabled for this MMS profile, select the following options to record *Antivirus Log* messages.
	Viruses	Record a log message when this MMS profile detects a virus.
	Blocked Files	Record a log message when antivirus file filtering enabled in this MMS profile blocks a file.
	Intercepted Files	Record a log message when this MMS profile intercepts a file.
	Oversized Files/Emails	Record a log message when this MMS profile encounters an oversized file or email message. Oversized files and email messages cannot be scanned for viruses.

MMS Scanning		If MMS scanning settings are enabled for this MMS profile, select the following options to record *Email Filter Log* messages.
	Notification Messages	Select to log the number of MMS notification messages sent.
	Bulk Messages	Select to log MMS Bulk AntiSpam events. You must also select which protocols to write log messages for in the MMS bulk email filtering part of the MMS profile. For more information, see "MMS bulk email filtering options" on page 2319.
	Carrier Endpoint Filter Block	Select to log MMS carrier end point filter events, such as MSISDN filtering.
	MMS Content Checksum	Select to log MMS content checksum activity.
	Content Block	Select to log content blocking events.

MMS Content Checksum

The MMS Content Checksum menu allows you to configure content checksum lists.

Configure MMS content checksum lists in *UTM Profiles* > *Carrier* > *MMS Content Checksum* using the following table.

MMS Content Checksum page	
Lists each individual content checksum list that you created. On this page, you can edit, delete or create a content checksum list.	
Create New	Creates a new MMS content checksum list. When you select *Create New*, you are automatically redirected to the New List. This page provides a name field and comment field. You must enter a name to go to MMS Content Checksum Settings page.
Edit	Modifies settings to a MMS content checksum. When you select *Edit*, you are automatically redirected to the MMS Content Checksum Settings page.
Delete	Removes an MMS content checksum from the page. To remove multiple content checksum lists from within the list, on the MMS Content Checksum page, in each of the rows of the content checksum lists you want removed, select the check box and then select *Delete*. To remove all content checksum lists from list, on the MMS Content Checksum page, select the check box in the check box column and then select *Delete*.
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in the content checksum list.

MMS Profiles	The MMS profile or profiles that have the MMS content checksum list applied. For example if two different MMS profiles use this content checksum list, they will both be listed here.
Comments	A description given to the MMS content checksum.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM Profiles* > *AntiVirus* > *Profile*), 1 appears in *Ref.* To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

Notification List

The Notification List menu allows you to configure a list of viruses. This virus list provides a list for scanning viruses in MMS messages. You can use one virus list in multiple MMS profiles, and configure multiple virus lists.

Notification list configuration settings

The following are notification list configuration settings in *UTM Profiles* > *Carrier* > *Notification List*.

Notification List page Lists all the notification lists that you created. On this page you can edit, delete or create a new notification list.	
Create New	Creates a new notification list. When you select *Create New*, you are automatically redirected to the New List page. You must enter a name to go to the Notification List Settings page.
Edit	Modifies settings within the notification list. When you select *Edit*, you are automatically redirected to the Notification List Settings page.

Delete	Removes a notification list from the list on the Notification List page. To remove multiple notification lists from within the list, on the Notification List page, in each of the rows of the notification lists you want removed, select the check box and then select *Delete*. To remove all notification lists from the list, on the Notification List page, select the check box in the check box column and then select *Delete*.
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in that content checksum list.
MMS Profiles	The MMS profile or profiles that are associated with
Comments	A description given to the MMS notification list.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM Profiles* > *Antivirus* > *Profile*), 1 appears in *Ref.* To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
Notification List Settings page Provides settings for configuring a notification list, which is a list of viruses and is used for scanning viruses in MMS messages. This list is called the Antivirus Notification List in an MMS profile.	
Name	If editing the name of a notification list, enter the new name in this field. You must select *OK* to save the change.
Comments	If you want to enter a comment, enter the comment in the field. You must select *OK* to save the change.
Create New	Creates a notification entry in the list. When you select *Create New*, you are automatically redirected to the New Entry page.
Edit	Modifies settings within a notification list. When you select *Edit*, you are automatically redirected to the Edit Entry page.

Delete	Removes a notification entry from the list on the page. To remove multiple notification entries from within the list, on the Notification List Settings page, in each of the rows of the entries you want removed, select the check box and then select *Delete*. To remove all notification entries from the list, on the Notification List Settings page, select the check box in the check box column and then select *Delete*.
Enable	Enables a notification entry that is disabled.
Disable	Disables a notification entry so that it is not active and available for use, but it is not deleted.
Remove All Entries	Removes all notification entries that are listed on the Notification List Settings page.
Enable	Displays whether or not the checksum is enabled.
Virus Name/Profile	The name of the virus that was added to the list.
Entry Type	The type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
New Entry page	
Virus Name/Profile	Enter the virus name.
Entry Type	Select the type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
Enable	Select to enable the virus in the list.

Message Flood

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse. A message flood occurs when a single subscriber sends a volume of messages that exceed the flood threshold that you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected. For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all outgoing messages blocked for 30 minutes.

Action	Description
Log	Add a log entry indicating that a message flood has occurred. You must also enable logging for *MMS Scanning* > *Bulk Messages* in the *Logging* section of the MMS protection profile.
DLP Archive	Save the first message to exceed the flood threshold, or all the messages that exceed the flood threshold, in the DLP archive. DLP archiving flood messages may not always produce useful results. Since different messages can be causing the flood, reviewing the archived messages may not be a good indication of what is causing the problem since the messages could be completely random.

Action		Description
	All messages	All the messages that exceed the flood threshold will be saved in the DLP archive.
	First message only	Save only the first message to exceed the flood threshold in the DLP archive. Other messages in the flood are not saved. For message floods this may not produce much useful information since a legitimate message could trigger the flood threshold.
Intercept		Messages that exceed the flood threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message will also quarantined for later examination. If the quarantine of intercepted messages is disabled, the *Intercept* action has no effect.
Block		Messages that exceed the flood threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each message will quarantined for later examination.
Alert Notification		If the flood threshold is exceeded, the FortiOS Carrier unit will send an MMS flood notification message. In the web-based manager when *Alert Notification* is selected it displays the fields to configure the notification.

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

Message flood configuration settings

The following are message flood configuration settings in *UTM Profiles* > *Carrier* > *Message Flood*.

Message Flood page **Lists the large amount of messages that are being sent to you, from outside sources.**	
Delete	Removes messages from the list. To remove multiple messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select *Delete*. To remove all messages from the list, on the Message Flood page, select the check box in the check box column and then select *Delete*.
Remove All Entries	Removes all messages from the list.
Protocol	The protocol used.
MMS Profile	The MMS profile that is used.
Sender	The sender's email address.
Level	The level of severity of the message.

Count	The count column can be up or down and these settings can be turned off by selecting beside the column's name.
Window Size (minutes)	The time in minutes.
Timer (minutes:seconds)	The time in seconds and in minutes. The timer column can be up or down and these settings turned off by selecting beside the column's name.
Page Controls	Use to navigate through the list.

Duplicate Message

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC.

The unit keeps track of the sent messages. If the same message appears more often than the threshold value that you have configured, action is taken. Possible actions are logging the duplicate messages, blocking or intercepting them, archiving, and sending an alert to inform an administrator that duplicate messages are occurring.

Duplicate message configuration settings

View duplicate messages in *UTM Profiles* > *Carrier* > *Duplicate Message*.

Duplicate Message page **Lists duplicates of messages that were sent to you.**	
Delete	Removes a message from the list. To remove multiple duplicate messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select *Delete*. To remove all duplicate messages from the list, on the Message Flood page, select the check box in the check box column and then select *Delete*.
Page Controls	Use to navigate through the list.
Remove All Entries	Removes all duplicate messages from the list.
Protocol	Either MM1 or MM4
Profile	The MMS profile that logs the detection.
Checksum	The checksum of the MMS message.
Status	Either flagged or blank. Flagged means that the actions defined in the MMS profile are taken. For more information, see "MMS bulk email filtering options" on page 2319.
Count	Displays the number of messages in the last window of time.

Window Size (minutes)	The period of time during which a message flood will be detected if the Message Flood Limit is exceeded.
Timer (minutes:seconds)	Either the time left in the window if the message is unflagged, or the time until the message will be unflagged if it is already flagged.

Carrier Endpoint Filter Lists

A carrier end point filter list contains carrier end point patterns. A pattern can match one carrier end point or can use wildcards or regular expressions to match multiple carrier end points. For each pattern, you select the action that the unit takes on a message when the pattern matches a carrier end point in the message. Actions include blocking the message, exempting the message from MMS scanning, and exempting the message from all scanning. You can also configure the pattern to intercept the message and content archive the message to a FortiAnalyzer unit.

Carrier endpoint filter lists configuration settings

The following are Carrier endpoint filter list configuration settings in *UTM Profiles* > *Carrier* > *Carrier Endpoint Filter Lists*.

Carrier Endpoint Filter Lists page	
Lists all the endpoint filters that you created. On this page, you can edit, delete or create a new endpoint filter list.	
Create New	Creates a new endpoint filter list. When you select *Create New*, you are automatically redirected to the New List page. You must enter a name to go to the Carrier Endpoint Filter Lists Settings page.
Edit	Modifies settings within an endpoint filter list in the list.
Delete	Removes an endpoint filter in the list. To remove multiple endpoint filter lists from within the list, on the Carrier Endpoint Filter List page, in each of the rows of the endpoint filter lists you want removed, select the check box and then select *Delete*. To remove all endpoint filter lists from the list, on the Carrier Endpoint Filter List page, select the check box in the check box column and then select *Delete*.
Name	The name of the endpoint filter.
# Entries	The number of carrier end point patterns in each carrier end point filter list.
MMS Profiles	The MMS profile that the carrier end point filter list is added to.
Comments	A description about the endpoint filter.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM Profiles* > *Antivirus* > *Profile*), 1 appears in *Ref.* To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
Carrier Endpoint Filter LIsts Settings page Provides settings for configuring an endpoint filter.	
Name	The name you entered on the New List page, after selecting *Create New* on the Carrier Endpoint Filter page.
Comments	A description about the endpoint filter. You can add one here if you did not enter one on the New List page.
Create New	Creates a new endpoint filter list. When you select *Create New*, you are automatically redirected to the New Entry page.
Edit	Select to modify the settings of a pattern in the list.
Delete	Select to remove a pattern in the list.
Enable	Enables a disabled pattern in the list.
Disable	Disables a pattern in the list.
Remove All Entries	Removes all patterns in the list on the Carrier Endpoint Filter Lists Settings page.
Enable	Indicates whether or not the pattern is enabled.
Pattern	Enter or change the pattern that FortiOS Carrier uses to match with carrier end points. The pattern can be a single carrier end point or consist of wildcards or Perl regular expressions that will match more than one carrier end point. Set *Pattern Type* to correspond to the pattern that you want to use.

Action		Select the action taken by FortiOS Carrier for messages from a carrier end point that matches the carrier end point pattern:
Pattern Type		The type of pattern chosen.
New Entry page		
Pattern		Enter or change the pattern that FortiOS Carrier uses to match with carrier end points. The pattern can be a single carrier end point or consist of wildcards or Perl regular expressions that will match more than one carrier end point. Set *Pattern Type* to correspond to the pattern that you want to use.
Action(s)		Select the action taken by FortiOS Carrier for messages from a carrier end point that matches the carrier end point pattern:
	Content Archive	MMS messages from the carrier end point are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
	Intercept	MMS messages from the carrier end point are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
Pattern Type		Select a pattern type as one of Single Carrier End Point, Wildcard or Regular Expression. Wildcard and Regular Expression will match multiple patterns where Single Carrier End Point matches only one.
Enable		Select to enable this carrier end point filter pattern.

GTP Profile

You can configure multiple GTP profiles within the GTP menu. GTP profiles concern GTP activity flowing through the unit. These GTP profiles are then applied to a security policy.

GTP profile configuration settings

The following are GTP profile configuration settings in *UTM Profiles* > *Carrier* > *GTP Profile*.

GTP Profile page Lists each GTP profile that you have created. On this page, you can edit, delete or create a new GTP profile.	
Create New	Creates a new GTP profile. When you select *Create New*, you are automatically redirected to the New page.
Edit	Modifies settings within a GTP profile in the list. When you select *Edit*, you are automatically redirected to Edit page.

Delete	Removes a GTP profile from the list. To remove multiple GTP profiles from within the list, on the GTP Profile page, in each of the rows of the profiles you want removed, select the check box and then select *Delete*. To remove all GTP profiles from within the list, on the GTP Profile page, select the check box in the check box column and then select *Delete*.
Name	The name of the GTP profile.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM Profiles* > *Antivirus* > *Profile*), 1 appears in *Ref.* To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New GTP Profile page **Provides settings for configuring a GTP profile.**	
Name	Enter a name for the GTP profile.
General Settings	Configure general options for the GTP profile. See "General settings options" on page 2338.
Message Type Filtering	Configure filtering for messages. See "Message type filtering options" on page 2340.
APN Filtering	Configure filtering options for APN. See "APN filtering options" on page 2340.
IMSI Filtering	Configure filtering options for IMSI. See "IMSI filtering options" on page 2341.
Advanced Filtering	Configure advanced filtering options. See "Advanced filtering options" on page 2343.
IE removal policy	Configure IE removal policy options. See "Information element removal policy options" on page 2346.
Encapsulated IP Traffic Filtering	Configure filtering options for encapsulated IP traffic. See "Encapsulated IP traffic filtering options" on page 2346.

Encapsulated Non-IP End User Address Filtering	Configure filtering options for encapsulated non-IP end user addresses. See “Encapsulated non-IP end user traffic filtering options” on page 2347.
Protocol Anomaly	Configure protocol anomaly options. See “Protocol anomaly prevention options” on page 2348.
Anti-Overbilling	Configure anti-overbilling options. See “Anti-overbilling options” on page 2349.
Log	Configure log options. See “Log options” on page 2349.

General settings options

The following are mostly house keeping options that appear in the General Settings area of the GTP configuration page.

General Settings section of the New GTP Profile page	
Sequence Number Validation	Enable to check that packets are not duplicated or out of order. GTP packets contain a Sequence Number field. This number tells the receiving GGSN the order of the packets it is receiving. Normally the GGSN compares this sequence number in the packets with its own sequence counter — if the two do not match, the packet is dropped. This sequence number validation can be off-loaded to the FortiOS Carrier freeing up resources on the GGSN.
GTP-in-GTP	Select *Allow* to enable GTP packets to be allowed to contain GTP packets, or a GTP tunnel inside another GTP tunnel. To block all GTP-in-GTP packets, select *Deny*.
Minimum Message Length	Enter the shortest possible message length in bytes. Normally this is controlled by the protocol, and will vary for different message types. If a packet is smaller than this limit, it is discarded as it is likely malformed and a potential security risk. The default minimum message length is 0 bytes.
Maximum Message Length	Enter the maximum allowed length of a GTP packet in bytes. A GTP packet contains three headers and corresponding parts GTP, UDP, and IP. If a packet is larger than the maximum transmission unit (MTU) size, it is fragmented to be delivered in multiple packets. This is inefficient, resource intensive, and may cause problems with some applications. By default the maximum message length is 1452 bytes.
Tunnel Limit	Enter the maximum number of tunnels allowed open at one time. For additional GTP tunnels to be opened, existing tunnels must first be closed. This feature can help prevent a form of denial of service attack on your network. This attack involves opening more tunnels than the network can handle and consuming all the network resources doing so. By limiting the number of tunnels at any one time, this form of attack will be avoided. The tunnel limiting applies to the Handover Group, and Authorized SGSNs and GGSNs.

Tunnel Timeout	Enter the maximum number of seconds that a GTP tunnel is allowed to remain active. After the timeout the unit deletes GTP tunnels that have stopped processing data. A GTP tunnel may hang for various reasons. For example, during the GTP tunnel tear-down stage, the "delete pdap context response" message may get lost. By setting a timeout value, you can configure the FortiOS Carrier firewall to remove the hanging tunnels. The default is 86400 seconds, or 24 hours.
Control plane message rate limit	Enter the number of packets per second to limit the traffic rate to protect the GSNs from possible Denial of Service (DoS) attacks. The default limit of *0* does not limit the message rate. GTP DoS attacks can include: • **Border gateway bandwidth saturation**: A malicious operator can connect to your GRX and generate high traffic towards your Border Gateway to consume all the bandwidth. • **GTP flood**: A GSN can be flooded by illegitimate traffic
Handover Group	Select the allowed list of IP addresses allowed to take over a GTP session when the mobile device moves locations. Handover is a fundamental feature of GPRS/UMTS, which enables subscribers to seamlessly move from one area of coverage to another with no interruption of active sessions. Session hijacking can come from the SGSN or the GGSN, where a fraudulent GSN can intercept another GSN and redirect traffic to it. This can be exploited to hijack GTP tunnels or cause a denial of service. When the handover group is defined it acts like a whitelist with an implicit default deny at the end — the GTP address must be in the group or the GTP message will be blocked. This stops handover requests from untrusted GSNs.
Authorized SGSNs	Use *Authorized SGSNs* to only allow authorized SGSNs to send packets through the unit and to block unauthorized SGSNs. Go to *Firewall Objects* > *Address* > *Address* and add the IP addresses of the authorized SGSNs to a firewall address or address group. Then set *Authorized SGSNs* to this firewall address or address group. You can use *Authorized SGSNs* to allow packets from SGSNs that have a roaming agreement with your organization.
Authorized GGSNs	Use *Authorized GGSNs* to only allow authorized GGSNs to send packets through the unit and to block unauthorized GGSNs. Go to *Firewall Objects* > *Address* > *Address* and add the IP addresses of the authorized GGSNs to a firewall address or address group. Then set *Authorized GGSNs* to this firewall address or address group. You can use Authorized GGSNs to allow packets from SGSNs that have a roaming agreement with your organization.

Message type filtering options

On the *New GTP Profile* page, you can select to allow or deny the different types of GTP messages, which is referred to as message type filtering. You must expand the Message Type Filtering section to access the settings.

The messages types include Path Management, Tunnel Management, Location Management, Mobility Management, MBMS, and GTP-U and Charging Management messages.

For enhanced security, Fortinet best practices dictate that you set Unknown Message Action to deny. This will block all unknown GTP message types, some of which may be malicious.

To configure message type filter options, expand *Message Type Filtering* in the GTP profile.

APN filtering options

An Access Point Name (APN) is an Information Element (IE) included in the header of a GTP packet. It provides information on how to reach a network.

An APN has the following format:

```
<network_id>[.mnc<mnc_int>.mcc<mcc_int>.gprs]
```

Where:

- `<network_id>` is a network identifier or name that identifies the name of a network, for example, `example.com` or `internet`.
- `[.mnc<mnc_int>.mcc<mcc_int>.gprs]` is the optional operator identifier that uniquely identifies the operator's PLMN, for example `mnc123.mcc456.gprs`.

Combining these two examples results in a complete APN of `internet.mnc123.mcc456.gprs`.

By default, the unit permits all APNs. However, you can configure APN filtering to restrict roaming subscribers' access to external networks.

APN filtering applies only to the GTP *create pdp request* messages. The unit inspects GTP packets for both APN and selected modes. If both parameters match and APN filter entry, the unit applies the filter to the traffic.

Additionally, the unit can filter GTP packets based on the combination of an IMSI prefix and an APN. For more information, see "IMSI filtering options" on page 2341.

You cannot add an APN when creating a new profile.

APN Filtering section on the New GTP Profile page	
Enable APN Filter	Select to enable APN filtering.
Default APN Action	Select the default action for APN filtering. If you select *Allow*, all sessions are allowed except those blocked by individual APN filters. If you select *Deny*, all sessions are blocked except those allowed by individual APN filters.
Value	The APN to be filtered.

Mode		The type of mode chosen that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription:
Action		The type of action that will be taken.
Edit		Modifies the settings within the filter. When you select *Edit*, the Edit window appears, which allows you to modify the settings of the APN.
Delete		Removes the APN from the list within the table, in the APN Filtering section.
Add APN		Adds a new APN filter to the list. When you select *Add APN*, the New window appears, which allows you to configure the APN settings.
New APN page		
Value		Enter an APN to be filtered. You can include wild cards to match multiple APNs. For example, the value *internet** would match all APNs that being with *internet*.
Mode		Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
	Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
	Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
	Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network
Action		Select *Allow* or *Deny*.

IMSI filtering options

The International Mobile Station Identity (IMSI) is used by a GPRS Support Node (GSN) to identify a mobile station. Three elements make up every IMSI:

- the mobile country code (MCC)
- the mobile network code (MNC)
- the mobile subscriber identification number (MSIN).

The subscriber's home network—the public land mobile network (PLMN)—is identified by the IMSI prefix, formed by combining the MCC and MNC.

By default, the unit allows all IMSIs. You can add IMSI prefixes to deny GTP traffic coming from non-roaming partners. Any GTP packets with IMSI prefixes not matching the prefixes you set will be dropped. GTP *Create pdp* request messages are filtered and only IMSI prefixes matching the ones you set are permitted. Each GTP profile can have up to 1000 IMSI prefixes set.

An IMSI prefix and an APN can be used together to filter GTP packets if you set an IMSI filter entry with a non-empty APN.

You cannot add an IMSI when creating a new profile. You must add it after the profile has been created and you are editing the profile.

IMSI Filtering section of the New GTP Profile page		
Enable IMSI Filter		Select to enable IMSI filtering.
Default IMSI Action		Select the default action for IMSI filtering. If you select *Allow*, all sessions are allowed except those blocked by individual IMSI filters. If you select *Deny*, all sessions are blocked except those allowed by individual IMSI filters.
APN		The APN that is part of the IMSI that will be filtered.
MCC-MNC		The MCC-MNC part of the IMSI that will be filtered.
Mode		The type of mode that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Action		The type of action that will be taken.
Edit		Modifies settings to an IMSI filter. When you select *Edit*, the Edit window appears, which allows you to modify the IMSI filter's settings.
Delete		Removes an IMSI filter from within the table, in the IMSI Filtering section.
Add IMSI		Adds a new IMSI filter to the list. When you select *Add IMSI*, the New window appears, which allows you to configure IMSI filter settings.
New IMSI page		
APN		Enter the APN part of the IMSI to be filtered.
MCC-MNC		Enter the MCC-MCC part of the IMSI to be filtered.
Mode		Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
	Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
	Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
	Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network
Action		Select *Allow* or *Deny*.

Advanced filtering options

The FortiOS Carrier firewall supports advanced filtering against the attributes RAT, RAI, ULI, APN restriction, and IMEI-SV in GTP to block specific harmful GPRS traffic and GPRS roaming traffic. The following table shows some of the GTP context requests and responses that the firewall supports.

Table 125: Attributes supported by FortiCarrier firewalls

	GTP Create PDP Context Request	GTP Create PDP Context Response	GTP Update PDP Context Request	GTP Update PDP Context Response
APN	yes	yes	-	
APN Restriction	yes	-	-	yes
IMEI-SV	yes	-	-	-
IMSI	yes	-	yes	-
RAI	yes	-	yes	-
RAT	yes	-	yes	-
ULI	yes	-	yes	-

When editing a GTP profile, select *Advanced Filtering* > *Add* to create and add a rule. When the rule matches traffic it will either allow or deny that traffic as selected in the rule.

Advanced Filtering section on New GTP Profile page	
Enable	Select to enable advanced filtering.
Default Action	Select the default action for advanced filtering. If you select *Allow*, all sessions are allowed except those blocked by individual advanced filters. If you select *Deny*, all sessions are blocked except those allowed by individual advanced filters.
Messages	The messages, for example, Create PDP Context Request.
APN Restriction	The APN restriction.
RAT Type	The RAT types associated with that filter.
ULI	The ULI pattern.
RAI	The RAI pattern.
IMEI	The IMEI pattern.
Action	The action that will be taken.
Edit	Modifies the filter's settings. When you select *Edit*, the Edit window appears, which allows you to modify the filter's settings.
Delete	Removes a filter from the list.
Add	Adds a filter to the list. When you select *Add*, the New window appears, which allows you to configure settings for messages, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI patterns as well as the type of action.
New Filtering page	

Messages	The PDP content messages this profile will match.
Create PDP Context Request	Select to allow create PDP context requests.
Create PDP Context Response	Select to allow create PDP context responses.
Update PDP Context Request	Select to allow update PDP context requests.
Update PDP Context Response	Select to allow update PDP context responses.
APN	Enter the APN.
APN Mode	Select an APN mode as one or more of • Mobile Station provided • Network provided • Subscription provided This field is only available when an APN has been entered.
Mobile Station provided	MS-provided PAN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did no verify the user's subscription to the network.
Subscription verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
APN Restriction	Select the type of restriction that you want. You can choose all of the types, or one of the types. You cannot choose multiple types. Types include: • all • Public-1 • Public-2 • Private-1 • Private-2
IMSI	Enter the IMSI.
MSISDN	Enter the MSISDN.

RAT Type	Optionally select the RAT type as any combination of the following: • Any • UTRAN • GERAN • Wifi • GAN • HSPA Some RAT types are GTPv1 specific.
ULI pattern	Enter the ULI pattern.
RAI pattern	Enter the RAI pattern.
IMEI pattern	Enter the IMEI pattern.
Action	Select either *Allow* or *Deny*.

Adding an advanced filtering rule

When adding a rule, use the following formats:

- Prefix, for example, range 31* for MCC matches MCC from 310 to 319.
- Range, for example, range 310-319 for MCC matches MCC from 310 to 319.
- Mobile Country Code (MCC) consists of three digits. The MCC identifies the country of domicile of the mobile subscriber.
- Mobile Network Code (MNC) consists of two or three digits for GSM/UMTS applications. The MNC identifies the home PLMN of the mobile subscriber. The length of the MNC (two or three digits) depends on the value of the MCC. Best practices dictate not to mix two and three digit MNC codes within a single MCC area.
- Location Area Code (LAC) is a fixed length code (of 2 octets) identifying a location area within a PLMN. This part of the location area identification can be coded using a full hexadecimal representation except for the following reserved hexadecimal values: 0000 and FFFE. These reserved values are used in some special cases when no valid LAI exists in the MS (see 3GPP TS 24.008, 3GPP TS 31.102 and 3GPP TS 51.011).
- Routing Area Code (RAC) of a fixed length code (of 1 octet) identifies a routing area within a location.
- CI or SAC of a fixed length of 2 octets can be coded using a full hexadecimal expression.
- Type Allocation Code (TAC) has a length of 8 digits.
- Serial Number (SNR) is an individual serial number identifying each equipment within each TAC. SNR has a length of 6 digits.
- Software Version Number (SVN) identifies the software version number of the mobile equipment. SVN has a length of 2 digits.

You cannot add an advanced filtering rule when creating a new profile. You must add it after the profile has been created and you are editing the profile.

Information element removal policy options

In some roaming scenarios, the unit is installed on the border of the PLMN and the GRX. In this configuration, the unit supports information element (IE) removal policies to remove any combination of R6 IEs (RAT, RAI, ULI, IMEI-SV and APN restrictions) from the types of messages described in "Advanced filtering options" on page 2343, prior to forwarding the messages to the HGGSN (proxy mode).

IE removal policy section of the New GTP Profile page	
Enable	Select to enable this option.
SGSN address of message IE	The firewall address or address group that contains the SGSN addresses.
IEs to be removed	The IE types that will be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.
Add	Adds an IE removal policy. When you select *Add*, the New window appears, which allows you to configure the IE policy.
Edit	Modifies settings from within the IE removal policy. When you select *Edit*, the Edit window appears, which allows you to modify the settings within the policy.
Delete	Removes the IE removal policy from the list.
New IE policy page	
SGSN address	Select a firewall address or address group that contains SGSN addresses.
IEs to be removed	Select one or more IE types to be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.

Encapsulated IP traffic filtering options

You can use encapsulated IP traffic filtering to filter GTP sessions based on information contained in the data stream. to control data flows within your infrastructure. You can configure IP filtering rules to filter encapsulated IP traffic from mobile stations by identifying the source and destination policies. For more information, see "When to use encapsulated IP traffic filtering (best practices)" on page 2403.

Expand *Encapsulated IP Traffic Filtering* in the GTP profile to reveal the options.

Encapsulated IP Traffic Filtering section of the New GTP Profile page	
Enable IP Filter	Select to enable encapsulated IP traffic filtering options.
Default IP Action	Select the default action for encapsulated IP traffic filtering. If you select *Allow*, all sessions are allowed except those blocked by individual encapsulated IP traffic filters. If you select *Deny*, all sessions are blocked except those allowed by individual encapsulated IP traffic filters.
Source	Select a source IP address from the configured firewall IP address or address group lists. Any encapsulated traffic originating from this IP address will be a match if the destination also matches.

Destination	Select a destination IP address from the configured firewall IP address or address group lists. Any encapsulated traffic being sent to this IP address will be a match if the destination also matches.
Action	The type of action that will be taken. Select to Allow or Deny encapsulated traffic between this source and Destination.
Edit	Modifies the source, destination or action settings.
Add IP Policy	Adds a new encapsulated IP traffic filter. When you select *Add IP Policy*, the New window appears which allows you to configure IP policy settings.
New (window)	
Source	Select the source firewall address or address group.
Destination	Select the destination firewall address or address group.
Action	Select *Allow* or *Deny*.

Encapsulated non-IP end user traffic filtering options

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications list only PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the “Assigned PPP DLL Protocol Numbers” sections of RFC1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

Encapsulated Non-IP End User Address Filtering section of the New GTP Profile page	
Enable Non-IP Filter	Select to enable encapsulated non-IP traffic filtering.
Default Non-IP Action	Select the default action for encapsulated non-IP traffic filtering. If you select *Allow*, all sessions are allowed except those blocked by individual encapsulated non-IP traffic filters. If you select *Deny*, all sessions are blocked except those allowed by individual encapsulated non-IP traffic filters.
Type	The type chosen, *AESTI* or *IETF.*
Start Protocol	The beginning protocol port number range.
End Protocol	The end of the protocol port number range.
Action	The type of action that will be taken.
Edit	Modify a non-IP filter's settings in the list. When you select *Edit*, the Edit window appears, which allows you to modify the Non-IP policy settings.
Delete	Remove a non-IP policy from the list.

Add Non-IP Policy	Add a new encapsulated non-IP traffic filter. When you select *Add Non-IP Policy*, you are automatically redirected to the New page.
New (window)	
Type	Select *AESTI* or *IETF*.
Start Protocol **End Protocol**	Select a start and end protocol from the list of protocols in RFC 1700. Allowed range includes 0 to 255 (0x00 to 0xff). Some common protocols include: • 33 (0x0021) Internet Protocol • 35 (0x0023) OSI Network Layer • 63 (0x003f) NETBIOS Framing • 65 (0x0041) Cisco Systems • 79 (0x004f) IP6 Header Compression • 83 (0x0053) Encryption
Action	Select *Allow* or *Deny*.

Protocol anomaly prevention options

Use protocol anomaly detection options to detect or deny protocol anomalies according to GTP standards and tunnel state. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of the protocol specifications. Packets cannot pass through if they fail the sanity check.

Protocol Anomaly section of the New GTP Profile page	
Invalid Reserved Field	GTP version 0 (GSM 09.60) headers specify a number of fields that are marked as ''Spare" and contain all ones (1). GTP packets that have different values in these fields are flagged as anomalies. GTP version 1 (GSM 29.060) makes better use of the header space and only has one, 1-bit, reserved field. In the first octet of the GTP version1 header, bit 4 is set to zero.
Reserved IE	Both versions of GTP allow up to 255 different Information Elements (IE). However, a number of Information Elements values are undefined or reserved. Packets with reserved or undefined values will be filtered.
Miss Mandatory IE	GTP packets with missing mandatory Information Elements (IE) will not be passed to the GGSN.
Out of State Message	The GTP protocol requires a certain level of state to be kept by both the GGSN and SGSN. Some message types can only be sent when in a specific GTP state. Packets that do not make sense in the current state are filtered or rejected Both versions of GTP allow up to 255 different message types. However, a number of message type values are undefined or reserved. Best practices dictate that packets with reserved or undefined values will be filtered.

Out of State IE	GTP Packets with out of order Information Elements are discarded.
Spoofed Source Address	The End User Address Information Element in the PDP Context Create & Response messages contain the address that the mobile station (MS) will use on the remote network. If the MS does not have an address, the SGSN will set the End User Address field to zero when sending the initial PDP Context Create message. The PDP Context Response packet from the GGSN will then contain an address to be assigned to the MS. In environments where static addresses are allowed, the MS will relay its address to the SGSN, which will include the address in the PDP Context Create Message. As the MS address is negotiated within the PDP Context creation handshake, any packets originating from the MS that contain a different source address are detected and dropped.

Anti-overbilling options

You can configure the FortiOS Carrier firewall to prevent overbilling subscribers for traffic over the. To enable anti-overbilling, you must configure both the Gn/Gp firewall and the Gi firewall.

Expand *Anti-Overbilling* in the GTP profile to reveal these settings.

Anti-Overbilling section of the New GTP Profile page	
Gi Firewall IP Address	The IP address of the unit's interface configured as a Gi gateway.
Port	The SG security port number. The default port number is port 21123. Change this number if your system uses a different SG port.
Interface	Select the unit interface configured as a Gi gateway.
Security Context ID	Enter the security context ID. This ID must match the ID entered on the server Gi firewall. The default security context ID is 696.

Log options

All the GTP logs are treated as a subtype of the event logs. To enable GTP logging, you must:

- configure the GTP log settings in a GTP profile
- enable GTP logging when you configure log and report settings.

To enable GTP logging after a GTP profile has been configured

1. Go to *Log & Report* > *Log Config* > *Log Setting*.
2. Select *Event Logging*, and select *GTP service event*.

3 Select *Apply*.

Log section of the New GTP Profile page	
Log Frequency	Enter the number of messages to drop between logged messages. An overflow of log messages can sometimes occur when logging rate-limited GTP packets exceed their defined threshold. To conserve resources on the syslog server and the FortiOS Carrier unit, you can specify that some log messages are dropped. For example, if you want only every twentieth message to be logged, set a logging frequency of 20. This way, 20 messages are skipped and the next logged. Acceptable frequency values range from 0 to 2147483674. When set to '0', no messages are skipped.
Forwarded Log	Select to log forwarded GTP packets.
Denied Log	Select to log GTP packets denied or blocked by this GTP profile.
Rate Limited Log	Select to log rate-limited GTP packets.
State Invalid Log	Select to log GTP packets that have failed stateful inspection.
Tunnel Limit Log	Select to log packets dropped because the maximum limit of GTP tunnels for the destination GSN is reached.

Extension Log	Select to log extended information about GTP packets. When enabled, this additional information will be included in log entries: • IMSI • MSISDN • APN • Selection Mode • SGSN address for signaling • SGSN address for user data • GGSN address for signaling • GGSN address for user data
Traffic count Log	Select to log the total number of control and user data messages received from and forwarded to the GGSNs and SGSNs that the unit protects. The unit can report the total number of user data and control messages received from and forwarded to the GGSNs and SGSNs it protects. Alternately, the total size of the user data and control messages can be reported in bytes. The unit differentiates between traffic carried by each GTP tunnel, and also between GTP-User and GTP-Control messages. The number of messages or the number of bytes of data received from and forwarded to the SGSN or GGSN are totaled and logged if a tunnel is deleted. When a tunnel is deleted, the log entry contains: • Timestamp • Interface name (if applicable) • SGSN IP address • GGSN IP address • TID • Tunnel duration time in seconds • Number of messages sent to the SGSN • Number of messages sent to the GGSN

Specifying logging types

You can configure the unit to log GTP packets based on their status with GTP traffic logging.

The status of a GTP packet can be any of the following 5 states:

- **Forwarded** - a packet that the unit transmits because the GTP policy allows it
- **Prohibited** - a packet that the unit drops because the GTP policy denies it
- **Rate-limited** - a packet that the unit drops because it exceeds the maximum rate limit of the destination GSN
- **State-invalid** - a packet that the unit drops because it failed stateful inspection
- **Tunnel-limited** - a packet that the unit drops because the maximum limit of GTP tunnels for the destination GSN is reached.

The following information is contained in each log entry:

- Timestamp
- Source IP address
- Destination IP address
- Tunnel Identifier (TID) or Tunnel Endpoint Identifier (TEID)
- Message type
- Packet status: forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited
- Virtual domain ID or name
- Reason to be denied if applicable.

MMS UTM features

FortiOS Carrier includes all the UTM features of FortiOS with extra features specific to MMS carrier networks.

This section includes:

Why scan MMS messages for viruses and malware?

The requirement for scanning MM1 content comes from the fact that MMS is an increasingly popular technique for propagating malware between mobile devices. See “MMS virus scanning” on page 2354.

Example: COMMWARRIOR

This is a virus for Series 60 type cell phones, such as Nokia, operating Symbian OS version 6 [or higher]. The object of the virus is to spread to other phones using Bluetooth and MMS as transport avenues. The targets are selected from the contact list of the infected phone and also sought via Bluetooth searching for other Bluetooth-enabled devices (phones, printers, gaming devices etc.) in the proximity of the infected phone.

This virus is more than a proof of concept - it has proven successfully its ability to migrate from a zoo collection to being in-the-wild. Currently, this virus is being reported in over 18 different countries around Europe, Asia and North America.

When the virus first infects a cell phone, a prompt is displayed asking the recipient if they want to install “Caribe”. Symptoms of an infected phone may include rapid battery power loss due to constant efforts by the virus to spread to other phones via a Bluetooth seek-and-connect outreach.

The following variants among others are currently scanned by the FortiOS Carrier devices, in addition to more signatures that cover all known threats.

- **SymbOS/COMWAR.V10B!WORM**

  Aliases: SymbOS.Commwarrior.B, SymbOS/Commwar.B, SymbOS/Commwar.B!wm, SymbOS/Commwar.B-net, SymbOS/Commwarrior.b!sis, SymbOS/Comwar.B, SymbOS/Comwar.B!wm, SymbOS/Comwar.B-wm, SYMBOS_COMWAR.B, SymbOS/Comwar.1.0.B!wormSYMBOS/COMWAR.V10B.SP!WORM [spanish version]

  First Discovered In The Wild: July 04, 2007

  Impact Level: 1

  Virus Class: Worm

  Virus Name Size: 23,320

- **SymbOS/Commwar.A!worm**

  Aliases: Commwarrior-A, SymbOS.Commwarrior.A [NAV], SymbOS/Commwar.A-net, SymbOS/Commwar_ezboot.A-ne, SymbOS/Comwar.A, SymbOS/Comwar.A-wm, SYMBOS_COMWAR.A [Trend]

  First Discovered In The Wild: May 16 2005

  Impact Level: 1

  Virus Class: Worm

  Virus Name Size: 27,936

- **SymbOS/Commwarriie.C-wm**

  Aliases: None

  First Discovered In The Wild: Oct 17 2005

  Impact Level: 1

  Virus Class: File Virus

  Virus Name Size: None

For the latest list of threats Fortinet devices detect, go to the FortiGuard Center Resource Library's Mobile index.

MMS virus scanning

You can use MMS virus scanning to scan content contained within MMS messages for viruses. FortiOS Carrier virus scanning can be applied to the MM1, MM3, MM4, and MM7 interfaces to detect and remove content containing viruses at many points in an MMS network. Perhaps the most useful interface to apply virus scanning would be the MM1 interface to block viruses sent by mobile users before they get into the service provider network.

To go to MMS virus scanning, go to *UTM Profiles* > *Carrier* > *MMS Profile*, select an existing or create a new profile, and expand *MMS Scanning*. See "MMS scanning options" on page 2317.

This section includes:

- MMS virus monitoring
- MMS virus scanning blocks messages (not just attachments)
- Scanning MM1 retrieval messages
- Configuring MMS file filtering
- Removing or replacing blocked messages
- Carrier Endpoint Block
- MMS Content Checksum
- Passing or blocking fragmented messages
- Client comforting
- Server comforting
- Handling oversized MMS messages

MMS virus monitoring

To enable MMS virus monitoring, expand *MMS Scanning* and enable *Monitor only* for the selected MMS types.

This feature causes the FortiOS Carrier unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Selecting this option enables reporting on viruses and other problems in MMS traffic without affecting users.

MMS virus scanning blocks messages (not just attachments)

To enable MMS virus scanning, expand *MMS Scanning* and enable *Virus Scan* for the selected MMS types.

Because MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configurations also apply to MM1 and MM7 scanning. See

MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configurations also apply to MM3 and MM4 scanning.

The message contents will be scanned for viruses, matched against the file extension blocking lists and scanned for banned words. All these items will be configured via the standard GUI interfaces available for the other protocols and will be controlled at the protection profile level with new options specifically for the MM1 messages.

The FortiOS Carrier unit extracts the sender's Mobile Subscriber Integrated Services Digital Network Number (MSISDN) from the HTTP headers if available. The `POST` payload will be sent to the scanunits which will parse the MMS content and scan each message data section. If any part of the data is to be blocked, the proxy will be informed, the connection to the MMSC will be reset and the FortiOS Carrier unit will return an `HTTP 200 OK` message with an `m-send-conf` payload to the client to prevent a retry. Finally the appropriate logging, alert, and replacement message events will be triggered.

For client notification, the `x-mms-response-status` and `x-mms-response-text` fields can also be customized as required.

Scanning MM1 retrieval messages

To scan MM1 retrieval messages, expand *MMS Scanning* and select *Scan MM1 message retrieval*.

Select to scan message retrievals that use MM1. If you enable *Virus Scan* for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.

Configuring MMS file filtering

To configure MMS file filtering, expand *MMS Scanning* and select *File Filter* for the selected MMS types.

When enabling file filtering there are two options available—builtin_patterns, and all_executables. Filtering built-in patterns allows you to leverage the FortiOS UTM file patterns, providing a much broader level of file protection. all_executables will filter any files that can be executed such as .exe and .sis files.

Removing or replacing blocked messages

To remove blocked messages, expand *MMS Scanning* and select *Remove Blocked* for the selected MMS types.

Select *Remove Blocked* remove blocked content from each protocol and replace it with the replacement message. If FortiOS Carrier is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message, select *Constant*.

If you only want to monitor blocked content, select *Monitor Only*.

Carrier Endpoint Block

A carrier endpoint defines a specific client on the carrier network. Typically the client IP address is used to identify the client, however on a carrier network this may be impractical when the client is using a mobile device. Other identifying information such as the MSIDSN number is used instead.

This information can be used to block a specific endpoint on the network. Reasons for blocking may include clients whose accounts have expired, clients from another carrier, clients who have sent malicious content (phishing, exploits, viruses, etc), or other violations of terms of use.

Enabling carrier endpoint blocking

To enable carrier endpoint blocking you first need to create a carrier endpoint filter list, and then enable it.

To enable carrier end point blocking - web-based manager

1. Create a carrier endpoint filter list. See
2. Go to *UTM Profiles* > *Carrier* > *MMS Profile*.
3. Select *Create New*, or select an existing profile to edit and select *Edit*.
4. Expand MMS Scanning.
5. Select one or more types of MMS messaging to enable end point blocking on.
6. Select the carrier endpoint filter list to use in matching the end points to be blocked.

In MMS Profile, endpoints can only be blocked.

Create a carrier endpoint filter list

A carrier endpoint filter list contains one or more carrier endpoints to match. When used in MMS scanning entries in the filter list that are matched are blocked.

You can configure multiple filter lists for different purposes and groups of clients, such as blocking clients, clients with different levels of service agreements, and clients from other carriers. See “Carrier endpoint filter lists configuration settings” on page 2334.

To create a carrier endpoint filter list - web-based manager

1. Go to *UTM Profiles* > *Carrier* > *Carrier Endpoint Filter Lists*.
2. Select *Create New*.
3. Enter a descriptive name for the filter list, such as `blocked_clients` or `CountryX_clients`, and select OK.
4. Select *Create New* to add one or more entries to the list.
5. Select OK to return to display the list of filter lists.

Configuring end point filter list entries

For each single end point or group of end points have part of their identifying information in common, you create an entry in the end point filter list.

For example a `blocked_clients` filter list may include entries for single end points added as each one needs to be blocked and a group of clients from a country that does not allow certain services.

To configure an end point filter list entry - web-based manager

1 Select *Create New*.

2 Enter the following information and select OK.

Name	Name of end point filter list. Select this name in an MMS protection profile.
Comments	Optional description of the end point filter list.
Check/Uncheck All	Select the check box to enable all end point patterns in the MMS filter list. Clear the check box to disable all entries on the MMS filter list. You can also select or clear individual check boxes to enable or disable individual end point patterns.
Pattern	The pattern that FortiOS Carrier uses to match with end points. The pattern can be a single end point or consist of wildcards or Perl regular expressions that will match more than one end point. For more on wildcard and regular expressions, see *Using wildcards and Perl regular expressions* in the *UTM* handbook chapter.
Action	Select the action taken by FortiOS Carrier for messages from a carrier end point that matches the end point pattern: **None -** No action is taken. **Block -** MMS messages from the end point are not delivered and FortiOS Carrier records a log message. **Exempt from mass MMS -** MMS messages from the end point are delivered and are exempt from mass MMS filtering. Mass MMS filtering is configured in MMS protection profiles and is also called MMS Bulk Email Filtering and includes MMS message flood protection and MMS duplicate message detection. A valid use of mass MMS would be when a service provider notifies customers of a system-wide event such as a shutdown. **Exempt from all scanning -** MMS messages from the end point are delivered and are exempt from all MMS protection profile scanning. MMS messages are not subject to protection profile filtering, just MMS protection profile filtering.
Content Archive	MMS messages from the end point are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
Intercept	MMS messages from the end point are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
Pattern Type	The pattern type: *Wildcard*, *Regular Expression*, or *Single end point*.
Enable	Select to enable this end point filter pattern.

Blocking network access based on end points

You can use end point IP filtering to block traffic from source IP addresses associated with end points. You can also configure FortiOS Carrier to record log messages whenever end point IP filtering blocks traffic. End point IP filtering blocks traffic at the IP level, before the traffic is accepted by a security policy.

To configure end point IP filtering, go to *UTM Profiles* > *Carrier* > *IP Filter* and add end points to the IP filter list. For each end point you can enable or disable both blocking traffic and logging blocked traffic.

You cannot add end point patterns to the end point IP filter list. You must enter complete and specific end points that are valid for your network.

The only action available is block. You cannot use end point IP filtering to exempt end points from IP filtering or to content archive or quarantine communication sessions.

FortiOS Carrier looks in the current user context list for the end points in the IP filter list and extracts the source IP addresses for these end points. Then any communication session with a source IP address that matches one of these IP addresses is blocked at the IP level, before the communication session is accepted by a security policy.

FortiOS Carrier dynamically updates the list of IP addresses to block as the user context list changes. Only these updated IP addresses are blocked by end point IP filtering.

For information about the carrier end points and the user context list, including how entries are added to and removed from this list, see For more information on carrier end points, see the FortiOS Handbook User Authentication chapter.

MMS Content Checksum

The MMS content checksum feature attempts to match checksums of known malicious MMS messages, and on a successful match it will be blocked. The checksums are applied to each part of the message—attached files and message body have separate checksums. These checksums are created with CRC-32, the same method as FortiAnalyzer checksums.

For example, if an MMS message contains a browser exploit in the message body, you can add the checksum for that message body to the list, and future occurrences of that exact message will be blocked. Content will be replaced by the content checksum block notification replacement message for that type of MMS message, and if it is enabled the event will be logged.

One possible implementation would to configure all .sis files to be intercepted. When one is found to be infected or malicious it would be added to the MMS content checksum list.

To use this feature a list of one or more malicious checksums must be created and then the feature is enabled using that list. For a detailed list of options, see “MMS Content Checksum” on page 2328.

To configure an MMS content checksum list

1. Go to *UTM Profiles* > *Carrier* > *MMS Content Checksum*.
2. Select *Create New*.
3. Enter a name for the list of checksums, and select OK.

   You are taken to the edit screen for that new list.

4 Select *Create New* to add a checksum.

5 Enter the *Name* and *Checksum*, and select OK.

The checksum is added to the list.

To add more checksums to the list, repeat steps 4 and 5.

To to remove a checksum from the list you can either delete the checksum or simply disable it and leave it in the list.

To enable MMS content checksums, expand *MMS Scanning* and select *MMS Content Checksum* for the selected MMS types. Select the checksum list to match.

Passing or blocking fragmented messages

Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.

The Interval is the time in seconds before client comforting starts after the download has begun, and the time between sending subsequent data.

The *Amount* is the number of bytes sent by client or server comforting at each interval.

Client comforting

In general, client comforting is available for for MM1 and MM7 messaging and provides a visual display of progress for web page loading or HTTP or FTP file downloads. Client comforting does this by sending the first few packets of the file or web page being downloaded to the client at configured time intervals so that the client is not aware that the download has been delayed. The client is the web browser or FTP client. Without client comforting, clients and their users have no indication that the download has started until the FortiOS Carrier unit has completely buffered and scanned the download. During this delay users may cancel or repeatedly retry the transfer, thinking it has failed.

The appearance of a client comforting message (for example, a progress bar) is client-dependent. In some instances, there will be no visual client comforting cue.

During client comforting, if the file being downloaded is found to be infected, then the FortiOS Carrier unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead the download stops, and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, then the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned (and therefore potentially infected) content to the client. Only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

MM1 and MM7 client comforting steps

Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.

The following steps show how client comforting works for a download of a 1 Mbyte file with the client comforting interval set to 20 seconds and the client comforting amount set to 512 bytes.

1 The client requests the file.

2 The FortiOS Carrier unit buffers the file from the server. The connection is slow, so after 20 seconds about one half of the file has been buffered.

3 The FortiOS Carrier unit continues buffering the file from the server, and also sends 512 bytes to the client.

4 After 20 more seconds, the FortiGate unit sends the next 512 bytes of the buffered file to the client.

5 When the file has been completely buffered, the client has received the following amount of data:

```
ca * (T/ci) bytes == 512 * (40/20) == 512 * 2 == 1024 bytes,
```

where `ca` is the client comforting amount, `T` is the buffering time and `ci` is the client comforting interval.

6 If the file does not contain a virus, the FortiOS Carrier unit sends the rest of the file to the client. If the file is infected, the FortiOS Carrier unit closes the data connection but cannot send a message to the client.

Server comforting

Server comforting can be selected for each protocol.

Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for FortiOS Carrier to buffer and scan large `POST` requests from slow clients.

The *Interval* is the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.

The *Amount* is the number of bytes sent by client or server comforting at each interval.

Handling oversized MMS messages

Select *Block* or *Pass* for files and email messages exceeding configured thresholds for each protocol.

The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.

Configuring MMS virus scanning

To apply MMS virus scanning you must configure MMS virus scanning in the MMS protection profile, and add the MMS protection profile to a security policy.

The MMS protection profile then applies to the traffic accepted by the security policy.

To apply MMS virus scanning - web-based manager

1. Go to *UTM Profiles* > *Carrier* > *MMS Profile*.
2. Select *Create New* to add an MMS protection profile called `MMS_virus_scan`.
3. Configure antivirus settings and save the new MMS protection profile.
4. Go to *Policy*.
5. Select *Create New* to add a security policy, or select *Edit* for the policy to which you want to add the protection profile.
6. Configure the security policy as required.
7. Select *UTM Profiles* > *MMS Profile* and select `MMS_virus_scan`.
8. Select *OK*.

Replacement messages

FortiOS Carrier generates replacement messages to notify the sending client that they have sent a virus.

FortiOS Carrier can generate an SMS/SMTP replacement message and an MMS/HTTP POST replacement message. In each case the recipient will be the sender of the initial virus message and a configurable MSISDN parameter will be available to determine the sender (From) – i.e. the FortiOS Carrier unit.

For SMS/SMTP notification a destination email address is configurable and can contain the marker `%%MSISDN%%` which will be replaced with the sender's MSISDN thereby allowing the message to be routed properly.

You need to clarify whether specific headers are required in the SMTP message and whether a predefined format for the message must to be followed. For the MMS message the body will be configurable and this could be specified in WML or SMIL.

For more information on FortiOS Carrier replacement messages, see "MMS Replacement messages" on page 2393. For more information on address translation, see For more information on carrier end points, see the FortiOS Handbook v3 User Authentication chapter.

Logging and reporting

With each virus infection, or file block, a syslog message is generated. The format of this syslog message is similar to:

```
2005-09-22 19:15:47 device_id=FGT5001ABCDEF1234
   log_id=0211060ABC type=virus subtype=infected pri=warning
   src=10.1.2.3 dst=10.2.3.4 src_int=port1 dst_int=port2
   service=mm1 status=blocked from="<sending MSISDN>"
   to="<receiving MSISDN>” file="eicar.com.txt"
   virus="EICAR_TEST_FILE" msg="The file eicar.com.txt is
   infected with EICAR_TEST_FILE. ref
   http://www.fortinet.com/VirusEncyclopedia/search/encyclopedi
   aSearch.do?method=quickSearchDirectly&virusName=EICAR_TEST_F
   ILE.
```

Note that the *from* and *to* fields are samples and not real values.

MMS logging options

You can enable logging in an MMS protection profile to write event log messages when the MMS protection profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS protection profile logging options to write an event log message every time a virus is detected.

To record these log messages you must first configure how the FortiOS Carrier unit stores log messages.

To configure MMS content archiving, go to *UTM Profiles* > *Carrier* > *MMS Profile*. Select *Create New* or select the *Edit* icon beside an existing profile. Expand *MMS Bulk AntiSpam Detection* > *Logging*. Complete the fields as described in the following table and select *OK*. For more a detailed list of options, see “Logging” on page 2327.

SNMP

A simple SNMP trap will be generated to inform the operators alerting system that a virus has been detected. This SNMP trap could contain the sending and receiving MSISDN however the initial solution would reflect the current behavior, i.e. only the fact that a virus has been detected will be communicated.

MMS file filtering

Use MMS file filtering to apply antivirus file filtering to MMS traffic. Select a file filter list to apply. To configure MMS file filtering, go to *UTM Profiles* > *Carrier* > *MMS Profile*, select an existing or create a new profile, and expand *MMS Scanning*.

Configure the FortiGate file filter to block files by:

- ***File pattern***: Files can be blocked by name, extension, or any other pattern. File pattern blocking provides the flexibility to block potentially harmful content.

  File pattern entries are not case sensitive. For example, adding `*.exe` to the file pattern list also blocks any files ending in `.EXE`.

  In addition to the built-in patterns, you can specify more file patterns to block.
- **File type**: Files can be blocked by type, without relying on the file name to indicate what type of files they are. When blocking by file type, the FortiGate unit analyzes the file and determines the file type regardless of the file name.

For standard operation, you can choose to disable file filter in the protection profile, and enable it temporarily to block specific threats as they occur.

The FortiGate unit can take either of these actions toward files that match a configured file pattern or type:

- **Allow**: the file is allowed to pass.

- **Block**: the file is blocked and a replacement messages will be sent to the user. If both file filter and virus scan are enabled, the FortiOS Carrier unit blocks files that match the enabled file filter and does not scan these files for viruses.
- **Intercept**: the file will be archived to the local hard disk or the FortiAnalyzer unit.

The FortiOS Carrier unit also writes a message to the virus log and sends an alert email message if configured to do so.

Files are compared to the enabled file patterns and then the file types from top to bottom. If a file does not match any specified patterns or types, it is passed along to antivirus scanning (if enabled). In effect, files are passed if not explicitly blocked.

Using the allow action, this behavior can be reversed with all files being blocked unless explicitly passed. Simply enter all the file patterns or types to be passed with the allow attribute. At the end of the list, add an all-inclusive wildcard (*.*) with a block action. Allowed files continue to antivirus scanning (if enabled) while files not matching any allowed patterns are blocked by the wildcard at the end.

Built-in patterns and supported file types

The FortiGate unit is preconfigured with a default list of file patterns:

- executable files (*.bat, *.com, and *.exe)
- compressed or archive files (*.gz, *.rar, *.tar, *.tgz, and *.zip)
- dynamic link libraries (*.dll)
- HTML application (*.hta)
- Microsoft Office files (*.doc, *.ppt, *.xl?)
- Microsoft Works files (*.wps)
- Visual Basic files (*.vb?)
- screen saver files (*.scr)
- program information files (*.pif)
- control panel files (*.cpl)

The FortiGate unit can take actions against the following file types:

Table 126: Supported file types

arj	activemime	aspack	base64	bat	binhex	bzip	bzip2
cab	class	cod	elf	exe	fsg	gzip	hlp
hta	html	jad	javascript	lzh	mime	msc	msoffice
petite	prc	rar	sis	tar	upx	uue	zip
unknown	ignored						

The “unknown” type is any file type that is not listed in the table. The “ignored” type is the traffic the FortiGate unit typically does not scan. This includes primarily streaming audio and video.

Filtering based on file name

There are filenames that are known to be associated with malware such as viruses and trojans. There are filenames you may associate with other undesirable content in addition to malware. In these situations you want to select specific filenames to filter.

You do not have to match the entire filename. For example if you wanted to block all files with the word `trojan` in them you could use wildcards to accomplish this - `*trojan*` . This allows you to select the entire filename, part of the filename, or just the file type to match.

The following procedure creates a filter list called `filterExampleFiles` that filters two files called `exampleTrojanFile.abc` and `*trojan*.def` . When completed, this file filter list can be included in an MMS profile.

To create a file filter based on file name - web-based manager

1 Go to *UTM Profiles* > *AntiVirus* > *File Filtering*.
2 Select *Create New*, to create a new file filtering list.
3 Name the list `filterExampleFiles`.
4 Select *Create New* to add a filter to the list.
5 Select File Name Pattern for Filter Type.
6 Enter `exampleTrojanFile.abc` .
7 Enter Block for the *Action*.
8 Select *Enable*, and *OK*.
9 Select *Create New* to add a filter to the list.
10 Select File Name Pattern for Filter Type.
11 Enter `*trojan*.def` .
12 Enter Block for the *Action*.
13 Select *Enable*, and *OK*.

Filtering based on file type

When filtering files, it is often useful to filter based on the file type. When malware finds a file type that allows them access to a system, the filename will change but the file type will remain the same. Even for preventing applications that are not malware but simply undesirable, filtering based on file type is often the easiest method.

Simply matching the file type, .zip for example, may not be as accurate a method as using the built-in patterns. If users see that .zip attachments are blocked, they may simply rename the file so the filters will allow it through. Checking against patterns can help prevent this bypassing.

There are two possible methods available to filter based on file type. If the file type is one of the built-in patterns, you can use them - for example blocking PalmOS files on your network since Palm devices are not supported. Otherwise, you can simply use wildcards to match the file type.

The following example will filter all batch files (`.bat`).

To filter files based on file type using file name pattern - web-based manager

1 Go to *UTM Profiles* > *AntiVirus* > *File Filter*.
2 Select *Create New* and name the list `blockedFileTypes`.
3 Select *Create New* to add files to the list.
4 Select `File name pattern` for *Filter Type*.
5 Enter `*.bat` for *Pattern.*
6 Select an *Action* of Block.

7 Select *Enable* and *OK*.

8 At the file filter list, select *OK*.

The file filter is now available to be used in an MMS profile, and will block all `.bat` files that MMS profile matches.

To filter files based on file type using file type - web-based manager

1 Go to *UTM Profiles* > *AntiVirus* > *File Filter*.

2 Select *Create New* and name the list `blockedFileTypes`.

3 Select *Create New* to add files to the list.

4 Select `File Type` for *Filter Type*.

5 Select `Batch File (bat)` for *File Type.*

6 Select an *Action* of Block.

7 Select *Enable* and *OK*.

8 At the file filter list, select *OK*.

The file filter is now available to be used in an MMS profile, and will block all batch files (that use `.bat` file extension) that the MMS profile matches.

MMS file filtering blocks messages (not just attachments)

When MMS file filtering finds a matching file in an MMS message, the entire message is blocked. This action is more secure, and can reduce the amount of processing required for that message. For example if one MMS message includes three files, and the first one is blocked then the other files won't be scanned or attempted to be matched because the whole message is already being blocked.

Configuring MMS file filtering

To apply MMS file filtering you must begin with a file filter list. You can create your own list or use the built-in patterns list. You then must create the file filter, then add the file filter list to an MMS profile, and then add the MMS profile to a security policy. The MMS profile, and the corresponding file filter then applies to the traffic accepted by the security policy.

The following procedure creates a file filtering list called `MMS_file_filter` that is used in the MMS profile called `filtering_profile`. The filter will be applied to all MMS message types.

To apply MMS file filtering

1 Go to *UTM Profiles* > *Antivirus* > *File Filter* and create a file filter list called `MMS_file_filter`.

2 Select *Create New* to add entries to filter specific file types.

3 Select *OK*.

4 Go to *UTM Profiles* > *Carrier* > *MMS Profile* and create a new profile called `filtering_profile`.

5 Expand MMS Scanning, and select all the MMS message types.

6 Select `MMS_file_filter` from the *Option* drop down menu.

7 Set other settings as required in the MMS profile.

8 Select *OK*.

9 Go to *Policy, and select Create New.*

10 *Within the new policy select UTM Profiles > MMS Profile, and select* `filtering_profile`.

11 Configure the security policy as required.

12 Select *OK*.

Configuring sender notifications

In most cases you will notify the sender that they are causing problems on the network — either by sending malware content, flooding the network, or some other unwanted activity. The notification assumes the sender is unaware of their activity and will stop or correct it when notified.

However, senders who are notified may use this information to circumvent administration's precautions. For example if flood notification is set to 1000 messages per minute, a notified user may simply reduce their message to 990 messages per minute if this flood is intentional. For this reason, not all problems include sender notifications.

There are two methods of notifying senders:

- MMS notifications
- Replacement messages

MMS notifications

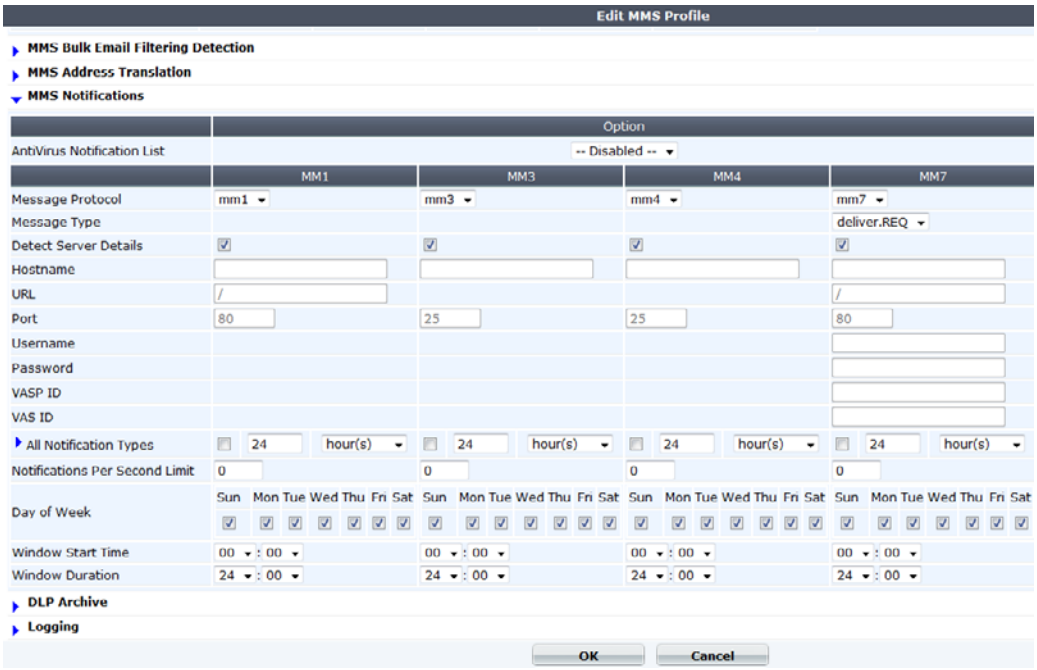
MMS notifications enable you to customize notifications for many different situations and differently for all the supported MMS message protocols — MM1, MM3, MM4, and MM7.

MMS notification types include:

- Content Filter
- File Block
- Carrier End Point Block
- Flood
- Duplicate
- MMS Content Checksum
- Virus Scan

Day of Week, *Window start time* and *Window Duration* define what days and what time of day alert notifications will be sent. This allows you to control what alerts are sent on weekends. It also lets you control when to start sending notifications each day. This can be useful if system maintenance is performed at the same time each night — you might want to start alert notifications after maintenance has completed. Another reason to limit the time alert messages are sent could be to limit message traffic to business hours.

Figure 246: Notifications screen for FortiOS Carrier MMS Profile



For MMS Notification options, see "MMS Notifications" on page 2324.

Replacement messages

FortiOS Carrier units and FortiGate units alike send replacement messages when messages or content is blocked, quarantined, or otherwise diverted from the receiver. In it's place a message is sent to notify the receiver what happened.

With FortiOS Carrier MMS replacement messages, send and receive message types are supported separately and receive their own custom replacement messages. This allows the network to potentially notify both the sender and reciever of the problem.

For example the replacement message *MM1 send-req file block message* is sent to the device that sent one or more files that were banned. The default message that is sent is `This device has sent %%NUM_MSG%% messages containing banned files in the last %%DURATION%% hours.` The two variables are replaced by the appropriate values.

Replacement messages are not as detailed or specific as MMS notifications, but they are also not as complicated to configure. They are also useful when content has been removed from an MMS message that was still delivered.

For more information on replacement messages, see "MMS Replacement messages" on page 2393.

MMS content-based Antispam protection

Expand *MMS Scanning* and select *Content Filter* in an MMS protection profile to create content filter black/white lists that block or allow MMS messages based on the content of the message.

Overview

A school computer lab may block age-inappropriate content. A place of business may block unproductive content. A public access internet cafe may block offensive and graphic content. Each installation has its own requirements for what content needs to be blocked, and in what language.

FortiOS Carrier provides the ability to create custom local dictionaries, black lists, and white lists in multiple languages enables you to protect your customers from malicious content around the world.

Content-based protection includes:

- Configurable dictionary
- Black listing
- White listing

Configurable dictionary

You can add a dictionary of configurable terms and phrases by going to *UTM Profiles* > *Web FIlter* > *Web Content FIlter*. The text of MMS messages can be searched for these terms and phrases. Add content filter lists that contain content that you want to match in MMS messages. For every match found, a score is added. If enough matches are found to set the total score above the configured threshold, the MMS message is blocked.

You can add words, phrases, wild cards and Perl regular expressions to create content patterns that match content in MMS messages. For more on wildcard and regular expressions, see *Using wildcards and Perl regular expressions* in the *UTM* handbook chapter.

For each pattern you can select *Block* or *Exempt*.

- Block adds an antispam black list pattern. A match with a block pattern blocks a message depending on the score of the pattern and the content filter threshold.
- Exempt adds an antispam white list pattern. A match with an exempt pattern allows the message to proceed through the FortiOS Carrier unit, even if other content patterns in the same content filter list would block it.

If a pattern contains a single word, the FortiOS Carrier unit searches for the word in MMS messages. If the pattern contains a phrase, the FortiOS Carrier unit searches for all of the words in the phrase. If the pattern contains a phrase in quotation marks, the FortiOS Carrier unit searches for the whole phrase.

You can create patterns with Simplified Chinese, Traditional Chinese, Cyrillic, French, Japanese, Korean, Spanish, Thai, or Western character sets.

Black listing

Black listing is the practice of banning entries on the list. For example if an IP address continuously sends viruses, it may be added to the black list. That means any computers that consult that list will not communicate with that IP address.

Sometimes computers or devices can be added to black lists for a temporary problem, such as a virus that is removed when notified. However, as a rule short of contacting the administrator in person to manually be removed form the black list, users have to wait and they generally will be removed after a period without problem.

White listing

White listing is the practice of adding all critical IP addresses to a list, such as company email and web servers. Then if those servers become infected and start sending spam or viruses, those servers are not blocked. This allows the critical traffic through, even if there might be some malicious traffic as well. Blocking all traffic from your company servers would halt company productivity.

Scores and thresholds

Each content pattern incudes a score. When a MMS message is matched with a pattern the score is recorded. If a message matches more than one pattern or matches the same pattern more than once, the score for the message increases. When the total score for a message equals or exceeds the threshold the message is blocked.

The default score for a content filter list entry is 10 and the default threshold is 10. This means that by default a message is blocked by a single match. You can change the scores and threshold so that messages can only be blocked if there are multiple matches. For example, you may only want to block messages that contain the phrase “example” if it appears twice. To do this, add the “example” pattern, set action to block and score to 5. Keep the threshold at 10. If “example” is found twice or more in a message the score adds up 10 (or more) and the message is blocked.

Configuring content-based antispam protection

To apply content-based antispam protection - web-based manager

1. Go to *UTM Profiles* > *Web Filter* > *Web Content Filter* and create or edit a web content filter list.
2. Go to *UTM Profiles* > *Carrier* > *MMS Profile* and add or edit an MMS protection profile.
3. Select *MMS Scanning* > *Content Filter* and select the web content filter list.
4. Optionally change the content filter *Threshold* and save the MMS protection profile.
5. Go to *Policy* and create or edit a policy.
6. Expand UTM heading and select MMS profile added above.
7. Select *OK*.
8. Configure the rest of the security policy as required, and select *OK*.

Configuring sender notifications

When someone on the MMS network sends an MMS message that is blocked, in most cases you will notify the sender. Typically an administrator is notified in addition to the sender so action can be taken if required.

There are two types of sender notifications available in FortiOS Carrier:

- MMS notifications
- Replacement messages

MMS notifications

MMS notifications to senders are configured in UTM Profiles > Carrier > MMS profile, under MMS Notifications.

In this section you can configure up to four different notification recipients for any combination of MM1/3/4/7 protocol MMS messages. Also for MM7 messages the message type can be `submit.REQ` or `deliver.REQ`.

Useful settings include:

- delay in message based on notification type
- limit on notifications per second to prevent a flood
- schedules for notifications
- log in details for MM7 messages.

For more information on MMS notifications, see "Notifying message flood senders and receivers" on page 2378 and "MMS Notifications" on page 2324.

Replacement messages

Replacement messages are features common to both FortiOS and FortiOS Carrier, however FortiOS Carrier has additional messages for the MMS traffic.

While each MMS protocol has its own different rec placement messages, the one common to all MMS protocols is the *MMS blocked content replacement message*. This is the message that the receiver of the message sees when their content is blocked.

For more information on replacement messages, see "MMS Replacement messages" on page 2393.

MMS DLP archiving

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management service. DLP archiving is available for FortiAnalyzer when you add a FortiAnalyzer unit to the FortiOS Carrier configuration. The FortiGuard Analysis and Management server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

You can configure full DLP archiving and summary DLP archiving. Full DLP archiving includes all content, for example, full email DLP archiving includes complete email messages and attachments. Summary DLP archiving includes just the meta data about the content, for example, email message summary records include only the email header.

You can archive MM1, MM3, MM4, and MM7 content:

Configuring MMS DLP archiving

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. For each protocol you can archive just session metadata (*Summary*), or metadata and a copy of the associated file or message (*Full*).

In addition to MMS protection profile DLP archive options you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select *DLP archiving* for carrier end point patterns in a *Carrier End Point List* and select the *Carrier End Point Block* option in the *MMS Scanning* section of an MMS Protection Profile

FortiOS Carrier only allows one sixteenth of its memory for transferring content archive files. For example, for FortiOS Carrier units with 128MB RAM, only 8MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

To configure MMS DLP archiving - web-based manager

1 Go to *UTM Profiles* > *Carrier* > *MMS Profile*.

2 Select *Create New* or select the *Edit* icon beside an existing profile.

3 Expand *MMS Bulk AntiSpam Detection* > *Content Archive*.

4 Complete the fields as described in "DLP Archive options" on page 2326.

5 Select *OK*.

Viewing DLP archives

You can view DLP archives from the FortiOS Carrier unit web-based manager. Archives are historical logs that are stored on a log device that supports archiving, such as a FortiAnalyzer unit.

These logs are accessed from either *Log&Report* > *DLP Archive* or if you subscribed to the FortiGuard Analysis and Management Service, you can view log archives from there.

The *DLP Archive* menu is only visible if one of the following is true.

- You have configured the FortiGate unit for remote logging and archiving to a FortiAnalyzer unit.
- You have subscribed to the FortiGuard Analysis and Management Service.

The following tabs are available when you are viewing DLP archives for one of these protocols.

- *E-mail* to view POP3, IMAP, SMTP, POP3S, IMAPS, SMTPS, and spam email archives.
- *Web* to view HTTP and HTTPS archives.
- *FTP* to view FTP archives.
- *IM* to view AIM, ICQ, MSN, and Yahoo! archives.
- *MMS* to view MMS archives.
- *VoIP* to view session control (SIP, SIMPLE and SCCP) archives.

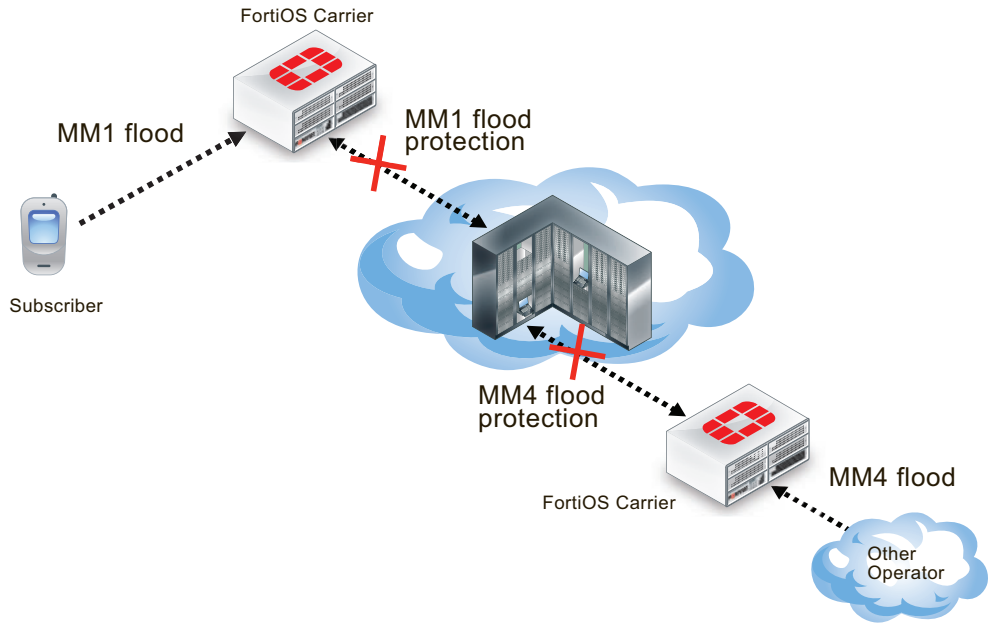
If you need to view log archives in Raw format, select *Raw* beside the *Column Settings* icon.

Message flood protection

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse.

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

Figure 247: MM1 and MM4 flood protection



The FortiOS Carrier unit keeps track of the number of messages each subscriber sends for the length of time you specify. If the number of messages a subscriber sends exceeds the threshold, a configured action is taken. Possible actions are logging the flood, blocking or intercepting messages in the flood, archiving the flood messages, and sending an alert message to inform the administrator that the flood is occurring.

You can create three different thresholds to take different levels of action at different levels of activity.

With this highly configurable system, you can prevent subscribers from sending more messages than you determine is acceptable, or monitor anyone who exceeds the thresholds.

Setting message flood thresholds

A message flood occurs when a single subscriber sends a volume of messages that exceeds the flood threshold you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected.

If a subscriber exceeds the message flood threshold and is blocked from sending more messages, any further attempts to send messages will re-start the block period. You must also enable logging for *MMS Scanning* > *Bulk Messages* in the Logging section of the MMS protection profile.

A subscriber is still able to receive messages while they are blocked from sending messages.

Example

For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all messages blocked for half an hour (30 minutes).

Using this example, if the subscriber exceeds the flood threshold, they are blocked from sending message for 30 minutes. If the subscriber tries to send any message after 15 minutes, the message will be blocked and the block period will be reset again to 30 minutes. The block period must expire with no attempts to send a message. Only then will the subscriber be allowed to send more messages.

To configure MM1 message flood threshold - web-based manager

1 Go to *UTM Profiles* > *Carrier* > *MMS Profile*.

2 Select *Create New*.

3 Enter `MM1 flood` for *Profile Name*.

4 Expand *MMS Bulk Email Filtering Detection*.

5 Enter the following information, and select *OK*.

MM1 (first column)	
Enable	Enable
Message Flood Window	60 minutes
Message Flood Limit	100
Message Flood Block Time	30 minutes
Message Flood Action	Block

To configure MM1 message flood threshold - CLI

```
config firewall mms-profile
  edit profile_name
    config flood mm1
      set status1 enable
      set window1 60
      set limit1 100
      set action1 block
```

```
        set block-time1 30
    end
end
```

The threshold values that you set for your network will depend on factors such as how busy your network is and the kinds of problems that your network and your subscribers encounter. For example, if your network is not too busy you may want to set message flood thresholds relatively high so that only an exceptional situation will exceed a flood threshold. Then you can use log messages and archived MMS messages to determine what caused the flood.

If your subscribers are experiencing problems with viruses that send excessive amounts of messages, you may want to set thresholds lower and enable blocking to catch problems as quickly as possible and block access to keep the problem from spreading.

Flood actions

When the FortiOS Carrier unit detects a message flood, it can take any combination of the five actions that you can configure for the flood threshold. For detailed options, see "Message Flood" on page 2331.

Notifying administrators of floods

You can configure alert notifications for message floods by selecting the Alert Notification message flood action.

The FortiOS Carrier unit sends alert notifications to administrators using the MM1, MM3, MM4, or MM7 content interface. To send an alert notification you must configure addresses and other settings required for the content interface.

For example, to send notifications using the MM1 content interface you must configure a source MSISDN, hostname, URL, and port to which to send the notification. You can also configure schedules for when to send the notifications.

Finally you can add multiple MSISDN numbers to the MMS protection profile and set which flood thresholds to send to each MSISDN.

Example — three flood threshold levels with different actions for each threshold

You can set up to three threshold levels to take different actions at different levels of activity.

The first example threshold records log messages when a subscriber's handset displays erratic behavior by sending multiple messages using MM1 at a relatively low threshold. The erratic behavior could indicate a problem with the subscriber's handset. For example, you may have determined for your network that if a subscriber sends more the 45 messages in 30 minutes that you want to record log messages as a possible indication or erratic behavior.

From the web-based manager in an MMS profile set message *Flood Threshold 1* to:

Enable	Selected
Message Flood Window	30 minutes

Message Flood Limit	45
Message Flood Action	Log

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config flood mm1
      set status1 enable
      set window1 30
      set limit1 45
      set action1 log
    end
end
```

Set a second higher threshold to take additional actions when a subscriber sends more that 100 messages in 30 minutes. Set the actions for this threshold to log the flood, archive the message that triggered the second threshold, and block the sender for 15 minutes.

From the web-based manager in an MMS profile set message *Flood Threshold 2* to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	100
Message Block Time	15 minutes
Message Flood Action	Log, DLP archive First message only, Block

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config flood mm1
      set status2 enable
      set window2 30
      set limit2 100
      set action2 block log archive-first
      set block-time2 15
    end
end
```

Set the third and highest threshold to block the subscriber for an extended period and sand an administrator alert if the subscriber sends more than 200 messages in 30 minutes. Set the actions for this threshold to block the sender for four hours (240 minutes), log the flood, archive the message that triggered the third threshold, and send an alert to the administrator.

From the web-based manager in an MMS profile set message *Flood Threshold 3* to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	200
Message Block Time	240 minutes
Message Flood Action	Log, Block, Alert Notification

Because you have selected the *Alert Notification* action you must also configure alert notification settings. For this example, the source MSISDN is 5551234—telephone number 555-1234. When administrators receive MMS messages from this MSIDSN they can assume a message flood has been detected.

In this example, alert notifications are sent by the FortiOS Carrier unit to the MMSC using MM1. The host name of the MMSC is `mmscexample`, the MMSC URL is `/`, and the port used by the MMSC is 80. In this example, the alert notification window starts at 8:00am and extends for eight hours on weekdays (Monday-Friday) and the minimum interval between message flood notifications is two hours.

Source MSISDN	5551234
Message Protocol	MM1
Hostname	mmscexample
URL	/
Port	80
Notifications Per Second Limit	0
Window Start Time	8:00
Window Duration	8:00
Day of Week	Mon, Tue, Wed, Thu, Fri, Sat
Interval	2 hours

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config notification alert-flood-1
      set alert-src-msisdn 5551234
      set set msg-protocol mm1
      set mmsc-hostname mmscexample
      set mmsc-url /
      set mmsc-port 80
      set rate-limit 0
      set tod-window-start 8:00
      set tod-window-duration 8:00
      set days-allowed monday tuesday wednesday thursday friday
      set alert-int 2
      set alert-int-mode hours
    end
end
```

You must also add the MSISDNs of the administrators to be notified of the message flood. In this example, the administrator flood threshold 3 alert notifications are sent to one administrator with MSISDN 5554321.

To add administrator's MSISDNs for flood threshold 3 from the web-based manager when configuring a protection profile, select *MMS Bulk Email Filtering Detection* > *Recipient MSISDN* > *Create New*.

MSISDN	5554321
Flood Level 3	Select

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config notif-msisdn
      edit 5554321
        set threshold flood-thresh-3
    end
end
```

Notifying message flood senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver that cause a message flood. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around flood protection. For this reason, no notification is set to the sender or receiver.

However, FortiOS Carrier does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as message floods. For information about how FortiOS Carrier responds when message flood detection blocks a message, see "FortiOS Carrier and MMS duplicate messages and message floods" on page 2301.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (`m-send.conf`) to the sender — otherwise the sender's handset would keep retrying the message. The `m-send.conf` message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the MMSC and the MMSC sends the `m-send.conf` message.

You can customize the `m-send.conf` message by editing the *MM1 send-conf flood message* MM1 replacement message (from the CLI the `mm1-send-conf-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted". To hide the fact that FortiOS Carrier is responding to a flood, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK":

```
config system replacemsg mm1 mm1-send-conf-flood
  set rsp-status ok
  set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender's handset would keep retrying the message). The m-retrieve.conf message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrive.conf message by editing the *MM1 retrieve-conf flood message* MM1 replacement message (from the CLI the `mm1-retr-conf-flood` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-flood
  set subject "Message blocked"
  set message "Message temporarily blocked by carrier"
end
```

Forward responses for MM4 message floods

When the FortiOS Carrier unit identifies an MM4 message as a flood message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 message flood action is set to Block and the MM4-forward.req message requested a response. For more information, see "FortiOS Carrier and MMS duplicate messages and message floods" on page 2301.

You can customize the MM4_forward.res message by editing the *MM4 flood message* MM4 replacement message (from the CLI the `mm4-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted" (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a flood, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK" for the MM4 message forward response

```
config system replacemsg mm4 mm4-flood
  set rsp-status ok
  set rsp-text "Message Forwarded OK"
end
```

Viewing DLP archived messages

If *DLP Archive* is a selected message flood action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages, but you can configure the DLP archive setting to save only the first message that exceeds the threshold. This still provides a sample of the offending messages without requiring as requiring as much storage.

To select only the first message in a flood for DLP archiving - web-based manager

1 Go to *UTM Profiles* > *Carrier* > *MMS Profile*.

2 Select an existing MMS Profile

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of messages sent by each subscriber regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The FortiOS Carrier unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a *Block* action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

Bypassing message flood protection based on user's carrier end points

You can use carrier end point filtering to exempt MMS sessions from message flood protection. Carrier end point filtering matches carrier end points in MMS sessions with carrier end point patterns.

If you add a carrier end point pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier end points bypass message flood protection. This allows legitimate bulk messages, such as system outage notifications, to be delivered without triggering message flood protection.

For more information on carrier end points, see the FortiOS Handbook User Authentication chapter.

Configuring message flood detection

To have the FortiOS Carrier unit check for message floods, you must first configure the flood threshold in an MMS profile, select the MMS profile in a protection profile, and select the protection profile in a security policy. All the traffic examined by the security policy will be checked for message floods according to the threshold values you set in the MMS profile.

Configure the MMS profile - web-based manager

1. Go to *Firewall Objects* > *MMS Profile*.
2. If you are editing an MMS profile, select the *Edit* icon of the MMS profile.

   If you are create a new MMS profile, select *Create New* and enter a profile name.
3. Expand *MMS Bulk Email Filtering Detection*.
4. Expand *Message Flood*.
5. Expand *Flood Threshold 1*.
6. Select the *Enable* check box for MM1 messages, MM4 messages, or both.
7. In the *Message Flood Window* field, enter the length of time the FortiOS Carrier unit will keep track of the number of messages each subscriber sends.

   If the FortiOS Carrier unit detects the quantity of messages specified in the *Message Flood Limit* sent during the number of minutes specified in the *Message Flood Window*, a message flood is in progress.
8. In the *Message Flood Limit* field, enter the number of messages required to trigger the flood.
9. In the *Message Flood Block Time* field, enter the length of time a user will be blocked from sending messages after causing the message flood.

10 Select the message flood actions the FortiOS Carrier unit will take when the message flood is detected.

11 Select OK.

Configure the protection profile - web-based manager

1 Go to *Firewall Objects* > *Protection Profile*.

2 If you are editing a protection profile, select the *Edit* icon of the protection profile.

If you are create a new protection profile, select *Create New* and enter a profile name.

3 Expand *MMS Profile*.

4 Select the MMS profile from the list.

5 Select OK.

Configure the security policy - web-based manager

1 Go to *Policy*.

2 Select the *Edit* icon of the security policy that controls the traffic in which you want to detect message floods.

3 Select the *Protection Profile* check box to enable the use of a protection profile.

4 Select the protection profile from the protection profile list.

5 Select OK.

Sending administrator alert notifications

When message floods are detected, the FortiOS Carrier unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the message flood action. Each message flood threshold can be configured separately.

This section includes:

- Configuring how and when to send alert notifications
- Configuring who to send alert notifications to

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 message floods. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
  - *submit.REQ* to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
  - *deliver.REQ* to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

For more information, see "MMS notifications" on page 2367.

To configure administrator alert notifications - web-based manager

1 Go to *Firewall Objects* > *MMS Profile* and edit or add a new MMS protection profile.

2 Expand *MMS Bulk Email Filtering Detection*.

There are three message flood thresholds.

3 Expand the threshold that you want to configure alert notification for.

4 For *Message Flood Action*, select the *Alert Notification* check box. Alert notification options appear.

5 For the *Source MSISDN*, enter the MSISDN from which the alert notification message will be sent.

6 Select the Message Protocol the alert notification will use: *MM1*, *MM3*, *MM4*, or *MM7*.

7 Add the information required by FortiOS Carrier to send messages using the selected message protocol:

8 For *Notifications Per Second Limit*, enter the number of notifications to send per second.

Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.

9 If required, change *Window Start Time* and *Window Duration* configure when the FortiOS Carrier unit sends alert notifications.

By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.

10 For *Day of Week*, select the days of the week to send notifications.

For example, you may only want to send alert notifications on weekends for higher thresholds.

11 In the *Interval field*, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.

All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the message flood threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1 Go to *Firewall Objects* > *MMS Profile*.

2 Select the *Edit* icon of the MMS profile in which you want to configure the alert notification recipients.

3 Expand *MMS Bulk Email Filtering Detection*.

4 Expand *Recipient MSISDN*.

5 Select *Create New*.

6 In the *New MSISDN* window, enter the MSISDN to use for flood threshold alert notification.

7 Select the duplicate thresholds at which to send alert notifications to the MSISDN.

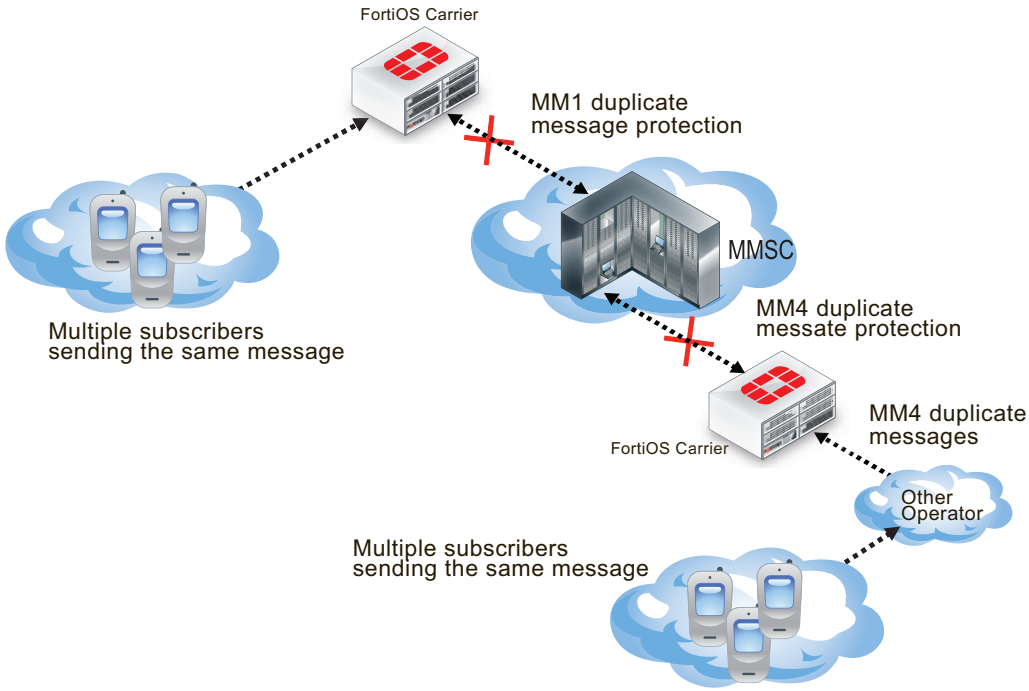
For the flood threshold to be able to send an alert notification to the MSISDN, the alert notification action must be enabled and configured within the flood threshold.

Duplicate message protection

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or other unwanted messages. Often, the same message will be sent by multiple subscribers. The message can be spam, viral marketing, or worm-generated messages. MMS duplicate prevention can help prevent this type of abuse by keeping track of the messages being sent.

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC. This can help prevent a potential flood that would otherwise become widespread between carriers.

Figure 248: MM1 and MM4 duplicate message protection



The FortiOS Carrier unit keeps track of the sent messages. If the same message appears more often than the threshold value you configure, then action is taken. Possible actions are logging the duplicates, blocking or intercepting duplicate messages, archiving the duplicate messages, and sending an alert to inform an administrator that duplicates are occurring.

With this highly configurable system, you can prevent the transmission of duplicate messages when there are more than you determine is acceptable.

For detailed configuration options, see “Duplicate Message” on page 2333.

Using message fingerprints to identify duplicate messages

The FortiOS Carrier unit detects duplicates by keeping a record of all the messages travelling on the network and comparing new messages to those that have already been sent.

Rather than save the messages, the FortiOS carrier creates a checksum using the message body and subject. This serves as a fingerprint to identify the message. If another message with the same message body and subject appears, the fingerprint will also be the same and the FortiOS Carrier unit will recognize it as a duplicate.

By creating and saving message fingerprints instead of saving the messages, the FortiOS Carrier unit can save resources and time.

Messages from any sender to any recipient

Duplicate message detection will detect duplicate messages regardless of the sender or recipient. To do this, message fingerprints are generated using only the message body and subject. The sender, recipient, and other header information is not included.

If multiple messages appear with the same subject and message body, the FortiOS Carrier unit will recognize them as being the same.

Setting duplicate message thresholds

The FortiOS Carrier recognizes all duplicate messages, but it will take action when it detects a volume of duplicate messages that exceed the duplicate threshold you set. The threshold defines the maximum number of duplicate messages allowed, the period during which the messages are considered, and the length of time the duplicate message can not be sent by anyone.

For example, you may determine that once a duplicate message is sent more than 300 times in an hour, any attempt to send the same duplicate message will be blocked for 30 minutes.

If a particular duplicate message exceeds the duplicate message threshold and is blocked, any further attempts to send the same message will re-start the block period.

Using the example above, if the duplicate message count exceeds the duplicate threshold, any attempt to send a copy of the duplicate message will be blocked for 30 minutes. If a subscriber tries to send a copy of the message after waiting 15 minutes, the message will be blocked and the block period will be reset to 30 minutes. The block period must expire with no attempts to send a duplicate message. Only then will a subscriber be allowed to send the message. Non-duplicate messages will not reset the block period.

Duplicate message actions

When the FortiOS Carrier unit detects that a duplicate message has exceeded duplicate threshold, it can take any combination of the five actions you configure for the duplicate threshold.

Action		Description
Log		Add a log entry indicating that a duplicate message event has occurred. You must also enable logging for *MMS Scanning* > *Bulk Messages* in the *Logging* section of the MMS protection profile.
DLP Archive		
	All messages	Save all the messages that exceed the duplicate threshold in the DLP archive.
	First message only	Save the first message to exceed the duplicate threshold in the DLP archive. Subsequent messages that exceed the duplicate threshold will not be saved.
Intercept		Messages that exceed the duplicate threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message is also quarantined for later examination. If the quarantine of intercepted messages is disabled, the *Intercept* action has no effect.
Block		Messages that exceed the duplicate threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each blocked message is quarantined for later examination.
Alert Notification		If the duplicate threshold is exceeded, the FortiOS Carrier unit will send an MMS duplicate message notification message.

Notifying duplicate message senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver of duplicate messages. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around duplicate message protection. For this reason, no notification is set to the sender or receiver.

However, the FortiOS Carrier unit does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as duplicate messages. For information about how FortiOS Carrier responds when message flood detection blocks a message, see “FortiOS Carrier and MMS duplicate messages and message floods” on page 2301.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (m-send.conf) to the sender (otherwise the sender's handset would keep retrying the message). The m-send.conf message is sent only when the MM1 duplicate message action is set to Block. For other duplicate message actions the message is actually delivered to the MMSC and the MMSC sends the m-send.conf message.

You can customize the m-send.conf message by editing the *MM1 send-conf duplicate message* MM1 replacement message (from the CLI the `mm1-send-conf-dupe` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted". To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK":

```
config system replacemsg mm1 mm1-send-conf-dupe
  set rsp-status ok
  set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender's handset would keep retrying). The m-retrieve.conf message is sent only when the `MM1duplicate` message action is set to Block. For other message flood actions the message is actually received by the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrive.conf message by editing the *MM1 retrieve-conf duplicate message* MM1 replacement message (from the CLI the `mm1-retr-conf-dupe` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-dupe
  set subject "Message blocked"
  set message "Message temporarily blocked by carrier"
end
```

Forward responses for duplicate MM4 messages

When the FortiOS Carrier unit identifies an MM4 message as a duplicate message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 duplicate message action is set to Block and the MM4-forward.req message requested a response. For more information, see "FortiOS Carrier and MMS duplicate messages and message floods" on page 2301.

You can customize the MM4_forward.res message by editing the *MM4 duplicate message* MM4 replacement message (from the CLI the `mm4-dupe` replacement message). You can customize the response status and message text for this message. The default response status is “Content not accepted” (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to “Success”. The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to “Success” and changes the message text to “Message Sent OK”:

```
config system replacemsg mm4 mm4-dupe
  set rsp-status ok
  set rsp-text “Message Forwarded OK”
end
```

Viewing DLP archived messages

If *DLP Archive* is a selected duplicate message action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages but you can configure the DLP archive setting to save only the first message that exceeds the threshold. See “Viewing DLP archived messages” on page 2379.

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of messages sent by each subscriber regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The FortiOS Carrier unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a *Block* action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

Bypassing duplicate message detection based on user’s carrier end points

You can use carrier end point filtering to exempt MMS sessions from duplicate message detection. Carrier end point filtering matches carrier end points in MMS sessions with carrier end point patterns. If you add a carrier end point pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier end points bypass duplicate message detection. For more information about end points, see *FortiOS Handbook User Authentication chapter*.

Configuring duplicate message detection

To have the FortiOS Carrier unit check for duplicate messages, configure the duplicate threshold in an MMS profile, select the MMS profile in a protection profile, and select the protection profile in a security policy.

1 Create an MMS profile and configure one or more of the duplicate thresholds as required.

2 Select the MMS profile in a protection profile.

3 Select the protection profile in a security policy.

All traffic matching the security policy will be checked for duplicate messages according to the settings in the MMS profile.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

The modular nature of the profiles allows you great flexibility in how you configure the scanning options. MMS profiles can be used in any number of protection profiles. Similarly, protection profiles can be used in any number of security policies.

In a complex configuration, there may be many security policies, each with a different protection profile and MMS profile. For a simpler network, you may have many security policies all using the same protection profile and MMS profile.

Sending administrator alert notifications

When duplicate messages are detected, the FortiOS Carrier unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the duplicate message action. Each duplicate message threshold can be configured separately.

This section includes:

- Configuring how and when to send alert notifications
- Configuring who to send alert notifications to

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 duplicate messages. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
  - *submit.REQ* to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
  - *deliver.REQ* to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server

- The URL of the server (usually “/”)
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

To configure administrator alert notifications - web-based manager

1 Go to *Firewall Objects* > *MMS Profile* and edit or add a new MMS protection profile.

2 Expand *MMS Bulk Email Filtering Detection*.

There are three duplicate message thresholds.

3 Expand the threshold that you want to configure alert notification for.

4 For *Duplicate Message Action*, select the *Alert Notification* check box. Alert notification options appear.

5 For the *Source MSISDN*, enter the MSISDN from which the alert notification message will be sent.

6 Select the Message Protocol the alert notification will use: *MM1*, *MM3*, *MM4*, or *MM7*.

7 Add the information required by FortiOS Carrier to send messages using the selected message protocol:

8 For *Notifications Per Second Limit*, enter the number of notifications to send per second.

Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.

9 If required, change *Window Start Time* and *Window Duration* configure when the FortiOS Carrier unit sends alert notifications.

By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.

10 For *Day of Week*, select the days of the week to send notifications.

For example, you may only want to send alert notifications on weekends for higher thresholds.

11 In the *Interval field*, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.

All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the duplicate threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1. Go to *Firewall Objects* > *MMS Profile*.
2. Select the *Edit* icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand *MMS Bulk Email Filtering Detection*.
4. Expand *Recipient MSISDN*.
5. Select *Create New*.
6. In the *New MSISDN* window, enter the MSISDN to use for duplicate threshold alert notification.
7. Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the duplicate threshold to be able to send an alert notification to the MSISDN, the duplicate message threshold alert notification action must be enabled and configured.

MMS Replacement messages

Go to *System* > *Config* > *Replacement Message* to change replacement messages and customize notifications that the FortiOS Carrier unit adds to MMS content streams and for administrator alert notifications.

The replacement messages configured here are the default replacement message group selected in a protection profile. To add a replacement message to a protection profile go to *Firewall Objects* > *Protection Profile*, add or edit a protection profile and in the and under *Replacement Messages* select a replacement message group. The *default* replacement message group is selected by default.

Disclaimer replacement messages provided by Fortinet are examples only.

This section includes:

Changing replacement messages

To change a replacement message list go to *System* > *Config* > *Replacement Message*. Use the expand arrows to view the replacement message that you want to change. You can change the content of the replacement message by editing the text and HTML codes and by working with replacement message tags.

Replacement messages can be text or HTML messages. You can add HTML code to HTML messages. Allowed Formats shows you which format to use in the replacement message. There is a limit of 8192 characters for each replacement message. The following fields and options are available when editing a replacement message. Different replacement messages have different sets of fields and options.

Message Setup	The name of the replacement message.
Allowed Formats	The type of content that can be included in the replacement message. Allowed formats can be either Text or HTML. You can include replacement message tags in text and HTML messages. Do not use HTML code in Text messages — it will be incorrectly displayed.

Size	The number of characters allowed in the replacement message. A typical size is 8192 characters. This is the combined total size of the messages text, any SMIL content, and image. Each part of the MMS replacement message is limited to smaller sizes — 1023 characters for message text, 1023 characters for SMIL content, and 6000 bytes for an image if included.
Response Status	Select a response status for the replacement message. Many options are available including `Content not accepted`, `Success`, and `Unspecified error`.
Priority	Set the priority used by the protocol for sending the message. This priority is not used by FortiOS Carrier — it is added to the message. Options include `Not Specified`, `Low`, `Normal`, and `High`.
Class	Select the classification used by the protocol for the message. The classification is not used by FortiOS Carrier but is added to the message. Select `Not Specified`, `Personal`, `Advertisement`, `Information`, or `Automatic`. Note that not all MMS replacement messages include this field.
Sender Visibility	Select whether to show or hide the message sender. You can also select *Not Specified*.
Use Sender MSISDN	Select to include the sender's MSISDN in the replacement message. If the *From* field is used, the *Use Sender MSISDN* field is disabled.
From	Enter the name to appear as the sender of the replacement message. You cannot include replacement message tags in the *From* field. If the *Use Sender MSISDN* field is selected, the *From* field is disabled.
Subject	Enter or edit the subject for the replacement message. You cannot include replacement message tags in the subject field.
Character Set	Select the character set to use for the replacement message. You can select UTF-8 or US ASCII.
Add SMIL Part	Select to include Synchronized Multimedia Integration Language (SMIL) code in the message. Enter SMIL code into the SMIL Contents part of the replacement message. The *Image* and *SMIL Contents* fields are disabled unless *Add SMIL Part* is selected.
Image	Select a replacement message image to include in the replacement message. Use the `%%IMAGE_CID%%` tag to include the image in the SMIL contents. Any image you select must be 6000 bytes or less in size.

SMIL Contents	Enter SMIL instructions for the replacement message to define multimedia content presentation. The size limit on the SMIL content is limited to 1023 characters.
Message Text	The body or editable text of the replacement message. The message text can include plain text, HTML instructions (if HTML is the allowed format) and replacement message tags. The size limit on this message is 1023 characters.

Multimedia content for MMS replacement messages

One of the main differences MMS replacement messages have is the addition of the Synchronized Multimedia Integration Language (SMIL) message portion. SMIL is a markup language, based on XML, that controls the presentation of media items such as text, images, audio, video, or even links to other SMIL presentations. This allows you to create a multimedia replacement message that includes your company colors and logo, an animated company logo, or other more advanced personations as appropriate. For more information on SMIL, see the W3C website http://www.w3.org/AudioVideo/.

The most important limit to be aware of is the size limit. The SMIL code portion can only be 1023 characters long which is the same maximum size for the regular message portion of the replacement message. If you include an image, its maximum size is 6000 bytes and valid formats are GIF, JPEG, PNG, or TIFF.

The following procedure will create an entry for a PNG image file called `test_image1`. It will then be included in the `MM1 send-req virus message` replacement message.

To upload an image for a SMIL message - web-based manager

1. Go to *System* > *Config* > *Replacement Message Image*.
2. Select *Create New.*
3. Enter `test_image1` for *Name*.
4. For *Content Type* select PNG.
5. Browse to the file location on your local computer using *Browse* next to *Upload*.
6. Select OK.

   At this point, you will see your image displayed with a tag of `test_image1`.

You can not edit a replacement message image. To change an entry, you must delete it, and create a new entry.

To use an image in an MMS replacement message - web-based manager

1. Go to *System* > *Config* > *Replacement Messages*.
2. Expand *MM1*.
3. Edit the `MM1 send-req virus message` replacement message.
4. Enable *Add SMIL Part*.
5. For *Image*, select `test_image1` from the drop down list.
6. Enter SMIL code to display the image as required.
7. Enter message text including any replacement message tags required.
8. Enter rest of information as required.

9 Select OK.

MMS replacement message types

There are three types of replacement message used with MMS. The three types are:

Table 127: MMS replacement messages

m-send-conf	These messages are sent in response to an m-send-req message initiated by the mobile client. This message can only contain a response code and a plain-text response message to the client.
m-retrieve-conf	These messages are sent in response to a GET request resulting in the return of an MMS message. A new message is built using the options specified in these replacement messages, including a WML format message, and sent back to the user to inform them of what has occurred.
m-send-req	These messages are sent to notify the user of how many messages have been sent from their phone that violate the message content rules. A message is built from the options specified in these replacement messages, including a WML format message, and sent to the MMSC for delivery to the client.

Replacement message tags

Replacement messages can include replacement message tags. When users receive the replacement message, the replacement message tag is replaced with content relevant to the message. Table 128 lists the replacement message tags that you can add.

Table 128: Replacement message tags

Tag	Description
%%AUTH_LOGOUT%%	The URL that will immediately delete the current policy and close the session. Used on the auth-keepalive page.
%%AUTH_REDIR_URL%%	The auth-keepalive page can prompt the user to open a new window which links to this tag.
%%CATEGORY%%	The name of the content category of the web site.
%%DEST_IP%%	The IP address of the request destination from which a virus was received. For email this is the IP address of the email server that sent the email containing the virus. For HTTP this is the IP address of web page that sent the virus.
%%DURATION%%	The amount of time in the reporting period. This is user defined in the protection profile.
%%EMAIL_FROM%%	The email address of the sender of the message from which the file was removed.
%%EMAIL_TO%%	The email address of the intended receiver of the message from which the file was removed.
%%FAILED_MESSAGE%%	The failed to login message displayed on the auth-login-failed page.

Table 128: Replacement message tags (Continued)

Tag	Description
%%FILE%%	The name of a file that has been removed from a content stream. This could be a file that contained a virus or was blocked by antivirus file blocking. %%FILE%% can be used in virus and file block messages.
%%FORTIGUARD_WF%%	The FortiGuard - Web Filtering logo.
%%FORTINET%%	The Fortinet logo.
%%IMAGE_CID%%	The reference name of an image you have uploaded to the FortiOS Carrier unit. Use this to display the image in the message. The message with the image is generated as a MIME multipart message For example if you upload a file called example.jpg, and call it example_logo, then %%IMAGE_CID%% would resolve to example_logo.
%%LINK%%	The link to the FortiClient Host Security installs download for the Endpoint Control feature.
%%HTTP_ERR_CODE%%	The HTTP error code. “404” for example.
%%HTTP_ERR_DESC%%	The HTTP error description.
%%KEEPALIVEURL%%	auth-keepalive-page automatically connects to this URL every %%TIMEOUT%% seconds to renew the connection policy.
%%MMS_SENDER%%	Senders MSISDN from message header.
%%MMS_RECIPIENT%%	Recipients MSISDN from message header.
%%MMS_SUBJECT%%	MMS Subject line to help with message identity.
%%MMS_HASH_CHECKSUM%%	Value derived from hash calculation - will only be shown on duplicate message alerts.
%%MMS_THRESH%%	Mass MMS alert threshold that triggered this alert.
%%NIDSEVENT%%	The IPS attack message. %%NIDSEVENT%% is added to alert email intrusion messages.
%%NUM_MSG%%	The number of times the device tried to send the message with banned content within the reporting period.
%%OVERRIDE%%	The link to the FortiGuard Web Filtering override form. This is visible only if the user belongs to a group that is permitted to create FortiGuard web filtering overrides.
%%OVRD_FORM%%	The FortiGuard web filter block override form. This tag must be present in the FortiGuard Web Filtering override form. It is not to be used in other replacement messages.
%%PROTOCOL%%	The protocol (http, ftp, pop3, imap, or smtp) in which a virus was detected. %%PROTOCOL%% is added to alert email virus messages.

Table 128: Replacement message tags (Continued)

Tag	Description
%%QUARFILENAME%%	The name of a file that has been removed from a content stream and added to the quarantine. This could be a file that contained a virus or was blocked by antivirus file blocking. %%QUARFILENAME%% can be used in virus and file block messages. Quarantining is only available on FortiOS Carrier units with a local disk.
%%QUOTA_INFO%%	Display information about the traffic shaping quota setting that is blocking the user. Used in traffic quota control replacement messages.
%%QUESTION%%	Authentication challenge question on auth-challenge page. Prompt to enter username and password on auth-login page.
%%SERVICE%%	The name of the web filtering service.
%%SOURCE_IP%%	The IP address of the request originator who would have received the blocked file. For email this is the IP address of the user's computer that attempted to download the message from which the file was removed.
%%TIMEOUT%%	Configured number of seconds between authentication keepalive connections. Used on the auth-keepalive page.
%%URL%%	The URL of a web page. This can be a web page that is blocked by web filter content or URL blocking. %%URL%% can also be used in http virus and file block messages to be the URL of the web page from which a user attempted to download a file that is blocked.
%%VIRUS%%	The name of a virus that was found in a file by the antivirus system. %%VIRUS%% can be used in virus messages

Replacement message groups

You can add up to five replacement message groups that can be applied to specific protection profiles allowing the customizing of messages for specific groups of users.

For example if your network has residential, corporate, and administrator users each group could have their own set of customized replacement messages with different information, graphics, and design. Another example could be if you provide services to five different companies, you could customize the replacement message groups for each company with their logo, colors, and so on.

You configure the default replacement message group from *System* > *Config* > *Replacement Message*. This replacement message group is the default replacement message group selected in a protection profile. All new replacement message groups that you add inherit their configuration from the default group.

Modifying messages in the default group automatically changes any messages that are unmodified in the other groups.

If you enable virtual domains (VDOMs) on the FortiOS Carrier unit, replacement message groups are configured separately for each virtual domain. Each virtual domain has its own default replacement message group, configured from *System* > *Config* > *Replacement Message*. When you modify a message in a replacement message group, a Reset icon appears beside the message in the group. You can select this Reset icon to reset the message in the replacement message group to the default version.

All MM1, MM4, MM7 notification messages (and MM1 retrieve-conf messages) can contain an SMIL layer and all MM4 notification messages can contain an HTML layer in the message. These layers can be used to brand messages by using logos uploaded to the unit via the *Manage Images* link found on the replacement message group configuration page. See "Multimedia content for MMS replacement messages" on page 2395.

Replacement message group example

In this example, the message group is for a customer company called Example.com. Your company is called MyCarrier. Their group will be named `example_group`. Their logo is in a file called `example_logo.jpg`. Their employees do not want excessive information in the messages, so three replacement messages will be changed (mm1 send-req, send-conf, and retrieve-conf virus) to just the barebones information as part of this example.

To upload the logo image - web-based manager

1. Go to *System* > *Config* > *Replacement Message Group* > *Manage Images*.
2. Select Create New.
3. Enter `example_logo` for *Name*, and select `JPEG` for *Content Type .*
4. Browse to the file location of the file `example_logo.jpg` on your computer.
5. Select *OK*.
6. Select Return to return to the *Replacement Message Group* list.

To create the message group - web-based manager

1. Go to *System* > *Config* > *Replacement Message Group.*
2. Select *Create New*.
3. Enter `example_group` for *Name*.
4. Select OK.
5. Select `example_group`, and select *Edit*.
6. Expand *MM1*.
7. Select *MM1 send-req virus message*.
8. Enter the following information.

Priority	Normal
Class	Information
Sender Visibility	Show
From	%%MSISDN%% MyCarrier
Subject	Virus infected message(s) detected
Add SMIL Part	Enable
Image	example_logo

9 Enter the following SMIL code:

```
<smil><head><meta name=”author” content=”MyCarrier” /></head>
<body><img src="cid:%%IMAGE_CID%%" longdesc=”Example.com logo”
    /></body>
</smil>
```

10 Enter the following replacement message code:

```
This device has sent %%NUM_MSG%% virus infected messages in the
    last %%DURATION%% hours. Contact MyCarrier customer support
    for farther instructions.
```

Configuring GTP on FortiOS Carrier

Configuring GTP support on FortiOS Carrier involves configuring a number of areas of features. Some features require longer explanations, and have their own chapters. The other features are addressed here.

This section includes:

- GTP support on the FortiOS Carrier unit
- Configuring General Settings on the FortiOS Carrier unit
- Configuring Encapsulated Filtering in FortiOS Carrier
- Configuring the Protocol Anomaly feature in FortiOS Carrier
- Configuring Anti-overbilling in FortiOS Carrier
- Logging events on the FortiOS Carrier unit

GTP support on the FortiOS Carrier unit

The FortiCarrier unit needs to have access to all traffic entering and exiting the carrier network for scanning, filtering, and logging purposes. This promotes one of two configurations — hub and spoke, or bookend.

A hub and spoke configuration with the FortiOS Carrier unit at the hub and the other GPRS devices on the spokes is possible for smaller networks where a lower bandwidth allows you to divide one unit into multiple virtual domains to fill multiple roles on the carrier network. It can be difficult with a single FortiOS Carrier as the hub to ensure all possible entry points to the carrier network are properly protected from potential attacks such as “Relayed network attacks” on page 2404.

A bookend configuration uses two FortiOS Carrier units to protect the carrier network between them with high bandwidth traffic. One unit handles traffic from mobile stations, SGSNs, and foreign carriers. The other handles GGSN and data network traffic. Together they ensure the network is secure.

The FortiOS Carrier unit can access all traffic on the network. It can also verify traffic between devices, and verify that the proper GPRS interface is being used. For example there is no reason for a Gn interface to be used to communicate with a mobile station — the mobile station will not know what to do with the data — so that traffic is blocked.

When you are configuring your FortiOS Carrier unit’s GTP profile, you must first configure the APN. It is critical to GTP communications — no traffic will flow without the APN.

The FortiOS Carrier unit does more than just forward and route GTP packets over the network. It also performs:

- Packet sanity checking
- GTP stateful inspection
- Protocol anomaly detection and prevention
- HA

- Virtual domain support

Packet sanity checking

The FortiOS Carrier firewall checks the following items to determine if a packet confirms to the UDP and GTP standards:

- GTP release version number — must be 0, 1, or 2
- Settings of predefined bits
- Protocol type
- UDP packet length

If the packet in question does not confirm to the standards, the FortiOS Carrier firewall drops the packet, so that the malformed or forged traffic will not be processed.

GTP stateful inspection

Apart from the static inspection (checking the packet header), the FortiOS Carrier firewall performs stateful inspection.

Stateful inspection provides enhanced security by keeping track of communications sessions and packets over a period of time. Both incoming and outgoing packets are examined. Outgoing packets that request specific types of incoming packets are tracked; only those incoming packets constituting a proper response are allowed through the firewall.

The FortiOS Carrier firewall can also index the GTP tunnels to keep track of them.

Using the enhanced Carrier traffic policy, the FortiOS Carrier firewall can block unwanted encapsulated traffic in GTP tunnels, such as infrastructure attacks. Infrastructure attacks involve attempts by an attacker to connect to restricted machines, such as GSN devices, network management systems, or mobile stations. If these attempts to connect are detected, they are to be flagged immediately by the firewall.

Protocol anomaly detection and prevention

The FortiOS Carrier firewall detects and optionally drops protocol anomalies according to GTP standards and specific tunnel states. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of protocol specifications. These packets are not seen on a production network. Protocol anomaly attacks exploit poor programming practices when decoding packets, and are typically used to maliciously impair system performance or elevate privileges.

FortiOS Carrier also detects IP address spoofing inside GTP data channel.

See “Configuring the Protocol Anomaly feature in FortiOS Carrier” on page 2405.

HA

FortiOS Carrier active-passive HA provides failover protection for the GTP tunnels. This means that an active-passive cluster can provide FortiOS Carrier firewall services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiOS Carrier firewall. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially for mission-critical environments.

FortiOS HA synchs TCP sessions by default, but UDP sessions are not synchronized by default. However synchronizing a session is only part of the solution if the goal is to continue GTP processing on a synchronized session after a HA switch. For that to be successful we also need to synch the GTP tunnel state. So, once the master completes tunnel setup then the GTP tunnel is synchronized to the slave.

For more information on HA in FortiOS, see "High Availability" on page 1983.

Virtual domain support

FortiOS Carrier is suited to both large and smaller carriers. A single FortiOS Carrier unit can serve either one large carrier, or several smaller ones through virtual domains. As with any FortiGate unit, FortiOS Carrier units have the ability to split their resources into multiple virtual units. This allows smaller carriers to use just the resources that they need without wasting the extra. For more information on virtual domains in FortiOS, see "Virtual Domains" on page 1875.

Configuring General Settings on the FortiOS Carrier unit

To configure the GTP General Settings, go to *UTM Profiles* > *Carrier* > *GTP Profile*, and edit a GTP profile. Expand *General Settings* to configure settings. See "General settings options" on page 2338.

Configuring Encapsulated Filtering in FortiOS Carrier

Encapsulated traffic on the GPRS network can come in a number of forms as it includes traffic that is "wrapped up" in another protocol. This detail is important for firewalls because it requires "unwrapping" to properly scan the data inside. If encapsulated packets are treated as regular packets, that inside layer will never be scanned and may allow malicious data into your network.

On FortiOS Carrier units, GTP related encapsulated filtering falls under encapsulated IP traffic filtering, and encapsulated non-IP end user address filtering.

Configuring Encapsulated IP Traffic Filtering

Generally there are a very limited number of IP addresses that are allowed to encapsulate GPRS traffic. For example GTP tunnels are a valid type of encapsulation when used properly. This is the GTP tunnel which uses the Gp or Gn interfaces between SGSNs and GGSNs. However, a GTP tunnel within a GTP tunnel is not accessible — FortiOS Carrier will either block or forward the traffic, but is not able to open it for inspection.

The ability to filter GTP sessions is based on information contained in the data stream and provides operators with a powerful mechanism to control data flows within their infrastructure. You can also configure IP filtering rules to filter encapsulated IP traffic from Mobile Stations.

To configure the Encapsulated IP Traffic Filtering, go to *UTM Profiles* > *Carrier* > *GTP Profile*, and edit a GTP profile. Expand *Encapsulated IP Traffic Filtering* to configure settings. See "Encapsulated IP traffic filtering options" on page 2346.

When to use encapsulated IP traffic filtering (best practices)

The following are the typical cases that need encapsulated IP traffic filtering:

Mobile station IP pools

In a well-designed network, best practices dictate that the mobile station address pool is to be completely separate from the GPRS network infrastructure range of addresses. Encapsulated IP packets originating from a mobile station will not contain source or destination addresses that fall within the address range of GPRS infrastructures. In addition, traffic originating from the users handset will not have destination/source IP addresses that fall within any Network Management System (NMS) or Charging Gateway (CG) networks.

Communication between mobile stations

Mobile stations on the same GPRS network are not be able to communicate with other mobile stations. Best practices dictate that packets containing both source and destination addresses within the mobile station's range of addresses are to be dropped.

Direct mobile device or internet attacks

It may be possible for attackers to wrap attack traffic in GTP protocols and submit the resulting GTP traffic directly to a GPRS network element from their mobile stations or a node on the Internet. It is possible that the receiving SGSN or GGSN would then strip off the GTP header and attempt to route the underlying attack. This underlying attack could have any destination address and would probably have a source address spoofed as if it were valid from that PLMN.

You cannot add an IE removal policy when you are creating a new profile.

Relayed network attacks

Depending on the destination the attack could be directly routed, such as to another node of the PLMN, or rewrapped in GTP for transmission to any destination on the Internet outside the PLMN depending on the routing table of the GSN enlisted as the unwitting relay.

The relayed attack could have any source or destination addresses and could be any of numerous IP network attacks, such as an attack to hijack a PDP context, or a direct attack against a management interface of a GSN or other device within the PLMN. Best practices dictate that any IP traffic originating on the Internet or from an MS with a destination address within the PLMN is to be filtered.

Configuring Encapsulated Non-IP End User Address Filtering

Much of the traffic on the GPRS network is in the form of IP traffic. However some parts of the network do not used IP based addressing, so the FortiOS Carrier unit is unable to perform Encapsulated IP Traffic Filtering.

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications only list PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the "Assigned PPP DLL Protocol Numbers" sections of RFC 1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

To configure the Encapsulated Non-IP End User Address Filtering, go to *UTM Profiles* > *Carrier* > *GTP Profile*, and edit a GTP profile. Expand *Encapsulated Non-IP End User Address Filtering* to configure settings. See "Encapsulated non-IP end user traffic filtering options" on page 2347.

Configuring the Protocol Anomaly feature in FortiOS Carrier

When anomalies do happen, it is possible for the anomaly to interrupt network traffic or consume network resources — if precautions were not taken. Anomalies can be generated by accident or maliciously, but both methods can have the same results — degrading the performance of the carrier network, or worse.

To configure GTP protocol anomalies, go to *UTM Profiles* > *Carrier* > *GTP Profile*, and edit a GTP profile. Expand the *Protocol Anomaly* option. See"Protocol anomaly prevention options" on page 2348.

The following are some examples:

- The GTP header specifies the length of the packet excluding the mandatory GTP header. In GTP version 0 (GSM 09.60), the mandatory GTP header size is 20 bytes, whereas GTP version 1 (GSM 29.060) specifies that the minimum length of the GTP header is 8 bytes. The GTP packet is composed of the header, followed by Information Elements typically presented in a Type-Length-Value format. It is possible for an attacker to create a GTP packet with a GTP header field length that is incompatible with the length of the necessary information elements.
- The same concepts are true for GTP version 2 headers even though there are different fields in them.
- It is similarly possible for an attacker to create a packet with an invalid IE length. Invalid lengths may cause protocol stacks to allocate incorrect amounts of memory, and thereby cause crashes or buffer overflows.

By default the FortiOS Carrier firewall detects these problems as well as other protocol anomalies and drops the packets. However, you can change the policy to allow them.

All protocol anomaly options are set to *Deny* by default.

Configuring Anti-overbilling in FortiOS Carrier

This section includes:

Overbilling in GPRS networks

GPRS overbilling attacks can be prevented with a properly configured FortiOS Carrier unit.

Overbilling can occur when a subscriber returns his IP address to the IP pool. Before the billing server closes it, the subscriber's session is still open and vulnerable. If an attacker takes control of the subscriber's IP address, he can send or receive data and the subscriber will be billed for the traffic.

Overbilling can also occur when an available IP address is reassigned to a new mobile station (MS). Subsequent traffic by the previous MS may be forwarded to the new MS. The new MS would then be billed for traffic it did not initiate.

Anti-overbilling with FortiOS Carrier

The FortiOS Carrier unit can be configured to assist with anti-overbilling measures. These measures ensure that the customer is only billed for connection time and data transfer that they actually use.

Anti-overbilling on the FortiOS Carrier unit involves:

- the FortiOS Carrier unit configures the overbilling settings in the GTP profile to notify the Gi firewall when a GTP tunnel is deleted
- the unit clears the sessions when the Gi firewall receives a notification from the Gn/Gp firewall about a GTP tunnel being deleted This way, the Gi firewall prevents overbilling by blocking traffic initiated by other users.

The three locations to configure anti-overbilling options include:

- *System* > *Network* > *Interface* > *Gi Gatekeeper* — enable to monitor Gi anti-overbilling traffic on this interface
- *System* > *Admin* > *Settings* > *Gi Gatekeeper Settings* — set the context ID and port that anti-overbilling will take place on.
- *UTM Profiles* > *Carrier* > *GTP Profile* > *Anti-Overbilling* — the IP address, port, interface and context ID to use for anti-overbilling measures.

For detailed options, see “Anti-overbilling options” on page 2349.

Logging events on the FortiOS Carrier unit

Logging on the FortiOS Carrier unit is just like logging on any other FortiOS unit. The only difference with FortiOS Carrier is that there are a few additional events that you can log beyond the regular ones. These additional events are covered here. For more information on other logging issues, see the *Logging and Reporting Guide* and *FortiOS CLI Reference*.

To enable FortiOS Carrier logging, go to *Log&Report* > *Event Log*, and ensure *GTP service event* is enabled. Once this option is selected, the logging options under *UTM Profiles* > *Carrier* > *GTP Profile* will be active.

To change FortiOS Carrier specific logging event settings, go to *UTM Profiles* > *Carrier* > *GTP Profile* and edit a GTP profile. Expand the *Log* section to change the settings. For detailed options, see “Log options” on page 2349.

The following information is contained in each log entry:

Timestamp	The time and date when the log entry was recorded
Source IP address	The sender’s IP address.
Destination IP address	The reciever’s IP address. The sender-receiver pair includes a mobile phone on the GPRS local network, and a device on a network external to the GPRS network, such as the Internet.

Tunnel Identifier (TID) **Tunnel Endpoint Identifier (TEID**	An identifier for the start and end points of a GTP tunnel. This information uniquely defines all tunnels. It is important for billing information based on the length of time the tunnel was active and how much data passed over the tunnel.
Message type	For available message types, see "Common message types on carrier networks" on page 2409.
Packet status	What action was performed on the packet. This field matches the logging options while you are configuring GTP logging. See "Anti-overbilling with FortiOS Carrier" on page 2406. The status can be one of forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited
Virtual domain ID or name	A FortiOS Carrier unit can be divided into multiple virtual units, each being a complete and self-contained virtual FortiCarrier unit. This field indicates which virtual domain (VDOM) was responsible for the log entry. If VDOMs are not enabled on your unit, this field will be `root`.
Reason to be denied if applicable	If the packet that generated this log entry was denied or blocked, this field will include what part of FortiOS denied or blocked that packet. Such as firewall, antivirus, webfilter, or spamfilter.

An example of the above log message format is for a Tunnel deleted log entry. When a tunnel is deleted, the log entry contains the following information:

- Timestamp
- Interface name (if applicable)
- SGSN IP address (source IP)
- GGSN IP address (destination IP)
- Tunnel ID
- Tunnel duration time in seconds
- Number of messages sent to the SGSN
- Number of messages sent to the GGSN

GTP message type filtering

FortiOS Carrier supports message filtering in GTP by the type of message.

This section includes:

Common message types on carrier networks

Carrier networks include many types of messages — some concern the network itself, others are content moving across the network, and still others deal with handshaking, billing, or other administration based issues.

GTP contains two major parts GTP for the control plane (GTP-C) and GTP for user data tunnelling (GTP-U). Outside of those areas there are only unknown message types.

GTP-C messages

GTP-C contains the networking layer messages. These address routing, versioning, and other similar low level issues.

When a subscriber requests a Packet Data Protocol (PDP) context, the SGSN will send a create PDP context request GTP-C message to the GGSN giving details of the subscriber's request. The GGSN will then respond with a create PDP context response GTP-C message which will either give details of the PDP context actually activated or will indicate a failure and give a reason for that failure. This is a UDP message on port 212.

GTP-C message types include Path Management Messages, Location Management Messages, and Mobility Management Messages.

Path Management Messages

Path management is used by one GSN to detect if another GSN is alive, or if it has restarted after a failure.

The path management procedure checks if a given GSN is alive or has been restarted after a failure. In case of SGSN restart, all MM and PDP contexts are deleted in the SGSN, since the associated data is stored in a volatile memory. In the case of GGSN restart, all PDP contexts are deleted in the GGSN.

Tunnel Management Messages

The tunnel management procedures are used to create, update, and delete GTP tunnels in order to route IP PDUs between an MS and an external PDN via the GSNs.

The PDP context contains the subscriber's session information when the subscriber has an active session. When a mobile wants to use GPRS, it must first attach and then activate a PDP context. This allocates a PDP context data structure in the SGSN that the subscriber is currently visiting and the GGSN serving the subscriber's access point.

Tunnel management procedures are defined to create, update, and delete tunnels within the GPRS backbone network. A GTP tunnel is used to deliver packets between an SGSN and a GGSN. A GTP tunnel is identified in each GSN node by a TEID, an IP address, and a UDP port number.

Location Management Messages

The location-management procedure is performed during the network-requested PDP context activation procedure if the GGSN does not have an SS7 MAP interface (i.e., Gc interface). It is used to transfer location messages between the GGSN and a GTP-MAP protocol-converting GSN in the GPRS backbone network.

Location management subprocedures are used between a GGSN that does not support an SS7 MAP interface (i.e., Gc interface) and a GTP-MAP protocol-conversing GSN. This GSN supports both Gn and Gc interfaces and is able to perform a protocol conversing between GTP and MAP.

Mobility Management Messages

The MM procedures are used by a new SGSN in order to retrieve the IMSI and the authentication information or MM and PDP context information in an old SGSN. They are performed during the GPRS attach and the inter-SGSN routing update procedures.

The MM procedures are used between SGSNs at the GPRS-attach and inter-SGSN routing update procedures. An identity procedure has been defined to retrieve the IMSI and the authentication information in an old SGSN. This procedure may be performed at the GPRS attach. A recovery procedure enables information related to MM and PDP contexts in an old SGSN to be retrieved. This procedure is started by a new SGSN during an inter-SGSN RA update procedure.

GTP-U messages

GTP-U is focused on user related issues including tunneling, and billing. GTP-U message types include MBMS messages, and GTP-U and Charging Management Messages

MBMS messages

Multimedia Broadcast and Multicast Services (MBMS) have recently begun to be offered over GSM and UMTS networks on UTRAN and GERAN radio access technologies. MBMS is mainly used for mobile TV, using up to four GSM timeslots for one MBMS connection. One MBMS packet flow is replicated by GGSN, SGSN and RNCs.

MBMS is split into the MBMS Bearer Service and the MBMS User Service. The MBMS User Service is basically the MBMS Service Layer and offers a Streaming- and a Download Delivery Method. The Streaming Delivery method can be used for continuous transmissions like Mobile TV services. The Download Method is intended for "Download and Play" services.

GTP-U and Charging Management Messages

SGSNs and GGSNs listen for GTP-U messages on UDP port 2152.

GTP‘ (GTP prime) is used for billing messages. It uses the common GTP messages (GTP Version Not Supported, Echo Request and Echo Response) and adds additional messages related to billing procedures.

Unknown Action messages

If the system doesn't know what type of message it is, it falls into this category. This is an important category of message because malformed messages may appear and need to be handled with security in mind.

Fortinet best practices dictate that you set *Unknown Action messages* to deny for security reasons.

Configuring message type filtering in FortiOS Carrier

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) traffic within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their network via tunneling.

In the CLI, there is a keyword for each type of GTP message for both message filtering, and for message rate limiting.

GTP message rate limiting is only accessible from the CLI using the command `configure firewall gtp`.

To configure GTP message type filtering - web-based manager

1. Go to *UTM Profiles* > *Carrier* > *GTP Profile*.
2. Select *Create New*.
3. Enter a name for this profile such as `msg_type_filtering`.
4. Select *Message Type Filtering* to expand it.
5. For each type of message in the list, select Allow or Deny. All messages are set to Allow by default.

Fortinet best practices dictate that the unknown message action should be set to Deny for security reasons as this will block malformed messages.

6. Optionally select and configure any other GTP features for this profile, such as logging.
7. Select OK to save the profile.
8. Apply the `msg_type_filtering` profile a security policy configured for GTP tunnel traffic.

To configure GTP message filtering and block Unknown Message Action messages- CLI

```
config firewall gtp
  edit msg_type_filtering
    config message-filter
      set unknown-message-action deny
    next
  end
end
```

Message Type Fields

Each of the following message types can be allowed or denied by your FortiOS Carrier unit depending on your carrier network and GTP traffic.

The message types include:

- Unknown Message Action
- Path Management Messages
- Tunnel Management Messages
- Location Management Messages
- Mobility Management Messages
- MBMS messages
- GTP-U and Charging Management Messages

Unknown Message Action

Set this message type to deny.

Many attempts to hack into a carrier network will result in this unknown message type and therefore it is denied for security reasons.

Path Management Messages

Message Type	Used by	Description
Echo Request/Response	GTP-C, GTP-U, GTP'	Echo Request is sent on a path to another GSN to determine if the other node is alive. Echo Response is the reply.
Version not Supported	GTP-C, GTP-U, GTP'	There are multiple versions of GTP. Both devices communicating must use the same version of GTP, or this message will be the response.
Support Extension Headers Notification		Extensions are optional parts that a device can choose to support or not. If a device includes these extensions, it must include headers for the extensions to sure ensure proper formatting.

Tunnel Management Messages

Message Type	Used by	Description
Create PDP Context Request/ Response	GTP-C	Sent from an SGSN to a GGSN node as part of a GPRS PDP Context Activation procedure or the Network-Requested PDP Context Activation procedure. A valid request initiates the creation of a tunnel.
Update PDP Context Request/ Response	GTP-C	Used when PDP Context information changes, such as when a mobile device changes location.
Delete PDP Context Request/ Response	GTP-C	Used to terminate a PDP Context, and confirm the context has been deleted.

Create AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS Anonymous Access PDP Context Activation. It is used to create a tunnel between a context in the SGSN and a context in the GGSN.
Delete AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS PDP Anonymous Access Context Deactivation procedure to deactivate an activated PDP Context. It contains Cause and Private Extension Information Elements
Error Indication	GTP-U	Sent to the GGSN when a tunnel PDU is received for the following conditions: — No PDP context exists — PDP context is inactive — No MM context exists — GGSN deletes its PDP context when the message is received.
PDU Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	When receiving a Tunneled PDU (T-PDU), the GGSN checks if a PDP context is established for the given PDP address. If no PDP context has been established, the GGSN may initiate the Network-requested PDP Context Activation procedure by sending a PDU Notification Request to the SGSN. **Reject Request -** Sent when the PDP context requested by the GGSN cannot be established.

Location Management Messages

Message Type	Used By	Description
Send Routing Information for GPRS Request/ Response	GTP-C	Sent by the GGSN to obtain location information for the MS. This message type contains the IMSI of the MS and Private Extension.
Failure Report Request/ Response	GTP-C	Sent by the GGSN to the HLR when a PDU reject message is received. The GGSN requests the HLR to set the flag and add the GGSN to the list of nodes to report to when activity from the subscriber that owns the PDP address is detected. The message contains the subscriber IMSI and Private Extension
Note MS GPRS Present Request/ Response	GTP-C	When the HLR receives a message from a mobile with MDFG set, it clears the MDFG and sends the Note MS Present message to all GGSN's in the subscriber's list. This message type contains subscriber IMSI, GSN Address and Private Extension

Mobility Management Messages

Message Type	Used By	Description
Identification Request/Response	GTP-C	Sent by the new SGSN to the old SGSN to request the IMSI for a MS when a GPRS Attach is done with a P-TMSI and the MS has changed SGSNs since the GPRS Detach was done.
SGSN context Request/ Response/ Acknowledge	GTP-C	Sent by the new SGSN to the old SGSN to request the MM and PDP Contexts for the MS.
Forward Relocation Request/ Response/ Complete/ Complete Acknowledge	GTP-C	Indicates mobile activation/deactivation within a Routing Area. This prevents paging of a mobile that is not active (visited VLR rejects calls from the HLR or applies Call Forwarding). Note that the mobile station does not maintain an attach/detach state. SRNS contexts contain for each concerned RAB the sequence numbers of the GTP-PDUs next to be transmitted in uplink and downlink directions.
Relocation Cancel Request/ Response	GTP-C	Send to cancel the relocation of a connection.
Forward SRNS Context/ Context Acknowledge	GTP-C	This procedure may be used to trigger the transfer of SRNS contexts from RNC to CN (PS domain) in case of inter system forward handover.
RAN Information Relay	GTP-C	Forward the Routing Area Network (RAN) information. A Routing Area (RA) is a subset of a GSM Location Area (LA). A RA is served by only one SGSN. Ensures that regular radio contact is maintained by the mobile

MBMS messages

Message Type	Used By	Description
MBMS Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	Notification of the radio access devices.
Create MBMS Context Request/ Response	GTP-C	Request to create an active MBMS context. The context will be pending until the response is received. Once active, the MBMS context allows the MS to receive data from a specific MBMS source
Update MBMS Context Request/ Response	GTP-C	
Delete MBMS Context Request/ Response	GTP-C	Request to deactivate the MBMS context. When the response is received, the MBMS context will be inactive.

GTP-U and Charging Management Messages

Message Type	Used By	Description
G-PDU	GTP-C, GTP-U	GPRS Packet data unit delivery message.
Node Alive Request/Response	GTP-C, GTP-U	Used to inform rest of network when a node starts service.
Redirection Request/Response	GTP-C, GTP-U	Used to divert the flow of CDRs from the CDFs to another CGF when the sender is being removed, or they are used when the CGF has lost its connection to a downstream system.
Data Record Transfer Request/Response	GTP-C, GTP-U	Used to reliably transport CDRs from the point of generation (SGSN/GGSN) to non-volatile storage in the CGF

GTP identity filtering

FortiOS Carrier supports a number of filtering methods based on subscriber identity such as APN filtering, IMSI filtering, and advanced filtering.

This section includes:

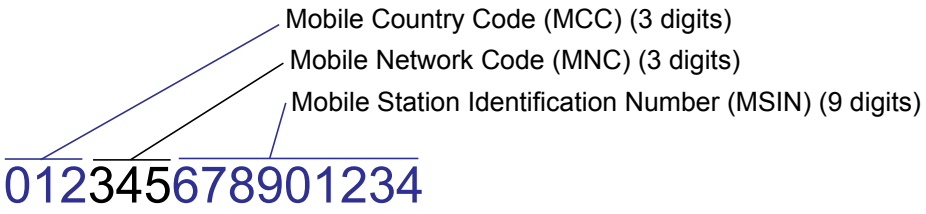
IMSI on carrier networks

The International Mobile Subscriber Identity (IMSI) number is central to identifying users on a carrier network. It is a unique number that is assigned to a cell phone or mobile device to identify it on the GMS or UTMS network.

Typical the IMSI number is stored on the SIM card of the mobile device and is sent to the network as required.

An IMSI number is 15 digits long, and includes the Mobile Country Code (MCC), Mobile Network Code (MNC), and Mobile Station Identification Number (MSIN).

Figure 249: IMSI codes



The Home Network Identity (HNI) is made up of the MCC and MNC. The HNI is used to fully identify a user's home network. This is important because some large countries have more than one country code for a single carrier. For example a customer with a mobile carrier on the East Coast of the United States would have a different MCC than a customer on the West Coast with the same carrier because even through the MNC would be the same the MCC would be different — the United States uses MCCs 310 to 316 due to its size.

If an IMSI number is not from the local carrier's network, IMSI analysis is performed to resolve the number into a Global Title which is used to access the user's information remotely on their home carrier's network for things like billing and international roaming.

See "Configuring IMSI filtering in FortiOS Carrier" on page 2421.

Other identity and location based information elements

IMSI focuses on the user, their location, and carrier network. There are other numbers used to identify different user related Information Elements (IE).

These identity and location based elements include:

- Access Point Number (APN)
- Mobile Subscriber Integrated Services Digital Network (MSISDN)
- Radio Access Technology (RAT) type
- User Location Information (ULI)
- Routing Area Identifier (RAI)
- International Mobile Equipment Identity (IMEI)

Access Point Number (APN)

The Access Point Number (APN) is used in GPRS networks to identify an IP packet data network that a user wants to communicate with. The Network Identifier describes the network and optionally the service on that network that the GGSN is connected to. The APN also includes the MCC and MCN, which together locate the network the GGSN belongs to. An example of an APN in the Barbados using Digicel as the carrier that is connecting to the Internet is `internet.mcc342.mnc750.gprs`.

When you are configuring your FortiOS Carrier unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

The access point can then be used in a DNS query to a private DNS network. This process (called APN resolution) gives the IP address of the GGSN which serves the access point. At this point a PDP context can be activated. See "Configuring APN filtering in FortiOS Carrier" on page 2420.

Mobile Subscriber Integrated Services Digital Network (MSISDN)

This is a 15-digit number that, along with the IMSI, uniquely identifies a mobile user. Normally this number includes a 2-digit country code, a 3-digit national destination code, and a 10-digit subscriber number or the phone number of the mobile device, and because of that may change over time if the user changes their phone number. The MSISDN number follows the ITU-T E.164 numbering plan.

Radio Access Technology (RAT) type

The RAT type represents the radio technology used by the mobile device. This can be useful in determining what services or content can be sent to a specific mobile device. FortiOS Carrier supports:

- **UMTS Terrestrial Radio Access Network (UTRAN)**, commonly referred to as 3G, routes many types of traffic including IP traffic. This is one of the faster types.
- **GSM EDGE Radio Access Network (GERAN)** is a key part of the GSM network which routes both phone calls and data.
- **Wireless LAN (WLAN)** is used but not as widely as the other types. It is possible for the mobile device to move from one WLAN to another such as from an internal WLAN to a commercial hot spot.
- **Generic Access Network (GAN)** can also be called unlicensed mobile access (UMA). It routes voice, data, and SIP over IP networks. GAN is commonly used for mobile devices that have a dual-mode and can hand-off between GSM and WLANs.

- **High Speed Packet Access (HSPA)** includes two other protocols High Speed Downlink and Uplink Packet Access protocols (HSDPA and HSUPA respectively). It improves on the older WCDMA protocols by better using the radio bandwidth between the mobile device and the radio tower. This results in an increased data transfer rate for the user.

RAT type is part of advanced filtering configuration. See "Configuring advanced filtering in FortiOS Carrier" on page 2422.

User Location Information (ULI)

Gives Cell Global Identity/Service Area Identity (CGI/SAI) of where the mobile station is currently located. The ULI and the RAI are commonly used together to identify the location of the mobile device.

ULI is part of advanced filtering configuration. See "Configuring advanced filtering in FortiOS Carrier" on page 2422.

Routing Area Identifier (RAI)

Routing Areas (RAs) divide the carrier network and each has its own identifier (RAI). When a mobile device moves from one routing area to another, the connection is handled by a different part of the network. There are normally multiple cells in a routing area. There is only one SSGN per routing area. The RAI and ULI are commonly used to determine a user's location.

RAI is part of advanced filtering configuration. See "Configuring advanced filtering in FortiOS Carrier" on page 2422.

International Mobile Equipment Identity (IMEI)

IMEI is a unique 15-digit number used to identify mobile devices on mobile networks. It is very much like the MAC address of a TCP/IP network card for a computer. It can be used to prevent network access by a stolen phone — the carrier knows the mobile phone's IMEI, and when it is reported stolen that IMEI is blocked from accessing the carrier network no matter if it has the same SIM card as before or not. It is important to note that the IMEI stays with the mobile phone or device where the other information is either location based or stored on the removable SIM card.

IMEI type is part of advanced filtering configuration. See "Configuring advanced filtering in FortiOS Carrier" on page 2422.

When to use APN, IMSI, or advanced filtering

At first glance APN, IMSI, and advanced filtering have parts in common. For example two can filter on APN, and another two can filter on IMSI. The difficulty is knowing when to use which type of filtering.

Figure 250: Identity filtering comparison

Filtering type	Filter on the following data:	When to use this type of filtering
APN	APN	Filter based on GTP tunnel start or destination
IMSI	IMSI, MCC-MNC	Filter based on subscriber information
Advanced	PDP context, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI	When you want to filter based on: user phone number (MSISDN) what wireless technology the user employed to get on the network (RAT type) user location (ULI and RAI) handset ID, such as for stolen phones (IMEI)

APN filtering is very specific — the only identifying information that is used to filter is the APN itself. This will always be present in GTP tunnel traffic, so all GTP traffic can be filtered using this value. See "Configuring APN filtering in FortiOS Carrier" on page 2420.

IMSI filtering can use a combination of the APN and MCC-MNC numbers. The MCC and MNC are part of the APN, however filtering on MCC-MNC separately allows you to filter based on country and carrier instead of just the destination of the GTP Tunnel. See "Configuring IMSI filtering in FortiOS Carrier" on page 2421.

Advanced filtering can go into much deeper detail covering PDP contexts, MSISDN, IMEI, and more not to mention APN, and IMSI as well. If you can't find the information in APN or IMSI that you need to filter on, then use Advanced filtering. See "Configuring advanced filtering in FortiOS Carrier" on page 2422.

Configuring APN filtering in FortiOS Carrier

To configure APN filtering go to *UTM Profiles* > *Carrier* > *GTP Profile. Select a profile or create a new one,* and expand *APN filtering*.

When you are configuring your FortiOS Carrier unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

For more information on APN, see "Access Point Number (APN)" on page 2418.

Enable APN Filter	Select to enable filtering based on APN value.
Default APN Action	Select either Allow or Deny for all APNs that are not found in the list. The default is Allow.
Value	Displays the APN value for this entry. Partial matches are allowed using wildcard. For example `*.mcc333.mcn111.gprs` would match all APNs from country `333` and carrier `111` on the gprs network.

Mode	Select one or more of the methods used to obtain APN values. Mobile Station provided - The APN comes from the mobile station where the mobile device connected. This is the point of entry into the carrier network for the user's connection. Network provided - The APN comes from the carrier network. Subscription Verified - The user's subscription has been verified for this APN. This is the most secure option.
Action	One of allow or deny to allow or block traffic associated with this APN.
Delete icon	Select to remove this APN entry from the list.
Edit icon	Select to change the information for this APN entry.
Add APN	Select to add an APN to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding APNs. A warning to this effect will be displayed when you select the *Add APN* button.

The Add APN button is not activated until you save the new GTP profile. When you edit that GTP profile, you will be able to add new APNs.

Configuring IMSI filtering in FortiOS Carrier

In many ways the IMSI on a GPRS network is similar to an IP address on a TCP/IP network. Different parts of the number provide different pieces of information. This concept is used in IMSI filtering on FortiOS Carrier.

To configure IMSI filtering go to *UTM Profiles* > *Carrier* > *GTP Profile* and expand *IMSI filtering*.

While both the APN and MCC-MCN fields are optional, without using one of these fields the IMSI entry will not be useful as there is no information for the filter to match.

Enable IMSI Filter	Select to turn on IMSI filtering.
Default IMSI Action	Select Allow or Deny. This action will be applied to all IMSI numbers except as indicated in the IMSI list that is displayed. The default value is Allow.
APN	The Access Point Number (APN) to filter on. This field is optional.
MCC-MNC	The Mobile Country Code (MCC) and Mobile Network Code (MNC) to filter on. Together these numbers uniquely identify the carrier and network of the GGSN being used. This field is optional.

Mode	Select the source of the IMSI information as one or more of the following: **Mobile Station provided -** the IMSI number comes from the mobile station the mobile device is connecting to. **Network provided -** the IMSI number comes from the GPRS network which could be a number of sources such as the SGSN, or HLR. **Subscription Verified -** the IMSI number comes from the user's home network which has verified the information. While Subscription Verified is the most secure option, it may not always be available. Selecting all three options will ensure the most complete coverage.
Action	Select the action to take when this IMSI information is encountered. Select one of Allow or Deny.
Delete Icon	Select the delete icon to remove this IMSI entry.
Edit Icon	Select the edit icon to change information for this IMSI entry.
Add IMSI	Select to add an IMSI to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding IMSIs. A warning to this effect will be displayed when you select the *Add IMSI* button.

Also see "IMSI filtering options" on page 2341.

Configuring advanced filtering in FortiOS Carrier

Compared to ADN or IMSI filtering, advanced filtering is well named. Advanced filtering can be viewed as a catch-all filtering option — if ADN or IMSI filtering doesn't do what you want, then advanced filtering will. The advanced filtering can use more information elements to provide considerably more granularity for your filtering.

Enable	Select to turn on advanced filtering.
Default Action	Select Allow or Deny as the default action to take when traffic does not match an entry in the advanced filter list .
Messages	Optionally select one or more types of messages this filter applies to: Create PDP Context Request, Create PDP Context Response, Update PDP Context Request, or Update PDP Context Response. Selecting *Create PDP Context Response* or *Update PDP Context Response limits RAT type to only GAN and HSPA, and disables the APN, APN Mode, IMSI, MSISDN, ULI, RAI,* and *IMEI fields.* To select *Update PDP Context Request*, *APN Restriction* must be set to *all*. Selecting *Update PDP Context Request disables the APN, MSISDN,* and *IMEI fields.* if all message types are selected, only the RAT Types of GAN and HSPA are available to select.

APN Restriction	APN Restriction either allows all APNs or restricts the APNs to one of four categories — Public-1, Public-2, Private-1, or Private-2. This can also be combined with a specific APN or partial APN as well as specifying the APN mode. See "Access Point Number (APN)" on page 2418.
RAT Type	Select one or more of the Radio Access Technology Types listed. These fields control how a user accesses the carrier's network. You can select one or more of UTRAN, GERAN, WLAN, GAN, HSPA, or any. See "Radio Access Technology (RAT) type" on page 2418.
ULI	The user location identifier. Often the ULI is used with the RAI to locate a user geographically on the carrier's network. The ULI is disabled when *Create PDP Context Response* or *Update PDP Context Response* messages are selected. See "User Location Information (ULI)" on page 2419.
RAI	The router area identifier. There is only one SGSN per routing area on a carrier network. This is often used with ULI to locate a user geographically on a carrier network. The RAI is disabled when *Create PDP Context Response* or *Update PDP Context Response* messages are selected. See "Routing Area Identifier (RAI)" on page 2419.
IMEI	The International Mobile Equipment Identity. The IMEI uniquely identifies mobile hardware, and can be used to block stolen equipment. The IMEI is only available when *Create PDP Context Request* or no messages are selected. See "International Mobile Equipment Identity (IMEI)" on page 2419
Action	Select Allow or Deny as the action when this filter matches traffic. The default is Allow.
Delete Icon	Select to delete this entry from the list.
Edit Icon	Select to edit this entry.
Add	Select to add an advanced filter to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding advanced filters. A warning to this effect will be displayed when you select the *Add* button.

Also see "Advanced filtering options" on page 2343.

Troubleshooting

This section highlights troubleshooting for Carrier related issues.

This section includes:

FortiOS Carrier diagnose commands

This section includes diagnose commands specific to FortiOS Carrier features such as GTP.

GTP related diagnose commands

This CLI command allows you to gain information on GTP packets, logs, statistics, and other information.

```
diag firewall gtp <command>
```

apn list <gtp_profile>	The APN list entries in the specified GTP profile
auth-ggsns show <gtp_profile>	The authorized GGSNs entries for the specified GTP profile. Any GGSNs not on this list will not be recognized.
auth-sgsns show <gtp_profile>	The authorized SGSNs list entries for the specified GTP profile. Any SGSNs not on this list will not be recognized.
handover-grp show <gtp_profile>	The handover group showing the range of allowed handover group IP addresses. The handover group acts like a whitelist of allowed GTP addresses with a default deny at the end — if the GTP address is not on the list, it is denied.
ie-remove-policy list <gtp_profile>	List of IE policies in the IE removal policy for this GTP profile. The information displayed includes the message count for this policy, the length of the SGSN, the list of IEs, and list of SGSN IP addresses.
imsi list <gtp_profile>	IMSI filter entries for this GTP profile. The information displayed includes the message count for this filter, length of the IMSI, the length of the APN and IMSI, and of course the IMSI and APN values.
invalid-sgsns-to-long list <gtp_profile>	List of SGSNs that do not match the filter criteria. These SGSNs will be logged.
ip-policy list <gtp_profile>	List the IP policies including message count for each policy, the action to take, the source and destination IP addresses or ranges, and masks.

noip-policy <gtp_profile>	List the non-IP policies including the message count, which mode, the action to take, and the start and end protocols to be used by decimal number.
path {list | flush}	Select list or flush. List the GTP related paths in FortiOS Carrier memory. Flush the GTP related paths from memory.
policy list <gtp_policy>	The GTP advanced filter policy information for this GTP profile. The information displayed for each entry includes a count for messages matching this filter, a hexidecimal mask of which message types to match, the associated flags, action to take on a match, APN selection mode, MSISDN, RAT types, RAI, ULI, and IMEI.
profile list	Displays information about the configured GTP profiles. You will not be able to see the bulk of the information if you do not log the output to a file.
runtime-stat flush	Select to flush the GTP runtime statistics from memory.
stat	Display the GTP runtime statistics — details on current GTP activity. This information includes how many tunnels are active, how many GTP profiles exist, how many IMSI filter entries, how many APN filter entries, advanced policy filter entries, IE remove policy filter entries, IP policy filter entries, clashes, and dropped packets.
tunnel {list | flush}	Select one of list or flush. List lists all the GTP tunnels currently active. Flush clears the list of active GTP tunnels.

Applying Intrusion and Prevention System (IPS) signatures to IP packets within GTP-U tunnels

GTP-U (GTP user data tunnelling) tunnels carry user data packets, signalling messages and error information. GTP-U uses UDP port 2152. FortiOS Carrier units can apply IPS intrusion protection and detection to GTP-U user data sessions.

To apply IPS to GTP-U user data sessions, add an IPS Sensor to a profile and add the profile to a security policy that accepts GTP-U tunnels. The security policy Service field must be set to GTP or ANY to accept GTP-U packets.

The FortiOS Carrier unit intercepts packets with destination port 2152, removes the GTP header and handles the packets as regular IP packets. Applying an IPS sensor to the IP packets, the FortiOS Carrier unit can log attacks and pass or drop packets depending on the configuration of the sensor.

If the packet is GTP-in-GTP, or a nested tunnel, the packets are passed or blocked without being inspected.

To apply an IPS sensor to GTP-U tunnels

1 Go to *UTM Profiles* > *Intrusion Protection* > *IPS Sensor* and select *Create New* to add an IPS Sensor.

2 Configure the IPS Sensor to detect attacks and log, drop, or pass attack packets.

See the Intrusion Protection section of the *FortiOS UTM Guide*.

3 Go to *Policy* > *Policy* and apply the IPS sensor to the security policy.

4 Go to *Policy* > *Policy* and select Create New to add a security policy or select a security policy.

5 Configure the security policy to accept GTP traffic.

In the security policy configure the source and destination settings to match the GTP traffic. Service to GTP or ANY so that the security policy accepts GTP traffic.

6 Select the GTP profile within the security policy.

7 Configure any other required security policy settings.

8 Select *OK* to save the security policy.

GTP packets are not moving along your network

When GTP packets are not getting to their destination, this could be caused by any one of a number of issues. General troubleshooting principals apply here.

The following sections provide some suggestions on how to troubleshoot this issue:

- Attempt to identify the section of your network with the problem
- Ensure you have an APN configured
- Check the logs and adjust their settings if required
- Check the routing table
- Perform a sniffer trace
- Generate specific packets to test the network

Attempt to identify the section of your network with the problem

The first step is to determine how widespread this problem is. Does it affect the whole GPRS network, or just one or two devices?

If the entire network is has this problem, the solution is likely a more general one such as ensuring the security policies allow GTP traffic to pass, the GTP profile specifies SSGNs and GSGNs, or ensuring the GTP general settings are not overly limiting.

If one part of the network is affected, the problem is more likely centered around configurations with those network devices specified such as the handover group, or authorized SGSNs/GGSNs. It is also possible that small portions of the network may have hardware related issues such as cabling or faulty hardware. This section does not address those issues, and assumes hardware is not the problem.

The handover group is a whitelist of GTP addresses allowed to handle GTP messages. If a device's address is not on this list, it will be denied.

Ensure you have an APN configured

When you configure your GTP profile, ensure you first configure the APN. Without it, there will be no flow of traffic. The APN is used in nearly all GTP communications and without it, the FortiOS Carrier unit doesn't have the information it needs.

Check the logs and adjust their settings if required

During normal operation, the log settings will show any problems on the network but may not provide the level of details required to fully troubleshoot the problem. The reason for this is that the level of detail required for troubleshooting would quickly overwhelm the daily logs without any real benefit.

GTP related events in the event log will have message IDs in the range 41216 to 41222. For more information on GTP log messages, see the *Log Message Reference*. For more information on logging in general, see the *Logging and Reporting* handbook chapter.

Once there is a problem to troubleshoot, check the logs to trace the traffic patterns and narrow down the possible sources of the problem. There may be enough detail for you to locate and fix the problem without changing the log settings.

Remember to set any changes you made to the log settings back to their original values when you are done troubleshooting. Otherwise, the amount of detail will overwhelm your logging.

However, if more detail is required you can change settings such as:

- Lower the Log Frequency number in GTP Profiles so fewer or no log messages are dropped. This will allow a more accurate picture of everything happening on the network, where you may have had only a partial picture before.
- Ensure all the GTP log events are enabled to provide you with a complete picture.
- Increase the minimum log level to Information or Debug to ensure you are seeing all possible log entries. This is found if you go to *Log&Report* > *Log Config* > *Log Setting* > *Local Logging & Archiving* > *Minimum log level.*
- Ensure that all relevant event types are enabled under *Log&Report* > *Log Config* > *Event Log.*

For more information on GTP related logging, see "Logging events on the FortiOS Carrier unit" on page 2406. See the log and report chapters of Logging and Reporting Guide and FortiOS CLI Reference.

General information to look for in the logs includes:

- Are all packets having problems or just certain types?
- Are all devices on the network having problem, or just certain devices?
- Is it just GTP traffic that is having problems or are all types of traffic having the same problem?

Check the routing table

On any network, the routing table determines how packets reach their destination. This is also true on a carrier network.

If the FortiOS Carrier unit is running in NAT mode, verify that all desired routes are in the routing table — local subnets, default routes, specific static routes, and dynamic routing protocols. For complete information, it is best to check the routing table in the CLI. This method provides more complete information.

If VDOMs are enabled on your FortiOS Carrier unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To check the routing table using the CLI

```
# get router info routing-table all
```

```
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS
   inter area
* - candidate default

S*      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S       1.0.0.0/8 [10/0] via 192.168.183.254, port2
S       2.0.0.0/8 [10/0] via 192.168.183.254, port2
C       10.142.0.0/23 is directly connected, port3
B       10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C       192.168.182.0/23 is directly connected, port2
```

Examining an entry from the routing table above:

```
B       10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates and administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

Perform a sniffer trace

When troubleshooting network traffic, it helps to look inside the headers of packets to determine if they are traveling along the route you expect. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your FortiOS Carrier unit has NP2 interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP2 interfaces, disable offloading on those interfaces.

What can sniffing packets tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the FortiOS Carrier unit, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the FortiOS Carrier unit is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing. This prevents an IP packet from being forwarded if its source IP address either does not belong to a locally attached subnet (local interface), or be a hop on the routing between the FortiOS Carrier and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`), however this will disable stateful inspection on the FortiOS Carrier unit and consequently cause many features to be turned off.

If you configure virtual IP addresses on your FortiOS Carrier unit, the unit will use those addresses in preference to the physical IP addresses. If not configured properly, secondary IP addresses can cause a broadcast storm. You will notice the secondary address being preferred when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How to sniff packets

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose>
   <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as `port1` or `internal`. This can also be `any` to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. `none` indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (‘).
<verbose>	The level of verbosity as one of: **1** - print header of packets **2** - print header and data from IP of packets **3** - print header and data from Ethernet of packets
<count>	The number of packets the sniffer reads before stopping. If you don't put a number here, the sniffer will run forever unit you stop it with `<CTRL C>`.

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the port1 interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh
   3177924955 ack 1854307757
```

```
0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh
   1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh
   4225311614 ack 3314279933
```

Generate specific packets to test the network

If some packets are being delivered as expected while others are not, or after you believe you have fixed the problem, it is a good idea to generate specific traffic to test your network.

For example if you discover through log messages and packet sniffing that Create PDP Context Request messages are not being delivered between two SGSNs, you can generate those specific messages on your network to confirm they are the problem, and later that you have solved the problem and they are now being delivered as expected.

This step requires a third party traffic generation tool, either hardware or software. This is not be supported by Fortinet.

Chapter 15 Deploying Wireless Networks

This FortiOS Handbook chapter contains the following sections:

Introduction to wireless networking explains the basic concepts of wireless networking and how to plan your wireless network.

Configuring a WiFi LAN explains how to set up a basic wireless network, prior to deploying access point hardware.

Access point deployment explains how to deploy access point hardware and add it to your wireless network configuration.

Wireless network monitoring explains how to monitor your wireless clients and how to monitor other wireless access points, potentially rogues, in your coverage area.

Configuring wireless network clients explains how to configure typical wireless clients to work with a WPA-Enterprise protected network.

Wireless network examples provides two examples. The first is a simple WiFi network using automatic configuration. The second is a more complex example of a business with two WiFi networks, one for employees and another for guests or customers.

Using a FortiWiFi unit as a client explains how to use a FortiWiFi unit as a wireless client to connect to other WiFi networks. This connection can take the place of an Ethernet connection where wired access to a network or to the Internet is not available.

WiFi Reference provides information about WiFi radio channels.

WiFi Controller Reference details the web-based manager pages that configure the WiFi controller, manage access points, and monitor your WiFi network.

Introduction to wireless networking

This chapter introduces some concepts you should understand before working with wireless networks, describes Fortinet's wireless equipment, and then describes the factors you need to consider in planning deployment of a wireless network.

The following topics are included in this section:

Wireless concepts

Wireless networking is radio technology, subject to the same characteristics and limitations as the familiar audio and video radio communications. Various techniques are used to modulate the radio signal with a data stream.

Bands and channels

Depending on the wireless protocol selected, you have specific channels available to you, depending on what region of the world you are in.

- IEEE 802.11a,b,and g protocols provide up to 14 channels in the 2.400-2.500 GHz Industrial, Scientific and Medical (ISM) band.
- IEEE 802.11a,n (5.150-5.250, 5.250-5.350, 5.725–5.875 GHz, up to 16 channels) in portions of Unlicensed National Information Infrastructure (U-NII) band

Note that the width of these channels exceeds the spacing between the channels. This means that there is some overlap, creating the possibility of interference from adjacent channels, although less severe than interference on the same channel. Truly non-overlapping operation requires the use of every fourth or fifth channel, for example ISM channels 1, 6 and 11.

The capabilities of your wireless clients is the deciding factor in your choice of wireless protocol. If your clients support it, 5GHz protocols have some advantages. The 5GHz band is less used than 2.4GHz and its shorter wavelengths have a shorter range and penetrate obstacles less. All of these factors mean less interference from other access points, including your own.

When configuring your WAP, be sure to correctly select the Geography setting to ensure that you have access only to the channels permitted for WiFi use in your part of the world.

For detailed information about the channel assignments for wireless networks for each supported wireless protocol, see "Wireless radio channels" on page 2503.

Power

Wireless LANs operate on frequencies that require no license but are limited by regulations to low power. As with other unlicensed radio operations, the regulations provide no protection against interference from other users who are in compliance with the regulations.

Power is often quoted in dBm. This is the power level in decibels compared to one milliwatt. 0dBm is one milliwatt, 10dBm is 10 milliwatts, 27dBm, the maximum power on Fortinet FortiAP equipment, is 500 milliwatts. The FortiGate unit limits the actual power available to the maximum permitted in your region as selected by the WiFi controller country setting.

Received signal strength is almost always quoted in dBm because the received power is very small. The numbers are negative because they are less than the one milliwatt reference. A received signal strength of -60dBm is one millionth of a milliwatt or one nanowatt.

Antennas

Transmitted signal strength is a function of transmitter power and antenna gain. Directional antennas concentrate the signal in one direction, providing a stronger signal in that direction than would an omnidirectional antenna.

FortiWiFi units have detachable antennas. However, these units receive regulatory approvals based on the supplied antenna. Changing the antenna might cause your unit to violate radio regulations.

Security

There are several security issues to consider when setting up a wireless network.

Whether to broadcast SSID

Users who want to use a wireless network must configure their computers with the wireless service set identifier (SSID) or network name. Broadcasting the SSID makes connection to a wireless network easier because most wireless client applications present the user with a list of network SSIDs currently being received. This is desirable for a public network.

To obscure the presence of a wireless network, do not broadcast the SSID. This does not prevent attempts at unauthorized access, however, because the network is still detectable with wireless network “sniffer” software.

Encryption

Wireless networking supports the following security modes for protecting wireless communication, listed in order of increasing security.

None — Open system. Any wireless user can connect to the wireless network.

WEP64 — 64-bit Web Equivalent Privacy (WEP). This encryption requires a key containing 10 hexadecimal digits.

WEP128 — 128-bit WEP. This encryption requires a key containing 26 hexadecimal digits.

WPA — 256-bit Wi-Fi Protected Access (WPA) security. This encryption can use either the TKIP or AES encryption algorithm and requires a key of either 64 hexadecimal digits or a text phrase of 8 to 63 characters. It is also possible to use a RADIUS server to store a separate key for each user.

WPA2 — WPA with security improvements fully meeting the requirements of the IEEE 802.11i standard. Configuration requirements are the same as for WPA.

For best security use the WPA2 with AES encryption and a RADIUS server to verify individual credentials for each user. WEP, while better than no security at all, is an older algorithm that is easily compromised. With either WEP or WAP, changing encryption passphrases on a regular basis further enhances security.

Separate access for employees and guests

Wireless access for guests or customers should be separate from wireless access for your employees. This does not require additional hardware. Both FortiWiFi units and FortiAP units support multiple wireless LANs on the same access point. Each of the two networks can have its own SSID, security settings, firewall policies, and user authentication.

A good practice is to broadcast the SSID for the guest network to make it easily visible to users, but not to broadcast the SSID for the employee network.

Two separate wireless networks are possible because multiple virtual APs can be associated with an AP profile. The same physical APs can provide two or more virtual WLANs.

Captive portal

As part of authenticating your users, you might want them to view a web page containing your acceptable use policy or other information. This is called a captive portal. No matter what URL the user initially requested, the portal page is returned. Only after authenticating and agreeing to usage terms can the user access other web resources.

For information about setting up a captive portal, see "Captive Portal security" on page 2452.

Power

Reducing power reduces unwanted coverage and potential interference to other WLANs. Areas of unwanted coverage are a potential security risk. There are people who look for wireless networks and attempt to access them. If your office WLAN is receivable out on the public street, you have created an opportunity for this sort of activity.

Monitoring for rogue APs

It is likely that there are APs available in your location that are not part of your network. Most of these APs belong to neighboring businesses or homes. They may cause some interference, but they are not a security threat. There is a risk that people in your organization could connect unsecured WiFi-equipped devices to your wired network, inadvertently providing access to unauthorized parties. The optional On-Wire Rogue AP Detection Technique compares MAC addresses in the traffic of suspected rogues with the MAC addresses on your network. If wireless traffic to non-Fortinet APs is also seen on the wired network, the AP is a rogue, not an unrelated AP.

Decisions about which APs are rogues are made manually on the Rogue AP monitor page. For detailed information about monitoring rogue APs, see "Monitoring rogue APs" on page 2470.

Suppressing rogue APs

When you have declared an AP to be a rogue, you have the option of suppressing it. To suppress and AP, the FortiGate WiFi controller sends reset packets to the rogue AP. Also, the MAC address of the rogue AP is blocked in the firewall policy. You select the suppression action on the Rogue AP monitor page. For more information, see “Suppressing rogue APs” on page 2473.

Rogue suppression is available only when there is a radio dedicated to scanning. It will not function during background scanning.

Authentication

Wireless networks usually require authenticated access. FortiOS authentication methods apply to wireless networks the same as they do to wired networks because authentication is applied in the firewall policy.

The types of authentication that you might consider include:

- user accounts stored on the FortiGate unit
- user accounts managed and verified on an external RADIUS, LDAP or TACACS+ server
- Windows Active Directory authentication, in which users logged on to a Windows network are transparently authenticated to use the wireless network.

This Wireless chapter of the FortiOS Handbook will provide some information about each type of authentication, but more detailed information is available in the Authentication chapter.

What all of these types of authentication have in common is the use of user groups to specify who is authorized. For each wireless LAN, you will create a user group and add to it the users who can use the WLAN. In the identity-based firewall policies that you create for your wireless LAN, you will specify this user group.

Some access points, including FortiWiFi units, support MAC address filtering. You should not rely on this alone for authentication. MAC addresses can be “sniffed” from wireless traffic and used to impersonate legitimate clients.

Wireless networking equipment

Fortinet produces two types of wireless networking equipment:

- FortiWiFi units, which are FortiGate units with a built-in wireless access point/client
- FortiAP units, which are wireless access points compliant with the CAPWAP standard that you can control from any FortiGate unit that supports the WiFi Controller feature.

FortiWiFi units

A FortiWiFi unit can:

- Provide an access point for clients with wireless network cards. This is called Access Point mode, which is the default mode.

or

- Connect the FortiWiFi unit to another wireless network. This is called Client mode. A FortiWiFi unit operating in client mode can only have one wireless interface.

or

- Monitor access points within radio range. This is called Monitoring mode. You can designate the detected access points as Accepted or Rogue for tracking purposes. No access point or client operation is possible in this mode. But, you can enable monitoring as a background activity while the unit is in Access Point mode.

FortiWiFi unit capabilities differ by model as follows:

Table 129: FortiWiFi model capabilities

Model	Radio	Simultaneous SSIDs
20C	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	7 for AP, 1 for monitoring
30B	802.11 b/g 2.4GHz	7 for AP, 1 for monitoring
40C	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	7 for AP, 1 for monitoring
50B	802.11 b/g 2.4GHz	7 for AP, 1 for monitoring
60B	802.11 b/g 2.4GHz 802.11 a 5GHz	7 for AP, 1 for monitoring
60C	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	7 for AP, 1 for monitoring
80/81CM	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	7 for AP, 1 for monitoring

Using a FortiWiFi unit as a managed AP

A FortiWiFi unit can also be used much like a FortiAP unit to provide an access point managed by another FortiGate unit. To use a FortiWiFi unit as a managed WAP, you need to switch it to wireless terminal mode by using the CLI as follows:

```
config system global
  set wireless-mode wtp
end
```

FortiWiFi-80CM supports WTP mode only in FortiOS 4.3 patch 2 or later.

The wireless functionality of a FortiWiFi unit in wireless terminal mode cannot be controlled from the unit itself.

If there are firewall devices between the WiFi controller FortiGate unit and the managed FortiWiFi units, make sure that ports 5246 and 5247 are open. These ports carry, respectively, the encrypted control channel data and the wireless network data. If needed, you can change these ports in the CLI:

```
config system global
  set wireless-controller-port <port_int>
end
```

This command sets the control channel port. The data channel port is always the control port plus one. The port setting must match on the access controller and all access points.

FortiAP units

FortiAP series wireless access points are controlled by a FortiGate unit over Ethernet. Capabilities differ by model as follows:

Table 130: FortiAP model capabilities

Model	Radio 1	Radio 2	Simultaneous SSIDs
210B (indoor)	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	N/A	7 for AP, 1 for monitoring
220A (indoor)	802.11 b/g/n 2.4GHz	802.11 a/n 5GHz	14 for AP, 2 for monitoring
220B (indoor)	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	802.11 b/g/n 2.4GHz	14 for AP, 2 for monitoring
222B (outdoor)	802.11 b/g/n 2.4GHz	802.11 a/n 5GHz	14 for AP, 2 for monitoring

Dual-band radios can function as an AP on either band or as a dual-band monitor. The monitoring function is also available during AP operation if Background Scan is enabled in the custom AP profile for the device.

Third-party WAPs

FortiOS implements the CAPWAP standard.

Deployment considerations

Several factors need to be considered when planning a wireless deployment.

Types of wireless deployment

This Handbook chapter describes two main types of wireless deployment: single WAP and multiple WAP. You will know which type of deployment you need after you have evaluated the coverage area environment.

Deployment methodology

1. Evaluate the coverage area environment.
2. Position access point(s).
3. Select access point hardware.
4. Install and configure the equipment.
5. Test and tune the network.

Evaluating the coverage area environment

Consider the following factors:

- **Size of coverage area** — Even under ideal conditions, reliable wireless service is unlikely beyond 100 metres outdoors or 30 metres indoors. Indoor range can be further diminished by the presence of large metal objects that absorb or reflect radio frequency energy. If wireless users are located on more than one floor of a building, a minimum of one WAP for each floor will be needed.

- **Bandwidth required** — Wireless interface data rates are between 11 and 150 Mb/s, depending on the 802.11 protocol that is used. This bandwidth is shared amongst all users of the wireless data stream. If wireless clients run network-intensive applications, fewer of them can be served satisfactorily by a single WAP.

  Note that on some FortiWiFi units you can define up to four wireless interfaces, increasing the available total bandwidth.
- **Client wireless capabilities** — The 802.11n protocol provides the highest data rates and has channels in the less interference-prone 5GHz band, but it is supported only on the latest consumer devices. The 802.11g protocol is more common but offers lower bandwidth. Some older wireless client equipment supports only 802.11b with a maximum data rate of 11Mb/s. WAP radios support the protocol that you select with backward compatibility to older modes. For example, if you select 802.11n, clients can also connect using 802.11g or 802.11b.

The most important conclusion from these considerations is whether more than one WAP is required.

Positioning access points

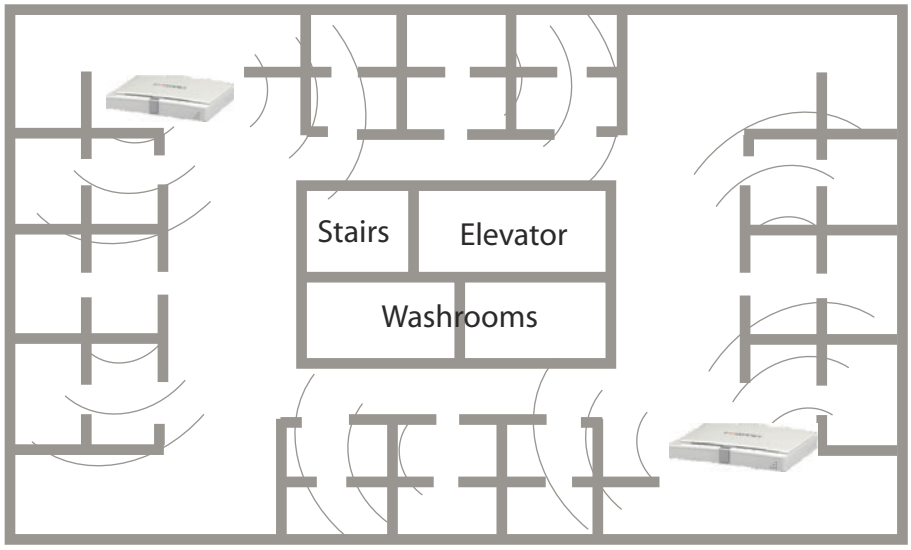
When placing the access point, your main concern is providing a strong signal to all users. A strong signal ensures a fast connection and efficient data transfer. A weaker signal means a greater chance of data transmission errors and the need to re-send information, slowing down data transfer.

Consider the following guidelines when placing access points:

- Physical barriers can impede the radio signals. Solid objects such as walls, furniture and people absorb radio waves, weakening the signal. Be aware of the physical barriers in your office space that may reduce a signal. If there is enough physical interference, you may encounter dead spots that receive no signal.
- Ensure the access point is located in a prominent location within a room for maximum coverage, rather than in a corner.
- Construction materials used in a building can also weaken radio signals. Rooms with walls of concrete or metal can affect the signal strength.

If you cannot avoid some of these impediments due to the shape of the office or building materials used, you may need to use multiple access points to help distribute the radio signal around the room. Figure 251 shows how positioning two FortiAP-220A units within a uniquely shaped office space helps to distribute signals around the area.

Figure 251: Using multiple APs to provide a constant strong signal.



This sample office has washrooms, a stairwell and an elevator shaft in the center of the building, making it impossible to use a single access point effectively. The elevator shaft and multiple metal stalls in the washrooms can cause signal degradation. However, placing access points in diagonally opposite areas of the office provides maximum coverage.

When using multiple access points, set each access point to a different channel to avoid interference in areas where signals from both access points can be received.

Selecting access point hardware

For a single WAP installation, you could deploy a single FortiWiFi unit. If the site already has a FortiGate unit that supports the WiFi controller feature, adding a FortiAP unit is the most economical solution.

For a multiple WAP deployment you need a FortiGate unit as a WiFi controller and multiple FortiAP units. A FortiWiFi unit can be used as a managed WAP, but it is more expensive.

The FortiAP unit offers more flexible placement. FortiWiFi units either sit on a shelf or are rack mounted. FortiAP units can be attached to any wall or ceiling, enabling you to locate them where they will provide the best coverage.

Single access point networks

A single access point is appropriate for a limited number of users in a small area. For example, you might want to provide wireless access for a group of employees in one area on one floor of an office building.

A good rule of thumb is that one access point for can serve 3000 to 4000 square feet of space, with no user more than 60 feet from the access point. Walls and floors reduce the coverage further, depending on the materials from which they are made.

Multiple access point networks

To cover a larger area, such as multiple floors of a building, or multiple buildings, multiple access points are required.

In the WiFi controller, you configure a single virtual access point, but the controller manages multiple physical access points that share the same configuration. A feature known as “fast roaming” enables users to move from one physical access point coverage area to another while retaining their authentication.

Fast Roaming

Users in a multi-AP network, especially with mobile devices, can move from one AP coverage area to another. But, the process of re-authentication can often take seconds to complete and this can impair wireless voice traffic and time sensitive applications. The FortiAP fast roaming feature solves this problem and is available only when moving between FortiAP units managed by the same FortiGate unit.

Fast roaming uses two standards-based techniques:

- Pairwise Master Key (PMK) Caching enables a RADIUS-authenticated user to roam away from an AP and then roam back without having to re-authenticate. To accomplish this, the FortiGate unit stores in a cache a master key negotiated with the first AP. This enables the 802.11i-specified method of “fast roam-back.”
- Pre-authentication or “fast-associate in advance” enables an 802.11 AP associated to a client to bridge to other APs over the wired network and pre-authenticate the client to the “next” AP to which the client might roam. This enables the PMK to be derived in advance of a roam and cached. When the client does roam, it will already have negotiated authentication in advance and will use its cached PMK to quickly associate to the next AP. This capability will ensure that wireless clients that support Pre-authentication to continue the data transfer without noticeable connection issues.

Automatic Radio Resource Provisioning

To prevent interference between APs, the FortiOS WiFi Controller includes the Automatic Radio Resource Provisioning (ARRP) feature. When enabled in an access point profile, this feature measures utilization and interference on the available channels and selects the clearest channel at each access point. The measurement can be repeated periodically to respond to changing conditions.

Configuring a WiFi LAN

When working with a FortiGate WiFi controller, you can configure your wireless network before you install any access points. If you are working with a standalone FortiWiFi unit, the access point hardware is already present but the configuration is quite similar. Both are covered in this section.

The following topics are included in this section:

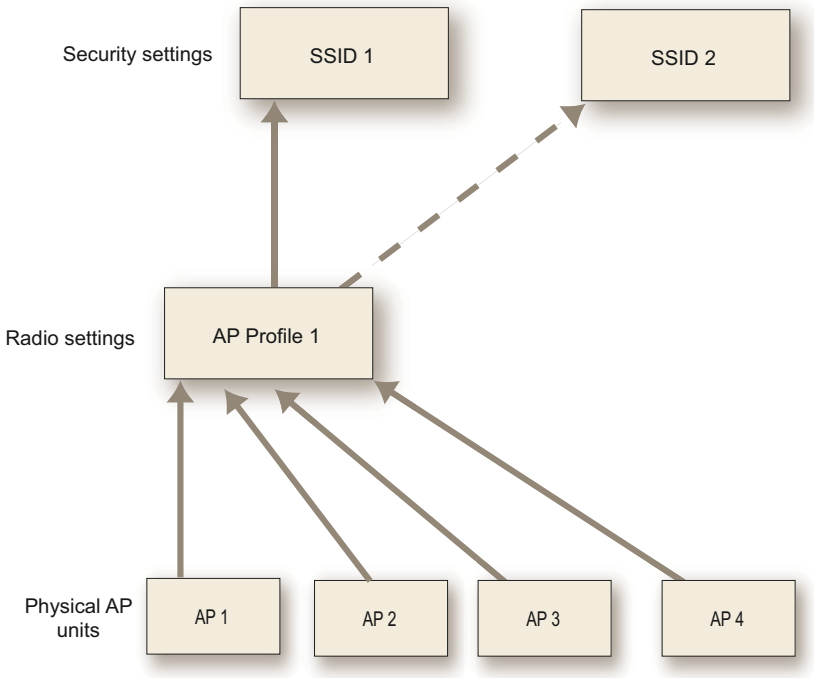
Overview of WiFi controller configuration

The FortiGate WiFi controller configuration is composed of three types of object, the SSID, the AP Profile and the physical Access Point.

- An **SSID** defines a virtual wireless network interface, including security settings. One SSID is sufficient for a wireless network, regardless how many physical access points are provided. You might, however, want to create multiple SSIDs to provide different services or privileges to different groups of users. Each SSID has separate firewall policies and authentication. Each radio in an access point can support up to 8 SSIDs.

  A more common use of the term SSID is for the identifier that clients must use to connect to the wireless network. Each SSID (wireless interface) that you configure will have an SSID field for this identifier. In Managed Access Point configurations you choose wireless networks by SSID values. In firewall policies you choose wireless interfaces by their SSID name.
- An **AP Profile** defines the radio settings, such as band (802.11g for example) and channel selection. The AP Profile names the SSIDs to which it applies. Managed APs can use automatic profile settings or you can create custom AP profiles.
- **Managed Access Points** represent local wireless APs on FortiWiFi units and FortiAP units that the FortiGate unit has discovered. There is one managed access point definition for each AP device. An access point definition can use automatic AP profile settings or select a custom AP Profile. When automatic profile settings are used, the managed AP definition also selects the SSIDs to be carried on the AP.

Figure 252: Conceptual view of FortiGate WiFi controller configuration



About SSIDs on FortiWiFi units

FortiWiFi units have a default SSID (wireless interface) named *wlan.* You can modify or delete this SSID as needed. As with external APs, the built-in wireless AP can be configured to carry any SSID.

The AP settings for the built-in wireless access point are located at *WiFi Controller* > *Managed Access Points* > *Local WiFi Radio*. The available operational settings are the same as those for external access points which are configured at *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.

About automatic AP profile settings

FortiOS simplifies wireless network configuration by providing an automatic setting for the access point profile. You can enable wireless AP operation and Rogue AP scanning with the radios in the AP automatically allocated as follows:

Table 131: Radio functions in automatic profile

No. of Radios	Wireless Access enabled	Rogue AP Scan enabled	Wireless Access and Rogue AP Scan enabled
1	Radio 1 - AP	Radio 1 - scan	Radio 1 - AP + background scan
2	Radio 1 - AP Radio 2 - disabled	Radio 1 - disabled Radio 2 - scan	Radio 1 - AP Radio 2 - scan

You can select which SSIDs (wireless networks) will be available through the access point and adjust the wireless power level of the AP.

Process to create a wireless network

To set up your wireless network, you will need to perform the following steps.

- Make sure the FortiGate wireless controller is configured for your geographic location. This ensures that the available radio channels and radio power are in compliance with the regulations in your region.
- Optionally, if you don't want to use automatic AP profile settings, configure a custom Access Point (AP) profile, specifying the radio settings and the SSIDs to which they apply.
- Configure one or more SSIDs for your wireless network. The SSID configuration includes DHCP and DNS settings.
- Configure the user group and users for authentication on the WLAN.
- Configure the firewall policy for the WLAN.
- Optionally, customize the captive portal.
- Configure access points.

  Configuration of the built-in AP on FortiWiFi units is described in this chapter. Connection and configuration of FortiAP units is described in the next chapter, "Access point deployment".

Setting your geographic location

The maximum allowed transmitter power and permitted radio channels for Wi-Fi networks depend on the region in which the network is located. By default, the WiFi controller is configured for the United States. If you are located in any other region, you need to set your location before you begin configuring wireless networks.

To change the location setting - CLI

To change the country to France, for example, enter

```
config wireless-controller setting
  set country FR
end
```

To see the list of country codes, enter a question mark ('?') instead of a country code.

Before changing the country setting, you must remove all Custom AP profiles. To do this, go to *WiFi Controller* > *Managed Access Points* > *Custom AP Profile*.

Creating a custom AP Profile

If the automatic AP profile settings don't meet your needs, you can define a custom AP Profile. For information about the automatic profile settings, see "About automatic AP profile settings" on page 2446.

An AP Profile configures radio settings and selects the Virtual APs to which the settings apply. FortiAP units contain two radio transceivers, making it possible, for example, to provide both 2.4GHz 802.11b/g/n and 5GHz 802.11a/n service from the same access point.

FortiAP units also provide a monitoring function for the Rogue AP feature.

To configure an AP Profile - web-based manager

1 Go to *WiFi Controller* > *Managed Access Points* > *Custom AP Profile* and select *Create New*.
2 Enter a *Name* for the AP Profile.
3 In *Platform*, select the FortiWiFi or FortiAP model to which this profile applies.
4 In *Mode*, select *Access Point*.
5 Optionally, enable *Background Scan* to support the Rogue AP feature.

   For more information see "Wireless network monitoring" on page 2469.
6 Optionally, select *Radio Resource Provision* to enable the ARRP feature.

   For more information see "Automatic Radio Resource Provisioning" on page 2443.
7 In *Band*, select the 802.11 wireless protocol that you want to support.

   Note that there are two choices for 802.11n. Select *802.11n* for 2.4GHz operation or *802.11n-5G* for 5GHz operation. The available choices depend on the radio's capabilities.
8 In *Channel*, select the channels that the AP is permitted to use. By default, all channels are selected.
9 Leave the *TX Power* at its default setting. You can adjust this later.
10 In *SSID*, use the arrow buttons to move the SSIDs (wireless LANs) to which these settings apply into the *Selected* list.
11 Repeat steps 4 though 10 for Radio 2, if required.

   Note that on the FortiAP-220 unit Radio 1 is 2.4GHz and Radio 2 is 5GHz.

   Radio 2 also supports 40MHz wide channels on the 5GHz band on 802.11n.
12 Select *OK*.

To configure an AP Profile - CLI

This example configures a FortiAP-220A to use only Radio 1 for 802.11g operation applied to SSID example_wlan.

```
config wireless-controller wtp-profile
  edit guest_prof
    config platform
      set type 220A
    end
    config radio-1
      set mode ap
      set band 802.11g
      set vaps example_wlan
    end
  end
```

Defining a wireless network interface (SSID)

You begin configuring your wireless network by defining one or more SSIDs to which your users will connect.

A virtual AP defines the SSID and security settings that can be applied to one or more physical APs. On the FortiGate unit, this creates a virtual network interface with the virtual AP's name. With this interface you can define the DHCP services, firewall policies, and other settings for your WiFi LAN.

To configure an SSID - web-based manager

1 Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.

2 Enter the *Interface Name* that will identify the wireless interface.

3 In the *Addressing Mode* section, enter the *IP/Netmask* for the interface.

If IPv6 is enabled, you can also enter an *IPv6 Address*.

4 In *Administrative Access*, select *Ping*.

Ping is useful for testing. For security it is better not to enable administrative access on wireless interfaces.

5 Enter the *SSID* for your WLAN and choose whether to enable *SSID Broadcast* or not.

For more information, see “Whether to broadcast SSID” on page 2436.

6 If you want to provide DHCP service to your clients, select *Enable DHCP* and enter the range of IP addresses to assign.

For more information, see “Configuring DHCP for WiFi clients” on page 2450.

7 Select the *Security Mode* and enter the required settings.

For more information, see “Configuring security” on page 2450.

8 If you want to prevent direct communication between your wireless clients, enable *Block Intra-SSID Traffic*.

9 Optionally, set the *Maximum Clients* limit.

The default of 0 sets no limit on the number of clients.

10 If you want to restrict access to the wireless network by MAC address, select *Enable MAC Filter*.

For more information, see “Adding a MAC filter” on page 2453.

11 Select OK.

Each Virtual AP that you create is a wireless interface that establishes a wireless LAN. Go to *System* > *Network* > *Interface* to configure its IP address.

To configure a virtual access point - CLI

This example creates an access point with SSID “example” and WPA2-Personal security. The wireless interface is named example_wlan.

```
config wireless-controller vap
  edit example_wlan
    set ssid "example"
    set broadcast-ssid enable
    set security wpa2-only-personal
    set passphrase "hardtoguess”
    set vdom root
  end
config system interface
  edit example_wlan
    set ip 10.10.120.1 255.255.255.0
  end
```

Configuring DHCP for WiFi clients

Wireless clients need to have IP addresses. If you use RADIUS authentication, each user's IP address can be stored in the Framed-IP-Address attribute. Otherwise, you need to configure a DHCP server on the WLAN interface to assign IP addresses to wireless clients.

To configure a DHCP server for WiFi clients - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID entry.
2. In the *WiFi Settings* section, select *Enable DHCP*.
3. In the *Address Start* and *Address End* fields, enter the IP address range to assign.

   The address range needs to be in the same subnet as the wireless interface IP address, but not include that address.
4. Set the *Default Gateway* to the wireless interface IP address.
5. Set the *Netmask* to an appropriate value, such as 255.255.255.0.
6. Enter the IP address of the *DNS Server* that your users will access.
7. Select *OK*.

The DHCP server automatically configures itself to serve only FortiAP units.

You can also configure DHCP through *System* > *Network* > *DHCP Server*, but that page offers additional options that might not be suitable for a wireless network.

To configure a DHCP server for WiFi clients - CLI

In this example, WiFi clients on the example_wlan interface are assigned addresses in the 10.10.120.2-9 range to connect with the WiFi access point on 10.10.120.1.

```
config system dhcp server
  edit 0
    set default-gateway 10.10.120.1
    set dns-service default
    set interface example_wlan
    set netmask 255.255.255.0
    config ip-range
      edit 1
        set end-ip 10.10.120.9
        set start-ip 10.10.120.2
      end
  end
```

You cannot delete an SSID (wireless interface) that has DHCP enabled on it.

Configuring security

The FortiGate WiFi controller supports both Wireless Equivalent Privacy (WEP) and Wi-Fi Protected Access (WPA) security. WPA support includes WPA2, which has additional security improvements.

WEP security uses an encryption key between the wireless device and the access point. WEP64 uses a key of ten hexadecimal digits. WEP128 keys are 26 digits long. WEP security is relatively easy to break. Wherever possible, use WPA security. WEP can be enabled only through the CLI.

WPA security offers more robust encryption that is much more difficult to break. WPA provides two methods of authentication: through RADIUS (802.1X) authentication or by pre-shared key.

WPA security with a preshared key for authentication is called WPA-Personal. This can work well for one person a small group of trusted people.But, as the number of users increases, it is difficult to distribute new keys securely and there is increased risk that the key could fall into the wrong hands.

A more secure form of WPA security is WPA-Enterprise. Users each have their own authentication credentials, verified through an authentication server, usually RADIUS. FortiOS can also authenticate WPA-Enterprise users through its built-in user group functionality. FortiGate user groups can include RADIUS servers and can select users by RADIUS user group. This makes possible Role-Based Access Control (RBAC).

WPA security can encrypt communication with either Temporal Key Integrity Protocol (TKIP) or Advanced Encryption Standard (AES). AES is the preferred encryption, but some older wireless clients do not support it. You can select the encryption during setup.

Captive Portal security connects users to an open web portal defined in replacement messages. To navigate to any location beyond the web portal, the user must pass FortiGate user authentication.

WPA-Personal security

WPA-Personal security setup requires only the preshared key that you will provide to your clients.

To configure WPA-Personal security - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID entry.
2. In *Security Mode*, select *WPA/WPA2-Personal*.
3. In *Data Encryption*, select *AES*.

   If some of your wireless clients do not support AES, select TKIP.
4. In *Pre-shared Key*, enter a key between 8 and 63 characters long.
5. Select *OK*.

To configure WPA-Personal security - CLI

```
config wireless-controller vap
  edit example_wlan
    set security wpa-personal
    set passphrase "hardtoguess"
    set encrypt AES
  end
```

WPA-Enterprise security

If you will use FortiOS user groups for authentication, go to *User* > *User Group* and create those groups first. The groups should be Firewall groups.

If you will use a RADIUS server to authenticate wireless clients, you must first configure the FortiGate unit to access the RADIUS server.

To configure FortiGate unit access to the RADIUS server - web-based manager

1 Go to *User* > *Remote* > *RADIUS* and select *Create New*.
2 Enter a *Name* for the server.
3 In *Primary Server Name/IP*, enter the network name or IP address for the server.
4 In *Primary Server Secret*, enter the shared secret used to access the server.
5 Optionally, enter the information for a secondary or backup RADIUS server.
6 Select *OK*.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
  edit exampleRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret aoewmntiasf
end
```

To configure WPA-Enterprise security - web-based manager

1 Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID entry.
2 In *Security Mode*, select *WPA/WPA2-Enterprise*.
3 In *Data Encryption*, select *AES*.

If some of your wireless clients do not support AES, select TKIP.

4 In *Authentication*, do one of the following:

- If you will use a RADIUS server for authentication, select *RADIUS* Server and then select the RADIUS server.
- If you will use a local user group for authentication, select *Usergroup* and then select the user group that is permitted to use the wireless network.

5 Select *OK*.

To configure WPA-Enterprise security - CLI

```
config wireless-controller vap
  edit example_wlan
    set security wpa-enterprise
    set encrypt AES
    set auth radius
    set radius-server exampleRADIUS
  end
```

Captive Portal security

Captive Portal security provides an access point that initially appears open. The wireless client can connect to the AP with no security credentials. The AP responds to the client's first HTTP request with a web page requesting user name and password. Until the user enters valid credentials, no communication beyond the AP is permitted.

The wireless controller authenticates users through the FortiGate user accounts. In the SSID configuration, you select the user groups that are permitted access through the captive portal.

The captive portal contains the following web pages:

- **Login page**—requests user credentials

- **Login failed page**—reports that the entered credentials were incorrect and enables the user to try again.
- **Disclaimer page**—is statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding.
- **Declined disclaimer page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting *Customize Portal Messages*. Each SSID can have its own unique portal content.

To configure Captive Portal security - web-based manager

1. Configure user groups as needed in *User* > *User Group*.
2. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID entry.
3. In *Security Mode*, select *Captive Portal*.
4. Optionally, select *Customize Portal Messages* and modify the portal pages that users of this SSID will see.
5. In *User Groups*, select the group(s) that are allowed to use the wireless network and move them to the *Selected* list.
6. Select *OK*.

Adding a MAC filter

On each SSID, you can create a MAC address filter list to either permit or exclude a list of clients identified by their MAC addresses.

This is actually not as secure as it appears. Someone seeking unauthorized access to your network can obtain MAC addresses from wireless traffic and use them to impersonate legitimate users. A MAC filter list should only be used in conjunction with other security measures such as encryption.

To configure a MAC filter list, you must use the CLI.

To configure a MAC filter - CLI

In this example, the MAC addresses 11:11:11:11:11:11 and 12:12:12:12:12:12 will be excluded from the example_wlan wireless interface.

```
config wireless-controller vap
  edit example_wlan
    config mac-filter-list
      edit 1
        set mac 11:11:11:11:11:11
        set mac-filter-policy deny
      edit 2
        set mac 12:12:12:12:12:12
        set mac-filter-policy deny
      end
    end
```

Configuring user authentication

You can perform user authentication when the wireless client joins the wireless network and when the wireless user communicates with another network through a firewall policy. WEP and WPA-Personal security rely on legitimate users knowing the correct key or passphrase for the wireless network. The more users you have, the more likely it is that the key or passphrase will become known to unauthorized people. WPA-Enterprise and captive portal security provide separate credentials for each user. User accounts can be managed through FortiGate user groups or an external RADIUS authentication server.

WPA-Enterprise authentication

If your WiFi network uses WPA-Enterprise authentication verified by a RADIUS server, you need to configure the FortiGate unit to connect to that RADIUS server.

Configuring connection to a RADIUS server - web-based manager

1 Go to *User* > *Remote* > *RADIUS* and select *Create New*.

2 Enter a *Name* for the server.

This name is used in FortiGate configurations. It is not the actual name of the server.

3 In *Primary Server Name/IP*, enter the network name or IP address for the server.

4 In *Primary Server Secret*, enter the shared secret used to access the server.

5 Optionally, enter the information for a secondary or backup RADIUS server.

6 Select *OK*.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
  edit exampleRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret aoewmntiasf
  end
```

To implement WPA-Enterprise security, you select this server in the SSID security settings. See “Configuring security” on page 2450.

To use the RADIUS server for authentication, you can create individual FortiGate user accounts that specify the authentication server instead of a password, and you then add those accounts to a user group. Or, you can add the authentication server to a FortiGate user group, making all accounts on that server members of the user group.

Creating a wireless user group

Most wireless networks require authenticated access. To enable creation of identity-based firewall policies, you should create at least one user group for your wireless users. You can add or remove users later. There are two types of user group to consider:

- A Firewall user group can contain user accounts stored on the FortiGate unit or external authentication servers such as RADIUS that contain and verify user credentials.
- A Directory Services user group is used for integration with Windows Active Directory or Novell eDirectory. The group can contain Windows or Novell user groups who will be permitted access to the wireless LAN. Fortinet Single Sign On (FSSO) agent must be installed on the network.

Configuring firewall policies for the SSID

For users on the WiFi LAN to communicate with other networks, firewall policies are required. Before you create firewall policies, you need to define any firewall addresses you will need. This section describes creating a WiFi network to Internet policy.

To create a firewall address for WiFi users - web-based manager

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information and select *OK*.

Address Name	Enter a name for the address, wifi_net for example.
Type	Select *Subnet / IP Range*
Subnet / IP Range	Enter the subnet address, 10.10.110.0/24 for example.
Interface	Select the interface where this address is used, e.g., example_wifi

To create a firewall address for WiFi users - CLI

```
config firewall address
  edit "wifi_net"
    set associated-interface "example_wifi"
    set subnet 10.10.110.0 255.255.255.0
  end
```

To create a firewall policy - web-based manager

1 Go to *Policy* > *Policy* and select *Create New*.

2 In *Source Interface/Zone*, select the wireless interface.

3 In *Source Address*, select the address of your WiFi network, wifi_net for example.

4 In *Destination Interface/Zone*, select the Internet interface, for example, *port1*.

5 In *Destination Address*, select *All*.

6 In *Service*, select ANY, or select the particular services that you want to allow, and then select the right arrow button to move the service to the *Selected Services* list.

7 In *Schedule*, select *Always*, unless you want to define a schedule for limited hours.

8 In *Action*, select ACCEPT.

9 Select *Enable NAT*.

10 Optionally, select *UTM* and set up UTM features for wireless users.

11 Select *OK*.

To create a firewall policy - CLI

```
config firewall policy
  edit 0
    set srcintf "example_wifi"
    set dstintf "port1"
    set srcaddr "wifi_net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
```

```
    set nat enable
end
```

Customizing captive portal pages

If you select Captive Portal authentication in the SSID, the wireless controller presents to the user pages defined in Captive Portal Default replacement pages.

The captive portal contains the following web pages:

- **Login page**—requests user credentials
- **Login failed page**—reports that the entered credentials were incorrect and enables the user to try again.
- **Disclaimer page**—is statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding.
- **Declined disclaimer page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

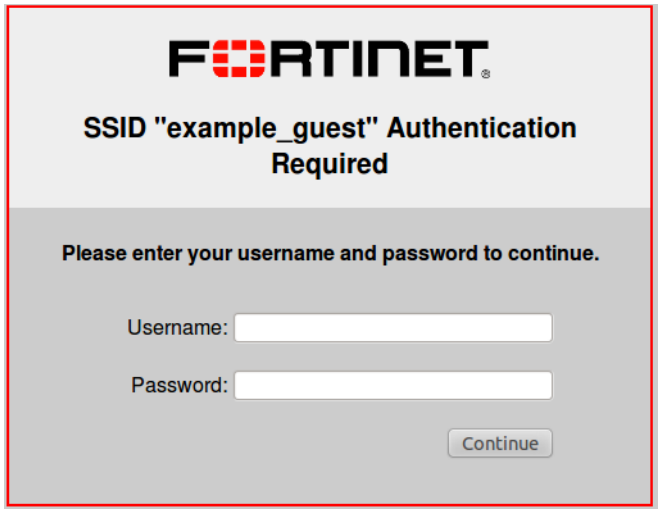
These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting *Customize Portal Messages*. Each SSID can have its own unique portal content.

Only the Login page and Login failed page are available in FortiOS 4.3.0. If you require a disclaimer, consider using the User Authentication disclaimer that can enabled in the firewall policy.

Modifying the login page

The login page requests the user's credentials. Typical modifications for this page would be to change the logo and modify some of the text.

Figure 253: Default captive portal login page



Changing the logo

You can replace the default Fortinet logo with your organization's logo. First, import the logo file into the FortiGate unit and then modify the Login page code to reference your file.

To import a logo file

1 Go to *System* > *Config* > *Replacement Message* and select *Manage Images*.
2 Select Create New.
3 Enter a *Name* for the logo and select the appropriate *Content Type*.
The file must not exceed 6000 bytes.
4 Select *Browse*, find your logo file and then select *Open*.
5 Select OK.

To specify the new logo in the replacement message

1 Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID.
The SSID *Security Mode* must be *Captive Portal*.
2 Make sure that Customize Portal Messages is selected and then select the adjacent Edit icon.
3 In the *Edit Message* window, select the *Login page* message.
4 In the Message HTML, find the %%IMAGE tag.
By default it specifies the Fortinet logo:%%IMAGE:logo_fw_auth%%
5 Change the image name to the one you provided for your logo.
The tag should now read, for example, %%IMAGE:mylogo%%
6 Select OK.

Modifying text

You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. There are two exceptions to this rule:

- The line “Please enter your username and password to continue” is provided by the %%QUESTION%% tag. You can replace this tag with text of your choice.
- The line “SSID ... Authentication Required” includes the name of the SSID, provided by the %%CPAUTH_SSID%% tag. You can remove or change the position of this tag.

Except for these items, you should not remove any tags because they may carry information that the FortiGate unit needs.

To modify login page text

1 Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID.
The SSID *Security Mode* must be *Captive Portal*.
2 Make sure that Customize Portal Messages is selected and then select the adjacent Edit icon.
3 In the *Edit Message* window, select the *Login page* message.
4 In the Message HTML box, edit the text, then select OK.
5 Select OK.

Modifying the login failed page

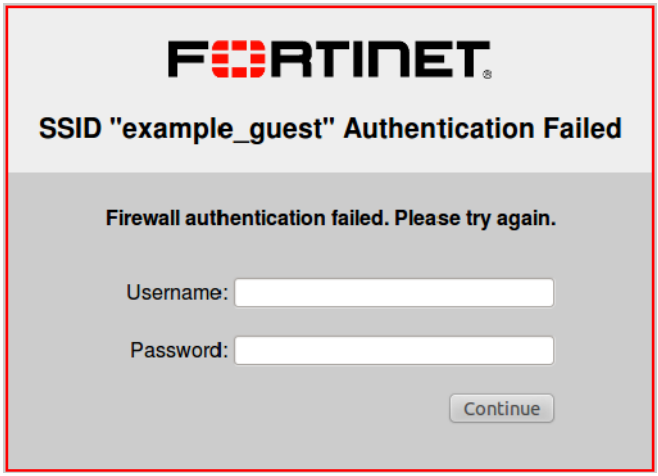
The Login failed page is similar to the Login page. It even contains the same login form. You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. There are two exceptions to this rule:

- The line “Firewall authentication failed. Please try again.” is provided by the %%FAILED_MESSAGE%% tag. You can replace this tag with text of your choice.

- The line “SSID ... Authentication Required” includes the name of the SSID, provided by the %%CPAUTH_SSID%% tag. You can remove or change the position of this tag.

Except for these items, you should not remove any tags because they may carry information that the FortiGate unit needs.

Figure 254: Default login failed page



Configuring the built-in access point on a FortiWiFi unit

Both FortiGate and FortiWiFi units have the WiFi controller feature. If you configure a WiFi network on a FortiWiFi unit, you can also use the built-in wireless capabilities in your WiFi network as one of the access points.

If Virtual Domains are enabled, you must select the VDOM to which the built-in access point belongs. You do this in the CLI. For example:

```
config wireless-controller global
  set local-radio-vdom vdom1
end
```

To configure the FortiWiFi unit’s built-in WiFi access point

1. Go to *WiFi Controller* > *Managed Access Points* > *Local WiFi Radio*.
2. Make sure that *AP Profile* is *Automatic*.
3. Make sure that *Enable WiFi Radio* is selected.
4. In *SSID*, if you do not want this AP to carry all SSIDs, select *Select SSIDs* and then select the required SSIDs.
5. Optionally, adjust the *TX Power* slider.

   If you have selected your location correctly (see “Setting your geographic location” on page 2447), the 100% setting corresponds to the maximum power allowed in your region.
6. If you do not want the built-in WiFi radio to be used for rogue scanning, select *Do not participate in Rogue AP scanning*.
7. Select *OK*.

If you want to connect external APs, such as FortiAP units, see the next chapter, “Access point deployment”.

Access point deployment

This chapter describes how to configure access points for your wireless network. The following topics are included in this section:

Overview

FortiAP units discover WiFi controllers. The administrator of the WiFi controller authorizes the FortiAP units that the controller will manage.

In most cases, FortiAP units can find WiFi controllers through the wired Ethernet without any special configuration. Review the following section, "Network topology for managed APs", to make sure that your method of connecting the FortiAP unit to the WiFi controller is valid. Then, you are ready to follow the procedures in "Discovering and authorizing APs" on page 2460.

If your FortiAP units are unable to find the WiFi controller, refer to "Advanced WiFi controller discovery" on page 2464 for detailed information about the FortiAP unit's controller discovery methods and how you can configure them.

Network topology for managed APs

The FortiAP unit can be connected to the FortiGate unit in any of the following ways:

Direct connection: The FortiAP unit is directly connected to the FortiGate unit with no switches between them. This configuration is common for locations where the number of FortiAP's matches up with the number of 'internal' ports available on the FortiGate. In this configuration the FortiAP unit requests an IP address from the FortiGate unit, enters discovery mode and should quickly find the FortiGate WiFi controller. This is also known as a wirecloset deployment. See Figure 255, below.

Switched Connection: The FortiAP unit is connected to the FortiGate WiFi controller by an Ethernet switch operating in L2 switching mode or L3 routing mode. There must be a routable path between the FortiAP unit and the FortiGate unit and ports 5246 and 5247 must be open. This is also known as a gateway deployment. See Figure 255, below

Connection over WAN: The FortiGate WiFi controller is off-premises and connected by a VPN tunnel to a local FortiGate. In this method of connectivity its best to configure each FortiAP with the static IP address of the WiFi controller. Each FortiAP can be configured with three WiFi controller IP addresses for redundant failover. This is also known as a datacenter remote management deployment. See Figure 256, below.

Figure 255: Wirecloset and Gateway deployments

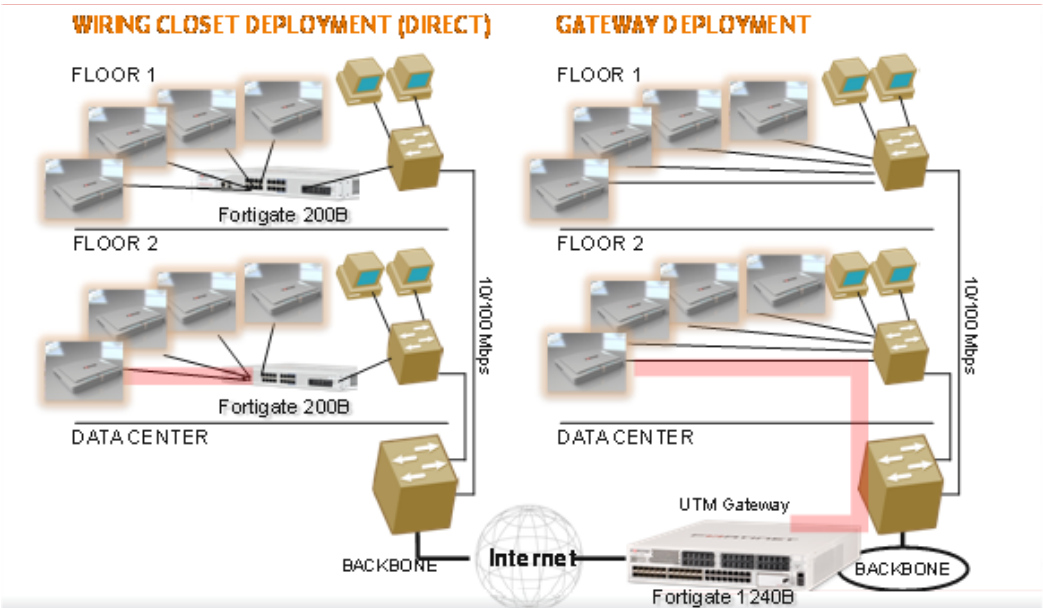


Figure 256: Remote deployment

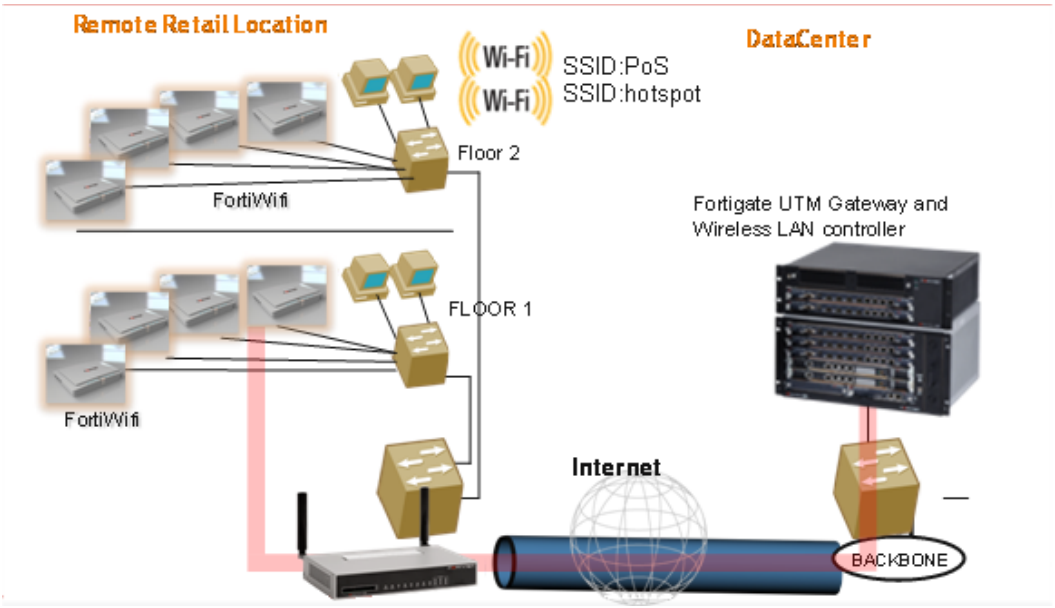


Discovering and authorizing APs

After you prepare your FortiGate unit, you can connect your APs to discover them using the discovery methods described earlier. To prepare the FortiGate unit, you need to

- Configure the network interface to which the AP will connect.
- Configure DHCP service on the interface to which the AP will connect.
- Connect the AP units and let the FortiGate unit discover them.
- Enable each discovered AP and configure it or assign it to an AP profile.

Configuring the network interface for the AP unit

The interface to which you connect your wireless access point needs an IP address. No administrative access, DNS Query service or authentication should be enabled.

To configure the interface for the AP unit - web-based manager

1 Go to *System* > *Network* > *Interface* and edit the interface to which the AP unit connects.

2 Set *Addressing Mode* to *Manual* and enter the IP address and netmask to use.

3 Enable *Dedicate this interface to FortiAP connection* and set *Reserve IP addresses for FortiAP* to the range of addresses that you want to use for FortiAP units.

The address range needs to be in the same subnet as the interface IP address, but not include that address. This step automatically configures a DHCP server for the AP units.

4 Select OK.

To configure the interface for the AP unit - CLI

```
config system interface
  edit port3
    set mode static
    set ip 192.168.8.1 255.255.255.0
  end
```

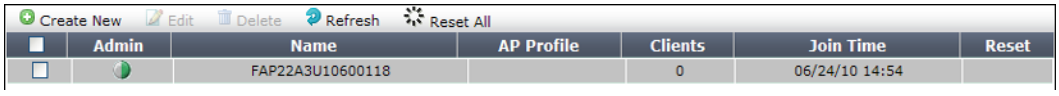
To configure the DHCP server for AP unit - CLI

```
config system dhcp server
  edit 0
    set default-gateway 192.168.8.1
    set interface wan2
    config ip-range
      edit 1
        set end-ip 192.168.8.9
        set start-ip 192.168.8.2
      end
    set netmask 255.255.255.0
  end
```

Enabling a discovered AP

Within two minutes of connecting the AP unit to the FortiGate unit, the discovered unit should be listed on *WiFi Controller* > *Managed Access Points* > *Managed FortiAP* page.

Figure 257: Discovered access point unit



To add the discovered AP unit - web-based manager

1 Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.

2 Select the FortiAP unit from the list and edit it.

3 Optionally, enter a *Name*. Otherwise, the unit will be identified by serial number.

4 Select *Authorize*.

5 Select *OK*.

The physical access point is now added to the system. If the rest of the configuration is complete, it should be possible to connect to the wireless network through the AP.

To add the discovered AP unit - CLI

First get a list of the discovered access point unit serial numbers:

```
get wireless-controller wtp
```

Add a discovered unit and associate it with AP-profile1, for example:

```
config wireless-controller wtp
  edit FAP22A3U10600118
    set admin enable
    set wtp-profile AP-profile1
  end
```

To use the automatic profile, leave the `wtp-profile` field unset.

To view the status of the added AP unit

```
config wireless-controller wtp
  edit FAP22A3U10600118
  get
```

The `join-time` field should show a time, not “N/A”. See the preceding web-based manager procedure for more information.

Configuring a managed AP

When you add a FortiAP unit, it is configured by default to

- use the Automatic profile
- operate at the maximum radio power permitted in your region
- carry all SSIDs

You can change the radio power and selection of SSIDs or assign the unit to a custom AP profile which defines the entire configuration for the AP.

To modify settings within Automatic profile - web-based manager

1 Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.

2 Select the FortiAP unit from the list and edit it.

AP Profile should be *Automatic*.

3 Make sure that *Enable WiFi Radio* is selected.

4 In *SSID*, if you do not want this AP to carry all SSIDs, select *Select SSIDs* and then select the required SSIDs.

5 Optionally, adjust the *TX Power* slider.

If you have selected your location correctly (see “Setting your geographic location” on page 2447), the 100% setting corresponds to the maximum power allowed in your region.

6 Select *OK*.

To modify settings within Automatic profile - CLI

When `wtp-profile` is unset (null value), the Automatic profile is in use and some of its settings can be adjusted. This example sets the AP to carry only the employee and guest SSIDs and operate at 80% of maximum power.

```
config wireless-controller wtp
  edit FAP22A3U10600118
    set radio-enable enable
    set vap-all disable
    set vaps employee guest
    set power-level 80
  end
```

To select a custom AP profile - web-based manager

1 Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.
2 Select the FortiAP unit from the list and edit it.
3 In *AP Profile*, select the custom AP Profile to use, and then select *Apply*.
Only AP Profiles that are appropriate for this AP unit are available.
4 Select *OK*.

To select a custom AP profile - CLI

```
config wireless-controller wtp
  edit FAP22A3U10600118
    set wtp-profile AP-profile1
  end
```

To select automatic AP profile - CLI

```
config wireless-controller wtp
  edit FAP22A3U10600118
    unset wtp-profile
  end
```

Updating FortiAP unit firmware

You can update the FortiAP unit's firmware from the FortiGate unit that acts as its WiFi controller.

Updating FortiAP firmware from the FortiGate unit

You can update the FortiAP firmware using either the web-based manager or the CLI. Only the CLI method can update all FortiAP units at once.

To update FortiAP unit firmware - web-based manager

1 Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.
2 Select the FortiAP unit from the list and edit it.
3 In *FortiAP OS Version*, select *[Upgrade]*.
4 Select *Browse* and locate the firmware upgrade file.
5 Select *OK*.
6 When the upgrade process completes, select *OK*.
The FortiAP unit restarts.

To update FortiAP unit firmware - CLI

1 Upload the FortiAP image to the FortiGate unit.
For example, the Firmware file is FAP_22A_v4.3.0_b0212_fortinet.out and the server IP address is 192.168.0.100.

```
execute wireless-controller upload-wtp-image tftp
   FAP_22A_v4.3.0_b0212_fortinet.out 192.168.0.100
```

If your server is FTP, change `tftp` to `ftp`, and if necessary add your user name and password at the end of the command.

2 Verify that the image is uploaded:

```
execute wireless-controller list-wtp-image
```

3 Upgrade the FortiAP units:

```
exec wireless-controller reset-wtp all
```

If you want to upgrade only one FortiAP unit, enter its serial number instead of `all`.

Updating FortiAP firmware from the FortiAP unit

You can connect to a FortiAP unit's internal CLI to update its firmware from a TFTP server on the same network. This method does not require access to the wireless controller.

1 Place the FortiAP firmware image on a TFTP server on your computer.

2 Connect the FortiAP unit to a separate private switch or hub or directly connect to your computer via a cross-over cable.

3 Change your computer's IP address to 192.168.1.3.

4 Telnet to IP address 192.168.1.2.

This IP address is overwritten if the FortiAP is connected to a DHCP environment. Ensure that the FortiAP unit is in a private network with no DHCP server.

5 Login with the username "admin" and no password.

6 Enter the following command.

For example, the FortiAP image file name is FAP_22A_v4.3.0_b0212_fortinet.out.

```
restore FAP_22A_v4.3.0_b0212_fortinet.out 192.168.1.3
```

Advanced WiFi controller discovery

A FortiAP unit can use any of four methods to locate a controller. By default, FortiAP units cycle through all four of the discovery methods. In most cases there is no need to make configuration changes on the FortiAP unit.

There are exceptions. The following section describes the WiFi controller discovery methods in more detail and provides information about configuration changes you might need to make so that discovery will work.

You can also configure a FortiWiFi unit to act as an AP. But in this case you must choose which discovery method it will use. See "Configuring a FortiWiFi unit as a WiFi AP" on page 2466.

Controller discovery methods

There are four methods that a FortiAP unit can use to discover a WiFi controller.

Static IP configuration

If FortiAP and the controller are not in the same subnet, broadcast and multicast packets cannot reach the controller. The admin can specify the controller's static IP on the AP unit. The AP unit sends a discovery request message in unicast to the controller. Routing must be properly configured in both directions.

To specify the controller's IP address on a FortiAP unit

```
cfg -a AC_IPADDR_1="192.168.0.1"
```

By default, the FortiAP unit receives its IP address by DHCP. If you prefer, you can assign the AP unit a static IP address.

To assign a static IP address to the FortiAP unit

```
cfg -a ADDR_MODE=STATIC
cfg -a AP_IPADDR="192.168.0.100"
cfg -a AP_NETMASK="255.255.255.0"
```

For information about connecting to the FortiAP CLI, see "Connecting to the FortiAP CLI" on page 2466.

Broadcast request

The AP unit broadcasts a discovery request message to the network and the controller replies. The AP and the controller must be in the same broadcast domain. No configuration adjustments are required.

Multicast request

The AP unit sends a multicast discovery request and the controller replies with a unicast discovery response message. The AP and the controller do not need to be in the same broadcast domain if multicast routing is properly configured.

The default multicast destination address is 224.0.1.140. It can be changed through the CLI. The address must be same on the controller and AP. For information about connecting to the FortiAP CLI, see "Connecting to the FortiAP CLI" on page 2466.

To change the multicast address on the controller

```
config wireless-controller global
  set discovery-mc-addr 224.0.1.250
end
```

To change the multicast address on a FortiAP unit

```
cfg -a AC_DISCOVERY_MC_ADDR="224.0.1.250"
```

For information about connecting to the FortiAP CLI, see "Connecting to the FortiAP CLI" on page 2466.

DHCP

If you use DHCP to assign an IP address to your FortiAP unit, you can also provide the WiFi controller IP address at the same time. This is useful if the AP is located remotely from the WiFi controller and other discovery techniques will not work.

When you configure the DHCP server, configure Option 138 to specify the WiFi controller IP address. You need to convert the address into hexadecimal. Convert each octet value separately from left to right and concatenate them. For example, 192.168.0.1 converts to C0A80001.

If Option 138 is used for some other purpose on your network, you can use a different option number if you configure the AP units to match.

To change the FortiAP DHCP option code

To use option code 139 for example, enter

```
cfg -a AC_DISCOVERY_DHCP_OPTION_CODE=139
```

For information about connecting to the FortiAP CLI, see "Connecting to the FortiAP CLI" below.

Connecting to the FortiAP CLI

The FortiAP unit has a CLI through which some configuration options can be set.

To access the FortiAP unit CLI

1. Connect your computer to the FortiAP directly with a cross-over cable or through a separate switch or hub.
2. Change your computer's IP address to 192.168.1.3
3. Telnet to IP address 192.168.1.2.

   Ensure that FortiAP is in a private network with no DHCP server for the static IP address to be accessible.
4. Login with user name admin and no password.
5. Enter commands as needed.
6. Optionally, use the `passwd` command to assign an administrative password for better security.
7. Save the configuration by entering the following command:

   ```
   cfg -c .
   ```
8. Unplug the FortiAP and then plug it back in, in order for the configuration to take effect.

When a WiFi controller has taken control of the FortiAP unit, Telnet access to the FortiAP unit's CLI is no longer available.

Configuring a FortiWiFi unit as a WiFi AP

FortiWiFi units can also be deployed as managed APs controlled by a FortiGate unit wireless controller.

In the CLI, enter

```
config system global
  set wireless-mode wtp
end
```

Setting the discovery mode

Unlike FortiAP units, a FortiWiFi unit deployed as an AP does not cycle through the discovery methods. You must select one discovery method to use.

To select DHCP discovery

```
config wireless-controller global
  set ac-discovery-type dhcp
end
```

The DHCP discovery method is the simplest to use and will work when the AP is connected directly to the WiFi controller unit.

To select multicast discovery

In this example, the FortiWiFi AP is configured for multicast discovery and its multicast address is changed:

```
config wireless-controller global
  set ac-discovery-type multicast
  set discovery-mc-addr 224.0.1.250
end
```

Discovery by multicast will work even when the FortiWiFi AP is not in the same domain as the WiFi controller.

Completing configuration

The rest of the configuration is located in `config wireless-controller` and is similar to the FortiGate WiFi controller configuration.

Wireless network monitoring

You can monitor both your wireless clients and other wireless networks that are available in your coverage area.

The following topics are included in this section:

Monitoring wireless clients

To view connected clients on a FortiWiFi unit

- Go to *WiFi Controller* > *Monitor* > *Client Monitor.*

The following information can be displayed, depending on the *Column Settings* you have selected.

Association Time	How long the client has been connected to this access point.
Auth	The type of authentication used.
Bandwidth Rx	Received bandwidth used by the client, in Kbps.
Bandwidth Tx	Transmit bandwidth used by the client, in Kbps.
Bandwidth Tx/Rx	*Bandwidth Rx* + *Bandwidth Tx*.
FortiAP	The serial number of the FortiAP unit to which the client connected.
Idle Time	The total time this session that the client was idle.
IP	The IP address assigned to the wireless client.
MAC	The MAC address of the wireless client.
Manufacturer	Manufacturer of the client wireless device.
Physical AP	The name of the physical access point with which the client is associated.
Rate	The data rate that the wireless connection can support.
Signal Strength / Noise	The signal-to-noise ratio in deciBels calculated from signal strength and noise level.
SSID	The SSID that the client connected to.
Virtual AP	The name of the virtual access point with which the client is associated.

Monitoring rogue APs

The access point radio equipment can scan for other available access points, either as a dedicated monitor or as a background scan performed while the access point is idle.

Discovered access points are listed in the *Rogue AP Monitor* list. You can then mark them as either Accepted or Rogue access points. This designation helps you to track access points. It does not affect anyone's ability to use these access points.

It is also possible to suppress rogue APs. See "Suppressing rogue APs" on page 2473.

On-wire rogue AP detection technique

Other APs that are available in the same area as your own APs are not necessarily rogues. A neighboring AP that has no connection to your network might cause interference, but it is not a security threat. A rogue AP is an unauthorized AP connected to your wired network. This can enable unauthorized access. When rogue AP detection is enabled, the *On-wire* column in the *Rogue AP Monitor* list shows a green up-arrow on detected rogues.

Rogue AP monitoring of WiFi client traffic builds a table of WiFi clients and the Access Points that they are communicating through. The FortiGate unit also builds a table of MAC addresses that it sees on the LAN. The FortiGate unit's on-wire correlation engine constantly compares the MAC addresses seen on the LAN to the MAC addresses seen on the WiFi network.

There are two methods of Rogue AP on-wire detection operating simultaneously: Exact MAC address match and MAC adjacency.

Exact MAC address match

If the same MAC address is seen on the LAN and on the WiFi network, this means that the wireless client is connected to the LAN. If the AP that the client is using is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue. This scheme works for non-NAT rogue APs.

MAC adjacency

If an access point is also a router, it applies NAT to WiFi packets. This can make rogue detection more difficult. However, an AP's WiFi interface MAC address is usually in the same range as its wired MAC address. So, the MAC adjacency rogue detection method matches LAN and WiFi network MAC addresses that are within a defined numerical distance of each other. By default, the MAC adjacency value is 7. If the AP for these matching MAC addresses is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue.

Limitations

On-wire rogue detection has some limitations. There must be at least one WiFi client connected to the suspect AP and continuously sending traffic. If the suspect AP is a router, its WiFi MAC address must be very similar to its Ethernet port MAC address.

Logging

Information about detected rogue APs is logged and uploaded to your FortiAnalyzer unit, if you have one. By default, rogue APs generate an alert level log, unknown APs generate a warning level log. This log information can help you with PCI-DSS compliance requirements.

Rogue AP scanning as a background activity

Each WiFi radio can perform monitoring of radio channels in its operating band while acting as an AP. It does this by briefly switching from AP to monitoring mode. By default, a scan period starts every 300 seconds. Each second a different channel is monitored for 20ms until all channels have been checked.

During heavy AP traffic, it is possible for background scanning to cause lost packets when the radio switches to monitoring. To reduce the probability of lost packets, you can set the CLI `ap-bgscan-idle` field to delay the switch to monitoring until the AP has been idle for a specified period. This means that heavy AP traffic may slow background scanning.

The following CLI example configures default background rogue scanning operation except that it sets `ap-bgscan-idle` to require 100ms of AP inactivity before scanning the next channel.

```
config wireless-controller wtp-profile
  edit ourprofile
    config radio-1
      set ap-bgscan enable
      set rogue-scan enable
      set ap-bgscan-period 300
      set ap-bgscan-intv 1
      set ap-bgscan-duration 20
      set ap-bgscan-idle 100
    end
  end
```

Configuring rogue scanning

Rogue scanning is easily enabled for all of your APs.

To enable the rogue AP scanning feature - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *Rogue AP Settings*.
2. Select *Enable Rogue AP Detection*.
3. Select *Enable On-wire Rogue AP Detection Technique* if you want to use that method of distinguishing rogues from neighbors.
4. Select *Apply*.

To enable the rogue AP scanning feature - CLI

```
config wireless-controller setting
  set ap-scan enable
  set on-wire-scan enable
end
```

To adjust MAC adjacency

You can adjust the maximum WiFi to Ethernet MAC difference used when determining whether an suspect AP is a rogue. For example, to change the adjacency to 8, enter

```
config wireless-controller global
  set rogue-scan-mac-adjacency 8
end
```

Exempting an AP from rogue scanning

By default, if Rogue AP Detection is enabled, it is enabled on all managed FortiAP units. Optionally, you can exempt an AP from scanning. You should be careful about doing this if your organization must perform scanning to meet PCI-DSS requirements.

To exempt an AP from rogue scanning - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.
2. Select which AP to edit.
3. Select *Do not participate in Rogue AP Scanning* and then select *OK*.

To exempt an AP from rogue scanning - CLI

This example shows how to exempt access point AP1 from rogue scanning.

```
config wireless-controller wtp
  edit AP1
    set ap-scan disable
  end
```

Using the Rogue AP Monitor

Go to *WiFi Controller* > *Monitor* > *Rogue AP Monitor* to view the list of other wireless access points that are receivable at your location. Available information about the APs includes:

SSID	channel
security type	signal strength
detected by which of your APs	MAC address
AP equipment vendor	on-wire status
time first seen	time last seen

The status of newly detected APs is Unclassified. You can manually change the status using the *Mark* menu.

	Rogue AP. Use this status for unauthorized APs attached to your wired networks. The On-wire detection technique determines which unknown APs are rogues.
	Accepted AP. Use this status for APs that are an authorized part of your network or are neighboring APs that are not a security threat.
	Unclassified AP. This is the initial status of a discovered AP. You can change an AP back to unclassified if you have mistakenly marked it as Rogue or Accepted.

Suppressing rogue APs

In addition to monitoring rogue APs, you can actively prevent your users from connecting to them. When suppression is activated against an AP, the FortiGate WiFi controller sends deauthentication messages to the rogue AP's clients, posing as the rogue AP, and also sends deauthentication messages to the rogue AP, posing as its clients. This is done using the monitoring radio.

To enable rogue AP suppression, you must enable monitoring of rogue APs with the on-wire detection technique. See "Monitoring rogue APs" on page 2470. The monitoring radio must be in the Dedicated Monitor mode.

To activate AP suppression against a rogue AP

1. Go to *WiFi Controller* > *Monitor* > *Rogue AP Monitor.*
2. When you see an AP listed that is a rogue detected "on-wire", select it and then select *Mark* > *Mark Rogue*.
3. To suppress an AP that is marked as a rogue, select it and then select *Suppress AP*.

To deactivate AP suppression

1. Go to *WiFi Controller* > *Monitor* > *Rogue AP Monitor.*
2. Select the suppressed rogue AP and then select *Suppress AP* > *Unsuppress AP*.

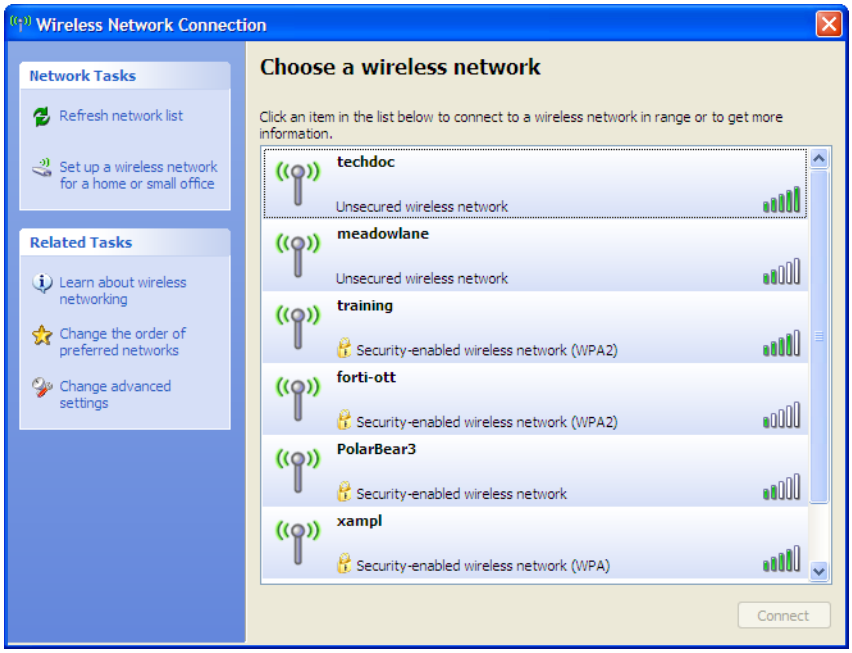
Configuring wireless network clients

This chapter shows how to configure typical wireless network clients to connect to a wireless network with WPA-Enterprise security. The following topics are included in this section:

Windows XP client

To configure the WPA-Enterprise network connection

1 In the Windows Start menu, go to *Control Panel* > *Network Connections* > *Wireless Network Connection* or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.

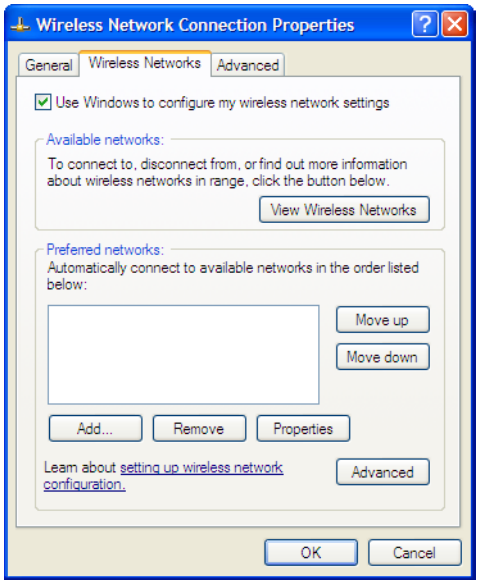


If you are already connected to another wireless network, the Connection Status window displays. Select *View Wireless Networks* on the *General* tab to view the list.

If the network broadcasts its SSID, it is listed. But do not try to connect until you have completed the configuration step below. Because the network doesn't use the Windows XP default security configuration, configure the client's network settings manually before trying to connect.

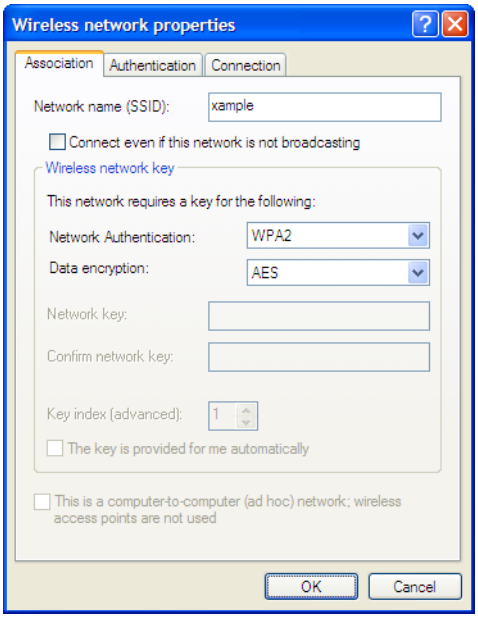
2 You can configure the WPA-Enterprise network to be accessible from the *View Wireless Networks* window even if it does not broadcast its SSID.

3 Select *Change Advanced Settings* and then select the *Wireless Networks* tab.



Any existing networks that you have already configured are listed in the *Preferred Networks* list.

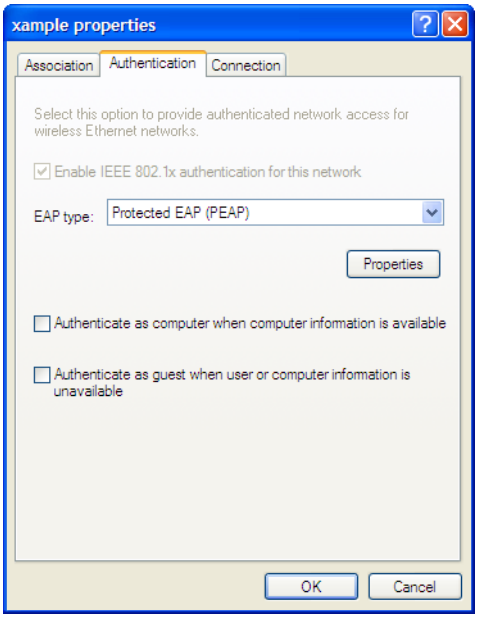
4 Select *Add* and enter the following information:



Network Name (SSID)	The SSID for your wireless network
Network Authentication	WPA2
Data Encryption	AES

5 If this wireless network does not broadcast its SSID, select *Connect even if this network is not broadcasting* so that the network will appear in the *View Wireless Networks* list.

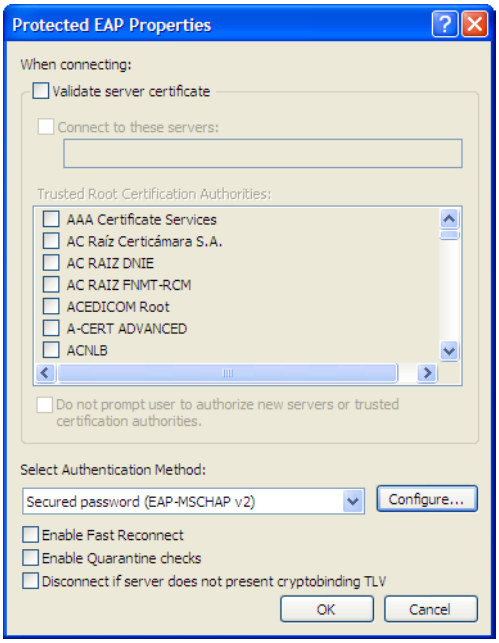
6 Select the *Authentication* tab.



7 In *EAP Type*, select *Protected EAP (PEAP)*.

8 Make sure that the other two authentication options are not selected.

9 Select *Properties*.



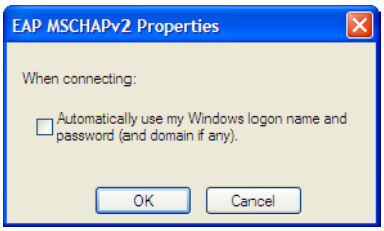
10 Make sure that *Validate server_certificate* is selected.

11 Select the server certificate UTN-USERFirst-Hardware.

12 In *Select Authentication Method*, select *Secured Password (EAP-MSCHAPv2)*.

13 Ensure that the remaining options are not selected.

14 Select *Configure*.



15 If your wireless network credentials are the same as your Windows logon credentials, select *Automatically use my Windows logon name and password*. Otherwise, make sure that this option is not selected.

16 Select OK. Repeat until you have closed all of the *Wireless Network Connection Properties* windows.

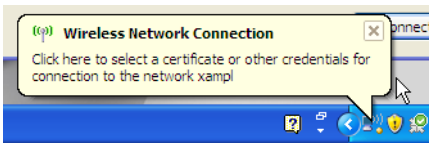
To connect to the WPA-Enterprise wireless network

1 Select the wireless network icon in the Notification area of the Taskbar.

2 In the *View Wireless Networks* list, select the network you just added and then select *Connect*.

You might need to log off of your current wireless network and refresh the list.

3 When the following popup displays, click on it.

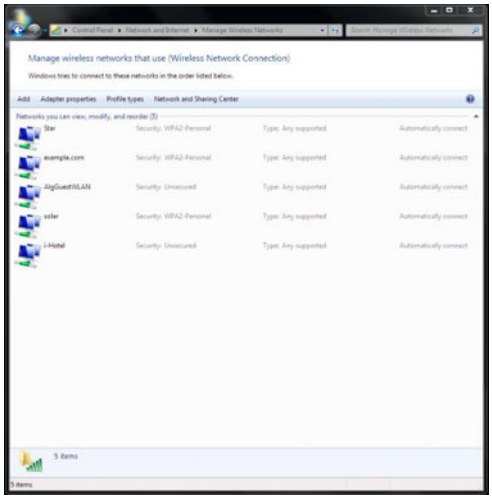


4 In the *Enter Credentials* window, enter your wireless network *User name*, *Password*, and *Logon domain* (if applicable). Then, select *OK*.

In future, Windows will automatically send your credentials when you log on to this network.

Windows 7 client

1 In the Windows Start menu, go to *Control Panel* > *Network and Internet* > *Network and Sharing Center* > *Manage Wireless Networks* or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.



2 Do one of the following:

- If the wireless network is listed (it broadcasts its SSID), select it from the list.
- Select *Add* > *Manually create a network profile*.

3 Enter the following information and select *Next*.

Network name	Enter the SSID of the wireless network. (Required only if you selected *Add*.)
Security type	WPA2-Enterprise
Encryption type	AES
Start this connection automatically	Select
Connect even if the network is not broadcasting.	Select

The Wireless Network icon will display a popup requesting that you click to enter credentials for the network. Click on the popup notification.

4 In the *Enter Credentials* window, enter your wireless network *User name*, *Password*, and *Logon domain* (if applicable). Then, select *OK*.

5 Select *Change connection settings*.

6 On the *Connection* tab, select *Connect automatically when this network is in range*.

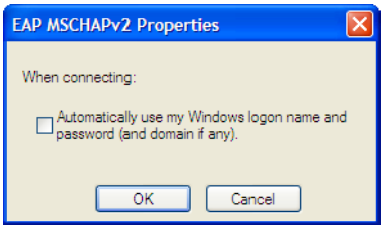
7 On the *Security* tab, select the Microsoft PEAP authentication method and then select *Settings*.

8 Make sure that *Validate server_certificate* is selected.

9 Select the server certificate UTN-USERFirst-Hardware.

10 In *Select Authentication Method*, select *Secured Password (EAP-MSCHAPv2)*.

11 Select *Configure*.



12 If your wireless network credentials are the same as your Windows logon credentials, select *Automatically use my Windows logon name and password*. Otherwise, make sure that this option is not selected.

13 Ensure that the remaining options are not selected.

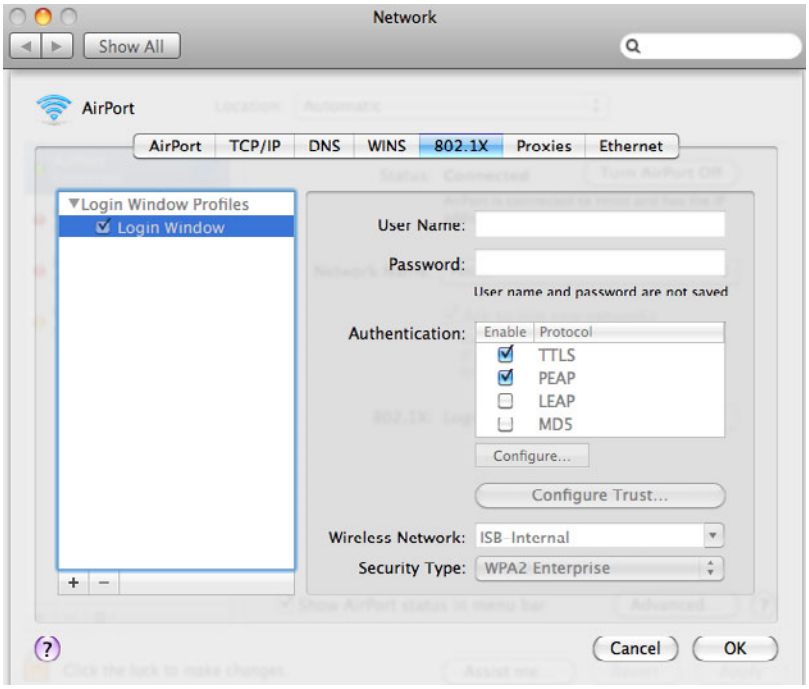
14 Select OK. Repeat until you have closed all of the *Wireless Network Properties* windows.

Mac OS client

To configure network preferences

1 Right-click the *AirPort* icon in the toolbar and select *Open Network Preferences*.

2 Select *Advanced* and then select the *802.1X* tab.



3 If there are no Login Window Profiles in the left column, select the + button and then select *Add Login Window Profile*.

4 Select the Login Window Profile and then make sure that both TTLS and PEAP are selected in *Authentication*.

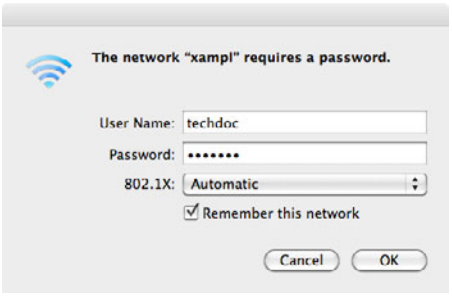
To configure the WPA-Enterprise network connection

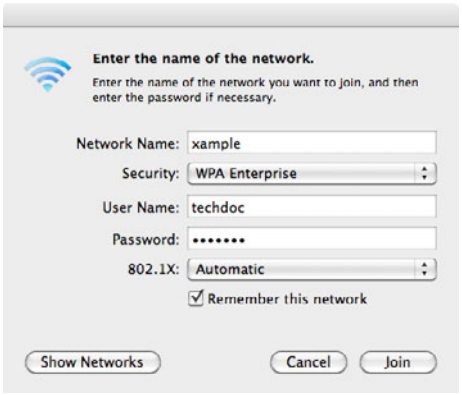
1 Select the *AirPort* icon in the toolbar.

2 Do one of the following:

- If the network is listed, select the network from the list.
- Select *Connect to Other Network*.

One of the following windows opens, depending on your selection.





3 Enter the following information and select *OK* or *Join*:

Network name	Enter the SSID of your wireless network. (Other network only)
Wireless Security	WPA Enterprise
802.1X	Automatic
Username **Password**	Enter your logon credentials for the wireless network.
Remember this network	Select.

You are connected to the wireless network.

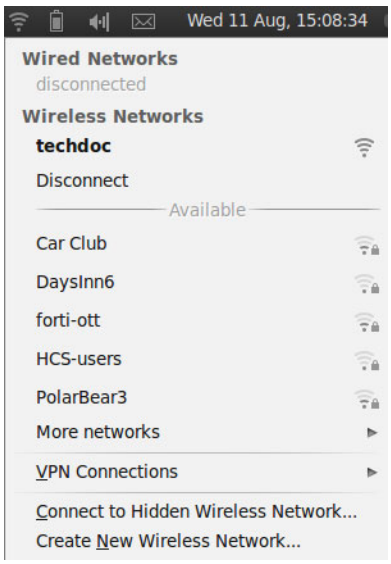
Mac OS supports only PEAP with MSCHAPv2 authentication and therefore can authenticate only to a RADIUS server, not an LDAP or TACACS+ server.

Linux client

This example is based on the Ubuntu 10.04 Linux wireless client.

To connect to a WPA-Enterprise network

1 Select the Network Manager icon to view the Wireless Networks menu.

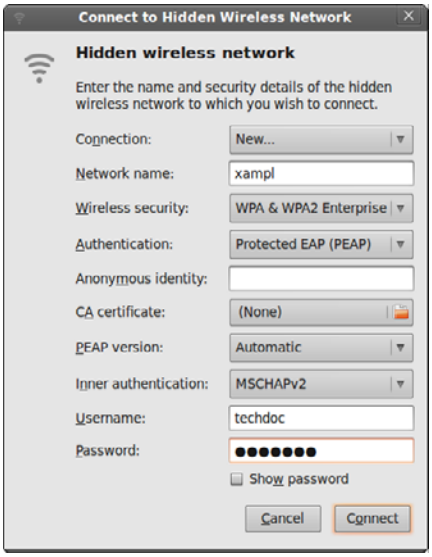


Wireless networks that broadcast their SSID are listed in the *Available* section of the menu. If the list is long, it is continued in the *More Networks* submenu.

2 Do one of the following:

- Select the network from the list (also check *More Networks*).
- Select *Connect to Hidden Wireless Network*.

One of the following windows opens, depending on your selection.



3 Enter the following information:

Connection	Leave as *New*. (Hidden network only)
Network name	Enter the SSID of your wireless network. (Hidden network only)
Wireless Security	WPA & WPA2 Enterprise
Authentication	Protected EAP (PEAP) for RADIUS-based authentication Tunneled TLS for TACACS+ or LDAP-based authentication
Anonymous identity	This is not required.
CA Certificate	If you want to validate the AP's certificate, select the UTN-USERFirst-Hardware root certificate. The default location for the certificate is /usr/share/ca-certificates/mozilla/.
PEAP version	Automatic (applies only to PEAP)
Inner authentication	MSCHAPv2 for RADIUS-based authentication PAP or CHAP for TACACS+ or LDAP-based authentication
Username **Password**	Enter your logon credentials for the wireless network.

4 If you did not select a CA Certificate above, you are asked to do so. Select Ignore.

5 Select *Connect.* You are connected to the wireless network.

To connect to a WPA-Enterprise network

1 Select the Network Manager icon to view the Wireless Networks menu.

2 Select the network from the list (also check *More Networks*).

If your network is not listed (but was configured), select *Connect to Hidden Wireless Network*, select your network from the Connection drop-down list, and then select *Connect*.

Troubleshooting

Using tools provided in your operating system, you can find the source of common wireless networking problems.

Checking that the client has received IP address and DNS server information

Windows XP

1. Double-click the network icon in the taskbar to display the *Wireless Network Connection Status* window. Check that the correct network is listed in the *Connection* section.
2. Select the *Support* tab.

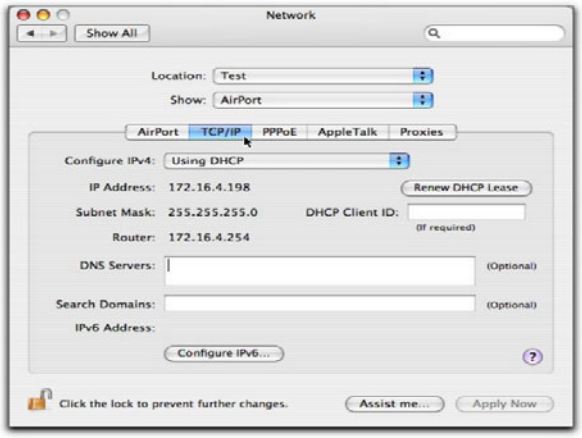
   Check that the *Address Type* is *Assigned by DHCP*. Check that the *IP Address*, *Subnet Mask*, and *Default Gateway* values are valid.
3. Select *Details* to view the DNS server addresses.

   The listed address should be the DNS serves that were assigned to the WAP. Usually a wireless network that provides access to the private LAN is assigned the same DNS servers as the wired private LAN. A wireless network that provides guest or customer users access to the Internet is usually assigned public DNS servers.
4. If any of the addresses are missing, select *Repair*.

   If the repair procedure doesn't correct the problem, check your network settings.

Mac OS

1. From the Apple menu, open *System Preferences* > *Network*.
2. Select *AirPort* and then select *Configure*.
3. On the *Network* page, select the *TCP/IP* tab.



4. If there is no IP address or the IP address starts with 169, select *Renew DHCP Lease*.
5. To check DNS server addresses, open a terminal window and enter the following command:

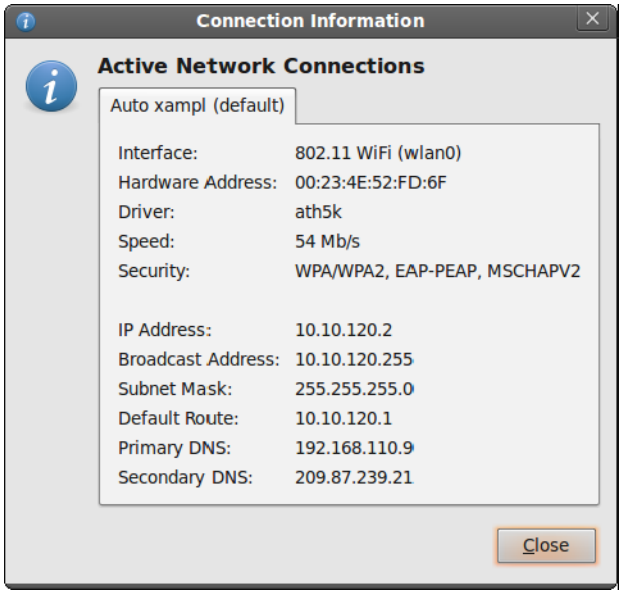
   ```
   cat /etc/resolv.conf
   ```

   Check the listed nameserver addresses. A network for employees should us the wired private LAN DNS server. A network for guests should specify a public DNS server.

Linux

This example is based on the Ubuntu 10.04 Linux wireless client.

1 Right-click the Network Manager icon and select *Connection Information*.



2 Check the IP address, and DNS settings. If they are incorrect, check your network settings.

Wireless network examples

This chapter provides an example wireless network configuration. The following topics are included in this section:

Basic wireless network

This example uses automatic configuration to set up a basic wireless network.

To configure this wireless network, you must:

- Configure authentication for wireless users
- Configure the SSID (WiFi network interface)
- Configure the firewall policy
- Configure and connect FortiAP units

Configuring authentication for wireless users

You need to configure user accounts and add the users to a user group. This example shows only one account, but multiple accounts can be added as user group members.

To configure a WiFi user - web-based manager

1 Go to *User* > *User* and select *Create New*.

2 Enter a *User Name* and *Password* and then select *OK*.

To configure the WiFi user group - web-based manager

1 Go to *User* > *User Group* and select *Create New*.

2 Enter the following information and then select OK:

Name	wlan_users
Type	*Firewall*
Allow SSL-VPN Access	Not selected.
Available Users/Groups / Members	Move users to the *Members* list.

To configure a WiFi user and the WiFi user group - CLI

```
config user user
  edit "user01"
    set type password
    set passwd "asdf12ghjk"
  end
```

```
config user group
  edit "wlan_users"
    set member "user01"
  end
```

Configuring the SSID

First, establish the SSID (network interface) for the network. This is independent of the number of physical access points that will be deployed. The network assigns IP addresses using DHCP.

To configure the SSID - web-based manager

1 Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.

2 Enter the following information and select OK:

Name		example_wifi
IP/Netmask		10.10.110.1/24
Administrative Access		Ping (to assist with testing)
SSID		example_wifi
Enable DHCP		Enable
	Address Range	10.10.110.2 - 10.10.110.199
	Netmask	255.255.255.0
	Default Gateway	Same As Interface IP
	DNS Server	Same as System DNS
Security Mode		WPA/WPA2-Enterprise
Data Encryption		AES
Authentication		Usergroup, select *wlan_users*.
Leave other settings at their default values.		

To configure the SSID - CLI

```
config wireless-controller vap
  edit example_wifi
    set ssid "example_wifi"
    set broadcast-ssid enable
    set security wpa-enterprise
    set auth usergroup
    set usergroup wlan_users
  end
config system interface
  edit example_wifi
    set ip 10.10.110.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.110.1
    set dns-service default
    set interface "example_wifi"
```

```
    config ip-range
      edit 1
        set end-ip 10.10.110.199
        set start-ip 10.10.110.2
      end
    set netmask 255.255.255.0
  end
```

Configuring firewall policies

A firewall policy is needed to enable WiFi users to access the Internet on port1. First you create firewall address for the WiFi network, then you create the example_wifi to port1 policy.

To create a firewall address for WiFi users - web-based manager

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information and select *OK*.

Address Name	wlan_user_net
Type	Subnet / IP Range
Subnet / IP Range	10.10.110.0/24
Interface	example_wifi

To create a firewall address for WiFi users - CLI

```
config firewall address
  edit "wlan_user_net"
    set associated-interface "example_wifi"
    set subnet 10.10.110.0 255.255.255.0
  end
```

To create a firewall policy for WiFi users - web-based manager

1 Go to *Firewall Objects* > *Policy* and select *Create New*.

2 Enter the following information and select *OK*:

Source Interface/Zone	example_wifi
Source Address	wlan_user_net
Destination Interface/Zone	port1
Destination Address	All
Action	ACCEPT
NAT	Enable NAT. Select *Use Destination Interface Address* (default).
Leave other settings at their default values.	

To create a firewall policy for WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "example_wifi"
    set dstintf "port1"
    set srcaddr "wlan_user_net"
    set dstaddr "all"
    set action accept
    set nat enable
  end
```

Connecting the FortiAP units

You need to connect each FortiAP unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to *System* > *Network* > *Interface* and edit the port3 interface.
2. Set the *Addressing mode* to *Manual* and set the *IP/Netmask* to `192.168.8.1`.
3. Enable *Connect FortiAP to this interface and* set *Reserve IP addresses for FortiAP* to `192.168.8.2 - 192.168.8.9`.

   This step automatically configures a DHCP server for the AP units. You can see this configuration in *System* > *Network* > *DHCP Server*.
4. Select *OK*.

To configure the interface for the AP unit - CLI

```
config system interface
  edit port3
    set mode static
    set ip 192.168.8.1 255.255.255.0
  end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
  edit 0
    set interface port3
    config ip-range
      edit 1
        set end-ip 192.168.8.9
        set start-ip 192.168.8.2
      end
      set netmask 255.255.255.0
      set vci-match enable
      set vci-string "FortiAP"
  end
```

To connect a FortiAP unit - web-based manager

1 Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.
2 Connect the FortiAP unit to port 3.
3 Periodically select *Refresh* while waiting for the FortiAP unit to be listed.

Recognition of the FortiAP unit can take up to two minutes.

If FortiAP units are connected but cannot be recognized, try disabling VCI-Match in the DHCP server settings.

4 When the FortiAP unit is listed, select the entry to edit it.

The *Edit Managed Access Point* window opens.

5 In *State*, select *Authorize.*
6 Make sure that AP Profile is set to *Automatic*.
7 In *SSID*, select *Automatically Inherit all SSIDs*.
8 Select *OK*.
9 Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP unit - CLI

1 Connect the FortiAP unit to port 3.
2 Enter

```
config wireless-controller wtp
```

3 Wait 30 seconds, then enter `get`.

Retry the `get` command every 15 seconds or so until the unit is listed, like this:

```
== [ FAP22A3U10600118 ]
wtp-id: FAP22A3U10600118
```

4 Edit the discovered FortiAP unit like this:

```
edit FAP22A3U10600118
  set admin enable
end
```

5 Repeat Steps 2 through 4 for each FortiAP unit.

A more complex example

This example creates multiple networks and uses custom AP profiles.

Scenario

In this example, Example Co. provides two wireless networks, one for its employees and the other for customers or other guests of its business. Guest users have access only to the Internet, not to the company's private network. The equipment for these WiFi networks consists of FortiAP-220A units controlled by a FortiGate unit.

The employee network operates in 802.11n mode on both the 2.4GHz and 5GHz bands. Client IP addresses are in the 10.10.120.0/24 subnet, with 10.10.120.1 the IP address of the WAP. The guest network also operates in 802.11n mode, but only on the 2.4GHz band. Client IP addresses are on the 10.10.115.0/24 subnet, with 10.10.115.1 the IP address of the WAP.

On FortiAP-220A units, the 802.11n mode also supports 802.11g and 802.11b clients on the 2.4GHz band and 802.11a clients on the 5GHz band.

The guest network WAP broadcasts its SSID, the employee network WAP does not.

The employees network uses WPA-Enterprise authentication through a FortiGate user group. The guest network features a captive portal. When a guest first tries to connect to the Internet, a login page requests logon credentials. Guests use numbered guest accounts authenticated by RADIUS. The captive portal for the guests includes a disclaimer page.

In this example, the FortiAP units connect to port 3 and are assigned addresses on the 192.168.8.0/24 subnet.

Configuration

To configure these wireless networks, you must:

- Configure authentication for wireless users
- Configure the SSIDs (network interfaces)
- Configure the AP profile
- Configure the WiFi LAN interface and a DHCP server
- Configure firewall policies

Configuring authentication for employee wireless users

Employees have user accounts on the FortiGate unit. This example shows creation of one user account, but you can create multiple accounts and add them as members to the user group.

To configure the user group for employee access - web-based manager

1 Go to *User* > *User Group* and select *Create New*.

2 Enter the following information and then select OK:

Name	employee-group
Type	*Firewall*
Allow SSL-VPN Access	Disabled
Available Users/Groups / Members	Move appropriate user accounts to the *Members* list.

To configure the user group for employee access - CLI

```
config user group
  edit "employee-group"
    set member "user01"
  end
```

The user authentication setup will be complete when you select the employee-group in the SSID configuration.

Configuring authentication for guest wireless users

Guests are assigned temporary user accounts created on a RADIUS server. The RADIUS server stores each user's group name in the Fortinet-Group-Name attribute. Wireless users are in the group named "wireless".

The FortiGate unit must be configured to access the RADIUS server.

To configure the FortiGate unit to access the guest RADIUS server - web-based manager

1 Go to *User* > *Remote* > *RADIUS* and select *Create New*.

2 Enter the following information and select OK:

Name	guestRADIUS
Primary Server Name / IP	10.11.102.100
Primary Server Secret	grikfwpfdfg
Secondary Server Name / IP	Optional
Secondary Server Secret	Optional
Authentication Scheme	Use default, unless server requires otherwise.
Leave other settings at their default values.	

To configure the FortiGate unit to access the guest RADIUS server - CLI

```
config user radius
  edit guestRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret grikfwpfdfg
  end
```

To configure the user group for guest access - web-based manager

1 Go to *User* > *User Group* and select *Create New*.

2 Enter the following information and then select OK:

Name		guest-group
Type		*Firewall*
Allow SSL-VPN Access		Disabled
Available Users/Groups / Members		Move *guestRADIUS* to the *Members* list.
Match one of these group names		Select Add and fill in the following fields:
	Remote Server	Select *guestRADIUS*.
	Group Name	Enter `wireless`

To configure the user group for guest access - CLI

```
config user group
  edit "guest-group"
    set member "guestRADIUS"
    config match
      edit 0
        set server-name "guestRADIUS"
        set group-name "wireless"
      end
  end
```

The user authentication setup will be complete when you select the guest-group user group in the SSID configuration.

Configuring the SSIDs

First, establish the SSIDs (network interfaces) for the employee and guest networks. This is independent of the number of physical access points that will be deployed. Both networks assign IP addresses using DHCP.

To configure the employee SSID - web-based manager

1 Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.

2 Enter the following information and select OK:

Interface Name		example_inc
IP/Netmask		10.10.120.1/24
Administrative Access		Ping (to assist with testing)
SSID		example_inc
Enable DHCP		Enable
	Address Range	10.10.120.2 - 10.10.120.199
	Netmask	255.255.255.0
	Default Gateway	Same As Interface IP
	DNS Server	Same as System DNS
Security Mode		WPA/WPA2-Enterprise
Data Encryption		AES
Authentication		Select *Usergroup*, then select *employee-group.*
Leave other settings at their default values.		

To configure the employee SSID - CLI

```
config wireless-controller vap
  edit example_inc
    set ssid "example_inc"
    set security wpa-enterprise
    set auth usergroup
    set usergroup employee-group
  end
config system interface
  edit example_inc
    set ip 10.10.120.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.120.1
    set dns-service default
    set interface example_inc
    config ip-range
      edit 1
        set end-ip 10.10.120.199
        set start-ip 10.10.120.2
```

```
    end
    set lease-time 7200
    set netmask 255.255.255.0
  end
```

To configure the example_guest SSID - web-based manager

1 Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.

2 Enter the following information and select OK:

Name		example_guest
IP/Netmask		10.10.115.1/24
Administrative Access		Ping (to assist with testing)
SSID		example_guest
Enable DHCP		Enable
	Address Range	10.10.115.2 - 10.10.115.50
	Netmask	255.255.255.0
	Default Gateway	Same as Interface IP
	DNS Server	Same as System DNS
Security Mode		Captive Portal
Customize Portal Messages		Select
User Groups		Select *guest-group*
Leave other settings at their default values.		

To configure the example_guest SSID - CLI

```
config wireless-controller vap
  edit example_guest
    set ssid "example_guest"
    set security captive-portal
    set selected-usergroups guest-group
  end
config system interface
  edit example_guest
    set ip 10.10.115.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.115.1
    set dns-service default
    set interface "example_guest"
    config ip-range
      edit 1
        set end-ip 10.10.115.50
        set start-ip 10.10.115.2
      end
    set lease-time 7200
    set netmask 255.255.255.0
  end
```

Configuring the custom AP profile

The custom AP Profile defines the radio settings for the networks. The profile provides access to both Radio 1 (2.4GHz) and Radio 2 (5GHz) for the employee virtual AP, but provides access only to Radio 1 for the guest virtual AP.

To configure the AP Profile - web-based manager

1 Go to *WiFi Controller* > *Managed Access Points*> *Custom AP Profile* and select *Create New*.

2 Enter the following information and select OK:

Name		example_AP
Platform		FAP220A
Radio 1		
	Mode	Access Point
	Background Scan	Enable
	Rogue AP On-wire Scan	Enabled.
	Radio Resource Provision	Not enabled.
	Band	802.11n
	Short Guard Interval	Not enabled.
	Channel	Select 1, 6, and 11.
	Tx Power	100%
	SSID	Select *example_inc* and *example_guest*.
Radio 2		
	Mode	Access Point
	Background Scan	Enable
	Rogue AP On-wire Scan	Enabled.
	Radio Resource Provision	Enabled.
	Band	802.11n_5G
	Short Guard Interval	Not enabled.
	20/40 MHz Channel Width	Not enabled.
	Channel	Select all.
	Tx Power	100%
	SSID	Select *example_inc*.

To configure the AP Profile - CLI

```
config wireless-controller wtp-profile
  edit "example_AP"
    config platform
      set type 220A
    end
    config radio-1
      set ap-bgscan enable
      set band 802.11n
```

```
    set channel "1" "6" "11"
    set rogue-scan enable
    set vaps "example_inc" "example_guest"
  end
  config radio-2
    set ap-bgscan enable
    set band 802.11n-5G
    set channel "36" "40" "44" "48" "149" "153" "157" "161"
       "165"
    set rogue-scan enable
    set vaps "example_inc"
  end
```

Configuring firewall policies

Identity-based firewall policies are needed to enable the WLAN users to access the Internet on Port1. First you create firewall addresses for employee and guest users, then you create the firewall policies.

To create firewall addresses for employee and guest WiFi users

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information and select *OK*.

Address Name	employee-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.120.0/24
Interface	example_inc

3 Select *Create New*, enter the following information and select *OK*.

Address Name	guest-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.115.0/24
Interface	example_guest

To create firewall policies for employee WiFi users - web-based manager

1 Go to *Policy* > *Policy* and select *Create New*.

2 Enter the following information and select OK:

Source Interface/Zone	example_inc
Source Address	employee-wifi-net
Destination Interface/Zone	port1
Destination Address	All
Schedule	always
Service	Any
Action	ACCEPT
NAT	Enable NAT

3 Optionally, select *UTM* and set up UTM features for wireless users.

4 Select *OK*.

5 Repeat steps 1 through 4 but select Internal as the Destination Interface/Zone to provides access to the ExampleCo private network.

To create firewall policies for employee WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "employee_inc"
    set dstintf "port1"
    set srcaddr "employee-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
    set schedule "always"
    set service "ANY"
  next
  edit 0
    set srcintf "employee_inc"
    set dstintf "internal"
    set srcaddr "employee-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
    set schedule "always"
    set service "ANY"
  end
```

To create a firewall policy for guest WiFi users - web-based manager

1 Go to *Policy* > *Policy* and select *Create New*.

2 Enter the following information and select OK:

Source Interface/Zone	example_guest
Source Address	guest-wifi-net
Destination Interface/Zone	port1
Destination Address	All
Schedule	always
Service	Any
Action	ACCEPT
NAT	Enable NAT

3 Optionally, select *UTM* and set up UTM features for wireless users.

4 Select *OK*.

To create a firewall policy for guest WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "example_guest"
    set dstintf "port1"
    set srcaddr "guest-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
  end
```

Connecting the FortiAP units

You need to connect each FortiAP-220A unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to *System* > *Network* > *Interface* and edit the port3 interface.
2. Set the *Addressing mode* to *Manual* and set the *IP/Netmask* to `192.168.8.1`.
3. Enable *Connect FortiAP to this interface and* set *Reserve IP addresses for FortiAP* to `192.168.8.2 - 192.168.8.9`.

   This step automatically configures a DHCP server for the AP units.
4. Select *OK*.

To configure the interface for the AP unit - CLI

```
config system interface
  edit port3
    set mode static
    set ip 192.168.8.1 255.255.255.0
  end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
  edit 0
    set interface port3
    config ip-range
      edit 1
        set end-ip 192.168.8.9
        set start-ip 192.168.8.2
      end
      set netmask 255.255.255.0
      set vci-match enable
      set vci-string "FortiAP"
  end
```

To connect a FortiAP-220A unit - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.
2. Connect the FortiAP unit to port 3.
3. Periodically select *Refresh* while waiting for the FortiAP unit to be listed.

   Recognition of the FortiAP unit can take up to two minutes.

   If there is persistent difficulty recognizing FortiAP units, try disabling VCI-Match in the DHCP server settings.
4. When the FortiAP unit is listed, select the entry to edit it.

   The *Edit Managed Access Point* window opens.
5. In *State*, select *Authorize.*
6. In the *AP Profile,* select *[Change]* and then select the *example_AP* profile.
7. Select *OK*.
8. Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP-220A unit - CLI

1. Connect the FortiAP unit to port 3.
2. Enter

   ```
   config wireless-controller wtp
   ```
3. Wait 30 seconds, then enter `get`.

   Retry the `get` command every 15 seconds or so until the unit is listed, like this:

   ```
   == [ FAP22A3U10600118 ]
   wtp-id: FAP22A3U10600118
   ```
4. Edit the discovered FortiAP unit like this:

   ```
   edit FAP22A3U10600118
     set admin enable
     set wtp-profile example_AP
   end
   ```
5. Repeat Steps 2 through 4 for each FortiAP unit.

Using a FortiWiFi unit as a client

A FortiWiFi unit by default operates as a wireless access point. But a FortiWiFi unit can also operate as a wireless client, connecting the FortiGate unit to another wireless network.

This section includes the following topics:

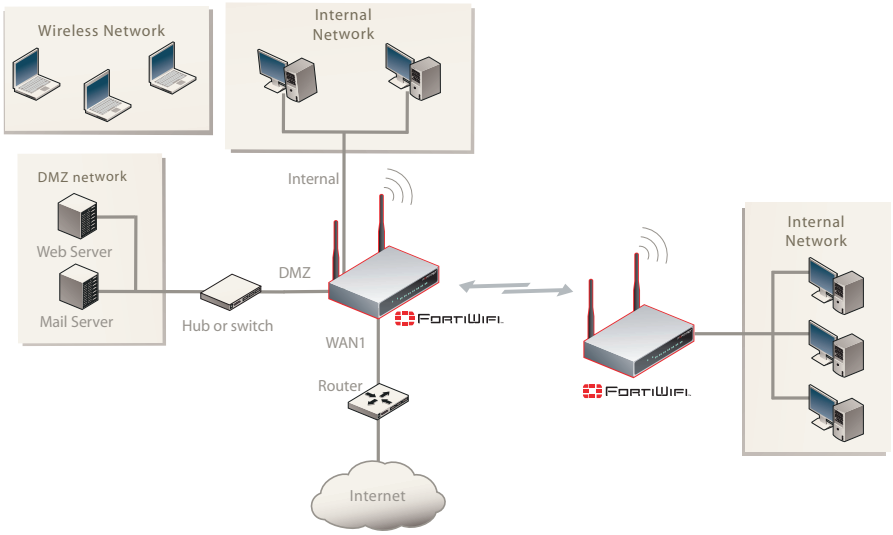
Use of client mode

In client mode, the FortiWiFi unit connects to a remote WiFi access point to access other networks or the Internet. This is most useful when the FortiWiFi unit is in a location that does not have a wired infrastructure.

For example, in a warehouse where shipping and receiving are on opposite sides of the building, running cables might not be an option due to the warehouse environment. The FortiWiFi unit can support wired users using its Ethernet ports and can connect to another access point wirelessly as a client. This connects the wired users to the network using the 802.11 WiFi standard as a backbone.

Note that in client mode the FortiWiFi unit cannot operate as an AP. WiFi clients cannot see or connect to the FortiWifi unit in Client mode.

Figure 258: FortiGate unit in Client mode



Configuring client mode

To set up the FortiAP unit as a WiFi client, you must use the CLI. Before you do this, be sure to remove any AP WiFi configurations such as SSIDs, DHCP servers, policies, and so on.

To configure wireless client mode

1 Change the WiFi mode to client.

In the CLI, enter the following commands:

```
config system global
  set wireless-mode client
end
```

Respond “y” when asked if you want to continue. The FortiWiFi unit will reboot.

2 Create a WiFi interface and configure the appropriate WiFi client settings.

For example, to configure the client for WPA-Personal authentication on the *our_wifi* SSID with passphrase *justforus*, enter the following in the CLI:

```
config system interface
  edit client_wifi
    set type wireless
    set mode dhcp
    set wifi-ssid our_wifi
    set wifi-security wpa-personal
    set wifi-passphrase "justforus"
  end
```

The WiFi interface client_wifi will receive an IP address using DHCP.

3 Configure a client_wifi to port1 policy.

You can use either CLI or web-based manager to do this. The important settings are:

Source Interface/Zone	client_wifi
Source Address	All
Destination Interface/Zone	port1
Destination Address	All
Action	ACCEPT
NAT	Enable NAT. Select *Use Destination Interface Address* (default).
Leave other settings at their default values.	

WiFi Reference

This chapter provides some reference information pertaining to wireless networks. The following topics are included in this section:

Wireless radio channels

IEEE 802.11a/n channels

Table 132 lists the channels supported on FortiWiFi products that support the IEEE 802.11a and 802.11n wireless standards. 802.11a is available on FortiWiFi models 60B and higher. 802.11n is available on FortiWiFi models 80CM and higher.

All channels are restricted to indoor usage except in the Americas, where both indoor and outdoor use is permitted on channels 52 through 64 in the United States.

Table 132: IEEE 802.11a/n (5-GHz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas				
		Americas	Europe	Taiwan	Singapore	Japan
34	5170					•
36	5180	•	•		•	
38	5190					
40	5200	•	•		•	•
42	5210					
44	5220	•	•		•	•
46	5230					
48	5240	•	•		•	•
149	5745	•		•	•	
153	5765	•		•	•	
157	5785	•		•	•	
161	5805	•		•	•	
165	5825	•			•	

IEEE 802.11b/g/n channel numbers

Table 133 lists IEEE 802.11b/g/n channels. All FortiWiFi units support 802.11b and 802.11g. Newer models also support 802.11n.

Mexico is included in the Americas regulatory domain. Channels 1 through 8 are for indoor use only. Channels 9 through 11 can be used indoors and outdoors. You must make sure that the channel number complies with the regulatory standards of Mexico.

Table 133: IEEE 802.11b/g/n (2.4-Ghz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas			
		Americas	EMEA	Israel	Japan
1	2412	•	•	•?	•
2	2417	•	•	•?	•
3	2422	•	•	•?	•

WiFi Controller Reference

This section introduces you to the web-based manager *WiFi Controller* menu.

The following topics are included in this section:

The word “unit” refers to the FortiGate unit. The words “FortiGate unit” are used when talking about different Fortinet products in one sentence. For example, “The Central Management menu provides the option of remotely managing your FortiGate unit by a FortiManager unit.”

WiFi Controller overview

The WiFi Controller menu configures WiFi networks on your FortiWiFi or FortiGate unit. Your WiFi networks can use any of the following WiFi networking equipment:

- your FortiWiFi unit’s built-in wireless access point/client (see “FortiWiFi units” on page 2438)
- FortiAP units—wireless access points compliant with the CAPWAP standard (see “FortiAP units” on page 2440)
- the built-in wireless access point/client of a FortiWiFi unit connected to your unit (see “Using a FortiWiFi unit as a managed AP” on page 2439)

Each of these pieces of WiFi networking equipment is an access point. Each access point can carry multiple networks to which clients can connect.

The WiFi Controller feature is available on all models running FortiOS or FortiOS Carrier, ***except*** model 30B.

The wireless controller feature can also:

- monitor activity on your WiFi networks
- monitor neighboring access points that might cause interference
- detect rogue (unauthorized) access points connected to your wired networks
- suppress access points that you have designated as rogues

WiFi Network

In the WiFi Network menu, you can configure SSID and rogue AP detection settings.

An SSID defines the security settings for a wireless LAN. For each SSID, the FortiGate unit creates a virtual network interface. You create firewall policies to control traffic between the SSID interface and other networks. Users need the correct security settings to connect to the access point, and they can also be required to authenticate to use a firewall policy.

A Rogue AP is an unauthorized AP connected to your network. This can be a security issue. Other APs may be receivable in your area. These APs belong to neighboring businesses or homes. They can cause interference but are not a security thereat. The on-wire detection technique can distinguish between neighbors and rogues.

This topic includes the following:

SSID list

The list of SSIDs (WiFi networks) at *WiFi Controller* > *WiFi Network* > *SSID* contains the following columns:

Create New	Creates a new SSID. When you select *Create New*, you are automatically redirected to the New SSID page. See SSID configuration settings.
Edit	Modifies an SSID's settings. When you select *Edit*, you are automatically redirected to the Edit SSID page. See SSID configuration settings.
Delete	Removes an SSID from the list on the SSID page. To remove multiple SSIDs from within the list, on the SSID page, in each of the rows of the SSIDs you want removed, select the check box and then select *Delete*. To remove all SSIDs from the list, on the SSID page, select the check box in the check box column and then select *Delete*.
SSID	The SSID or network name for the wireless interface.
Administrative Status	Indicates whether the SSID's administrative status is up or down. A green up arrow indicates that it is up; a red down arrow indicates that it is not.
Security mode	The type of security for the wireless interface: **WPA/WPA2 Personal** — user must know pre-shared key value to connect. **WPA/WPA2 Enterprise** — user must know user name and password to connect. **Captive Portal** — user connects to the open access point and then must authenticate to use the network

Data Encryption	The type of encryption for the wireless interface in WPA/WPA2 modes. AES is the most secure, but some older clients support only TKIP.
Clients	The maximum number of clients permitted to connect simultaneously.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a firewall policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.*. To view the location of the referenced object, select the number in *Ref.*, and the *Object Usage* window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy and so, when this icon is selected, the user is redirected to the Edit Policy page. **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting than the object is referenced with. For example, av_1 profile is referenced with a firewall policy, and that firewall policy's settings appear within the table.

SSID configuration settings

When you edit an SSID or create a new one in *WiFi Controller* > *WiFi Network* > *SSID*, the following configuration settings are available:

Interface Name	Enter a name for the SSID.
Administrative Status	Select to have the SSID's status either up or down. If the SSID's status is down, the SSID is not being used. If the SSID's status is up, the SSID is being used.
Addressing Mode	
IP/Netmask	Enter the IP address and netmask for the SSID.
IPv6 Address	Enter the IPv6 address. This is available only when IPv6 has been enabled on the unit.
Administrative Access	Select the administrative access for the SSID.
IPv6 Administrative Access	If you have IPv6 addresses, select the administrative access for IPv6 for SSID.
Enable Explicit Web Proxy	Select to enable explicit web proxy for the SSID.

WiFi Settings		
SSID		Enter the SSID. By default, this field contains fortinet.
Enable DHCP		Select to enable a DHCP server and configure basic DHCP server settings. The *Address Start* and *Address End* settings are used to create an appropriate DHCP server in the DHCP server list. If the unit is in transparent mode, the DHCP server settings will be unavailable.
	Address Range	Enter the starting IP address of the DHCP server.
	Netmask	Enter the netmask of the DHCP server.
	Default Gateway	Enter the default gateway for the DHCP server.
	DNS Server	Enter the DNS server.
Security Mode		Select the security mode for the wireless interface. Wireless users must use the same security mode to be able to connect to this wireless interface. Additional security mode options are available in the CLI.
		WPA/WPA2-Personal – WPA or WPA2 security. WPA is WiFi protected access. WPA2 is WPA with additional security features. There is one shared key (password) that all users use.
		WPA/WPA2-Enterprise – similar to WPA/WPA2-Personal, but is best used for enterprise networks. Each user is separately authenticated by user name and password.
		Captive Portal – authenticates users through a customizable web page.
	Customize Portal Messages	Available only when *Security Mode* is *Captive Portal*. Select to customize the endpoint replacement messages. When you select *Edit*, the Edit Message window appears. Within the window, you can modify each one of the endpoint replacement messages.
	User Groups	Available only when *Security Mode* is *Captive Portal*. Select the user groups that can authenticate. To select a user group, select the group in *Available* and then use the -> arrow to move that group to *Selected*. To remove a user group from *Selected*, select the group and then use the <- arrow to move the group back to *Available*.
Data Encryption		Available only when *Security Mode* is *WPA/WPA2-Enterprise*. Select *TKIP* or *AES* encryption as appropriate for the capabilities of your wireless clients. This is available for WPA/WPA2 security modes.
Pre-shared Key		Available only when *Security Mode* is *WPA/WPA2-Personal*. Enter the encryption key that the clients must use.

Authentication	Available only when *Security Mode* is *WPA/WPA2-Enterprise*. Select one of the following: *RADIUS Server* — Select the RADIUS server that will authenticate the clients. *Usergroup* – Select the user group that can authenticate.
Block Intra-SSID Traffic	Select to enable the unit to block intra-SSID traffic.
Maximum Clients	Select to limit the number of clients permitted to connect simultaneously. Enter the limit value.
Comments	Enter a description or comment for the SSID.

Rogue AP Settings

From the Rogue AP Settings page, you can enable rogue AP detection and the on-wire rogue AP detection technique. Rogue APs are APs that are not known to the WiFi controller and these unknown APs can be monitored by using these two features.

The feature, *Enable On-Wire Rogue AP Detection Technique*, determines which unknown APs are actually connected to your network. The unknown APs are considered rogues.

You can enable or disable these settings in *WiFi Controller* > *WiFi Network* > *Rogue AP Settings*.

Managed access points

The WiFi controller needs to be configured to manage each physical access point and configure its radio settings for the wireless LAN.

From the Managed Access Points menu, you can configure managed FortiAP and local WiFi radio settings and create custom AP profiles.

This topic contains the following:

- Local WiFi Radio configuration settings
- Managed FortiAP list
- Managed FortiAP configuration settings
- Custom AP Profiles
- Custom AP Profile Settings

The Local WiFi Radio submenu is available only on FortiWiFi units.

Local WiFi Radio configuration settings

Go to *WiFi Controller* > *Managed Access Points* > *Local WiFi Radio* to configure the WiFi radio facility of your FortiWiFi unit. FortiGate units do not have this page.

Local WiFi Radio page Displays the local WiFi radio settings. From this page you can change the local WiFi settings, such as changing the AP profile. You must select *Apply* to save the changes.	
AP Profile	Select *Change* to change the profile. A drop-down list appears when you select *Change*; select the profile from the list and then select *Apply*.
Enable Wireless Radio	Select to enable the wireless radio settings on the unit.
Automatically Inherit All SSIDs	Select to have the unit automatically inherit all SSID broadcasts.
Select SSIDs	Select to manually choose which SSID broadcasts.
TX Power	Displays the transmission power in percent. Use the slider to change the power.
Channel	The channel that the unit is broadcasting on. For example, channel 2.
Band	The IEEE wireless protocol that the unit is using.

Managed FortiAP list

Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP* to view the list of managed APs that have discovered the WiFi Controller. On this page, you can edit, delete, authorize, ignore or restart access points.

Edit	Modifies a managed physical AP's settings. When you select *Edit*, you are automatically redirected to the Managed FortiAP configuration settings.
Delete	Removes a managed physical AP in the list on the Managed Physical AP page. To remove multiple managed APs from within the list, on the Managed Physical AP page, in each of the rows of the APs you want removed, select the check box and then select *Delete*. To remove all APs in the list, on the Managed Physical AP page, select the check box in the check box column, and then select *Delete*.
Column Settings	Not all columns are shown by default. Select *Column Settings* to choose which columns to display.
Refresh	Select to refresh the current information on the page.
Restart	Select to restart an AP.
Show Ignored	Select to show the FortiAP units that the unit currently ignores.
State	The state of the FortiAP unit. The state is indicated by an icon, for example, if there is a blue question mark, this indicates that the unit is connecting.
Status	The status of the FortiAP unit.

Name	The name or serial number of the physical AP.
Clients	The maximum number of clients that are permitted to connect simultaneously. When you click on the number, you are automatically redirected to *WiFi Controller* > *Monitor* > *Client Monitor*.
SSIDs	The SSIDs of the FortiAP unit.
Connecting From	The wired IP address of the FortiAP unit.

Managed FortiAP configuration settings

You can select a managed AP on the *WiFi Controller* > *Managed Access Points* > *Managed FortiAP* page and modify the following settings:

Serial Number	The serial number of the unit (read-only).
Name	Enter a name for the access point. Otherwise, the serial number is displayed as the AP name.
Description	Select *Change* to change the existing description. If there is no description, “N/A” displays.
Managed AP status section	
Status	Indicates the connection status of the access point. For example, if the access point is connecting, *Connecting* displays.
Connecting From	The IP address of the unit.
State	The type of state the unit is in. Select *Authorize* to authorize the managed access point. If you want to deauthorize the managed access point, select *Deauthorize*.
Wireless Settings	
AP Profile	The name of the AP Profile or Automatic if a custom profile is not used. Select *Change* to select a different profile or Automatic settings, then select *Apply*.
Wireless Settings with Automatic AP Profile	
Enable WiFi Radio	Select to enable operation of this AP.
SSID	Automatically Inherit all SSIDs — AP will carry all WiFi networks. Select SSIDs — selects individual SSIDs for this AP to carry.
Tx Power	Adjust AP transmitter power. The 100% setting is the maximum permitted in your country.
Band	The WiFi radio band to be used. 802.11n, for example.
Channel	The radio channel currently in use.
Do not participate in Rogue AP Scanning	Select if AP performance is poor due to heavy traffic. The scanning function can affect performance.
Wireless Settings with Custom AP Profile	
Radio 1	Specific information about the AP’s first radio.
Radio 2	Specific information about the AP’s second radio.

Custom AP Profiles

The following are profile configuration settings in *WiFi Controller* > *Managed Access Points* > *Custom AP Profile*.

Custom AP Profile page Lists each individual physical FortiAP that are currently on your network. On this page, you can edit, delete, authorize, ignore or restart.	
Create New	Creates a new AP profile. When you select *Create New*, you are automatically redirected to the Custom AP Profile Settings page.
Edit	Modifies a managed physical AP settings. When you select *Edit*, you are automatically redirected to the Custom AP Profile Settings page.
Delete	Removes a managed physical AP in the list on the Managed Physical AP page. To remove multiple managed APs from within the list, on the Managed Physical AP page, in each of the rows of the APs you want removed, select the check box and then select *Delete*. To remove all APs in the list, on the Managed Physical AP page, select the check box in the check box column, and then select *Delete*.
Name	The name of the AP profile.
Comments	A description or comment about the AP profile.
Platform	The type of model that is associated with the AP profile.
Radio 1	The selected radio band and channels for the first (or only) radio in the managed access point.
Radio 2	The selected radio band and channels for the second radio in the managed access point. This is for FortiAP units only.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a firewall policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.*. To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy and so, when the icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy, and that firewall policy's settings appear within the table.

Custom AP Profile Settings

You can edit or create new custom AP profiles on the *WiFi Controller* > *Managed Access Points* > *Custom AP Profile* page.

Name	Enter a name for the AP profile.
Comments	Enter a description or comment about the AP profile. This is optional.
Platform	Select the type of Fortinet platform that will be using the AP profile. For example, FortiWiFi-60C.
Radio 1 settings / Radio 2 settings Radio 1 settings are the same as Radio 2 settings except for the options for Channel. ***Note:*** *Radio 2* settings are available only for FortiAP models with dual radios.	
Mode	Select the type of mode. • *Disable* – no mode is set. • *Access Point* – allows for the platform to be an access point • *Dedicated Monitor* – allows for the platform to be a dedicated monitor
Background Scan	Select to enable a background scan, which monitors for rogue APs. This is for the Rogue AP feature. By default, a background scan is disabled.
Radio Resource Provision	Select to enable the radio resource provision feature.
Band	Select the IEEE wireless protocol that is available to the region.
Short Guard Interval	Select to enable the short guard interval feature for 802.11n.
20/40 Mhz Channel Width	Select to enable the channel width to have 20/40 megahertz for 802.11n-5G.
Channel	Select the channel or channels to include. These channels change with regards to what IEEE wireless protocol you selected in *Band*.
TX Power	By default, the TX power is set to 100% of the maximum power permitted in your region. To change the level, drag the slider.
SSID	Choose the SSIDs (WiFi networks) that APs using this profile will carry. Select the required SSIDs in the *Available* list and use the -> arrow to move them to the *Selected* list. To remove an SSID from the *Selected* list, select the SSID and then use the <- arrow to move it back to the *Available* list.

Monitor

The Monitor menu allows you to view monitored wireless activity.

This topic contains the following:

Client Monitor

In *WiFi Controller* > *Monitor* > *Client Monitor,* you can view information about wireless clients of your managed access points.

Refresh	Update the information in the table.
Filter Settings	Select to filter the information on the page. *Filters* appears automatically after selecting *Filter Settings*, below the column headings. Use to configure filter settings. • To apply a filter setting, select the plus sign beside *Add new filter* and then select and enter the information required. Repeat to add other filter settings. • To modify settings, select *Change* beside the setting and edit the settings. • To clear all filter settings, select the icon beside *Clear all filters*. • To use a filter icon to filter settings within a column, select the filter icon in the column; *Filters* appears. Within *Filters*, configure the settings for that column. **Note:** *Filter Settings* configures all filter settings. Filter icons are used to configure filter settings within that column.
Column Settings	Select the columns to display in the list. You can also determine the order in which they appear.
Page Controls	Use to navigate through the list.
Information columns Actual columns displayed depends on *Column Settings*.	
MAC	The MAC address of the wireless client.
Auth	The authentication type.
IP	The IP address assigned to the wireless client.
FortiAP	The name of the physical access point with which the client is associated.
SSID	The SSID for the managed access point.
Bandwidth Tx/Rx	*The current bandwidth.*
Signal Strength/Noise	The signal-to-noise ratio in deciBels calculated from signal strength and noise level.
Association Time	The time period that the client has been connected to this access point.
Bandwidth Rx	Received bandwidth used by the client, in Kbps.

Bandwidth Tx	Transmit bandwidth used by the client, in Kbps.
Idle Time	The total time this session that the client was idle.
Rate	The data rate of the client connection.
Manufacturer	The manufacturer of the client wireless device.

Rogue AP Monitor

View information about detected APs in *WiFi Controller* > *Monitor* > *Rogue AP Monitor*. You can also mark and suppress rogue APs.

Mark	Select the down arrow to mark the AP as accepted, rogue or unclassified.
Suppress AP	Select the down arrow to suppress the AP or unsuppress the AP. Available only if the AP is marked as a rogue AP.
Column Settings	Select the columns to display in the list. You can also determine the order in which they appear.
Refresh	Select to update the information. *none* means no updates.
Show Accepted	Select to show only the accepted APs.
Total detected APs	Displays the total number of APs that are detected by the FortiGate unit.
Information Columns Actual columns displayed depends on *Column Settings*.	
State	The state of the rogue AP.
Online Status	A green check mark indicates an active access point. A grey X indicates that the access point is inactive.
SSID	The wireless service set identifier (SSID) or network name for the wireless interface.
Security Type	The type of security currently being used.
Channel	The wireless radio channel that the access point uses.
MAC Address	The MAC address of the Wireless interface.
Vendor Info	The name of the vendor.
Signal Strength	The relative signal strength of the AP. Mouse over the symbol to view the signal-to-noise ratio.
Detected By	The name or serial number of the AP unit that detected the signal.
On-wire	A green up-arrow indicates a suspected rogue, based on the on-wire detection technique. A red down-arrow indicates AP is not a suspected rogue.

Chapter 16 VoIP Solutions: SIP & FortiGate Voice

This FortiOS Handbook chapter contains the following sections:

FortiGate VoIP solutions: SIP describes FortiGate SIP support.

Example FortiGate Voice branch office configuration describes how to configure a FortiGate Voice-80C unit to operate in NAT/Route mode and provide basic UTM and SIP services for an example branch office network.

FortiGate Voice web-based manager configuration reference describes FortiGate Voice web-based manager configuration settings.

Using the PBX user web portal describes how to log into and use the FortiGate Voice PBX portal.

FortiGate Voice VoIP, PBX, and PSTN CLI Reference describes FortiGate Voice VoIP, PBX, and PSTN CLI commands.

FortiGate VoIP solutions: SIP

This chapter includes the following sections:

SIP overview

The Session Initiation Protocol (SIP) is an IETF application layer signaling protocol used for establishing, conducting, and terminating multiuser multimedia sessions over TCP/IP networks using any media. SIP is often used for Voice over IP (VoIP) calls but can be used for establishing streaming communication between end points.

SIP employs a request and response transaction model similar to HTTP for communicating between endpoints. SIP sessions being with a SIP client sending a SIP request message to another client to initiate a multimedia session. The other client responds with a SIP response message. Using these request and response messages, the clients engage in a SIP dialog to negotiate how to communicate and then start, maintain, and end the communication session.

SIP commonly uses TCP or UDP port 5060 and/or 5061. Port 5060 is used for non-encrypted SIP signaling sessions and port 5061 is typically used for SIP sessions encrypted with Transport Layer Security (TLS).

Devices involved in SIP communications are called SIP User Agents (UAs) (also sometimes called a User Element (UE)). UAs include User Agent Clients (UACs) that communicate with each other and User Agent Servers (UASs) that facilitate communication between UACs. For a VoIP application, an example of a UAC would be a SIP phone and an example of a UAS would be a SIP proxy server.

A SIP message contain headers that include client and server names and addresses required for the communication sessions. The body of a SIP message contains Session Description Protocol (SDP) statements that establish the media communication (port numbers, protocols and codecs) that the SIP UAs use. SIP VoIP most commonly uses the Real Time Protocol (RTP) and the Real Time Control Protocol (RTCP) for voice communication. Once the SIP dialog establishes the SIP call the VoIP stream can run independently, although SIP messages can affect the VoIP stream by changing port numbers or addresses and by ending it.

Once SIP communication and media settings are established, the UAs communicate with each using the established media settings. When the communication session is completed, one of the UAs ends the session by sending a final SIP request message and the other UA sends a SIP response message and both UAs end the SIP call and stop the media stream.

FortiGate units provide security for SIP communications using the SIP session helper and the SIP ALG:

- The SIP session-helper provides basic high-performance support for SIP calls passing through the FortiGate unit by opening SIP and RTP pinholes and performing source and destination IP address and port translation for SIP and RTP packets and for the IP addresses and port numbers in the SIP headers and the SDP body of the SIP messages. For more about the SIP session helper, see "The SIP session helper" on page 2536.
- The SIP Application Layer Gateway (ALG) provides the same features as the session helper plus additional advanced features such as deep SIP message inspection, SIP logging, SIP IPv6 support, SIP message checking, HA failover of SIP sessions, and SIP rate limiting. For more about the SIP ALG, see "The SIP ALG" on page 2541.

There are a large number of SIP-related Internet Engineering Task Force (IETF) documents (Request for Comments) that define behavior of SIP and related applications. FortiGate units provide complete support of RFC 3261 for SIP and RFC 4566 for SDP. FortiGate units also provide support for other SIP and SIP-related RFCs and performs "Deep SIP message inspection" on page 2586 for SIP statements defined in other SIP RFCs.

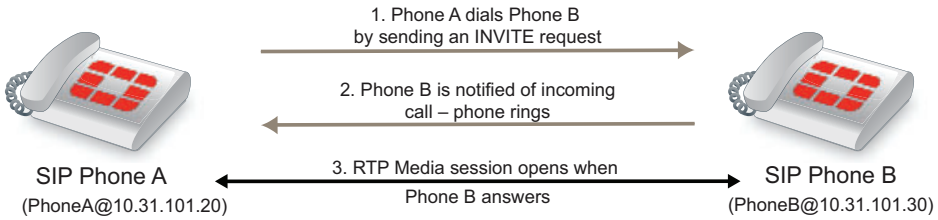
Common SIP VoIP configurations

This section describes some common SIP VoIP configurations and simplified SIP dialogs for these configurations. This section also shows some examples of how adding a FortiGate unit affects SIP processing.

Peer to peer configuration

In the peer to peer configuration shown in Figure 259, two SIP phones (in the example, FortiFones) communicate directly with each other. The phones send SIP request and response messages back and forth between each other to establish the SIP session.

Figure 259: SIP peer to peer configuration

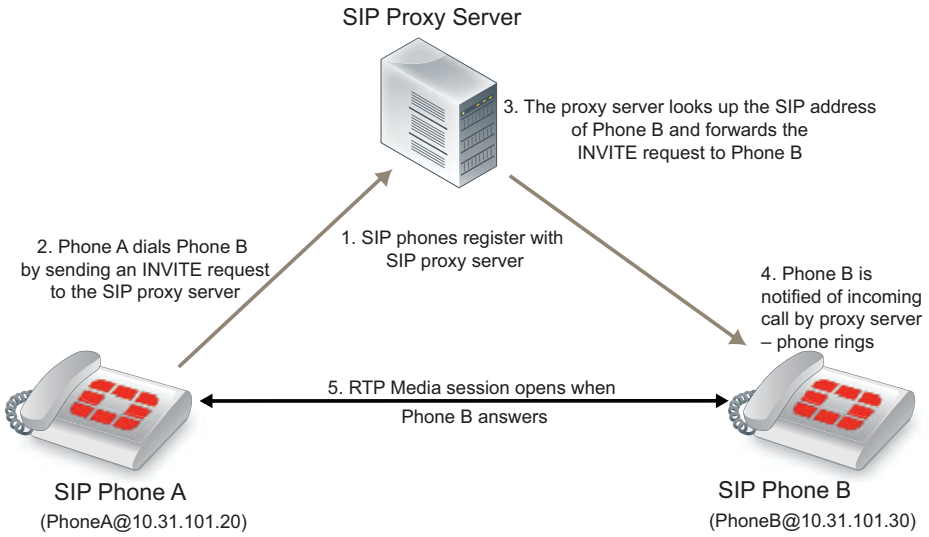


Peer to peer configurations are not very common because they require the SIP phones to keep track of the names and addresses of all of the other SIP phones that they can communicate with. In most cases a SIP proxy or re-direct server maintains addresses of a large number of SIP phones and a SIP phone starts a call by contacting the SIP proxy server.

SIP proxy server configuration

A SIP proxy server act as intermediary between SIP phones and between SIP phones (for example, two FortiFones) and other SIP servers. As shown in Figure 260, SIP phones send request and response messages the SIP proxy server. The proxy server forwards the messages to other clients or to other SIP proxy servers. Proxy servers can hide SIP phones by proxying the signaling messages. To the other users on the VoIP network, the signaling invitations look as if they come from the SIP proxy server.

Figure 260: SIP in proxy mode

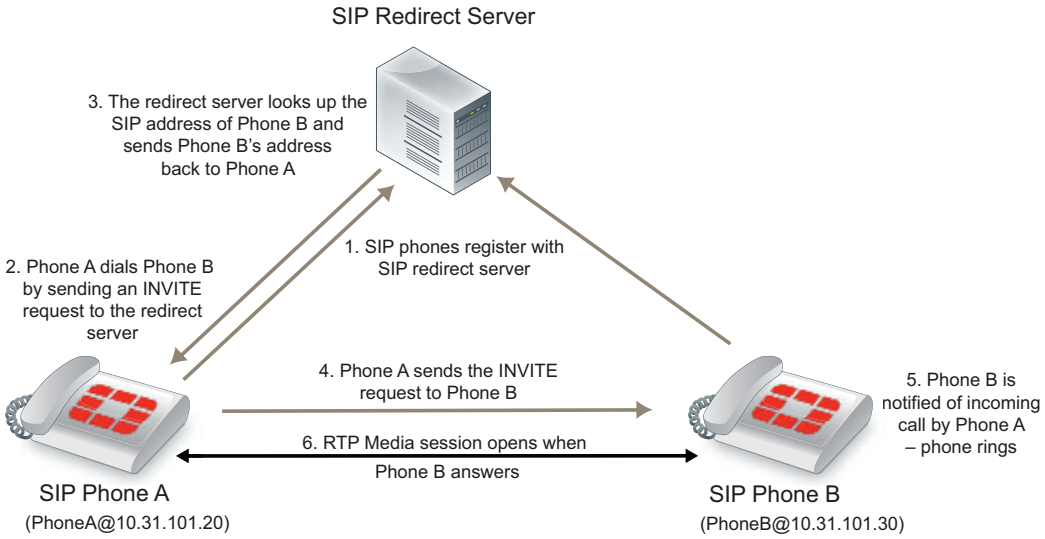


A common SIP configuration would include multiple networks of SIP phones. Each of the networks would have its own SIP server. Each SIP server would proxy the communication between phones on its own network and between phones in different networks.

SIP redirect server configuration

A SIP redirect server accepts SIP requests, maps the addresses in the request into zero or more new addresses and returns those addresses to the client. The redirect server does not initiate SIP requests or accept calls. As shown in Figure 261, SIP clients send INVITE requests to the redirect server, which then looks up the destination address. The redirect server returns the destination address to the client. The client uses this address to send the INVITE request directly to the destination SIP client.

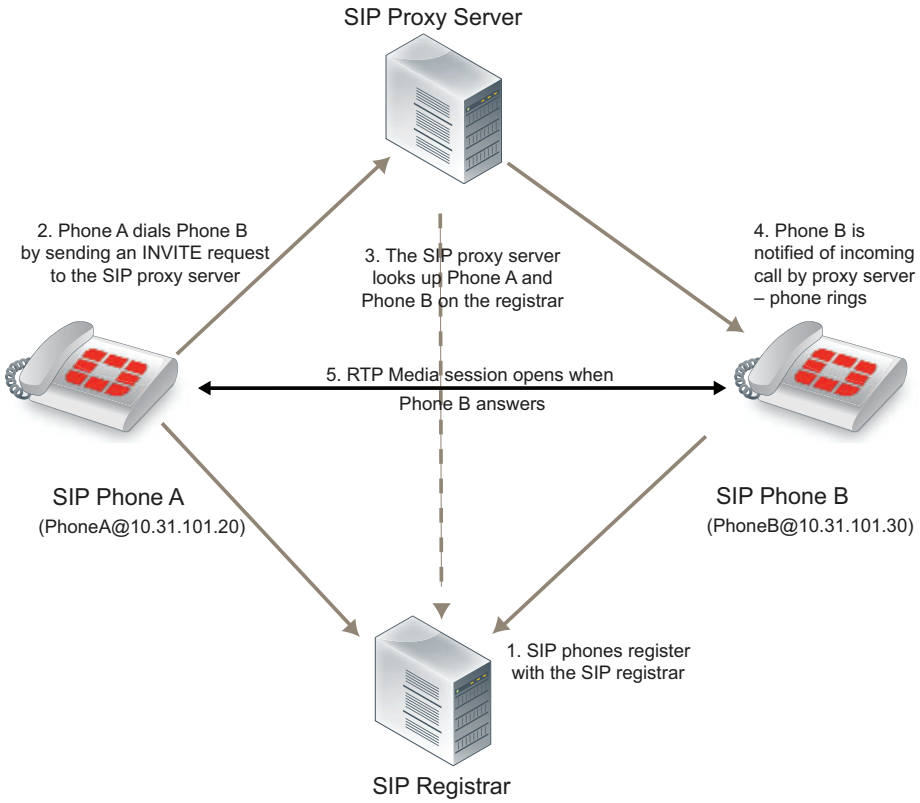
Figure 261: SIP in redirect mode



SIP registrar configuration

A SIP registrar accepts SIP REGISTER requests from SIP phones for the purpose of updating a location database with this contact information. This database can then become a SIP location service that can be used by SIP proxy severs and redirect servers to locate SIP clients. As shown in Figure 262, SIP clients send REGISTER requests to the SIP registrar.

Figure 262: SIP registrar and proxy servers

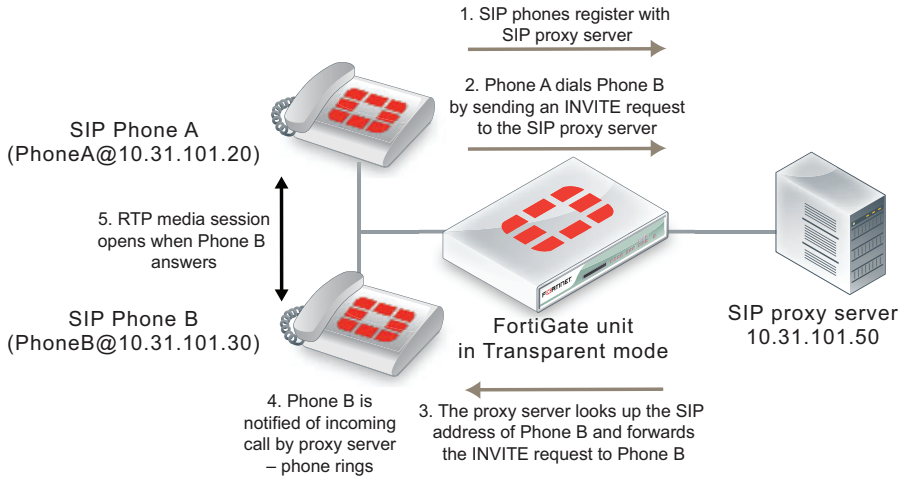


SIP with a FortiGate unit

Depending on your security requirements and network configuration FortiGate units may be in many different places in a SIP configuration. This section shows a few examples.

Figure 263 shows a FortiGate unit installed between a SIP proxy server and SIP phones on the same network. The FortiGate unit is operating in Transparent mode so both the proxy server and the phones are on the same subnet. In this configuration, called SIP inspection without address translation, the FortiGate unit could be protecting the SIP proxy server on the private network by implementing SIP security features for SIP sessions between the SIP phones and the SIP proxy server.

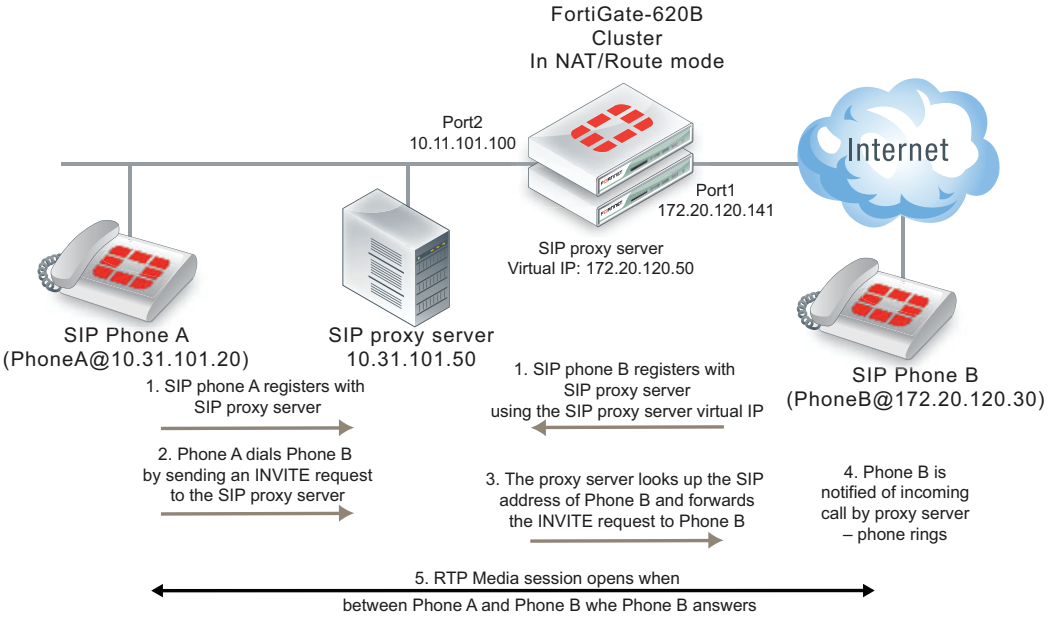
Figure 263: SIP network with FortiGate unit in Transparent mode



The phones and server use the same SIP dialogs as they would if the FortiGate unit was not present. However, the FortiGate unit can be configured to control which devices on the network can connect to the SIP proxy server and can also protect the SIP proxy server from SIP vulnerabilities.

Figure 264 shows a FortiGate unit operating in NAT/Route mode and installed between a private network and the Internet. Some SIP phones and the SIP proxy server are connected to the private network and some SIP phones are connected to the Internet. The SIP phones on the Internet can connect to the SIP proxy server through the FortiGate unit and communication between SIP phones on the private network and SIP phones on the Internet must pass through the FortiGate unit.

Figure 264: SIP network with FortiGate unit in NAT/Route mode



The phones and server use the same SIP dialog as they would if the FortiGate unit was not present. However, the FortiGate unit can be configured to control which devices on the network can connect to the SIP proxy server and can also protect the SIP proxy server from SIP vulnerabilities. In addition, the FortiGate unit has a firewall virtual IP that forwards packets sent to the SIP proxy server Internet IP address (172.20.120.50) to the SIP proxy server internal network IP address (10.31.101.30).

Since the FortiGate unit is operating in NAT/Route mode it must translate packet source and destination IP addresses (and optionally ports) as the sessions pass through the FortiGate unit. Also, the FortiGate unit must translate the addresses contained in the SIP headers and SDP body of the SIP messages. As well the FortiGate unit must open SIP and RTP pinholes through the FortiGate unit. SIP pinholes allow SIP signalling sessions to pass through the FortiGate between phones and between phones and SIP servers. RTP pinholes allow direct RTP communication between the SIP phones once the SIP dialog has established the SIP call. Pinholes are opened automatically by the FortiGate unit. Administrators do not add security policies for pinholes or for RTP sessions. All that is required is a security policy that accepts SIP traffic.

Opening an RTP pinhole means opening a port on a FortiGate interface to allow RTP traffic to use that port to pass through the FortiGate unit between the SIP phones on the Internet and SIP phones on the internal network. A pinhole only accepts packets from one RTP session. Since a SIP call involves at least two media streams (one from Phone A to Phone B and one from Phone B to Phone A) the FortiGate unit opens two RTP pinholes. Phone A sends RTP packets through a pinhole in port2 and Phone B sends RTP packets through a pinhole in port1. The FortiGate unit opens the pinholes when required by the SIP dialog and closes the pinholes when the SIP call is completed. The FortiGate unit opens new pinholes for each SIP call.

Each RTP pinhole actually includes two port numbers. The RTP port number as defined in the SIP message and an RTCP port number, which is the RTP port number plus 1. For example, if the SIP call used RTP port 3346 the FortiGate unit would create a pinhole for ports 3346 and 3347.

SIP messages and media protocols

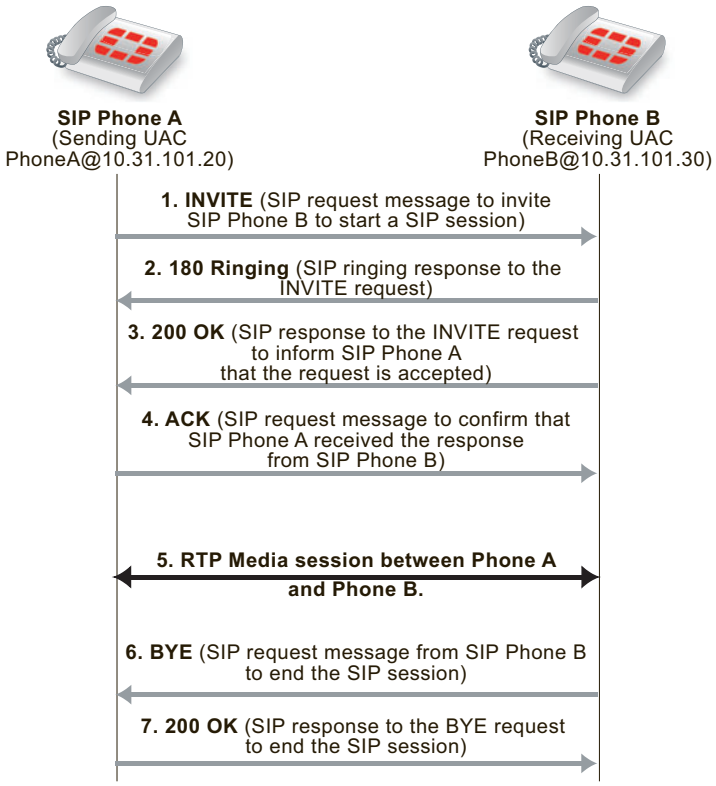
This section provides an overview of SIP messages and how they communicate information about SIP sessions and how SDP, RTP, and RTCP fits in with SIP communications.

SIP uses clear text messages to start, maintain, and end media sessions between SIP user agent clients (UACs) and user agent servers (UASs). These messages form a SIP dialog. A typical SIP dialog begins with an INVITE request message sent from a UAC to another UAC or to a UAS. The first INVITE request message attempts to start a SIP call and includes information about the sending UAC and the receiving UAC as well as information about the communication session.

If only two UACs are involved as shown in Figure 265, the receiving UAC (Phone B) responds with a 180 Ringing and then a 200 OK SIP response message that informs Phone A that Phone B received and accepted the request. Phone A then sends an ACK message to notify Phone B that the SIP response was received. Phone A and Phone B can then participate in the RTP media session set up by the SIP messages.

When the phone call is complete, one of the UACs (in the example Phone B) hangs up sending a BYE request message to Phone A. Phone A then sends a 200 OK response to Phone B acknowledging that the session has ended.

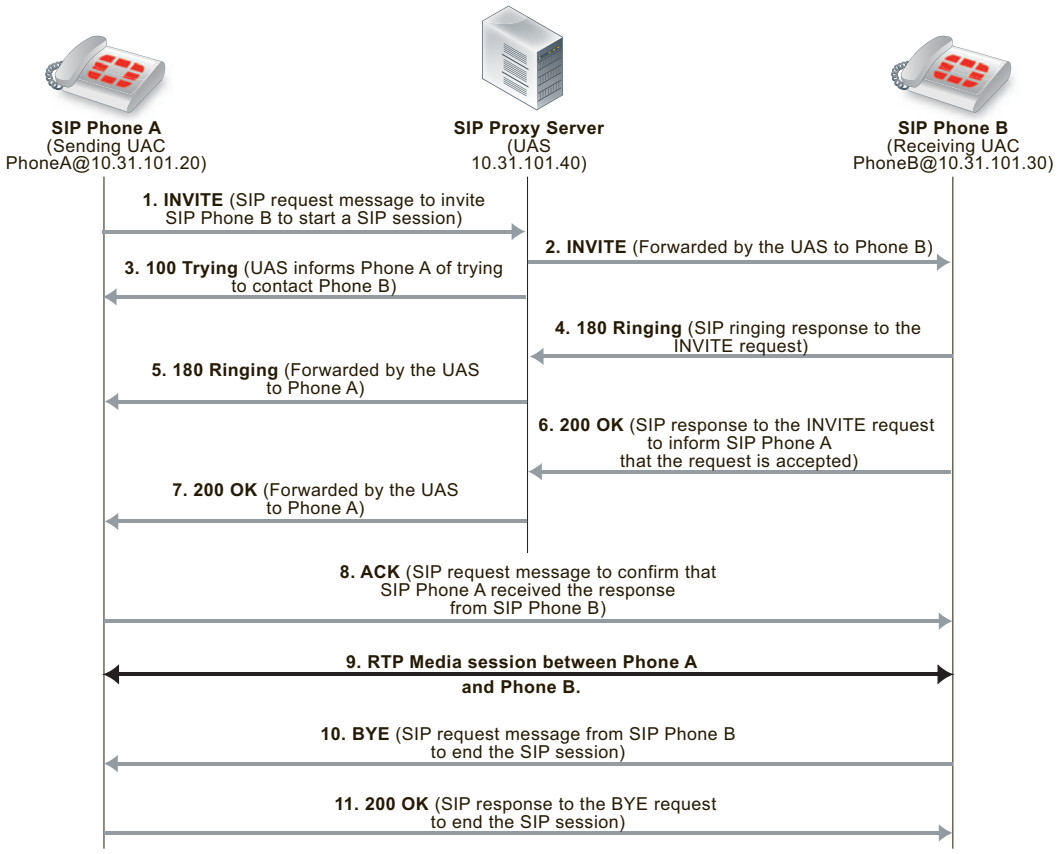
Figure 265: Basic SIP dialog between two UACs



If a UAS in the form of a SIP proxy server is involved, similar messages are sent and received, but the proxy server participates as an intermediary in the initial call setup. In the example in Figure 266 the SIP proxy server receives the INVITE request from Phone A and forwards it to Phone B. The proxy server then sends a 100 Trying response to Phone A. Phone B receives the INVITE request and responds with a 180 Ringing and then a 200 OK SIP response message. These messages are received by the proxy server and forwarded to Phone A to notify Phone A that Phone B received and accepted the request. Phone A then sends an ACK message to notify Phone B that the SIP response was received. This response is received by the proxy server and forwarded to Phone B. Phone A and Phone B can then participate in the media session independently of the proxy server.

When the phone call is complete Phone B hangs up sending a BYE request message to Phone A. Phone A then sends a 200 OK response to Phone B acknowledging that the session has ended.

Figure 266: Basic SIP dialog between UACs with a SIP proxy server UAS



The SIP messages include SIP headers that contain names and addresses of Phone A, Phone B and the proxy server. This addressing information is used by the UACs and the proxy server during the call set up.

The SIP message body includes Session Description Protocol (SDP) statements that Phone A and Phone B use to establish the media session. The SDP statements specify the type of media stream to use for the session (for example, audio for SIP phone calls) and the protocol to use for the media stream (usually the Real Time Protocol (RTP) media streaming protocol).

Phone A includes the media session settings that it would like to use for the session in the INVITE message. Phone B includes its response to these media settings in the 200 OK response. Phone A's ACK response confirms the settings that Phone A and Phone B then use for the media session.

Hardware accelerated RTP processing

FortiGate units can offload RTP packet processing to network processor (NP) interfaces. This acceleration greatly enhance the overall throughput and resulting in near speed RTP performance.

SIP request messages

SIP sessions always start with a SIP request message (also just called a SIP request). SIP request messages also establish, maintain, and terminate SIP communication sessions. Table 134 lists some common SIP request message types.

Table 134: Common SIP request message types

Message Type	Description
INVITE	A client sends an INVITE request to invite another client to participate in a multimedia session. The INVITE request body usually contains the description of the session.
ACK	The originator of an INVITE message sends an ACK request to confirm that the final response to an INVITE request was received. If the INVITE request did not contain the session description, it must be included in the ACK request.
PRACK	In some cases, SIP uses provisional response messages to report on the progress of the response to a SIP request message. The provisional response messages are sent before the final SIP response message. Similar to an ACK request message, a PRACK request message is sent to acknowledge that a provisional response message has been received.
OPTIONS	The UA uses OPTIONS messages to get information about the capabilities of a SIP proxy. The SIP proxy server replies with a description of the SIP methods, session description protocols, and message encoding that are supported.
BYE	A client sends a BYE request to end a session. A BYE request from either end of the SIP session terminates the session.
CANCEL	A client sends a CANCEL request to cancel a previous INVITE request. A CANCEL request has no effect if the SIP server processing the INVITE sends a final response to the INVITE before receiving the CANCEL.
REGISTER	A client sends a REGISTER request to a SIP registrar server with information about the current location (IP address and so on) of the client. A SIP registrar server saves the information it receives in REGISTER requests and makes this information available to any SIP client or server attempting to locate the client.
Info	For distributing mid-session signaling information along the signaling path for a SIP call. I
Subscribe	For requesting the current state and state updates of a remote node.
Notify	Informs clients and servers of changes in state in the SIP network.
Refer	Refers the recipient (identified by the Request-URI) to a third party according to the contact information in the request.
Update	Opens a pinhole for new or updated SDP information.
Response codes (1xx, 202, 2xx, 3xx, 4xx, 5xx, 6xx)	Indicates the status of a transaction. For example: 200 OK, 202 Accepted, or 400 Bad Request.

SIP response messages

SIP response messages (often just called SIP responses) provide status information in response to SIP request messages. All SIP response messages include a response code and a reason phrase. There are five SIP response message classes. They are described below.

There are also two types of SIP response messages, provisional and final. Final response messages convey the result of the request processing, and are sent reliably. Provisional responses provide information on the progress of the request processing, but may not be sent reliably. Provisional response messages start with 1xx and are also called informational response messages.

Informational (or provisional)

Informational or provisional responses indicate that a request message was received and imply that the endpoint is going to process the request. Information messages may not be sent reliably and may not require an acknowledgement.

If the SIP implementation uses Provisional Response Acknowledgement (PRACK) (RFC 3262) then informational or provisional messages are sent reliably and require a PRACK message to acknowledge that they have been received.

Informational responses can contain the following reason codes and reason phrases:

```
100 Trying
180 Ringing
181 Call is being forwarded
182 Queued
183 Session progress
```

Success

Success responses indicate that a request message was received, understood, and accepted. Success responses can contain the following reason codes and reason phrases:

```
200 OK
202 Accepted
```

Redirection

Redirection responses indicate that more information is required for the endpoint to respond to a request message. Redirection responses can contain the following reason codes and reason phrases:

```
300 Multiple choices
301 Moved permanently
302 Moved temporarily
305 Use proxy
380 Alternative service
```

Client error

Client error responses indicate that a request message was received by a server that contains syntax that the server cannot understand (i.e. contains a syntax error) or cannot comply with. Client error responses include the following reason codes and reason phrases:

```
400 Bad request              401 Unauthorized
402 Payment required         403 Forbidden
404 Not found                405 Method not allowed
```

```
406 Not acceptable           407 Proxy authentication required
408 Request time-out          409 Conflict
410 Gone                      411 Length required
413 Request entity too large 414 Request-URL too large
415 Unsupported media type    420 Bad extension
480 Temporarily not available
481 Call leg/transaction does not exist
482 Loop detected             483 Too many hops
484 Address incomplete        485 Ambiguous
486 Busy here                 487 Request canceled
488 Not acceptable here
```

Server error

Server error responses indicate that a server was unable to respond to a valid request message. Server error responses include the following reason codes and reason phrases:

```
500 Server internal error
501 Not implemented
502 Bad gateway
502 Service unavailable
504 Gateway time-out
505 SIP version not supported
```

Global failure

Global failure responses indicate that there are no servers available that can respond to a request message. Global failure responses include the following reason codes and reason phrases:

```
600 Busy everywhere
603 Decline
604 Does not exist anywhere
606 Not acceptable
```

SIP message start line

The first line in a SIP message is called the start line. The start line in a request message is called the request-line and the start line in a response message is called the status-line.

Request-line	The first line of a SIP request message. The request-line includes the SIP message type, the SIP protocol version, and a Request URI that indicates the user or service to which this request is being addressed. The following example request-line specifies the INVITE message type, the address of the sender of the message (`inviter@example.com`), and the SIP version: `INVITE sip:inviter@example.com SIP/2.0`
Status-line	The first line of a SIP response message. The status-line includes the SIP protocol version, the response code, and the reason phrase. The example status-line includes the SIP version, the response code (`200`) and the reason phrase (`OK`). `SIP/2.0 200 OK`

SIP headers

Following the start line, SIP messages contain SIP headers (also called SIP fields) that convey message attributes and to modify message meaning. SIP headers are similar to HTTP header fields and always have the following format:

```
<header_name>:<value>
```

SIP messages can include the SIP headers listed in Table 135:

Table 135: SIP headers

SIP Header	Description
Allow	Lists the set of SIP methods supported by the UA generating the message. All methods, including ACK and CANCEL, understood by the UA MUST be included in the list of methods in the Allow header field, when present. For example: `Allow: INVITE, ACK, OPTIONS, CANCEL, BYE`
Call-ID	A globally unique identifier for the call, generated by the combination of a random string and the sender's host name or IP address. The combination of the To, From, and Call-ID headers completely defines a peer-to-peer SIP relationship between the sender and the receiver. This relationship is called a SIP dialog. `Call-ID: ddeg45e793@10.31.101.30`
Contact	Included in SIP request messages, the Contact header contains the SIP URI of the sender of the SIP request message. The receiver uses this URI to contact the sender. For example: `Contact: Sender <sip:sender@10.31.100.20>t`
Content-Length	The number of bytes in the message body (in bytes). `Content-Length: 126`
Content-Type	In addition to SIP headers, SIP messages include a message body that contains information about the content or communication being managed by the SIP session. The Content-Type header specifies what the content of the SIP message is. For example, if you are using SIP with SDP, the content of the SIP message is SDP code. `Content-Type: application/sdp`
CSeq	The command sequence header contains a sequence integer that is increased for each new SIP request message (but is not incremented in the response message). This header also incudes the request name found in the request message request-line. For example: `CSeq: 1 INVITE`
Expires	Gives the relative time after which the message (or content) expires. The actual time and how the header is used depends on the SIP method. For example: `Expires: 5`
From	Identifies the sender of the message. Responses to a message are sent to the address of the sender. The following example includes the sender's name (`Sender`) and the sender's SIP address (`sender@10.31.101.20`.): `From: Sender <sip:sender@10.31.101.20>`

Table 135: SIP headers (Continued)

SIP Header	Description
Max-forwards	An integer in the range 0-255 that limits the number of proxies or gateways that can forward the request message to the next downstream server. Also called the number of hops, this value is decreased every time the message is forwarded. This can also be useful when the client is attempting to trace a request chain that appears to be failing or looping in mid-chain. For example: `Max-Forwards: 30`
P-Asserted-Identity	The P-Asserted-Identity header is used among trusted SIP entities to carry the identity of the user sending a SIP message as it was verified by authentication. See RFC 3325. The header contains a SIP URI and an optional display-name, for example: `P-Asserted-Identity: "Example Person" <sip:10.31.101.50>`
RAck	Sent in a PRACK request to support reliability of information or provisional response messages. It contains two numbers and a method tag. For example: `RAck: 776656 1 INVITE`
Record-Route	Inserted into request messages by a SIP proxy to force future requests to be routed through the proxy. In the following example, the host at IP address 10.31.101.50 is a SIP proxy. The `lr` parameter indicates the URI of a SIP proxy in Record-Route headers. `Record-Route: <sip:10.31.101.50;lr>`
Route	Forces routing for a request message through one or more SIP proxies. The following example includes two SIP proxies: `Route: <sip:172.20.120.10;lr>, <sip:10.31.101.50;lr>`
RSeq	The RSeq header is used in information or provisional response messages to support reliability of informational response messages. The header contains a single numeric value. For example: `RSeq: 33456`
To	Identifies the receiver of the message. The address in this field is used to send the message to the receiver. The following example includes the receiver's name (`Receiver`) and the receiver's SIP address (`receiver@10.31.101.30`.): `To: Receiver <sip:receiver@10.31.101.30>`
Via	Indicates the SIP version and protocol to be used for the SIP session and the address to which to send the response to the message that contains the Via field. The following example Via field indicates to use SIP version 2, UDP for media communications, and to send the response to 10.31.101.20 using port 5060. `Via: SIP/2.0/UDP 10.31.101.20:5060`

The SIP message body and SDP session profiles

The SIP message body describes the session to be initiated. For example, in a SIP phone call the body usually includes audio codec types, sampling rates, server IP addresses and so on. For other types of SIP session the body could contain text or binary data of any type which relates in some way to the session. The message body is included in request and response messages.

Two possible SIP message body types:

- Session Description Protocol (SDP), most commonly used for SIP VoIP.
- Multipurpose Internet Mail Extensions (MIME)

SDP is most often used for VoIP and FortiGate units support SDP content in SIP message bodies. SDP is a text-based protocol used by SIP to control media sessions. SDP does not deliver media but provides a session profile that contains media details, transport addresses, parameter negotiation, and other session description metadata for the participants in a media session. The participants use the information in the session profile to negotiate how to communicate and to manage the media session. SDP is described by RFC 4566.

An SDP session profile always contains session information and may contain media information. Session information appears at the start of the session profile and media information (using the `m=` attribute) follows.

SDP session profiles can include the attributes listed in Table 136.

Table 136: SDP session profile attributes

Attribute	Description
a=	Attributes to extend SDP in the form `a=<attribute>` or `a=<attribute>:<value>`.
b=	Contains information about the bandwidth required for the session or media in the form `b=<bandwidth_type>:<bandwidth>`.
c=	Connection data about the session including the network type (usually IN for Internet), address type (IPv4 or IPv6), the connection source address, and other optional information. For example: `c=IN IPv4 10.31.101.20`
i=	A text string that contains information about the session. For example: `i=A audio presentation about SIP`
k=	Can be used to convey encryption keys over a secure and trusted channel. For example: `k=clear:444gdduudjffdee`

Table 136: SDP session profile attributes (Continued)

Attribute	Description

m=	Media information, consisting of one or more lines all starting with `m=` and containing details about the media including the media type, the destination port or ports used by the media, the protocol used by the media, and a media format description.
	`m=audio 49170 RTP 0 3`
	`m-video 3345/2 udp 34`
	`m-video 2910/2 RTP/AVP 3 56`
	Multiple media lines are needed if SIP is managing multiple types of media in one session (for example, separate audio and video streams).
	Multiple ports for a media stream are indicated using a slash. `3345/2` udp means UDP ports 3345 and 3346. Usually RTP uses even-numbered ports for data with the corresponding one-higher odd ports used for the RTCP session belonging to the RTP session. So `2910/2 RTP/AVP` means ports 2910 and 2912 are used for RTP and 2911 and 2913 are used for RTCP.
	Media types include `udp` for an unspecified protocol that uses UDP, `RTP` or `RTP/AVP` for standard RTP and `RTP/SAVP` for secure RTP.

o=	The sender's username, a session identifier, a session version number, the network type (usually IN for Internet), the address type (for example, IPv4 or IPv6), and the sending device's IP address. The `o=` field becomes a universal identifier for this version of this session description. For example: `o=PhoneA 5462346 332134 IN IP4 10.31.101.20`

r=	Repeat times for a session. Used if a session will be repeated at one or more timed intervals. Not normally used for VoIP calls. The times can be in different formats. For example.
	`r=7d 1h 0 25h`
	`r=604800 3600 0 90000`

s=	Any text that describes the session or s= followed by a space. For example: `s=Call from inviter`
t=	The start and stop time of the session. Sessions with no time restrictions (most VoIP calls) have a start and stop time of 0. `t=0 0`
v=	SDP protocol version. The current SDP version is 0 so the v= field is always: `v=0`
z=	Time zone adjustments. Used for scheduling repeated sessions that span the time between changing from standard to daylight savings time. `z=2882844526 -1h 2898848070 0`

Example SIP messages

The following example SIP INVITE request message was sent by PhoneA to PhoneB. The first nine lines are the SIP headers. The SDP profile starts with v=0 and the media part of the session profile is the last line, starting with m=.

```
INVITE sip:PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 10.31.101.50:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
```

```
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneA@10.31.101.20
Content-Type: application/sdp
Content-Length: 124
v=0
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
s=Let's Talk
t=0 0
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
```

The following example shows a possible 200 OK SIP response message in response to the previous INVITE request message. The response includes `200 OK` which indicates success, followed by an echo of the original SIP INVITE request followed by PhoneB's SDP profile.

```
SIP/2.0 200 OK
Via: SIP/2.0/UDP 10.31.101.50:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneB@10.31.101.30
Content-Type: application/sdp
Content-Length: 107
v=0
o=PhoneB 124333 67895 IN IP4 172.20.120.30
s=Hello!
t=0 0
c=IN IP4 172.20.120.30
m=audio 3456 RTP 0
```

SIP can support multiple media streams for a single SIP session. Each media steam will have its own c= and m= lines in the body of the message. For example, the following message includes three media streams:

```
INVITE sip:PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 10.31.101.20:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneA@10.31.101.20
Content-Type: application/sdp
Content-Length: 124
v=0
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
s=Let's Talk
t=0 0
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
c=IN IP4 10.31.101.20
m=audio 49172 RTP 0 3
c=IN IP4 10.31.101.20
m=audio 49174 RTP 0 3
```

The SIP session helper

The SIP session-helper is a high-performance solution that provides basic support for SIP calls passing through the FortiGate unit by opening SIP and RTP pinholes and by performing NAT of the addresses in SIP messages.

The SIP session helper:

- Understands SIP dialog messages.
- Keeps the states of the SIP transactions between SIP UAs and SIP servers.
- Translates SIP header and SDP information to account for NAT operations performed by the FortiGate unit.
- Opens up and closes dynamic SIP pinholes for SIP signalling traffic.
- Opens up and closes dynamic RTP and RTSP pinholes for RTP and RTSP media traffic.
- Provides basic SIP security as an access control device.
- Uses the intrusion protection (IPS) engine to perform basic SIP protocol checks.

SIP session helper configuration overview

The SIP session helper is enabled by default and set to listen for SIP traffic on TCP or UDP port 5060. SIP sessions using port 5060 accepted by a security policy that does not include a VoIP profile are processed by the SIP session helper.

You can enable and disable the SIP session helper, change the TCP or UDP port that the session helper listens on for SIP traffic, and enable or disable SIP NAT tracing. If the FortiGate unit is operating with multiple VDOMs, each VDOM can have a different SIP session helper configuration.

To have the SIP session helper process SIP sessions you need to add a security policy that accepts SIP sessions on the configured SIP UDP or TCP ports. The security policies can have service set to ANY, or to the SIP pre-defined firewall service, or a custom firewall service. The SIP pre-defined firewall service restricts the security policy to only accepting sessions on UDP port 5060.

If NAT is enabled for security policies that accept SIP traffic, the SIP session helper translates addresses in SIP headers and in the RDP profile and opens up pinholes as required for the SIP traffic. This includes security policies that perform source NAT and security policies that contain virtual IPs that perform destination NAT and port forwarding. No special SIP configuration is required for this address translation to occur, it is all handled automatically by the SIP session helper according to the NAT configuration of the security policy that accepts the SIP session.

To use the SIP session helper you must not add a VoIP profile to the security policy. If you add a VoIP profile, SIP traffic bypasses the SIP session helper and is processed by the SIP ALG.

In most cases you would want to use the SIP ALG since the SIP session helper provides limited functionality. However, the SIP session helper is available and can be useful for high-performance solutions where a high level of SIP security is not a requirement.

Disabling and enable the SIP session helper

You can use the following steps to disable the SIP session helper. You might want to disable the SIP session helper if you don't want the FortiGate unit to apply NAT or other SIP session help features to SIP traffic. With the SIP session helper disabled, the FortiGate unit can still accept SIP sessions if they are allowed by a security policy, but the FortiGate unit will not be able to open pinholes or NAT the addresses in the SIP messages.

To disable the sip session helper

1 Enter the following command to find the sip session helper entry in the session-helper list:

```
show system session-helper
  .
  .
  .
edit 13
  set name sip
  set port 5060
  set protocol 17
next
  .
  .
  .
```

This command output shows that the sip session helper listens in UDP port 5060 for SIP sessions.

2 Enter the following command to delete session-helper list entry number 13 to disable the sip session helper:

```
config system session-helper
  delete 13
end
```

If you want to use the SIP session helper you can verify whether it is enabled or disabled using the `show system session-helper` command.

You do not have to disable the SIP session helper to use the SIP ALG.

If the SIP session helper has been disable by being removed from the session-helper list you can use the following command to enable the SIP session helper by adding it back to the session helper list:

```
config system session-helper
  edit 0
    set name sip
    set port 5060
    set protocol 17
end
```

Changing the port numbers that the SIP session helper listens on

You can use the following command to change the port number that the SIP session helper listens on for SIP traffic to 5061. The SIP session helper listens on the same port number for UDP and TCP SIP sessions. In this example, the SIP session helper is session helper 13:

```
config system session-helper
  edit 13
    set port 5061
  end
```

The `config system settings` options `sip-tcp-port` and `sip-udp-port` control the ports that the SIP ALG listens on for SIP sessions. See "Changing the port numbers that the SIP ALG listens on" on page 2545.

Your FortiGate unit may use a different session helper number for SIP. Enter the following command to view the session helpers:

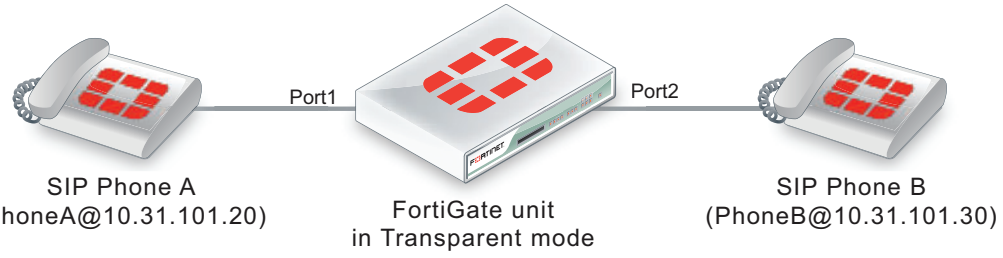
```
show system session-helper
  .
  .
  .
  edit 13
    set name sip
    set port 5060
    set protocol 17
  end
  .
  .
  .
```

Configuration example: SIP session helper in Transparent Mode

Figure 267 shows an example SIP network consisting of a FortiGate unit operating in Transparent mode between two SIP phones. Since the FortiGate unit is operating in Transparent mode both phones are on the same network and the FortiGate unit and the SIP session helper does not perform NAT. Even though the SIP session helper is not performing NAT you can use this configuration to apply SIP session helper security features to the SIP traffic.

The FortiGate unit requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A.

Figure 267: SIP network with FortiGate unit in Transparent mode



General configuration steps

The following general configuration steps are required for this SIP configuration. This example includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the firewall service to ANY to allow traffic other than SIP on UDP port 5060.

1 Add firewall addresses for Phone A and Phone B.

2 Add a security policy that accepts SIP sessions initiated by Phone A.

3 Add a security policy that accepts SIP sessions initiated by Phone B.

Configuration steps - web-based manager

To add firewall addresses for the SIP phones

1 Go to *Firewall Objects* > *Address*.

2 Add the following addresses for Phone A and Phone B:

Address Name	Phone_A
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	port1

Address Name	Phone_B
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.30/255.255.255.255
Interface	port2

To add security policies to accept SIP sessions

1 Go to *Policy* > *Policy* > *Policy*.

2 Select Create New to add a security policy.

3 Add a security policy to allow Phone A to send SIP request messages to Phone B:

Source Interface/Zone	port1
Source Address	Phone_A
Destination Interface/Zone	port2
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT

4 Select *OK*.

5 Add a security policy to allow Phone B to send SIP request messages to Phone A:

Source Interface/Zone	port2
Source Address	Phone_B

Destination Interface/Zone	port1
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT

6 Select *OK*.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to accept SIP sessions

1 Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
  edit Phone_A
    set associated interface port1
    set type ipmask
    set subnet 10.31.101.20 255.255.255.255
  next
  edit Phone_B
    set associated interface port2
    set type ipmask
    set subnet 10.31.101.30 255.255.255.255
  end
```

2 Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Phone_A
    set dstaddr Phone_B
    set action accept
    set schedule always
    set service SIP
  next
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr Phone_B
    set dstaddr Phone_A
    set action accept
    set schedule always
    set service SIP
    set utm-status enable
  end
```

SIP session helper diagnose commands

You can use the `diagnose sys sip` commands to display diagnostic information for the SIP session helper.

Use the following command to set the debug level for the SIP session helper. Different debug masks display different levels of detail about SIP session helper activity.

```
diagnose sys sip debug-mask <debug_mask_int>
```

Use the following command to display the current list of SIP dialogs being processed by the SIP session help. You can also use the `clear` option to delete all active SIP dialogs being processed by the SIP session helper.

```
diagnose sys sip dialog {clear | list}
```

Use the following command to display the current list of SIP NAT address mapping tables being used by the SIP session helper.

```
diagnose sys sip mapping list
```

Use the following command to display the current SIP session helper activity including information about the SIP dialogs, mappings, and other SIP session help counts. This command can be useful to get an overview of what the SIP session helper is currently doing.

```
diagnose sys sip status
```

The SIP ALG

In most cases you should use the SIP Application Layer Gateway (ALG) for processing SIP sessions. The SIP ALG provides the same basic SIP support as the SIP session helper. Additionally, the SIP ALG provides a wide range of features that protect your network from SIP attacks, can apply rate limiting to SIP sessions, can check the syntax of SIP and SDP content of SIP messages, and provide detailed logging and reporting of SIP activity.

You apply the SIP ALG to SIP traffic by adding a VoIP profile with SIP enabled to a security policy that accepts SIP traffic. The SIP session helper is automatically bypassed by traffic accepted by a security policy that includes a VoIP profile.

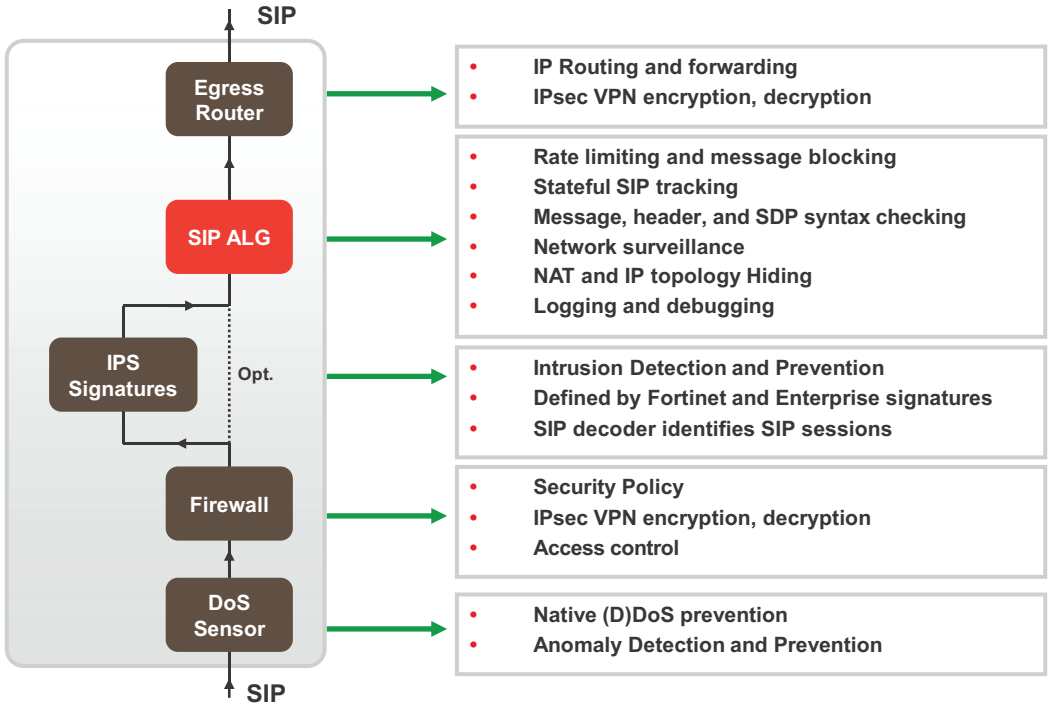
As shown in Figure 268, the FortiGate SIP ALG intercepts SIP packets after they have been routed by the routing module, accepted by a security policy and passed through DoS and IPS Sensors (if DoS and IPS are enabled). The ALG raises SIP packets to the application layer, analyzes the SIP and SDP addressing information in the SIP messages, makes adjustments (for example, NAT) to this addressing if required, and then sends the packets out the egress interface to their destination.

The SIP ALG provides:

- All the same features as the SIP session help including NAT and SIP and RTP Pinholes.

  In addition for the ALG you can enable or disable RTP pinholing, SIP register pinholing and SIP contact pinholing. In a signalling only environment where the RTP stream bypasses the FortiGate unit, you can disable RTP pinholing to improve performance.
- SIP TCP and UDP support
- SIP Message order checking
- Configurable Header line length maximums

Figure 268: The SIP ALG works at the application level after ingress packets are accepted by a security policy



- Message fragment assembly (TCP)

  If SIP messages are fragmented across multiple packets, the FortiGate unit assembles the fragments, does inspection and pass the message in its entirety to the SIP server as one packet. This offloads the server from doing all the TCP processing of fragments.
- L4 Protocol Translation
- Message Flood Protection

  Protects a SIP server from intentional or unintentional DoS of flooding INVITE, REGISTER, and other SIP methods by allowing control of the rate that these massages pass through the FortiGate unit.
- SIP message type filtering

  The FortiGate unit can prevent specified SIP message types from passing through the FortiGate unit to a SIP server. For example In a voice only SIP implementation, there may be no need to permit a SUBSCRIBE message to ever make it's way to the SIP call processor. Also, if a SIP server cannot process some SIP message types you can use SIP message type filtering to block them. For example, a SIP server could have a bug that prevents it from processing certain SIP messages. In this case you can temporarily block these message types until problem with the SIP server has been fixed.
- SIP statistics and logging
- SIP over IPv6
- Deep SIP message syntax checking (also called deep SIP header inspection or SIP fuzzing protection). Prevents attacks that use malformed SIP messages. Can check many SIP headers and SDP statements. Configurable bypass and modification options.

- Hosted NAT traversal, Resolves IP address issue in SIP and SDP lines due to NAT-PT in far end firewall. Important feature for VoIP access networks.
- SIP High Availability (HA), including active-passive clustering and session pickup (session failover) for SIP sessions.
- Geographical Redundancy. In an HA configuration, if the active SIP server fails (missing SIP heartbeat messages or SIP traffic) SIP sessions can be redirected to a secondary SIP server in another location.
- SIP per request method message rate limitation with configurable threshold for SIP message rates per request method. Protects SIP servers from SIP overload and DoS attacks.
- RTP Bypass, Supports configurations with and without RTP pinholing. May inspect and protect SIP signaling only.
- SIP NAT with IP address conservation. Performs SIP and RTP aware IP Network Address translation. Preserves the lost IP address information in the SDP profile i= line for later processing/debugging in the SIP server. See "NAT with IP address conservation" on page 2573.
- IP topology hiding

  The IP topology of a network can be hidden through NAT and NAPT manipulation of IP and SIP level addressing. For example, see "SIP NAT configuration example: destination address translation (destination NAT)" on page 2567.
- SIP inspection without address translation

  The SIP ALG inspects SIP messages but addresses in the messages are not translated. This feature can be applied to a FortiGate unit operating in Transparent mode or in NAT/Route mode. In Transparent mode you add normal Transparent mode security policies that enable the SIP ALG and include a VoIP profile that causes the SIP ALG to inspect SIP traffic as required. For an example configuration, see "Configuration example: SIP in Transparent Mode" on page 2550.

  For a FortiGate unit operating in NAT/Route mode, if SIP traffic can pass between different networks without requiring NAT because is supported by the routing configuration, you can add security policies that accept SIP traffic without enabling NAT. In the VoIP profile you can configure the SIP ALG to inspect SIP traffic as required.

SIP ALG configuration overview

To apply the SIP ALG, you add a SIP VoIP profile to a security policy that accepts SIP sessions. All SIP sessions accepted by the security policy will be processed by the SIP ALG using the settings in the VoIP profile. The VoIP profile contains settings that are applied to SIP, Session Initiation Protocol for Instant Messaging and Presence Leveraging Extensions (SIMPLE) and Skinny Call Control Protocol (SCCP) sessions. You configure SIP and SCCP settings separately. SIP settings also apply to SIMPLE sessions.

Enabling VoIP support on the web-based manager

Before you begin adding VoIP profiles to security policies you may have to enable VoIP support on the web-based manager. To do this, on the web-based manager go to *System* > *Admin* > *Settings* and make sure that the VoIP Support on GUI checkbox is selected.

From the CLI you can also enter the following command enable VoIP support on the GUI:

```
config system global
  set gui-voip-profile enable
```

```
end
```

VoIP profiles

To add a new VoIP profile from the web-based manager go to *UTM Profiles* > *VoIP* > *Profile* and select *Create New*.

For SIP, from the web-based manager you can configure the VoIP profile to limit the number of SIP REGISTER and INVITE requests and enable logging of SIP sessions and SIP violations. Many additional options for configuring how the ALG processes SIP sessions are available from the CLI.

Use the following command to add a VoIP profile named VoIP_Pro_1 from the CLI:

```
config voip profile
  edit VoIP_Pro_1
end
```

FortiGate units include two pre-defined VoIP profiles. On the web-based manager these profiles look identical. However, the CLI-only settings result in the following functionality.

default	The most commonly used VoIP profile. This profile enables both SIP and SCCP and places the minimum restrictions on what calls will be allowed to negotiate. This profile allows normal SCCP, SIP and RTP sessions and enables the following security settings: • `block-long-lines` to block SIP messages with lines that exceed maximum line lengths. • `block-unknown` to block unrecognized SIP request messages. • `log-call-summary` to write log messages that record SIP call progress (similar to DLP archiving). • `nat-trace` (see "NAT with IP address conservation" on page 2573). • `contact-fixup` perform NAT on the IP addresses and port numbers in SIP headers in SIP CONTACT messages even if they don't match the session's IP address and port numbers.
strict	This profile is available for users who want to validate SIP messages and to only allow SIP sessions that are compliant with RFC 3261. In addition to the settings in the default VoIP profile, the strict profile sets all SIP deep message inspection header checking to block and drop SIP messages that contain malformed SIP or SDP lines that can be detected by the ALG. For more information about SIP deep header inspection, see "Deep SIP message inspection" on page 2586.

Neither of the default profiles applies SIP rate limiting or message blocking. To apply more ALG features to SIP sessions you can clone (copy) the pre-defined VoIP profiles and make your own modifications to them. For example, to clone the default profile and configure the limit for SIP NOTIFY request messages to 1000 messages per second per security policy and block SIP INFO request messages.

```
config voip profile
  clone default to my_voip_pro
  edit my_voip_pro
    config sip
      set notify-rate 1000
      set block-info enable
    end
end
```

Changing the port numbers that the SIP ALG listens on

Most SIP configurations use TCP or UDP port 5060 for SIP sessions. If your SIP network uses different ports for SIP sessions you can use the following command to configure the SIP ALG to listen on a different TCP or UDP ports. For example, to change the TCP port to 5061 and the UDP port to 5065.

```
config system settings
  set sip-tcp-port 5061
  set sip-udp-port 5065
end
```

Disabling the SIP ALG in a VoIP profile

SIP is enabled by default in a VoIP profile. Usually you would want SIP to be enabled in a VoIP profile. But in some cases if you are just using the VoIP profile for SCCP you can use the following command to disable SIP in a VoIP profile.

```
config voip profile
  edit VoIP_Pro_2
    config sip
      set status disable
    end
end
```

SIP ALG get and diagnose commands

You can use the following commands to display diagnostic information for the SIP ALG.

Use the following commands to enter a test level to display information about the SIP ALG.

```
get test sip <test_level_int>
diagnose test application sip <test_level_int>
```

Use the following command to list all active SIP calls being processed by the SIP ALG. You can also use the `clear` option to delete all active SIP calls being processed by the SIP ALG.

```
diagnose sys sip-proxy calls {clear | list}
```

Use the following commands to use filters to display specific information about the SIP ALG and the session that it is processing.

```
diagnose sys sip-proxy filter <filter_options>
diagnose sys sip-proxy log-filter <filter_options>
```

Use the following command to display the active SIP rate limiting meters and their current settings.

```
diagnose sys sip-proxy meters list
```

Use the following command to display status information about the SIP sessions being processed by the SIP ALG. You can also clear all SIP ALG statistics.

```
diagnose sys sip-proxy stats {clear | list}
```

Conflicts between the SIP ALG and the session helper

Even if the SIP session helper is enabled, if a security policy with a VoIP profile that has SIP enabled accepts a SIP session on the TCP or UDP port that the SIP ALG listens on the ALG is used. You don’t need to turn off the session helper to use the ALG.

You may find that the session helper is being used for some SIP sessions even when you only want to use the ALG. This happens if a policy that does not include a VoIP profile is accepting SIP sessions. The VoIP profile could have been left out of the policy by mistake or the wrong policy could be accepting SIP sessions.

Consider a configuration with a SIP server on a private network that is contacted by SIP phones on the Internet and on the private network (similar to the configuration in Figure 264 on page 2524). The FortiGate unit that provides NAT between the private network and the Internet requires a security policy with a firewall virtual IP that allows the SIP phones on the Internet to contact the SIP server. The FortiGate unit also requires outgoing security policies to allow the SIP phones and the SIP server to contact the SIP phones on the Internet.

If a VoIP profile is not added to one of the outgoing security policies the SIP sessions accepted by that policy will be processed by the SIP session helper instead of the SIP ALG. Also, its possible that some of the SIP sessions could be accepted by a general outgoing policy instead of the policy intended for SIP traffic. You can fix the first problem by adding a VoIP profile to the policy. You can fix the second problem by reviewing the security policy order and source and destination addresses in the security policies and determining if there is a conflict between these and the IP addresses of the SIP server or SIP phones on the Internal network.

You can use `diagnose sys sip` commands to determine if the SIP session helper is processing SIP sessions. For example, the following command displays the overall status of the SIP sessions being processed by the SIP session helper:

The `diagnose sys sip` commands only display current status information. To see activity the SIP session helper has to actually be processing SIP sessions when you enter the command. For example, if the SIP session helper had been used for processing calls that ended 5 minutes ago, the command output would show no SIP session helper activity.

```
diagnose sys sip status
dialogs: max=32768, used=0
mappings: used=0
dialog hash by ID: size=2048, used=0, depth=0
dialog hash by RTP: size=2048, used=0, depth=0
mapping hash: size=2048, used=0, depth=0
count0: 0
count1: 0
count2: 0
count3: 0
count4: 0
```

This command output shows that the session helper is not processing SIP sessions because all of the used and count fields are 0. If any of these fields contains non-zero values then the SIP session helper may be processing SIP sessions.

Also, you can check to see if some ALG-only features are not being applied to all SIP sessions. For example, the VoIP usage widget on the FortiGate dashboard displays statistics for SIP and SCCP calls processed by the ALG but not for calls processed by the session helper. So if you see fewer calls than expected the session helper may be processing some of them.

Other logging and monitoring features such as log messages and DLP archiving are only supported by the ALG.

Finally, you can check the policy usage and session information dashboard widgets to see if SIP sessions are being accepted by the wrong security policies.

Stateful SIP tracking, call termination, and session inactivity timeout

The SIP ALG tracks SIP dialogs over their lifespan between the first INVITE message and the Final 200 OK and ACK messages. For every SIP dialog, stateful SIP tracking reviews every SIP message and makes adjustment to SIP tracking tables as required. These adjustments include source and destination IP addresses, address translation, dialog expiration information, and media stream port changes. Such changes can also result in dynamically opening and closing pinholes. You can use the `diagnose sys sip-proxy stats list` and the `diagnose sys sip-proxy filter` command to view the SIP call data being tracked by the SIP ALG.

The SIP ALG uses the SIP Expires header line to time out a SIP dialog if the dialog is idle and a Re-INVITE or UPDATE message is not received. The SIP ALG gets the Session-Expires value, if present, from the 200 OK response to the INVITE message. If the SIP ALG receives an INVITE before the session times out, all timeout values are reset to the settings in the new INVITE message or to default values. As a precautionary measure, the SIP ALG uses hard timeout values to set the maximum amount of time a call can exist. This ensures that the FortiGate unit is protected if a call ends prematurely.

When a SIP dialog ends normally, the SIP ALG deletes the SIP call information and closes open pinholes. A SIP call can also end abnormally due to an unexpected signaling or transport event that cuts off the call. When a call ends abnormally the SIP messages to end the call may not be sent or received. A call can end abnormally for the following reasons:

- Phones or servers crash during a call and a BYE message is not received.
- To attack a SIP system, a malicious user never send a BYE message.
- Poor implementations of SIP fail to process Record-Route messages and never send a BYE message.
- Network failures prevent a BYE message from being received.

Any phone or server in a SIP call can cancel the call by sending a CANCEL message. When a CANCEL message is received by the FortiGate unit, the SIP ALG closes open pinholes. Before terminating the call, the ALG waits for the final 200 OK message.

The SIP ALG can be configured to terminate SIP calls if the SIP dialog message flow or the call RTP (media) stream is interrupted and does not recover. You can use the following commands to configure terminating inactive SIP sessions and to set timers or counters to control when the call is terminated by the SIP ALG.

Adding a media stream timeout for SIP calls

Use the following command in a VoIP profile to terminate SIP calls accepted by a security policy containing the VoIP profile when the RTP media stream is idle for 100 seconds.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set call-keepalive 100
    end
end
```

You can adjust this setting between 1 and 10,080 seconds. The default call keepalive setting of 0 disables terminating a call if the media stream is interrupted. Set call keepalive higher if your network has latency problems that could temporarily interrupt media streams. If you have configured call keepalive and the FortiGate unit terminates calls unexpectedly you can increase the call keepalive time to resolve the problem.

Call keep alive should be used with caution because enabling this feature results in extra FortiGate CPU overhead and can cause delay/jitter for the VoIP call. Also, the FortiGate unit terminates the call without sending SIP messages to end the call. And if the SIP endpoints send SIP messages to terminate the call they will be blocked by the FortiGate unit if they are sent after the FortiGate unit terminates the call.

Adding an idle dialog setting for SIP calls

Use the following command in a VoIP profile to terminate SIP calls when for a single security policy, when the configured number of SIP calls (or dialogs) has stopped receiving SIP messages or has not received legitimate SIP messages. Using this command you can configure how many dialogs that have been accepted by a security policy that the VoIP profile is added to become idle before the SIP ALG deletes the oldest ones. The following command sets the maximum number of idle dialogs to 200:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-idle-dialogs 200
    end
end
```

Idle dialogs would usually be dialogs that have been interrupted because of errors or problems or as the result of a SIP attack that opens a large number of SIP dialogs without closing them. This command provides a way to remove these dialogs from the dialog table and recover memory and resources being used by these open and idle dialogs.

You can adjust this setting between 1 and a very high number. The default maximum idle dialogs setting of 0 disables this feature. Set maximum dialogs higher if your network has latency problems that could temporarily interrupt SIP messaging. If you have configured max idle dialogs and the FortiGate unit terminates calls unexpectedly you can increase the max idle dialogs number to resolve the problem.

Changing how long to wait for call setup to complete

In some cases and some configurations your SIP system may experience delays during call setup. If this happens, some SIP ALG timers may expire before call setup is complete and drop the call. In some cases you may also want to reduce the amount of time the SIP ALG allows for call setup to complete.

You can use the `provisional-invite-expiry-time` SIP VoIP profile option to control how long the SIP ALG waits for provisional INVITE messages before assuming that the call setup has been interrupted and the SIP call should be dropped. The default value for this timer is 210 seconds. You can change it to between 10 and 3600 seconds.

Use the following command to change the expiry time to 100 seconds.

```
config voip profile
  edit Profile_name
    config sip
      set provisional-invite-expiry-time 100
    end
end
```

SIP and RTP/RTCP

FortiGate units support the Real Time Protocol (RTP) application layer protocol for the VoIP call audio stream. RTP uses dynamically assigned port numbers that can change during a call. SIP control messages that start a call and that are sent during the call inform callers of the port number to use and of port number changes during the call.

During a call, each RTP session will usually have a corresponding Real Time Control Protocol (RTCP) session. By default, the RTCP session port number is one higher than the RTP port number.

The RTP port number is included in the `m=` part of the SDP profile. In the example above, the SIP INVITE message includes RTP port number is 49170 so the RTCP port number would be 49171. In the SIP response message the RTP port number is 3456 so the RTCP port number would be 3457.

How the SIP ALG creates RTP pinholes

The SIP ALG requires the following information to create a pinhole. The SIP ALG finds this information in SIP messages and some is provided by the SIP ALG:

Protocol	UDP (Extracted from SIP messages by the SIP ALG.)
Source IP	Any
Source port	Any
Destination IP	The SIP ALG extracts the destination IP address from the c= line in the SDP profile. The c= line can appear in either the session or media part of the SDP profile. The SIP ALG uses the IP address in the c= line of the media part of the SDP profile first. If the media part does not contain a c= line, the SIP ALG checks the c= line in the session part of the SDP profile. If the session part of the profile doesn't contain a c= line the packet is dropped. Pinholes for RTP and RTCP sessions share the same destination IP address.
Destination port	The SIP ALG extracts the destination port number for RTP from the m= field and adds 1 to this number to get the RTCP port number.
Lifetime	The length of time during which the pinhole will be open. When the lifetime ends, the SIP ALG removes the pinhole.

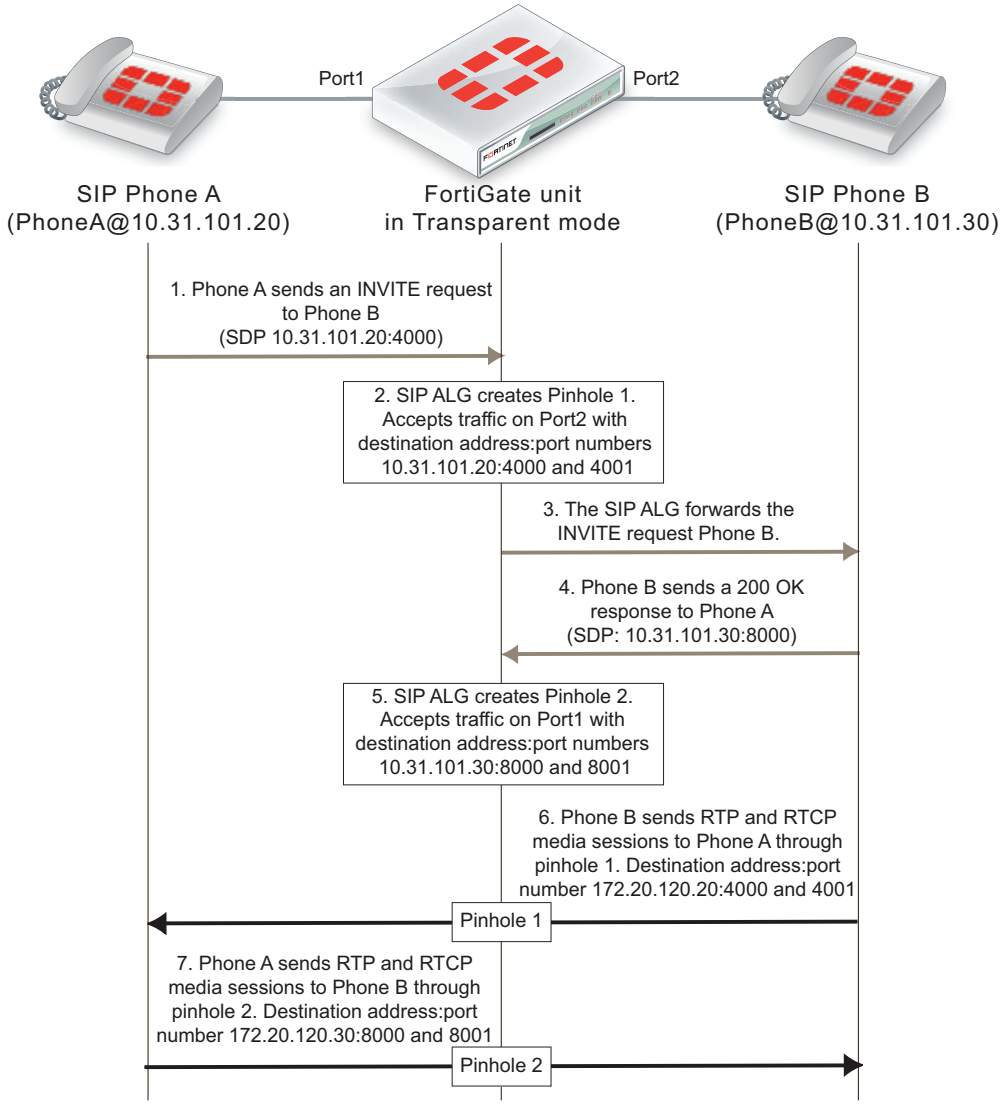
The SIP ALG keeps RTP pinholes open as long as the SIP session is alive. When the associated SIP session is terminated by the SIP ALG or the SIP phones or servers participating in the call, the RTP pinhole is closed.

Figure 269 shows a simplified call setup sequence that shows how the SIP ALG opens pinholes. Phone A and Phone B are installed on either side of a FortiGate unit operating in Transparent mode. Phone A and Phone B are on the same subnet. The FortiGate unit includes a security policy that accepts SIP sessions from port1 to port2 and from port2 to port1. The FortiGate unit does not require an RTP security policy, just the SIP policy.

You can see from this diagram that the SDP profile in the INVITE request from Phone A indicates that Phone A is expecting to receive a media stream sent to its IP address using port 4000 for RTP and port 4001 for RTCP. The SIP ALG creates pinhole 1 to allow this media traffic to pass through the FortiGate unit. Pinhole 1 is opened on the Port2 interface and will accept media traffic sent from Phone B to Phone A.

When Phone B receives the INVITE request from Phone A, Phone B will know to send media streams to Phone A using destination IP address 10.31.101.20 and ports 4000 and 4001. The 200 OK response sent from Phone B indicates that Phone B is expecting to receive a media stream sent to its IP address using ports 8000 and 8001. The SIP ALG creates pinhole 2 to allow this media traffic to pass through the FortiGate unit. Pinhole 2 is opened on the Port1 interface and will accept media traffic sent from Phone A to Phone B.

Figure 269: SIP call setup with a FortiGate unit in Transparent mode

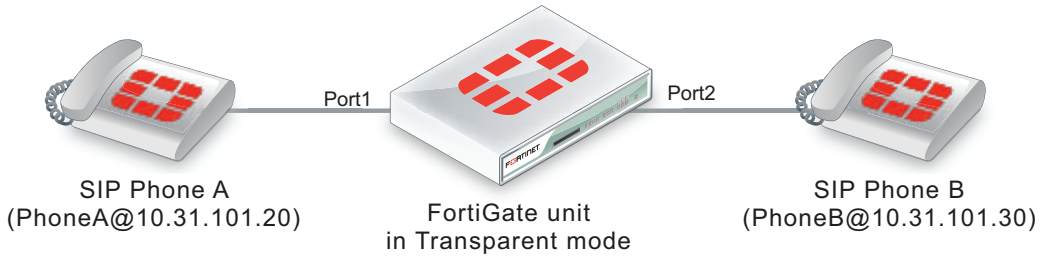


Configuration example: SIP in Transparent Mode

Figure 270 shows an example SIP network consisting of a FortiGate unit operating in Transparent mode between two SIP phones. Since the FortiGate unit is operating in Transparent mode both phones are on the same network and the FortiGate unit and the SIP ALG does not perform NAT. Even though the SIP ALG is not performing NAT you can use this configuration to apply SIP security features to the SIP traffic.

The FortiGate unit requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A.

Figure 270: SIP network with FortiGate unit in Transparent mode



General configuration steps

The following general configuration steps are required for this SIP configuration. This example uses the default VoIP profile. The example also includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the security service to ANY to allow traffic other than SIP on UDP port 5060.

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A and includes the default VoIP profile.
3. Add a security policy that accepts SIP sessions initiated by Phone B and includes the default VoIP profile.

Configuration steps - web-based manager

Before you begin this procedure you may have to enable VoIP support on the web-based manager by going to *System* > *Admin* > *Settings* and selecting the VoIP Support on GUI checkbox.

To add firewall addresses for the SIP phones

1. Go to *Firewall Objects* > *Address*.
2. Add the following addresses for Phone A and Phone B:

Address Name	Phone_A
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	port1

Address Name	Phone_B
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.30/255.255.255.255
Interface	port2

To add security policies to apply the SIP ALG to SIP sessions

1 Go to *Policy* > *Policy* > *Policy*.

2 Select Create New to add a security policy.

3 Add a security policy to allow Phone A to send SIP request messages to Phone B:

Source Interface/Zone	port1
Source Address	Phone_A
Destination Interface/Zone	port2
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT
UTM	Select
Protocol Options	default
Enable VoIP	Select and select the default VoIP profile.

4 Select *OK*.

5 Add a security policy to allow Phone B to send SIP request messages to Phone A:

Source Interface/Zone	port2
Source Address	Phone_B
Destination Interface/Zone	port1
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT
UTM	Select
Protocol Options	default
Enable VoIP	Select (And select the default VoIP profile)

6 Select *OK*.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to apply the SIP ALG to SIP sessions

1 Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
  edit Phone_A
    set associated interface port1
    set type ipmask
    set subnet 10.31.101.20 255.255.255.255
  next
```

```
  edit Phone_B
    set associated interface port2
    set type ipmask
    set subnet 10.31.101.30 255.255.255.255
  end
```

2 Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Phone_A
    set dstaddr Phone_B
    set action accept
    set schedule always
    set service SIP
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
  next
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr Phone_B
    set dstaddr Phone_A
    set action accept
    set schedule always
    set service SIP
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
  end
```

RTP enable/disable (RTP bypass)

You can configure the SIP ALG to stop from opening RTP pinholes. Called RTP bypass, this configuration can be used when you want to apply SIP ALG features to SIP signalling messages but do not want the RTP media streams to pass through the FortiGate unit. The FortiGate unit only acts as a signalling firewall and RTP media session bypass the FortiGate unit and no pinholes need to be created.

Enter the following command to enable RTP bypass in a VoIP profile by disabling opening RTP pinholes:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set rtp disable
    end
end
```

Opening and closing SIP register and non-register pinholes

You can use the `open-register-pinhole` and `open-contact-pinhole` VoIP profile CLI options to control whether the FortiGate unit opens register and non-register pinholes. Non-register pinholes are usually opened for SIP INVITE requests.

By default for new VoIP profiles and for both pre-defined VoIP profiles `open-register-pinhole` is enabled and the FortiGate unit opens pinholes for SIP Register request messages. You can disable `open-register-pinhole` so that the FortiGate unit does not open pinholes for SIP Register request messages.

By default for new VoIP profiles and for the default pre-defined VoIP profile `open-contact-pinhole` is enabled and the FortiGate unit opens pinholes for non-Register SIP request messages. You can disable `open-contact-pinhole` so that the FortiGate unit does not open pinholes for non-register requests. This option is not enabled for the strict pre-defined VoIP profile.

Usually you would want to open these pinholes. Keeping them closed may prevent SIP from functioning properly through the FortiGate unit. They can be disabled, however, for interconnect scenarios (where all SIP traffic is between proxies and traveling over a single session). In some cases these settings can also be disabled in access scenarios if it is known that all users will be registering regularly so that their contact information can be learned from the register request.

You might want to prevent pinholes from being opened to avoid creating a pinhole for every register or non-register request. Each pinhole uses additional system memory, which can affect system performance if there are hundreds or thousands of users, and requires refreshing which can take a relatively long amount of time if there are thousands of active calls.

To configure a VoIP profile to prevent opening register and non-register pinholes:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set open-register-pinhole disable
      set open-contact-pinhole disable
    end
end
```

In some cases you may not want to open pinholes for the port numbers specified in SIP Contact headers. For example, in an interconnect scenario when a FortiGate unit is installed between two SIP servers and the only SIP traffic through the FortiGate unit is between these SIP servers pinholes may not need to be opened for the port numbers specified in the Contact header lines.

If you disable `open-register-pinhole` then pinholes are not opened for ports in Contact header lines in SIP Register messages. If you disable `open-contact-pinhole` then pinholes are not opened for ports in Contact header lines in all SIP messages except SIP Register messages.

Accepting SIP register responses

You can enable the VoIP profile `reg-diff-port` options to accept a SIP Register response message from a SIP server even if the source port of the Register response message is different from the destination port.

Most SIP servers use 5060 as the source port in the SIP register response. Some SIP servers, however, may use a different source port. If your SIP server uses a different source port, you can enable `reg-diff-port` and the SIP ALG will create a temporary pinhole when Register request from a SIP client includes a different source port. The FortiGate unit will accept a SIP Register response with any source port number from the SIP server.

Enter the following command to enable accepting any source port from a SIP server:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set reg-diff-port enable
    end
end
```

How the SIP ALG performs NAT

In most Network Address Translation (NAT) configurations, multiple hosts in a private network share a single public IP address to access the Internet. For sessions originating on the private network for the Internet, NAT replaces the private IP address of the PC in the private subnet with the public IP address of the NAT device. The NAT device converts the public IP address for responses from the Internet back into the private address before sending the response over the private network to the originator of the session.

Using NAT with SIP is more complex because of the IP addresses and media stream port numbers used in SIP message headers and bodies. When a caller on the private network sends a SIP message to a phone or SIP server on the Internet, the SIP ALG must translate the private network addresses in the SIP message to IP addresses and port numbers that are valid on the Internet. When the response message is sent back to the caller, the SIP ALG must translate these addresses back to valid private network addresses.

In addition, the media streams generated by the SIP session are independent of the SIP message sessions and use varying port numbers that can also change during the media session. The SIP ALG opens pinholes to accept these media sessions, using the information in the SIP messages to determine the pinholes to open. The ALG may also perform port translation on the media sessions.

When an INVITE message is received by the SIP ALG, the FortiGate unit extracts addressing and port number information from the message header and stores it in a SIP dialog table. Similar to an IP session table the data in the dialog table is used to translate addresses in subsequent SIP messages that are part of the same SIP call.

When the SIP ALG receives a response to the INVITE message arrives, (for example, an ACK or 200 OK), the SIP ALG compares the addresses in the message fields against the entries in the SIP dialog table to identify the call context of the message. The SIP ALG then translates addresses in the SIP message before forwarding them to their destination.

The addressing and port number information in SDP fields is used by the ALG to reserve ports for the media session and create a NAT mapping between them and the ports in the SDP fields. Because SDP uses sequential ports for the RTP and RTCP channels, the ALG provides consecutive even-odd ports.

Source address translation

When a SIP call is started by a phone on a private network destined for a phone on the Internet, only source address translation is required. The phone on the private network attempts to contact the actual IP address of the phone on the Internet. However, the source address of the phone on the private network is not routable on the Internet so the SIP ALG must translate all private IP addresses in the SIP message into public IP addresses.

To configure the FortiGate for source address translation you add security policy that accepts sessions from the internal network destined for the Internet. You must enable NAT for the security policy and add a VoIP profile.

When a SIP request is received from the internal to the external network, the SIP ALG replaces the private network IP addresses and port numbers in the SIP message with the IP address of the FortiGate interface connected to the Internet. Depending on the content of the message, the ALG translates addresses in the Via:, Contact:, Route:, and Record-Route: SIP header fields. The message is then forwarded to the destination (either a VoIP phone or a SIP server on the Internet).

The VoIP phone or server in the Internet sends responses to these SIP messages to the external interface of the FortiGate unit. The addresses in the response messages are translated back into private network addresses and the response is forwarded to the originator of the request.

For the RTP communication between the SIP phones, the SIP ALG opens pinholes to allow media through the FortiGate unit on the dynamically assigned ports negotiated based on information in the SDP and the Via:, Contact:, and Record-Route: header fields. The pinholes also allow incoming packets to reach the Contact:, Via:, and Record-Route: IP addresses and ports. When processing return traffic, the SIP ALG inserts the original Contact:, Via:, Route:, and Record-Route: SIP fields back into the packets.

Destination address translation

Incoming calls are directed from a SIP phone on the Internet to the interface of the FortiGate unit connected to the Internet. To receive these calls you must add a security policy to accept SIP sessions from the Internet. The security policy requires a firewall virtual IP. SIP INVITE messages from the Internet connect to the external IP address of the virtual IP. The SIP ALG uses the destination address translation defined in the virtual IP to translated the addresses in the SIP message to addresses on the private network.

When a 200 OK response message arrives from the private network, the SIP ALG translates the addresses in the message to Internet addresses and opens pinholes for media sessions from the private network to the Internet.

When the ACK message is received for the 200 OK, it is also intercepted by the SIP ALG. If the ACK message contains SDP information, the SIP ALG checks to determine if the IP addresses and port numbers are not changed from the previous INVITE. If they are, the SIP ALG deletes pinholes and creates new ones as required. The ALG also monitors the Via:, Contact:, and Record-Route: SIP fields and opens new pinholes as required.

Call Re-invite messages

SIP Re-INVITE messages can dynamically add and remove media sessions during a call. When new media sessions are added to a call the SIP ALG opens new pinholes and update SIP dialog data. When media sessions are ended, the SIP ALG closes pinholes that are no longer needed and removes SIP dialog data.

How the SIP ALG translates IP addresses in SIP headers

The SIP ALG applies NAT to SIP sessions by translating the IP addresses contained in SIP headers. For example, the following SIP message contains most of the SIP fields that contain addresses that need to be translated:

```
INVITE PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 172.20.120.50:5434
From: PhoneA@10.31.101.20
To: PhoneB@172.20.120.30
Call-ID: a12abcde@172.20.120.50
Contact: PhoneA@10.31.101.20:5434
Route: <sip:example@172.20.120.50:5060>
Record-Route: <sip:example@172.20.120.50:5060>
```

How IP address translation is performed depends on whether source NAT or destination NAT is applied to the session containing the message:

Source NAT translation of IP addresses in SIP messages

Source NAT translation occurs for SIP messages sent from a phone or server on a private network to a phone or server on the Internet. The source addresses in the SIP header fields of the message are typically set to IP addresses on the private network. The SIP ALG translates these addresses to the address the FortiGate unit interface connected to the Internet.

Table 137: Source NAT translation of IP addresses in SIP request messages

SIP header	NAT action
To:	None
From:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Call-ID:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Via:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Request-URI:	None
Contact:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Record-Route:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Route:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.

Response messages from phones or servers on the Internet are sent to the FortiGate unit interface connected to the Internet where the destination addresses are translated back to addresses on the private network before forwarding the SIP response message to the private network.

Table 138: Source NAT translation of IP addresses in SIP response messages

SIP header	NAT action
To:	None

Table 138: Source NAT translation of IP addresses in SIP response messages

SIP header	NAT action
From:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.
Call-ID:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.
Via:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.
Request-URI:	N/A
Contact:	None
Record-Route:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.
Route:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.

Destination NAT translation of IP addresses in SIP messages

Destination NAT translation occurs for SIP messages sent from a phone or server on the Internet to a firewall virtual IP address. The destination addresses in the SIP header fields of the message are typically set to the virtual IP address. The SIP ALG translates these addresses to the address of a SIP server or phone on the private network on the other side of the FortiGate unit.

Table 139: Destination NAT translation of IP addresses in SIP request messages

SIP header	NAT action
To:	Replace VIP address with address on the private network as defined in the firewall virtual IP.
From:	None
Call-ID:	None
Via:	None
Request-URI:	Replace VIP address with address on the private network as defined in the firewall virtual IP.
Contact:	None
Record-Route:	None
Route:	None

SIP response messages sent in response to the destination NAT translated messages are sent from a server or a phone on the private network back to the originator of the request messages on the Internet. These reply messages are accepted by the same security policy that accepted the initial request messages, The firewall VIP in the original security policy contains the information that the SIP ALG uses to translate the private network source addresses in the SIP headers into the firewall virtual IP address.

Table 140: Destination NAT translation of IP addresses in SIP response messages

SIP header	NAT action
To:	None

Table 140: Destination NAT translation of IP addresses in SIP response messages

SIP header	NAT action
From:	Replace private network address with firewall VIP address.
Call-ID:	None
Via:	None
Request-URI:	N/A
Contact:	Replace private network address with firewall VIP address.
Record-Route:	Replace private network address with firewall VIP address.
Route:	None

How the SIP ALG translates IP addresses in the SIP body

The SDP session profile attributes in the SIP body include IP addresses and port numbers that the SIP ALG uses to create pinholes for the media stream.

The SIP ALG translates IP addresses and port numbers in the o=, c=, and m= SDP lines. For example, in the following lines the ALG could translate the IP addresses in the o= and c= lines and the port number (49170) in the m= line.

```
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
```

If the SDP session profile includes multiple RTP media streams, the SIP ALG opens pinholes and performs the required address translation for each one.

The two most important SDP attributes for the SIP ALG are c= and m=. The c= attribute is the connection information attribute. This field can appear at the session or media level. The syntax of the connection attribute is:

```
c=IN {IPV4 | IPV6} <destination_ip_address>
```

Where

- `IN` is the network type. FortiGate units support the `IN` or Internet network type.
- `{IPV4 | IPV6}` is the address type. FortiGate units support IPv4 or IPv6 addresses in SDP statements. However, FortiGate units do not support all types of IPv6 address translation. See “SIP over IPv6” on page 2585.
- `<destination_IP_address>` is the unicast numeric destination IP address or domain name of the connection in either IPv4 or IPv6 format.

The syntax of the media attribute is:

```
m=audio <port_number> RTP <format_list>
```

Where

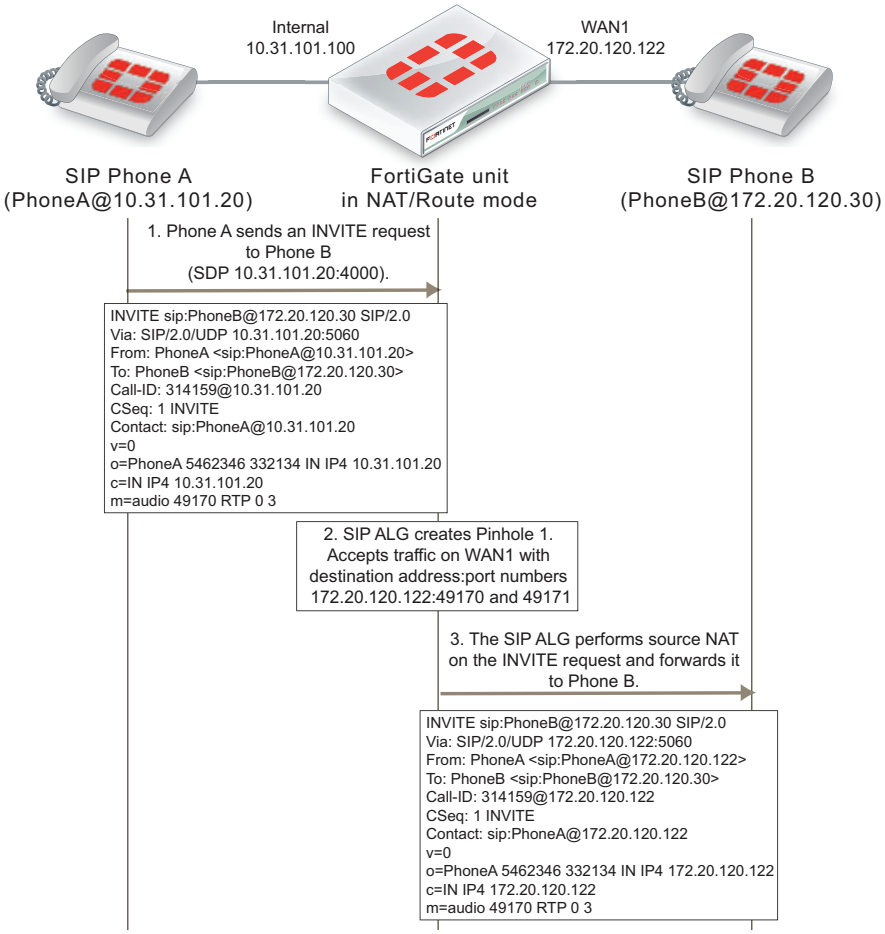
- `audio` is the media type. FortiGate units support the `audio` media type.
- `<port_number>` is the destination port number used by the media stream.
- `RTP` is the application layer transport protocol used for the media stream. FortiGate units support the Real Time Protocol (RTP) transport protocol.
- `<format_list>` is the format list that provides information about the application layer protocol that the media uses.

SIP NAT scenario: source address translation (source NAT)

Figure 271 and Figure 272 show a source address translation scenario involving two SIP phones on different networks, separated by a FortiGate unit. In the scenario, SIP Phone A sends an INVITE request to SIP Phone B and SIP Phone B replies with a 200 OK response and then the two phones start media streams with each other.

To simplify the diagrams, some SIP messages are not included (for example, the Ringing and ACK response messages) and some SIP header lines and SDP profile lines have been removed from the SIP messages.

Figure 271: SIP source NAT scenario part 1: INVITE request sent from Phone A to Phone B

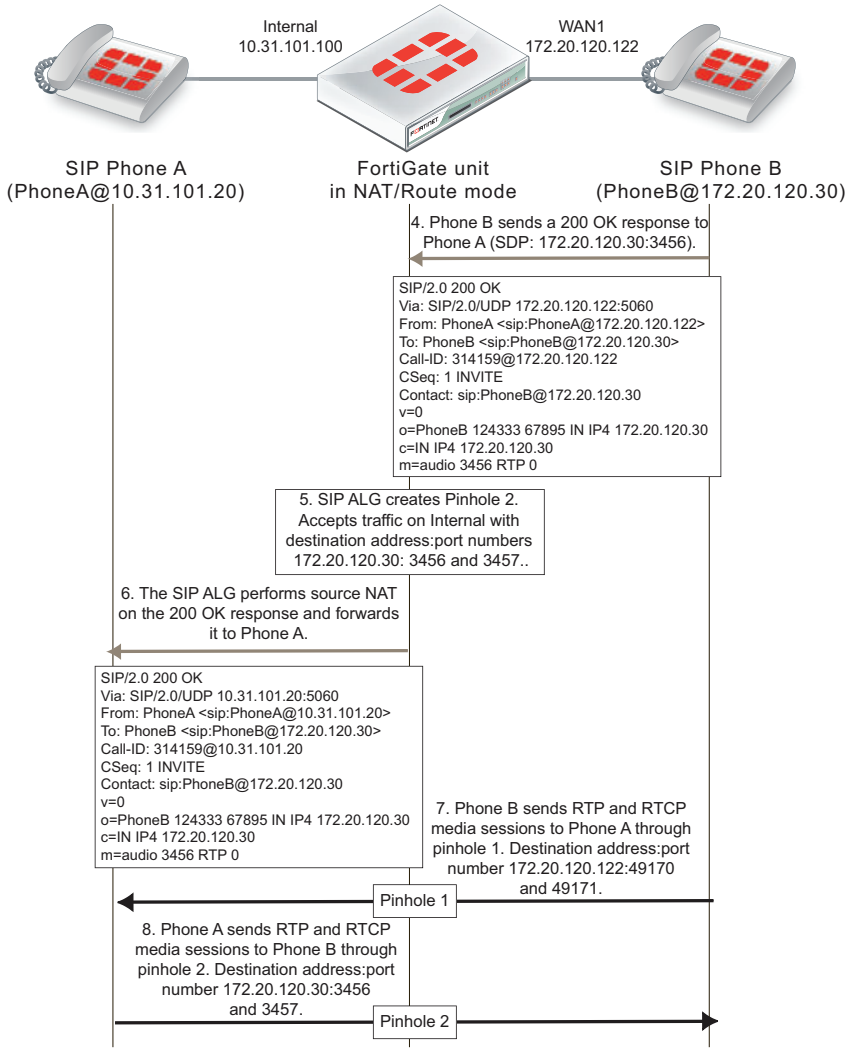


For the replies to SIP packets sent by Phone A to be routable on Phone Bs network, the FortiGate unit uses source NAT to change their source address to the address of the WAN1 interface. The SIP ALG makes similar changes the source addresses in the SIP headers and SDP profile. For example, the original INVITE request from Phone A includes the address of Phone A (10.31.101.20) in the from header line. After the INVITE request passes through the FortiGate unit, the address of Phone A in the From SIP header line is translated to 172.20.120.122, the address of the FortiGate unit WAN1 interface. As a result, Phone B will reply to SIP messages from Phone A using the WAN1 interface IP address.

The FortiGate unit also opens a pinhole so that it can accept media sessions sent to the WAN1 IP address using the port number in the m= line of the INVITE request and forward them to Phone A after translating the destination address to the IP address of Phone A.

Phone B sends the 200 OK response to the INVITE message to the WAN1 interface. The SDP profile includes the port number that Phone B wants to use for its media stream. The FortiGate unit forwards 200 OK response to Phone A after translating the addresses in the SIP and SDP lines back to the IP address of Phone A. The SIP ALG also opens a pinhole on the Internal interface that accepts media stream sessions from Phone A with destination address set to the IP address of Phone B and using the port that Phone B added to the SDP m= line.

Figure 272: SIP source NAT scenario part 2: 200 OK returned and media streams established



SIP NAT scenario: destination address translation (destination NAT)

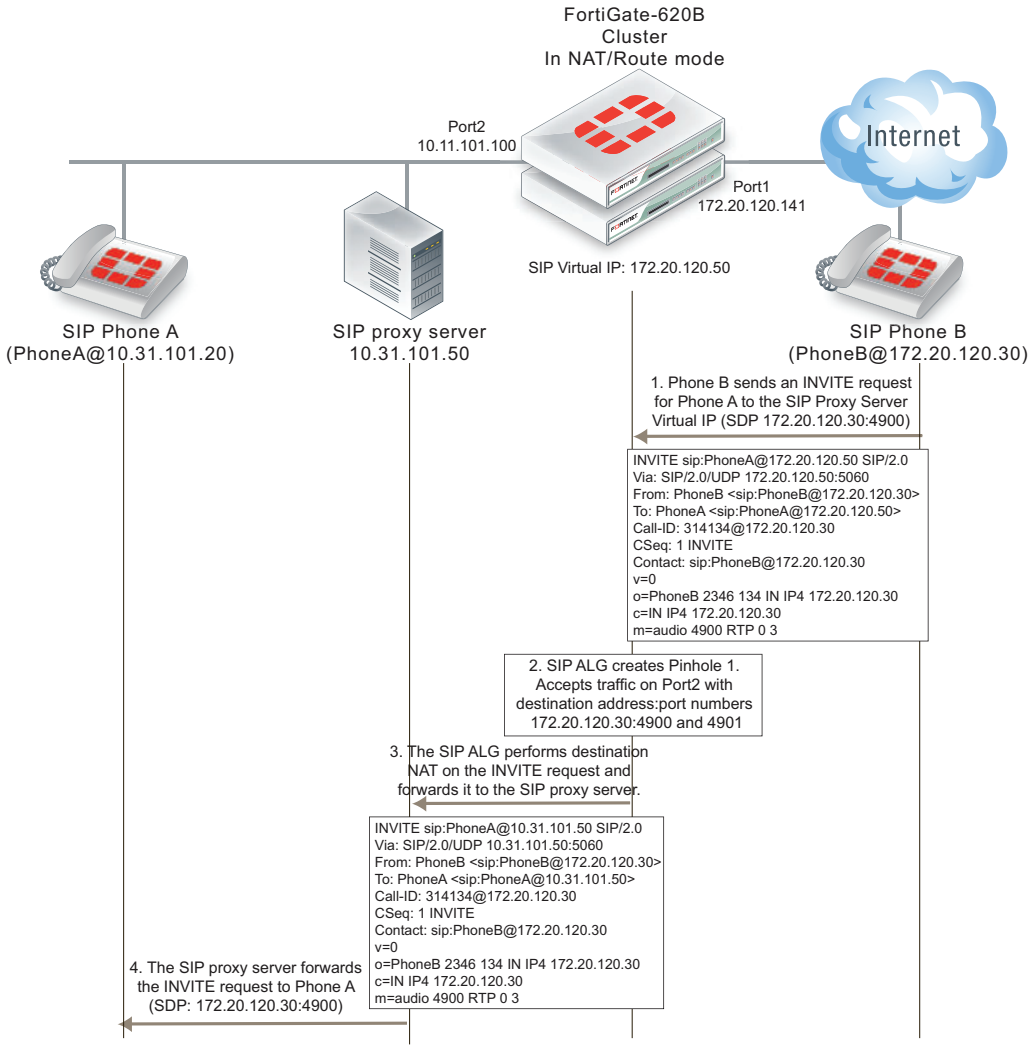
Figure 273 and Figure 274 show how the SIP ALG translates addresses in a SIP INVITE message sent from SIP Phone B on the Internet to SIP Phone A on a private network using the SIP proxy server. Because the addresses on the private network are not visible from the Internet, the security policy on the FortiGate unit that accepts SIP sessions includes a virtual IP. Phone A sends SIP the INVITE message to the virtual IP address. The FortiGate unit accepts the INVITE message packets and using the virtual IP, translates the destination address of the packet to the IP address of the SIP proxy server and forwards the SIP message to it.

To simplify the diagrams, some SIP messages are not included (for example, the Ringing and ACK response messages) and some SIP header lines and SDP profile lines have been removed from the SIP messages.

The SIP ALG also translates the destination addresses in the SIP message from the virtual IP address (172.20.120.50) to the SIP proxy server address (10.31.101.50). For this configuration to work, the SIP proxy server must be able to change the destination addresses for Phone A in the SIP message from the address of the SIP proxy server to the actual address of Phone A.

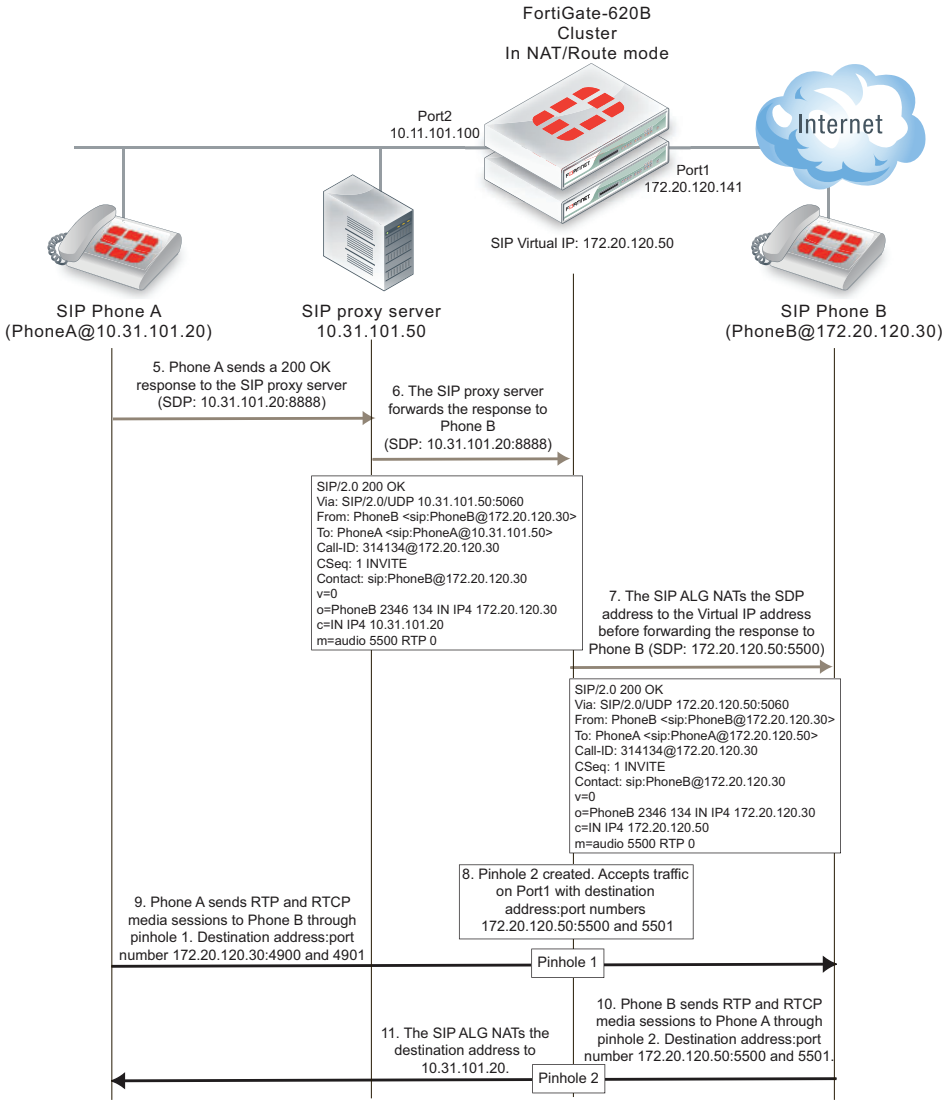
The SIP ALG also opens a pinhole on the Port2 interface that accepts media sessions from the private network to SIP Phone B using ports 4900 and 4901.

Figure 273: SIP destination NAT scenario part 1: INVITE request sent from Phone B to Phone A



Phone A sends a 200 OK response back to the SIP proxy server. The SIP proxy server forwards the response to Phone B. The FortiGate unit accepts the 100 OK response. The SIP ALG translates the Phone A addresses back to the SIP proxy server virtual IP address before forwarding the response back to Phone B. The SIP ALG also opens a pinhole using the SIP proxy server virtual IP which is the address in the o= line of the SDP profile and the port number in the m= line of the SDP code.

Figure 274: SIP destination NAT scenario part 2: 200 OK returned to Phone B and media streams established

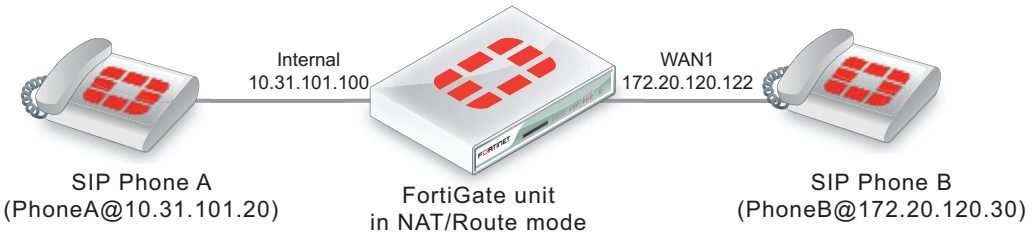


The media stream from Phone A is accepted by pinhole one and forwarded to Phone B. The source address of this media stream is changed to the SIP proxy server virtual IP address. The media stream from Phone B is accepted by pinhole 2 and forwarded to Phone B. The destination address of this media stream is changed to the IP address of Phone A.

SIP NAT configuration example: source address translation (source NAT)

This configuration example shows how to configure the FortiGate unit to support the source address translation scenario shown in Figure 275. The FortiGate unit requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A. Both of these policies must include source NAT. In this example the networks are not hidden from each other so destination NAT is not required.

Figure 275: SIP source NAT configuration



General configuration steps

The following general configuration steps are required for this SIP configuration. This example uses the default VoIP profile. The example also includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the firewall service to ANY to allow traffic other than SIP on UDP port 5060.

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A and includes the default VoIP profile.
3. Add a security policy that accepts SIP sessions initiated by Phone B and includes the default VoIP profile.

Configuration steps - web-based manager

To add firewall addresses for the SIP phones

1. Go to *Firewall Objects* > *Address*.
2. Add the following addresses for Phone A and Phone B:

Address Name	Phone_A
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	Internal

Address Name	Phone_B
Type	Subnet / IP Range
Subnet / IP Range	172.20.120.30/255.255.255.255
Interface	wan1

To add security policies to apply the SIP ALG to SIP sessions

1. Go to *Policy* > *Policy* > *Policy*.
2. Select Create New to add a security policy.
3. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Source Interface/Zone	internal
Source Address	Phone_A

Destination Interface/Zone	wan1
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT
Enable NAT	Select
UTM	Select
Protocol Options	default
Enable VoIP	Select and select the default VoIP profile.

4 Select *OK*.

5 Add a security policy to allow Phone B to send SIP request messages to Phone A:

Source Interface/Zone	wan1
Source Address	Phone_B
Destination Interface/Zone	internal
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT
Enable NAT	Select
UTM	Select
Protocol Options	default
Enable VoIP	Select (And select the default VoIP profile)

6 Select *OK*.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to apply the SIP ALG to SIP sessions

1 Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
  edit Phone_A
    set associated interface internal
    set type ipmask
    set subnet 10.31.101.20 255.255.255.255
  next
  edit Phone_B
    set associated interface wan1
    set type ipmask
    set subnet 172.20.120.30 255.255.255.255
  end
```

2 Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

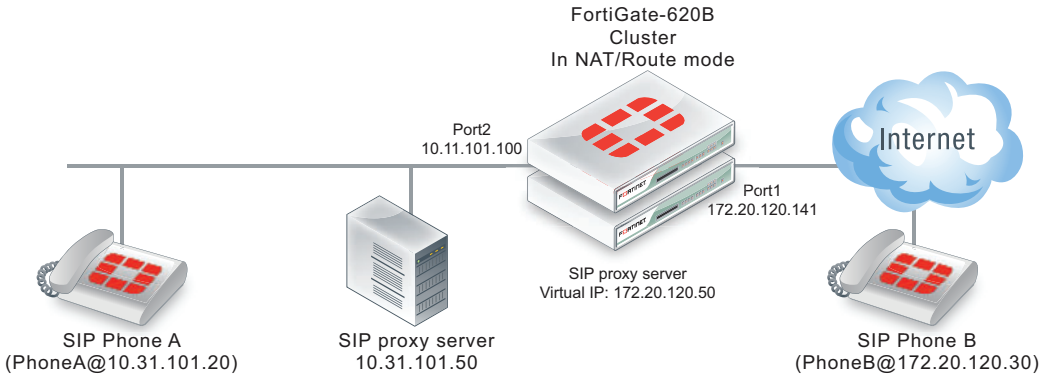
```
config firewall policy
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr Phone_A
    set dstaddr Phone_B
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
  next
  edit 0
    set srcintf wan1
    set dstintf internal
    set srcaddr Phone_B
    set dstaddr Phone_A
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
  end
```

SIP NAT configuration example: destination address translation (destination NAT)

This configuration example shows how to configure the FortiGate unit to support the destination address translation scenario shown in Figure 276. The FortiGate unit requires two SIP security policies:

- A destination NAT security policy that allows SIP messages to be sent from the Internet to the private network. This policy must include destination NAT because the addresses on the private network are not routable on the Internet.
- A source NAT security policy that allows SIP messages to be sent from the private network to the Internet.

Figure 276: SIP destination NAT scenario part two: 200 OK returned to Phone B and media streams established



General configuration steps

The following general configuration steps are required for this destination NAT SIP configuration. This example uses the default VoIP profile.

1. Add the SIP proxy server firewall virtual IP.
2. Add a firewall address for the SIP proxy server on the private network.
3. Add a destination NAT security policy that accepts SIP sessions from the Internet destined for the SIP proxy server virtual IP and translates the destination address to the IP address of the SIP proxy server on the private network.
4. Add a security policy that accepts SIP sessions initiated by the SIP proxy server and destined for the Internet.

Configuration steps - web-based manager

To add the SIP proxy server firewall virtual IP

1. Go to *Firewall Objects* > *Virtual IP* > *Virtual IP.*
2. Add the SIP proxy server virtual IP.

Name	SIP_Proxy_VIP
External Interface	port1
Type	Static NAT
External IP Address/Range	172.20.120.50
Mapped IP Address/Range	10.31.101.50

To add a firewall address for the SIP proxy server

1. Go to *Firewall Objects* > *Address*.
2. Add the following for the SIP proxy server:

Address Name	SIP_Proxy_Server
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.50/255.255.255.255
Interface	port2

To add the security policies

1 Go to *Policy* > *Policy* > *Policy*.

2 Add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	port2
Destination Address	SIP_Proxy_VIP
Schedule	always
Service	SIP
Action	ACCEPT
Enable NAT	Select
UTM	Select
Protocol Options	default
Enable VoIP	Select and select the default VoIP profile.

3 Select *OK*.

4 Add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

Source Interface/Zone	port2
Source Address	SIP_Proxy_Server
Destination Interface/Zone	port1
Destination Address	all
Schedule	always
Service	SIP
Action	ACCEPT
Enable NAT	Select
UTM	Select
Protocol Options	default
Enable VoIP	Select (And select the default VoIP profile)

5 Select *OK*.

Configuration steps - CLI

To add the SIP proxy server firewall virtual IP and firewall address

1 Enter the following command to add the SIP proxy server firewall virtual IP.

```
config firewall vip
  edit SIP_Proxy_VIP
    set type static-nat
    set extip 172.20.120.50
```

```
    set mappedip 10.31.101.50
    set extintf port1
  end
```

2 Enter the following command to add the SIP proxy server firewall address.

```
config firewall address
  edit SIP_Proxy_Server
    set associated interface port2
    set type ipmask
    set subnet 10.31.101.50 255.255.255.255
  end
```

To add security policies

1 Enter the following command to add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr SIP_Proxy_VIP
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
  end
```

2 Enter the following command to add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr SIP_Proxy_Server
    set dstaddr all
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
  end
```

Additional SIP NAT scenarios

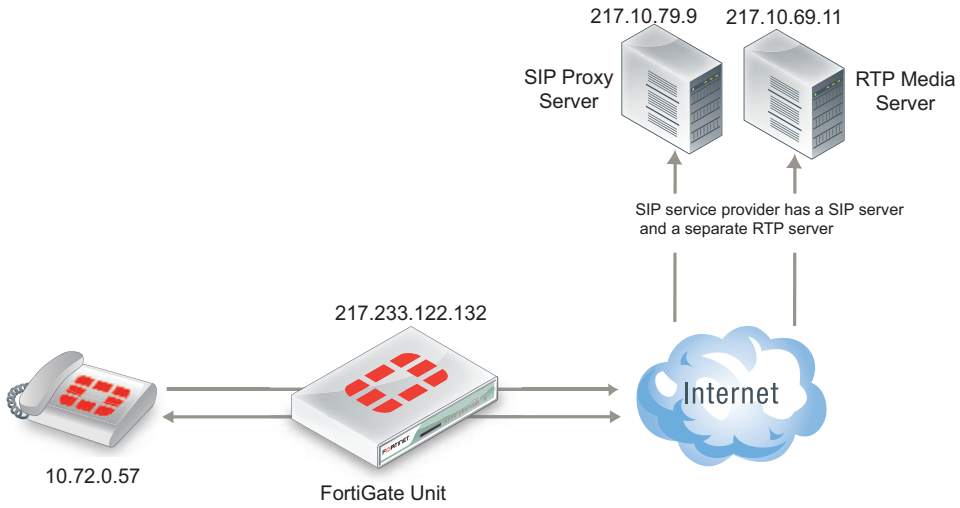
This section lists some additional SIP NAT scenarios.

Source NAT (SIP and RTP)

In the source NAT scenario shown in Figure 277, a SIP phone connects to the Internet through a FortiGate unit with and IP address configured using PPPoE. The SIP ALG translates all private IPs in the SIP contact header into public IPs.

You need to configure an internal to external SIP security policy with NAT selected, and include a VoIP profile with SIP enabled.

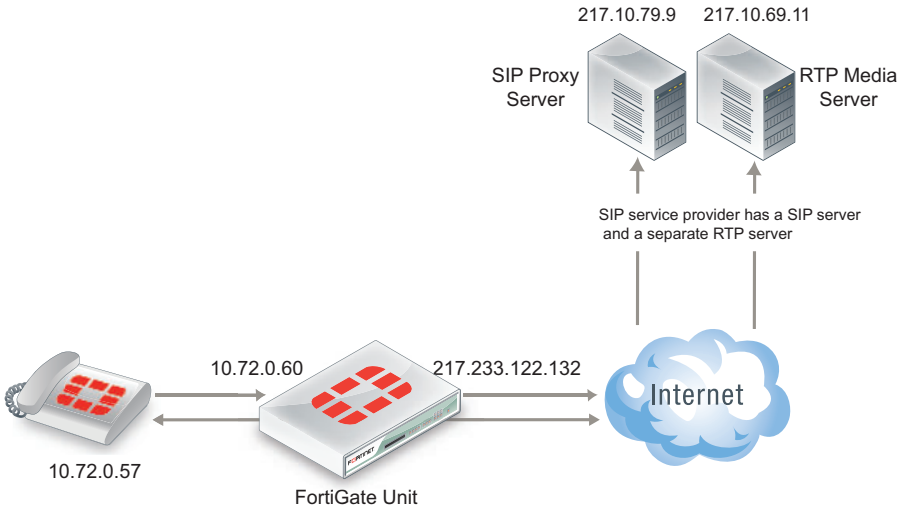
Figure 277: SIP source NAT



Destination NAT (SIP and RTP)

In the following destination NAT scenario, a SIP phone can connect through the FortiGate unit to private IP address using a firewall virtual IP (VIP). The SIP ALG translates the SIP contact header to the IP of the real SIP proxy server located on the Internet.

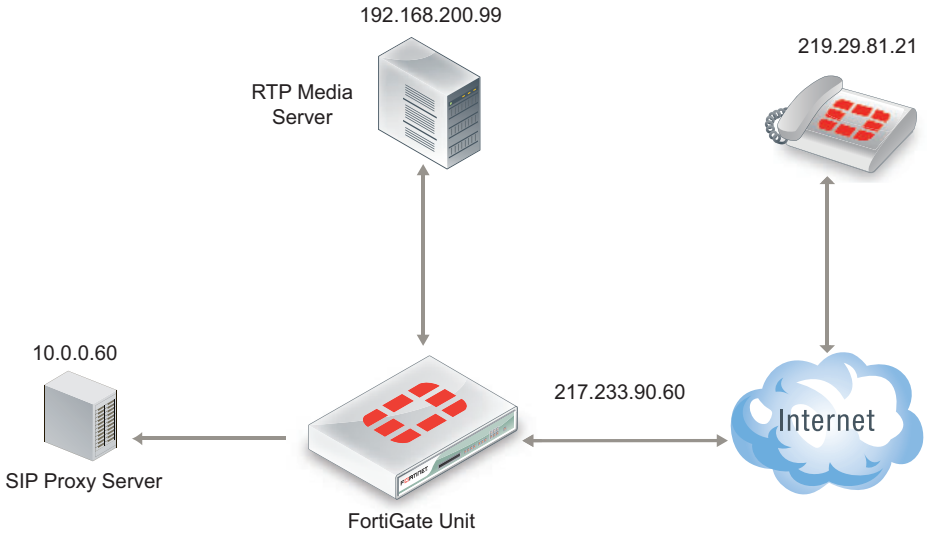
Figure 278: SIP destination NAT



In the scenario, shown in Figure 278, the SIP phone connects to a VIP (10.72.0.60). The SIP ALG translates the SIP contact header to 217.10.79.9, opens RTP pinholes, and manages NAT.

The FortiGate unit also supports a variation of this scenario where the RTP media server's IP address is hidden on a private network or DMZ.

Figure 279: SIP destination NAT-RTP media server hidden



In the scenario shown in Figure 279, a SIP phone connects to the Internet. The VoIP service provider only publishes a single public IP. The FortiGate unit is configured with a firewall VIP. The SIP phone connects to the FortiGate unit (217.233.90.60) and using the VIP the FortiGate unit translates the SIP contact header to the SIP proxy server IP address (10.0.0.60). The SIP proxy server changes the SIP/SDP connection information (which tells the SIP phone which RTP media server IP it should contact) also to 217.233.90.60.

Source NAT with an IP pool

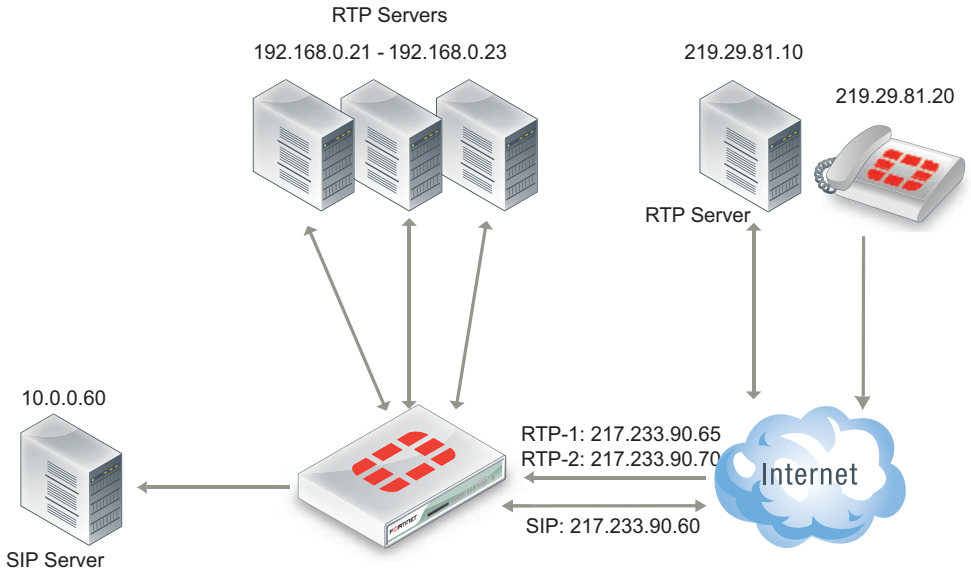
You can choose *NAT* with the *Dynamic IP Pool* option when configuring a security policy if the source IP of the SIP packets is different from the interface IP. The FortiGate ALG interprets this configuration and translates the SIP header accordingly.

This configuration also applies to destination NAT.

Different source and destination NAT for SIP and RTP

This is a more complex scenario that a SIP service provider may use. It can also be deployed in large-scale SIP environments where RTP has to be processed by the FortiGate unit and the RTP server IP has to be translated differently than the SIP server IP.

Figure 280: Different source and destination NAT for SIP and RTP



In this scenario, shown in Figure 280, assume there is a SIP server and a separate media gateway. The SIP server is configured so that the SIP phone (219.29.81.20) will connect to 217.233.90.60. The media gateway (RTP server: 219.29.81.10) will connect to 217.233.90.65.

What happens is as follows:

1. The SIP phone connects to the SIP VIP. The FortiGate ALG translates the SIP contact header to the SIP server: 219.29.81.20 > 217.233.90.60 (> 10.0.0.60).
2. The SIP server carries out RTP to 217.233.90.65.
3. The FortiGate ALG opens pinholes, assuming that it knows the ports to be opened.
4. RTP is sent to the RTP-VIP (217.233.90.65.) The FortiGate ALG translates the SIP contact header to 192.168.0.21.

NAT with IP address conservation

In a source or destination NAT security policy that accepts SIP sessions, you can configure the SIP ALG or the SIP session helper to preserve the original source IP address of the SIP message in the i= line of the SDP profile. NAT with IP address conservation (also called SIP NAT tracing) changes the contents of SIP messages by adding the source IP address of the originator of the message into the SDP i= line of the SIP message. The SDP i= line is used for free-form text. However, if your SIP server can retrieve information from the SDP i= line, it can be useful for keeping a record of the source IP address of the originator of a SIP message when operating in a NAT environment. You can use this feature for billing purposes by extracting the IP address of the originator of the message.

Configuring SIP IP address conservation for the SIP ALG

You can use the following command to enable or disable SIP IP address conservation in a VoIP profile for the SIP ALG. SIP IP address conservation is enabled by default in a VoIP profile.

```
config voip profile
  edit VoIP_Pro_1
    config sip
```

```
      set nat-trace disable
    end
end
```

If the SIP message does not include an i= line and if the original source IP address of the traffic (before NAT) was 10.31.101.20 then the FortiGate unit would add the following i= line.

```
i=(o=IN IP4 10.31.101.20)
```

You can also use the `preserve-override` option to configure the SIP ALG to either add the original o= line to the end of the i= line or replace the i= line in the original message with a new i= line in the same form as above for adding a new i= line.

By default, `preserver-override` is disabled and the SIP ALG adds the original o= line to the end of the original i= line. Use the following command to configure the SIP ALG to replace the original i= line:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set preserve-override enable
    end
end
```

Configuring SIP IP address conservation for the SIP session helper

You can use the following command to enable or disable SIP IP address conservation for the SIP session helper. IP address conservation is enabled by default for the SIP session helper.

```
config system settings
  set sip-nat-trace disable
end
```

If the SIP message does not include an i= line and if the original source IP address of the traffic (before NAT) was 10.31.101.20 then the FortiGate unit would add the following i= line.

```
i=(o=IN IP4 10.31.101.20)
```

Controlling how the SIP ALG NATs SIP contact header line addresses

You can enable `contact-fixup` so that the SIP ALG performs normal SIP NAT translation to SIP contact headers as SIP messages pass through the FortiGate unit.

Disable `contact-fixup` if you do not want the SIP ALG to perform normal NAT translation of the SIP contact header if a Record-Route header is also available. If `contact-fixup` is disabled, the FortiGate ALG does the following with contact headers:

- For Contact in Requests, if a Record-Route header is present and the request comes from the external network, the SIP Contact header is not translated.
- For Contact in Responses, if a Record-Route header is present and the response comes from the external network, the SIP Contact header is not translated.

If `contact-fixup` is disabled, the SIP ALG must be able to identify the external network. To identify the external network, you must use the `config system interface` command to set the `external` keyword to `enable` for the interface that is connected to the external network.

Enter the following command to perform normal NAT translation of the SIP contact header:

```
config voip profile
```

```
  edit VoIP_Pro_1
    config sip
      set contact-fixup enable
    end
end
```

Controlling NAT for addresses in SDP lines

You can use the `no-sdp-fixup` option to control whether the FortiGate unit performs NAT on addresses in SDP lines in the SIP message body.

The `no-sdp-fixup` option is disabled by default and the FortiGate unit performs NAT on addresses in SDP lines. Enable this option if you don't want the FortiGate unit to perform NAT on the addresses in SDP lines.

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set no-sdp-fixup enable
    end
end
```

Translating SIP session destination ports

Using port forwarding virtual IPs you can change the destination port of SIP sessions as they pass through the FortiGate unit.

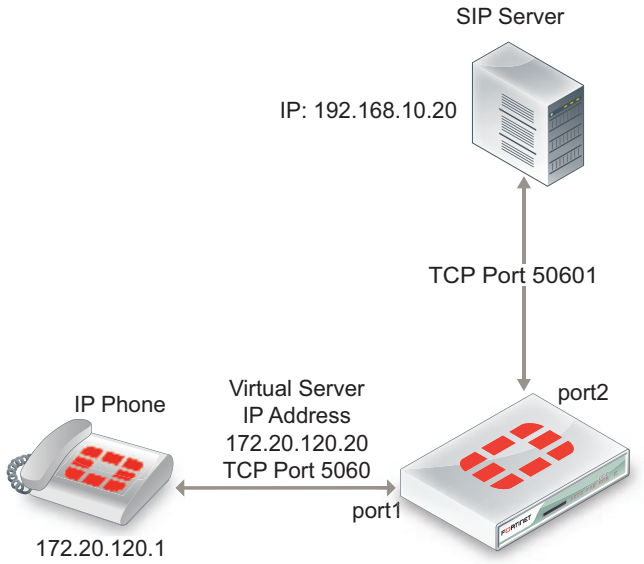
This section describes:

- Translating SIP sessions to a different destination port
- Translating SIP sessions to multiple destination ports

Translating SIP sessions to a different destination port

To configure translating SIP sessions to a different destination port you must add a static NAT virtual IP that translates tie SIP destination port to another port destination. In the example the destination port is translated from 5060 to 50601. This configuration can be used if SIP sessions uses different destination ports on different networks.

Figure 281: Example translating SIP sessions to a different destination port



To translate SIP sessions to a different destination port

1 Add the static NAT virtual IP.

This virtual IP forwards traffic received at the port1 interface for IP address 172.20.120.20 and destination port 5060 to the SIP server at IP address 192.168.10.20 with destination port 5061.

```
config firewall vip
  edit "sip_port_trans_vip"
    set type static-nat
    set portforward enable
    set protocol tcp
    set extip 172.20.120.20
    set extport 5060
    set extintf "port1"
    set mappedip 192.168.10.20
    set mappedport 50601
    set comment "Translate SIP destination port"
  end
```

2 Add a security policy that includes the virtual IP and the default VoIP profile.

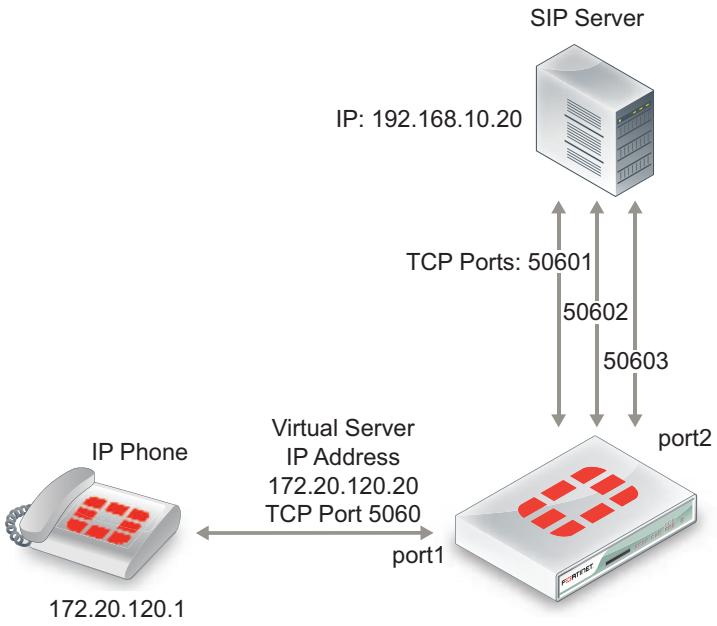
```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "all"
    set dstaddr "sip_port_trans_vip"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
    set comments "Translate SIP destination port"
```

```
end
```

Translating SIP sessions to multiple destination ports

You can use a load balance virtual IP to translate SIP session destination ports to a range of destination ports. In this example the destination port is translated from 5060 to the range 50601 to 50603. This configuration can be used if your SIP server is configured to receive SIP traffic on multiple ports.

Figure 282: Example translating SIP traffic to multiple destination ports



To translated SIP sessions to multiple destination ports

1 Add the load balance virtual IP.

This virtual IP forwards traffic received at the port1 interface for IP address 172.20.120.20 and destination port 5060 to the SIP server at IP address 192.168.10.20 with destination port 5061.

```
config firewall vip
  edit "sip_port_ldbl_vip"
    set type load-balance
    set portforward enable
    set protocol tcp
    set extip 172.20.120.20
    set extport 5060
    set extintf "port1"
    set mappedip 192.168.10.20
    set mappedport 50601-50603
    set comment "Translate SIP destination port range"
  end
```

2 Add a security policy that includes the virtual IP and VoIP profile.

```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
```

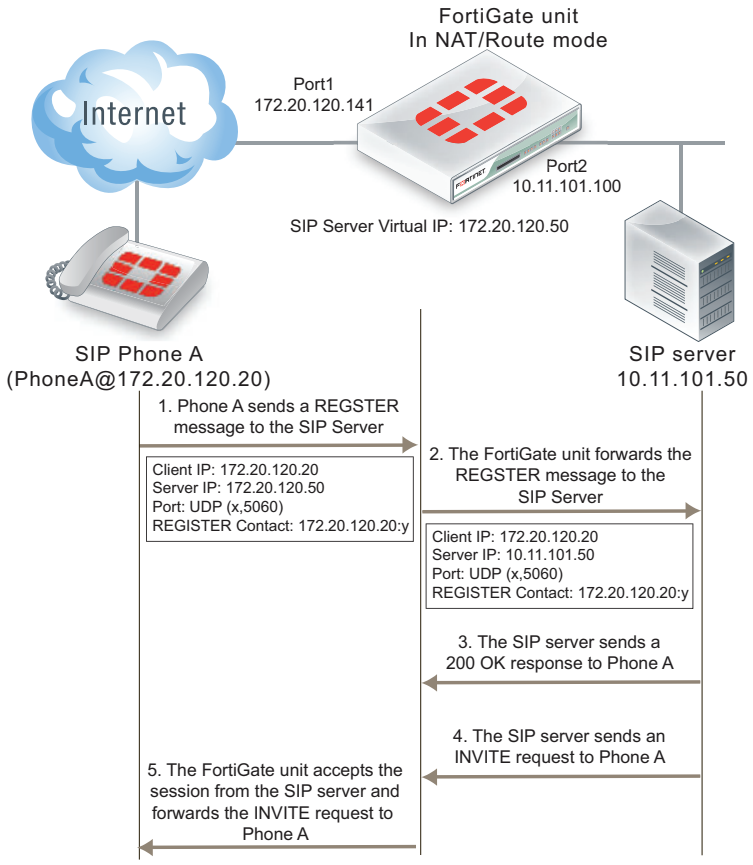
```
    set srcaddr "all"
    set dstaddr "sip_port_ldbl_vip"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
    set comments "Translate SIP destination port"
end
```

Enhancing SIP pinhole security

You can use the `strict-register` option in a SIP VoIP profile to open smaller pinholes.

As shown in Figure 283 when FortiGate unit is protecting a SIP server on a private network, the FortiGate unit does not have to open a pinhole for the SIP server to send INVITE requests to a SIP Phone on the Internet after the SIP Phone has registered with the server.

Figure 283: FortiGate unit protecting a SIP server on a private network



In the example, a client (SIP Phone A) sends a REGISTER request to the SIP server with the following information:

```
Client IP: 10.31.101.20
Server IP: 10.21.101.50
```

```
Port: UDP (x,5060)
REGISTER Contact: 10.31.101.20:y
```

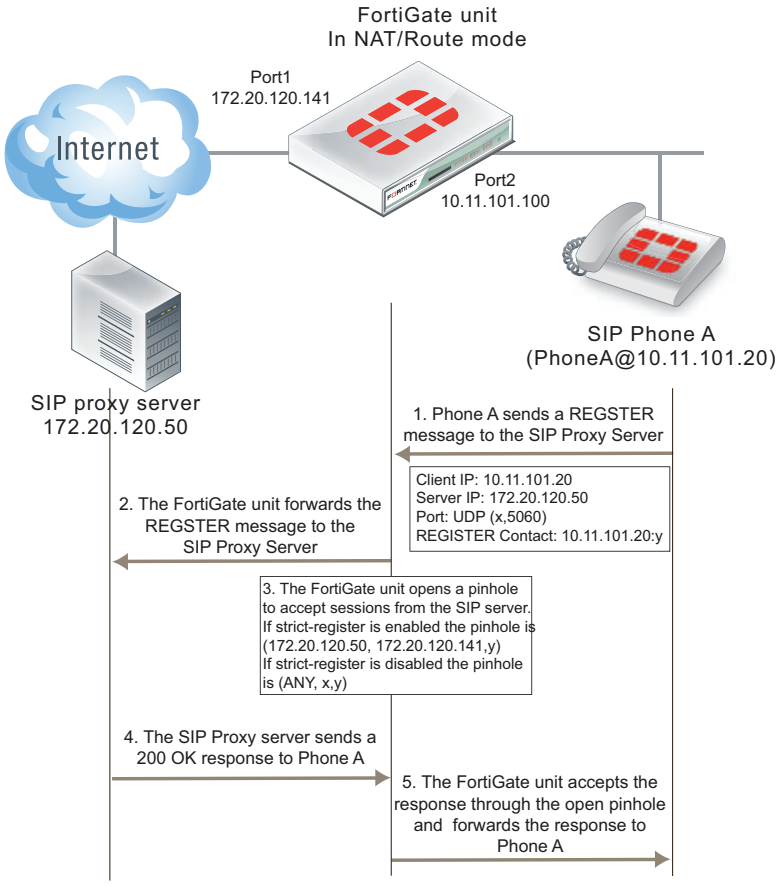
Where `x` and `y` are ports chosen by Phone A.

As soon as the server sends the 200 OK reply it can forward INVITE requests from other SIP phones to SIP Phone A. If the SIP proxy server uses the information in the REGISTER message received from SIP Phone A the INVITE messages sent to Phone A f will only get through the FortiGate unit if an policy has been added to allow the server to send traffic from the private network to the Internet. Or the SIP ALG must open a pinhole to allow traffic from the server to the Internet. In most cases the FortiGate unit is protecting the SIP server so there is no reason not to add a security policy to all the SIP server to send outbound traffic to the Internet.

In a typical SOHO scenario shown in Figure 284, SIP Phone A is being protected from the Internet by a FortiGate unit. In most cases the FortiGate unit would not allow incoming traffic from the Internet to reach the private network. So the only way that an INVITE request from the SIP server can reach SIP Phone A is if the SIP ALG creates an incoming pinhole. All pinholes have three attributes:

```
(source address, destination address, destination port)
```

Figure 284: SOHO configuration, FortiGate unit protecting a network with SIP phones



The more specific a pinhole is the more secure it is because it will accept less traffic. In this situation, the pinhole would be more secure if it only accepted traffic from the SIP server. This is what happens if `strict-register` is enabled in the VoIP profile that accepts the REGISTER request from Phone A.

```
(SIP server IP address, client IP address, destination port)
```

If `strict-register` is disabled (the default configuration) the pinhole is set up with the following attributes

```
(ANY IP address, client IP address, destination port)
```

This pinhole allows connections through the FortiGate unit from ANY source address which is a much bigger and less secure pinhole. In most similar network configurations you should enable `strict-register` to improve pinhole security.

Enabling `strict-register` can cause problems when the SIP registrar and SIP proxy server are separate entities with separate IP addresses.

Enter the following command to enable `strict-register` in a VoIP profile.

```
config voip profile
  edit Profile_name
    config SIP
      set strict-register enable
  end
```

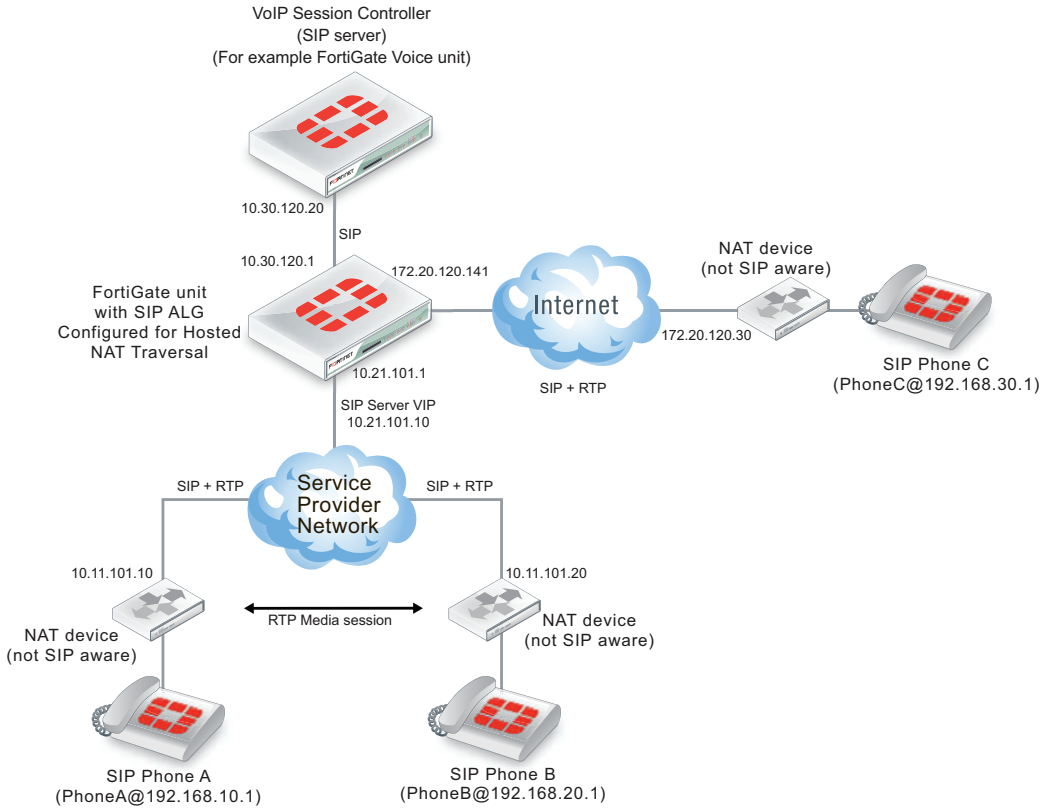
Hosted NAT traversal

With the increase in the use of VoIP and other media traffic over the Internet, service provider network administrators must defend their networks from threats while allowing voice and multimedia traffic to flow transparently between users and servers and among users. A common scenario could involve providing SIP VoIP services for customers with SIP phones installed behind NAT devices that are not SIP aware. NAT devices that are not SIP aware cannot translate IP addresses in SIP headers and SDP lines in SIP packets but can and do perform source NAT on the source or addresses of the packets. In this scenario the user's SIP phones would communicate with a SIP proxy server to set up calls between SIP phones. Once the calls are set up RTP packets would be communicated directly between the phones through each user's NAT device.

The problem with this configuration is that the SIP headers and SDP lines in the SIP packets sent from the phones and received by the SIP proxy server would contain the private network addresses of the VoIP phones that would not be routable on the service provider network or on the Internet. One solution could be to for each customer to install and configure SIP aware NAT devices. If this is not possible, another solution requires implement hosted NAT traversal.

In a hosted NAT traversal (HNT) configuration (for example, see Figure 285), a FortiGate unit is installed between the NAT device and the SIP proxy server and configured with a VoIP profile that enables SIP hosted NAT traversal. Security policies that include the VoIP profile also support destination NAT using a firewall virtual IP. When the SIP phones connect to the SIP server IP address the security policy accepts the SIP packets, the virtual IP translates the destination addresses of the packets to the SIP server IP address, and the SIP ALG NAT traversal configuration translates the source IP addresses on the SIP headers and SDP lines to the source address of the SIP packets (which would be the external IP address of the NAT devices). The SIP server then sees the SIP phone IP address as the external IP address of the NAT device. As a result SIP and RTP media sessions are established using the external IP addresses of the NAT devices instead of the actual IP addresses of the SIP phones.

Figure 285: FortiGate SIP Hosted NAT Traversal configuration



Configuration example: Hosted NAT traversal for calls between SIP Phone A and SIP Phone B

The following address translation takes place to allow a SIP call from SIP Phone A to SIP Phone B in Figure 285.

1. SIP Phone A sends a SIP Invite message to the SIP server. Packet source IP address: 192.168.10.1, destination IP address: 10.21.101.10.
2. The SIP packets are received by the NAT device which translates the source address of the SIP packets from 192.168.10.1 to 10.11.101.20.
3. The SIP packets are received by the FortiGate unit which translates the packet destination IP address to 10.30 120.20. The SIP ALG also translates the IP address of the SIP phone in the SIP header and SDP lines from 192.168.10.1 to 10.11.101.20.
4. The SIP server accepts the Invite message and forwards it to SIP Phone B at IP address10.11.101.20. The SIP server has this address for SIP Phone B because SIP packets from SIP Phone B have also been translated using the hosted NAT traversal configuration of the SIP ALG.
5. When the SIP call is established, the RTP session is between 10.11.101.10 and 10.11.101.20 and does not pass through the FortiGate unit. The NAT devices translated the destination address of the RTP packets to the private IP addresses of the SIP phones.

General configuration steps

The following general configuration steps are required for this destination NAT SIP configuration. This example uses the default VoIP profile.

1 Add a VoIP profile that enables hosted NAT translation.

2 Add a SIP proxy server firewall virtual IP.

3 Add a firewall address for the SIP proxy server on the private network.

4 Add a destination NAT security policy that accepts SIP sessions from the Internet destined for the SIP proxy server virtual IP and translates the destination address to the IP address of the SIP proxy server on the private network.

5 Add a security policy that accepts SIP sessions initiated by the SIP proxy server and destined for the Internet.

Configuration steps - web-based manager

To add the SIP proxy server firewall virtual IP

1 Go to *Firewall Objects* > *Virtual IP* > *Virtual IP.*

2 Add the SIP proxy server virtual IP.

Name	SIP_Proxy_VIP
External Interface	port1
Type	Static NAT
External IP Address/Range	172.20.120.50
Mapped IP Address/Range	10.31.101.50

To add a firewall address for the SIP proxy server

1 Go to *Firewall Objects* > *Address*.

2 Add the following for the SIP proxy server:

Address Name	SIP_Proxy_Server
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.50/255.255.255.255
Interface	port2

To add the security policies

1 Go to *Policy* > *Policy* > *Policy*.

2 Add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	port2
Destination Address	SIP_Proxy_VIP
Schedule	always

Service	SIP
Action	ACCEPT
Enable NAT	Select
UTM	Select
Protocol Options	default
Enable VoIP	Select and select the default VoIP profile.

3 Select *OK*.

4 Add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

Source Interface/Zone	port2
Source Address	SIP_Proxy_Server
Destination Interface/Zone	port1
Destination Address	all
Schedule	always
Service	SIP
Action	ACCEPT
Enable NAT	Select
UTM	Select
Protocol Options	default
Enable VoIP	Select (And select the default VoIP profile)

5 Select *OK*.

Configuration steps - CLI

To add a VoIP profile that enables hosted NAT translation.

1 Enter the following command to add a VoIP profile named HNT that enables hosted NAT traversal. This command shows how to clone the default VoIP profile and enable hosted NAT traversal.

```
config voip profile
  clone default to HNT
  edit HNT
    config sip
      set hosted-nat-traversal enable
    end
end
```

To add the SIP proxy server firewall virtual IP and firewall address

2 Enter the following command to add the SIP proxy server firewall virtual IP.

```
config firewall vip
  edit SIP_Proxy_VIP
    set type static-nat
    set extip 10.21.101.10
    set mappedip 10.30.120.20
```

```
    set extintf port1
  end
```

3 Enter the following command to add the SIP proxy server firewall address.

```
config firewall address
  edit SIP_Proxy_Server
    set associated interface port2
    set type ipmask
    set subnet 10.30.120.20 255.255.255.255
  end
```

To add security policies

1 Enter the following command to add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone A to send SIP request messages to the SIP proxy server.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr SIP_Proxy_VIP
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set voip-profile HNT
  end
```

2 Enter the following command to add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B:

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr SIP_Proxy_Server
    set dstaddr all
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
  end
```

Hosted NAT traversal for calls between SIP Phone A and SIP Phone C

The following address translation takes place to allow a SIP call from SIP Phone A to SIP Phone C in Figure 285 on page 2581.

1 SIP Phone A sends a SIP Invite message to the SIP server. Packet source IP address: 192.168.10.1 and destination IP address: 10.21.101.10.

2 The SIP packets are received by the NAT device which translates the source address of the SIP packets from 192.168.10.1 to 10.11.101.20.

3 The SIP packets are received by the FortiGate unit which translates the packet destination IP address to 10.30 120.20. The SIP ALG also translates the IP address of the SIP phone in the SIP header and SDP lines from 192.168.10.1 to 10.11.101.20.

4 The SIP server accepts the Invite message and forwards it to SIP Phone C at IP address 172.20.120.30. The SIP server has this address for SIP Phone C because SIP packets from SIP Phone C have also been translated using the hosted NAT traversal configuration of the SIP ALG.

5 When the SIP call is established, the RTP session is between 10.11.101.10 and 172.20.120.30. The packets pass through the FortiGate unit which performs NAT as required.

Restricting the RTP source IP

Use the following command in a VoIP profile to restrict the RTP source IP to be the same as the SIP source IP when hosted NAT traversal is enabled.

```
config voip profile
  edit VoIP_HNT
    config sip
      set hosted-nat-traversal enable
      set hnt-restrict-source-ip enable
    end
end
```

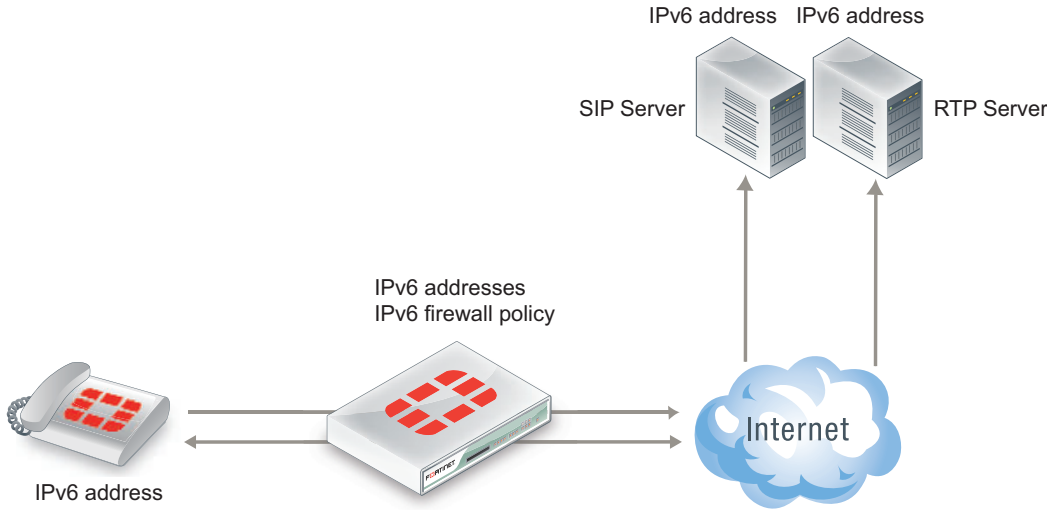
SIP over IPv6

FortiGate units operating in NAT/Route and in Transparent mode support SIP over IPv6. The SIP ALG can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGate units cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

In the scenario shown in Figure 286, a SIP phone connects to the Internet through a FortiGate unit operating. The phone and the SIP and RTP servers all have IPv6 addresses.

The FortiGate unit has IPv6 security policies that accept SIP sessions. The SIP ALG understands IPv6 addresses and can forward IPv6 sessions to their destinations. Using SIP application control features the SIP ALG can also apply rate limiting and other settings to SIP sessions.

Figure 286: SIP support for IPv6

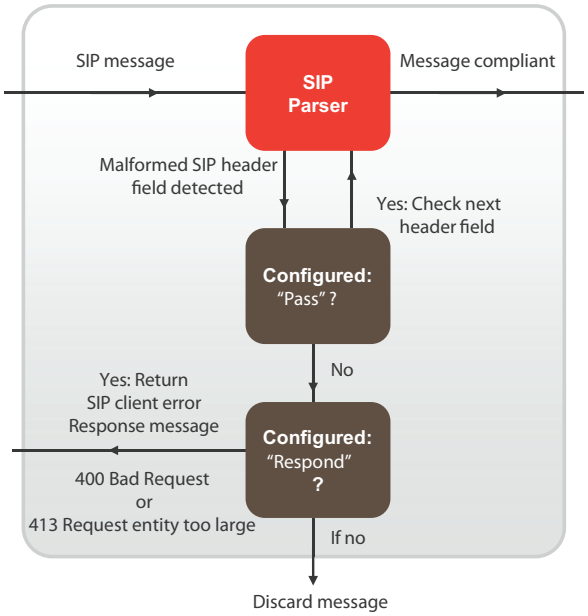


To enable SIP support for IPv6 add an IPv6 security policy that accepts SIP packets and includes a VoIP profile.

Deep SIP message inspection

Deep SIP message syntax inspection (also called Deep SIP header inspection or SIP fuzzing protection) provides protection against malicious SIP messages by applying SIP header and SDP profile syntax checking. SIP Fuzzing attacks can be used by attackers to discover and exploit vulnerabilities of a SIP entity (for example a SIP proxy server). Most often these attacks could crash or compromise the SIP entity.

Figure 287: Deep SIP message inspection



- **Checks the SIP request message Request-line**
- **Checks the following SIP header fields:**
  - **Allow, Call-id, Contact, Content-length, Content-type, CSeq, Expires, From, Max-Forwards, P-asserted-identity, Rack, Record-Route, Route, Rseq, To, Via**
- **Checks all SDP profile lines**
- **Configurable header and body length checks**
- **Optional logging of message violations**

Deep SIP message inspection checks the syntax of each SIP header and SDP profile line to make sure they conform to the syntax defined in the relevant RFC and IETF standard. You can also configure the SIP ALG to inspect for:

- Unknown SIP message types (message types not defined in a SIP RFC) this option is enabled by default and can be disabled. When enabled unknown message types are discarded. Configured using the `block-unknown` option.
- Unknown line types (message line types that are not defined in any SIP or SDP RFC). Configured using the `unknown-header` option.
- Messages that are longer than a configured maximum size. Configured using the `max-body-length` option.
- Messages that contain one or more lines that are longer that a set maximum line length (default 998 characters). Configured using the `max-line-length` option.

Actions taken when a malformed message line is found

When a malformed message line or other error is found the SIP ALG can be configured to discard the message containing the error, pass the message without any other actions, or responding to the message with a 400 Bad Request or 413 Request entity too large client error SIP response message and then discard the message. (For information about client error SIP response messages, see "Client error" on page 2529.)

If a message line is longer than the configured maximum, the SIP ALG sends the following message:

```
SIP/2.0 413 Request Entity Too Large, <optional_info>
```

If a message line is incorrect or in an unknown message line is found, the SIP ALG sends the following message:

```
SIP/2.0 400 Bad Request, <optional_info>
```

The `<optional_info>` provides more information about why the message was rejected. For example, if the SIP ALG finds a malformed Via header line, the response message may be:

```
SIP/2.0 400 Bad Request, malformed Via header
```

If the SIP ALG finds a malformed message line, and the action for this message line type is discard, the message is discarded with no further checking or responses. If the action is pass, the SIP ALG continues parsing the SIP message for more malformed message lines. If the action is respond, the SIP ALG sends the SIP response message and discards the message containing the malformed line with no further checking or response. If only malformed message line types with action set to pass are found, the SIP ALG extracts as much information as possible from the message (for example for NAT and opening pinholes, and forwards the message to its destination).

If a SIP message containing a malformed line is discarded the SIP ALG will not use the information in the message for call processing. This could result in the call being terminated. If a malformed line in a SIP message includes information required for the SIP call that the SIP ALG cannot interpret (for example, if an IP address required for SIP NAT is corrupted) the SIP ALG may not be able to continue processing the call and it could be terminated. Discarded messages are counted by SIP ALG static message counters.

Logging and statistics

To record a log message each time the SIP ALG finds a malformed header, enable logging SIP violations in a VoIP profile. In all cases, when the SIP ALG finds an error the FortiGate unit records a malformed header log message that contains information about the error. This happens even if the action is set to pass.

If, because of recording log messages for deep message inspection, the CPU performance is affected by a certain amount, the FortiGate unit records a critical log message about this event and stops writing log messages for deep SIP message inspection.

The following information is recorded in malformed header messages:

- The type of message line in which the error was found.
- The content of the message line in which the error was found (it will be truncated if it makes the log message too long)
- The column or character number in which the error was found (to make it easier to determine what caused the error)

Deep SIP message inspection best practices

Because of the risks imposed by SIP header attacks or incorrect data being allowed and because selecting drop or respond does not require more CPU overhead than pass you would want to set all tests to drop or respond. However, in some cases malformed lines may be less of a threat or risk. For example, the SDP i= does not usually contain information that is parsed by any SIP device so a malformed i= line may not pose a threat.

You can also used the pre-defined VoIP profiles to apply different levels of deep message inspection. The default VoIP profile sets all deep message inspection options to pass and the strict VoIP profile sets all deep message inspection options to discard. From the CLI you can use the `clone` command to copy these pre-defined VoIP profiles and then customize them for your requirements.

Configuring deep SIP message inspection

You configure deep SIP message inspection in a VoIP profile. All deep SIP message inspection options are available only from the CLI.

Enter the following command to configure deep SIP message inspection to discard messages with malformed Request-lines (the first line in a SIP request message):

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set malformed-request-line respond
    end
end
```

You cannot configure message inspection for the Status-line, which is the first line in a SIP response message.

Table 141 lists the SIP header lines that the SIP ALG can inspect and the CLI command for configuring the action for each line type. The table also lists the RFC that the header line is defined in.

Table 141: SIP header lines that the SIP ALG can inspect for syntax errors

SIP Header line	VoIP profile option	RFC
Allow	`malformed-header-allow`	RFC 3261
Call-ID	`malformed-header-call-id`	RFC 3261
Contact	`malformed-header-contact`	RFC 3261

Table 141: SIP header lines that the SIP ALG can inspect for syntax errors

SIP Header line	VoIP profile option	RFC
Content-Length	malformed-header-content-length	RFC 3261
Content-Type	malformed-header-content-type	RFC 3261
CSeq	malformed-header-cseq	RFC 3261
Expires	malformed-header-expires	RFC 3261
From	malformed-header-from	RFC 3261
Max-forwards	malformed-header-max-forwards	RFC 3261
P-Asserted-Identity	malformed-header-p-asserted-identity	RFC 3325
RAck	malformed-header-rack	RFC 3262
Record-Route	malformed-header-record-route	RFC 3261
Route	malformed-header-route	RFC 3261
RSeq	malformed-header-rseq	RFC 3262
To	malformed-header-to	RFC 3261
Via	malformed-header-via	RFC 3261

Table 142 lists the SDP profile lines that the SIP ALG inspects and the CLI command for configuring the action for each line type. SDP profile lines are defined by RFC 4566 and RFC 2327.

Table 142: SDP profile lines that the SIP ALG can inspect for syntax errors

Attribute	VoIP profile option
a=	malformed-header-sdb-a
b=	malformed-header-sdp-b
c=	malformed-header-sdp-c
i=	malformed-header-sdp-i
k=	malformed-header-sdp-k
m=	malformed-header-sdp-m
o=	malformed-header-sdp-o
r=	malformed-header-sdp-r
s=	malformed-header-sdp-s
t=	malformed-header-sdp-t
v=	malformed-header-sdp-v
z=	malformed-header-sdp-z

Discarding SIP messages with some malformed header and body lines

Enter the following command to configure deep SIP message inspection to discard SIP messages with a malformed Via line, a malformed route line or a malformed m= line but to pass messages with a malformed i= line or a malformed Max-Forwards line

```
config voip profile
  edit VoIP_Pro_Name
    config sip
```

```
      set malformed-header-via discard
      set malformed-header-route discard
      set malformed-header-sdp-m discard
      set malformed-header-sdp-i pass
      set malformed-header-max-forwards pass
    end
end
```

Discarding SIP messages with an unknown SIP message type

Enter the following command to discard SIP messages with an unknown SIP message line type as defined in all current SIP RFCs:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set unknown-header discard
    end
end
```

Discarding SIP messages that exceed a message size

Enter the following command to set the maximum size of a SIP message to 200 bytes. Messages longer than 200 bytes are discarded.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-body-length 200
    end
end
```

The `max-body-length` option checks the value in the SIP Content-Length header line to determine body length. The Content-Length can be larger than the actual size of a SIP message if the SIP message content is split over more than one packet. SIP message sizes vary widely. The size of a SIP message can also change with the addition of Via and Record-Route headers as the message is transmitted between users and SIP servers.

Discarding SIP messages with lines longer than 500 characters

Enter the following command to set the length of a SIP message line to 500 characters and to block messages that include lines with 500 or more characters:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-line-length 500
      set block-long-lines enable
    end
end
```

Blocking SIP request messages

You may want to block different types of SIP requests:

- to prevent SIP attacks using these messages.

- If your SIP server cannot process some SIP messages because of a temporary issue (for example a bug that crashes or compromises the server when it receives a message of a certain type).
- Your SIP implementation does not use certain message types.

When you enable message blocking for a message type in a VoIP profile, whenever a security policy containing the VoIP profile accepts a SIP message of this type, the SIP ALG silently discards the message and records a log message about the action.

Use the following command to configure a VoIP profile to block SIP CANCEL and Update request messages:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set block-cancel enable
      set block-update enable
    end
end
```

SIP uses a variety of text-based messages or requests to communicate information about SIP clients and servers to the various components of the SIP network. Since SIP requests are simple text messages and since the requests or their replies can contain information about network components on either side of the FortiGate unit, it may be a security risk to allow these messages to pass through.

Table 143 lists all of the VoIP profile SIP request message blocking options. All of these options are disabled by default.

Blocking SIP OPTIONS messages may prevent a redundant configuration from operating correctly. See "Supporting geographic redundancy when blocking OPTIONS messages" on page 2595 for information about resolving this problem.

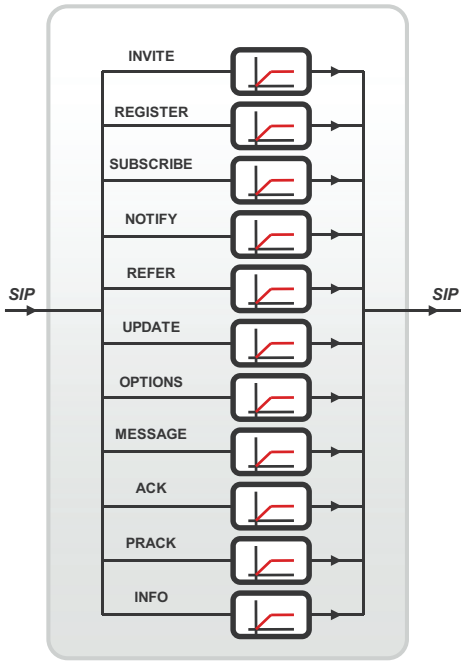
Table 143: Options for blocking SIP request messages

SIP request message	SIP message blocking CLI Option
ACK	block-ack
BYE	block-bye
Cancel	block-cancel
INFO	block-info
INVITE	block-invite
Message	block-message
Notify	block-notify
Options	block-options
PRACK	block-prack
Publish	block-publish
Refer	block-refer
Register	block-register
Subscribe	block-subscribe
Update	block-update

SIP rate limiting

Configurable threshold for SIP message rates per request method. Protects SIP servers from SIP overload and DoS attacks.

Figure 288: SIP rate limiting



- **SIP message rate limitation**
- **Individually configurable per SIP method**
- **When threshold is hit additional messages with this method will be discarded**
- **Prevents SIP server from getting overloaded by flash crowds or Denial-of-Service attacks.**
- **May block some methods at all** (with extra “block” option)
- **Can be disabled (unlimited rate)**

FortiGate units support rate limiting for the following types of VoIP traffic:

- Session Initiation Protocol (SIP)
- Skinny Call Control Protocol (SCCP) (most versions)
- Session Initiation Protocol for Instant Messaging and Presence Leveraging Extensions (SIMPLE).

You can use rate limiting of these VoIP protocols to protect the FortiGate unit and your network from SIP and SCCP Denial of Service (DoS) attacks. Rate limiting protects against SIP DoS attacks by limiting the number of SIP REGISTER and INVITE requests that the FortiGate unit receives per second. Rate limiting protects against SCCP DoS attacks by limiting the number of SCCP call setup messages that the FortiGate unit receives per minute.

You configure rate limiting for a message type by specifying a limit for the number of messages that can be received per second. The rate is limited per security policy. When VoIP rate limiting is enabled for a message type, if the a single security policy accepts more messages per second than the configured rate, the extra messages are dropped and log messages are written when the messages are dropped.

Use the following command to configure a VoIP profile to limit the number of INVITE messages accepted by each security policy that the VoIP profile is added to 100 INVITE messages a second:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set invite-rate 100
    end
```

```
end
```

If you are experiencing denial of service attacks from traffic using these VoIP protocols, you can enable VoIP rate limiting and limit the rates for your network. Limit the rates depending on the amount of SIP and SCCP traffic that you expect the FortiGate unit to be handling. You can adjust the settings if some calls are lost or if the amount of SIP or SCCP traffic is affecting FortiGate unit performance.

Table 144 lists all of the VoIP profile SIP rate limiting options. All of these options are set to 0 so are disabled by default.

Table 144: Options for SIP rate limiting

SIP request message	Rate Limiting CLI Option
ACK	ack-rate
BYE	bye-rate
Cancel	cancel-rate
INFO	info-rate
INVITE	invite-rate
Message	message-rate
Notify	notify-rate
Options	options-rate
PRACK	prack-rate
Publish	publish-rate
Refer	refer-rate
Register	register-rate
Subscribe	subscribe-rate
Update	update-rate

Limiting the number of SIP dialogs accepted by a security policy

In addition to limiting the rates for receiving SIP messages, you can use the following command to limit the number of SIP dialogs (or SIP calls) that the FortiGate unit accepts.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-dialogs 2000
    end
end
```

This command sets the maximum number of SIP dialogs that can be open for SIP sessions accepted by any security policy that you add the VoIP profile to. The default setting of 0 does not limit the number of dialogs. You can add a limit to control the number of open dialogs and raise and lower it as required. You might want to limit the number of open dialogs for protection against SIP-based attackers opening large numbers of SIP dialogs. Every dialog takes memory and FortiGate CPU resources to process. Limiting the number of dialogs may improve the overall performance of the FortiGate unit. Limiting the number of dialogs will not drop calls in progress but may prevent new calls from connecting.

SIP logging and DLP archiving

You can enable SIP logging and logging of SIP violations, and SIP DLP archiving a VoIP profile. To record SIP log messages you must also enable VoIP event logging in the FortiGate unit event logging configuration.

To view SIP log messages go to *Log&Report* > *Log Access* > *Event*.

To view SIP DLP archive messages to go *Log&Report* > *Archive Access* > *VoIP*.

Use the following command enable SIP logging, SIP archiving, and logging of SIP violations in a VoIP profile:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set log-call-summary enable
      set log-violations enable
    end
end
```

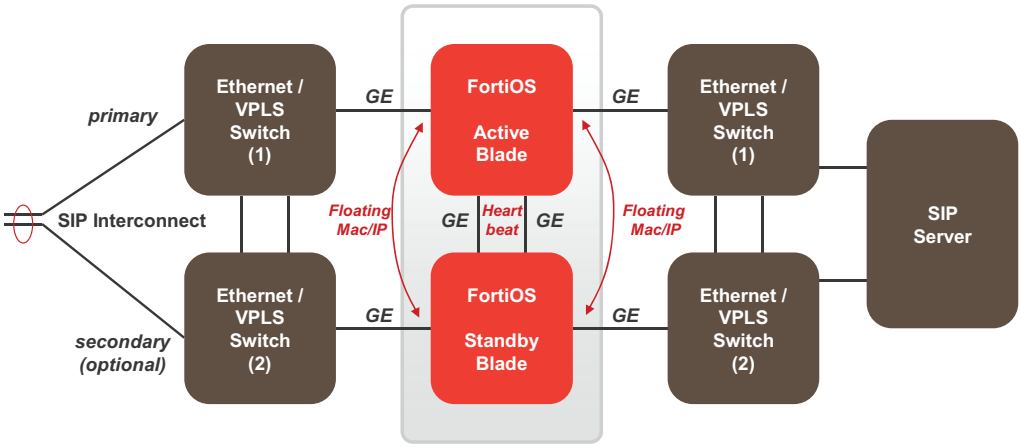
SIP and HA: session failover and geographic redundancy

FortiGate high availability supports SIP session failover (also called stateful failover) for active-passive HA. To support SIP session failover, create a standard HA configuration and select the Enable Session Pick-up option.

SIP session failover replicates SIP states to all cluster units. If an HA failover occurs, all in progress SIP calls (setup complete) and their RTP flows are maintained and the calls will continue after the failover with minimal or no interruption.

SIP calls being set up at the time of a failover may lose signaling messages. In most cases the SIP clients and servers should use message retransmission to complete the call setup after the failover has completed. As a result, SIP users may experience a delay if their calls are being set up when an HA a failover occurs. But in most cases the call setup should be able to continue after the failover.

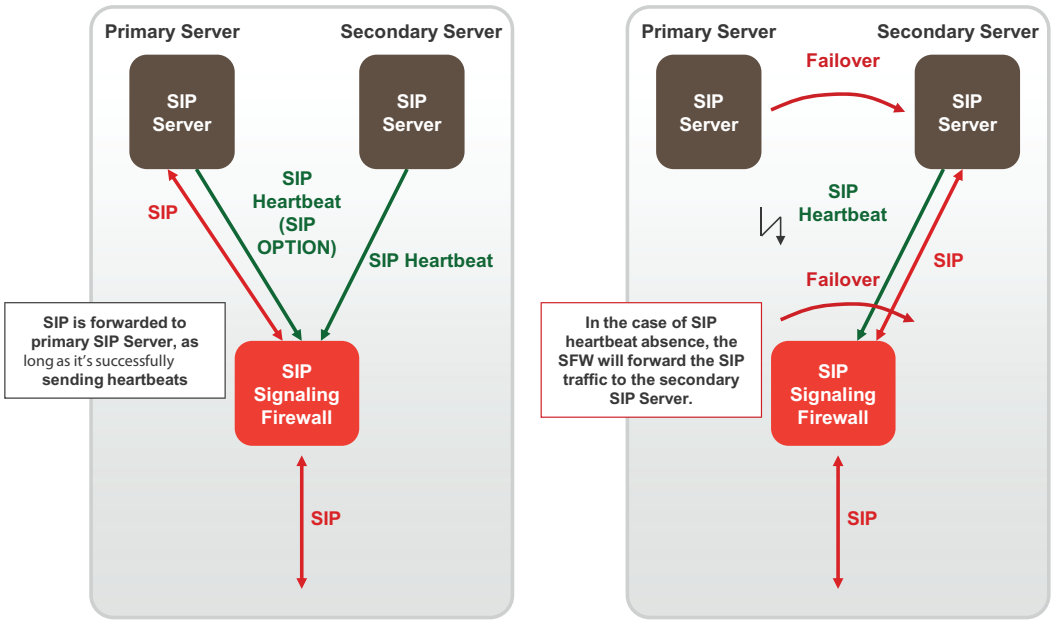
Figure 289: SIP HA session failover



SIP geographic redundancy

Maintains a active-standby SIP server configuration, which even supports geographical distribution. If the active SIP server fails (missing SIP heartbeat messages or SIP traffic) FortiOS will redirect the SIP traffic to a secondary SIP server.

Figure 290: SIP geographic redundancy



Supporting geographic redundancy when blocking OPTIONS messages

For some geographic redundant SIP configurations, the SIP servers may use SIP OPTIONS messages as heartbeats to notify the FortiGate unit that they are still operating (or alive). This is a kind of passive SIP monitoring mechanism where the FortiGate unit isn't actively monitoring the SIP servers and instead the FortiGate unit passively receives and analyzes OPTIONS messages from the SIP servers.

If FortiGate units block SIP OPTIONS messages because `block-options` is enabled, the configuration may fail to operate correctly because the OPTIONS messages are blocked by one or more FortiGate units.

However, you can work around this problem by enabling the `block-geo-red-options` application control list option. This option causes the FortiGate unit to refresh the local SIP server status when it receives an OPTIONS message before dropping the message. The end result is the heartbeat signals between geographically redundant SIP servers are maintained but OPTIONS messages do not pass through the FortiGate unit.

Use the following command to block OPTIONS messages while still supporting geographic redundancy:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set block-options disable
      set block-geo-red-options enable
    end
```

```
end
```

The `block-options` option setting overrides the `block-geo-red-options` option. If `block-options` is enabled the FortiGate unit only blocks SIP OPTIONS messages and does not refresh local SIP server status.

Support for RFC 2543-compliant branch parameters

RFC 3261 is the most recent SIP RFC, it obsoletes RFC 2543. However, some SIP implementations may use RFC 2543-compliant SIP calls.

The `rfc2543-branch` VoIP profile option allows the FortiGate unit to support SIP calls that include an RFC 2543-compliant branch parameter in the SIP Via header. This option also allows FortiGate units to support SIP calls that include Via headers that are missing the branch parameter.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set rfc2543-branch enable
    end
end
```

SIP and IPS

You can enable IPS in security policies that also accept SIP sessions to protect the SIP traffic from SIP-based attacks. If you enable IPS in this way then by default the pinholes that the SIP ALG creates to allow RTP and RTCP to flow through the firewall will also have IPS enabled.

This inheritance of the IPS setting can cause performance problems if the RTP traffic volume is high since IPS checking may reduce performance in some cases. Also if you are using network processor (NP) interfaces to accelerate VoIP performance, when IPS is enabled for the pinhole traffic is diverted to the IPS and as a result is not accelerated by the network processors.

You can use the following CLI command to disable IPS for the RTP pinhole traffic.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set ips-rtp disable
    end
end
```

SIP debugging

SIP debug log format

Assuming that `diagnose debug console timestamp` is enabled then the following shows the debug that is generated for an INVITE if `diag debug appl sip -1` is enabled:

```
2010-01-04 21:39:59 sip port 26 locate session for 192.168.2.134:5061 ->

```

SIP-proxy filter per VDOM

You can use the `diagnose sys sip-proxy xxx` command in a VDOM to get info about how SIP is operating in each VDOM.

SIP-proxy filter command

Use the `diagnose system sip-proxy filter` to filter diagnose information for the SIP ALG. The following filters are available:

```
diag sys sip-proxy filter vd
diag sys sip-proxy filter dst-addr4
diag sys sip-proxy filter dst-addr6
diag sys sip-proxy filter dst-port
diag sys sip-proxy filter identity-policy
diag sys sip-proxy filter negate
diag sys sip-proxy filter policy
diag sys sip-proxy filter policy-type
diag sys sip-proxy filter profile-group
diag sys sip-proxy filter src-addr4
diag sys sip-proxy filter src-addr6
diag sys sip-proxy filter src-port
diag sys sip-proxy filter vd
diag sys sip-proxy filter voip-profile
```

You can clear, view and negate/invert the sense of a filter using these commands:

```
diag sys sip-proxy filter clear
diag sys sip-proxy filter list
diag sys sip-proxy filter negate
```

SIP debug log filtering

You can filter by VDOM/IP/PORT and by policy and VoIP profile. The filtering can be controlled by:

```
diagnose system sip-proxy log-filter
```

The list of filters is:

```
diag sys sip-proxy log-filter vd
diag sys sip-proxy log-filter dst-addr4
diag sys sip-proxy log-filter dst-addr6
diag sys sip-proxy log-filter dst-port
diag sys sip-proxy log-filter identity-policy
diag sys sip-proxy log-filter policy
diag sys sip-proxy log-filter policy-type
diag sys sip-proxy log-filter profile-group
diag sys sip-proxy log-filter src-addr4
diag sys sip-proxy log-filter src-addr6
diag sys sip-proxy log-filter src-port
diag sys sip-proxy log-filter vd
diag sys sip-proxy log-filter voip-profile
```

You can clear, view and negate/invert the sense of a filter using these commands:

```
diag sys sip-proxy log-filter clear
diag sys sip-proxy log-filter list
diag sys sip-proxy log-filter negate
```

SIP debug setting

Control of the SIP debug output is governed by the following command

```
diagnose debug application sip <debug_level_int>
```

Where the `<debug_level_int>` is a bitmask and the individual values determine whether the listed items are logged or not. The `<debug_level_int>` can be

1 - configuration changes. Mainly addition/deletion/modification of virtual domains.

2 - (TCP) connection accepts or connects, redirect creation

4 - create or delete a session

16 - any IO read or write

32 - an ASCII dump of all data read or written

64 - Include HEX dump in the above output

128 - any activity related to the use of the FortiCarrier dynamic profile feature to determine the correct profile-group to use

256 - log summary of interesting fields in a SIP call

1024 - any activity related to SIP geo-redundancy.

2048 - any activity related to HA syncing of SIP calls.

SIP test commands

Use the following command to control or inspect the behavior of the SIP ALG.

```
diagnose test application sip <test_level_int>
```

Where `<test_level_int>` can be

1 - Display memory statistics summary

2 - Display all memory statistics

3 - Display debug consoles

4 - Display all SIP redirects

20 - Display SIP per-policy configurations

21 - Display SIP VoIP profiles

22 - Display SIP meters

23 - Display SIP VIPs

24 - Display SIP RTP policies

30 - Display SIP stats summary

31 - Display per VDOM SIP stats

50 - Display all SIP idle calls

51 - Display all SIP sessions

70 - Start measuring scheduler times

71 - Stop measuring scheduler times

72 - Display scheduler times

99 - Restart SIP -- this will drop all SIP calls as well as all IM and SCCP

Display SIP rate-limit data

You can use the `diagnose sys sip-proxy meters` command to display SIP rate limiting data.

For the following command output `rate 1` shows that the current (over last second) measured rate for INVITE/ACK and BYTE was 1 per second, the `peak 1` shows that the peak rate recorded is 1 per second, the `max 0` shows that there is no maximum limit set, the `count 18` indicates that 18 messages were received and `drop 0` indicates that none were dropped due to being over the limit.

```
diag sys sip-proxy meters
```

```
sip
sip vd: 0
sip policy: 1
sip identity-policy: 0
sip policy-type: IPv4
sip profile-group:
sip dialogs: 18
sip dialog-limit: 0
sip UNKNOWN:  rate 0  peak 0  max 0  count 0  drop 0
sip ACK:  rate 1  peak 1  max 0  count 18  drop 0
sip BYE:  rate 1  peak 1  max 0  count 18  drop 0
sip CANCEL:  rate 0  peak 0  max 0  count 0  drop 0
sip INFO:  rate 0  peak 0  max 0  count 0  drop 0
sip INVITE:  rate 1  peak 1  max 0  count 18  drop 0
sip MESSAGE:  rate 0  peak 0  max 0  count 0  drop 0
sip NOTIFY:  rate 0  peak 0  max 0  count 0  drop 0
sip OPTIONS:  rate 0  peak 0  max 0  count 0  drop 0
sip PRACK:  rate 0  peak 0  max 0  count 0  drop 0
sip PUBLISH:  rate 0  peak 0  max 0  count 0  drop 0
sip REFER:  rate 0  peak 0  max 0  count 0  drop 0
sip REGISTER:  rate 0  peak 0  max 0  count 0  drop 0
sip SUBSCRIBE:  rate 0  peak 0  max 0  count 0  drop 0
sip UPDATE:  rate 0  peak 0  max 0  count 0  drop 0
sip PING:  rate 0  peak 0  max 0  count 0  drop 0
sip YAHOOREF:  rate 0  peak 0  max 0  count 0  drop 0
```

VoIP Profile options

The following are VoIP profile configuration settings in *UTM Profiles* > *VoIP* > *Profile*.

Profile page

Lists the profiles that you created for SIP and SCCP protocols. On this page, you can edit, delete or create a new profile for VoIP protocols.

You are redirected to this page when you select *View List* on the Edit VoIP Profile page.

Create New	Creates a new VoIP profile. When you select *Create New*, you are automatically redirected to the New VoIP Profile page.
Edit	Modifies settings within a VoIP profile. When you select *Edit*, you are automatically redirected to the Edit VoIP Profile page.
Delete	Removes a VoIP profile from the list on the Profile page. To remove multiple VoIP profiles from within the list, on the Profile page, in each of the rows of the profiles you want removed, select the check box and then select *Delete*. To remove all VoIP profiles from the list, on the Profile page, select the check box in the check box column and then select *Delete*.
Name	The name of the profile.
Comments	A description about the profile. This is an optional setting.
Ref.	Displays the number of times the VoIP is referenced to other objects.

New VoIP Profile page

Provides settings for configuring SIP and SCCP options within the profile.

This page appears when you select *Create New* on the Edit VoIP Profile page. If you are on the Profile page, and you select *Create New*, you will be redirected to the New VoIP Profile page.

Name	Enter a name for the profile.
Comments	Enter a description about the profile. This is optional.
SIP	Configuration settings for SIP protocols.
Limit REGISTER requests	Enter a number for limiting the time it takes to register requests.
Limit INVITE requests	Enter a number to limit invitation requests.
SCCP	Configuration settings for SCCP protocols.
Limit Call Setup	Enter a number to limit call setup time.

Example FortiGate Voice branch office configuration

This section describes how to configure a FortiGate Voice-80C unit to operate in NAT/Route mode and provide basic UTM and SIP services for the example branch office network shown in Figure 291 on page 2604. The non-PSTN parts of this example configuration also apply to FortiGate Voice models that do not include PSTN interfaces.

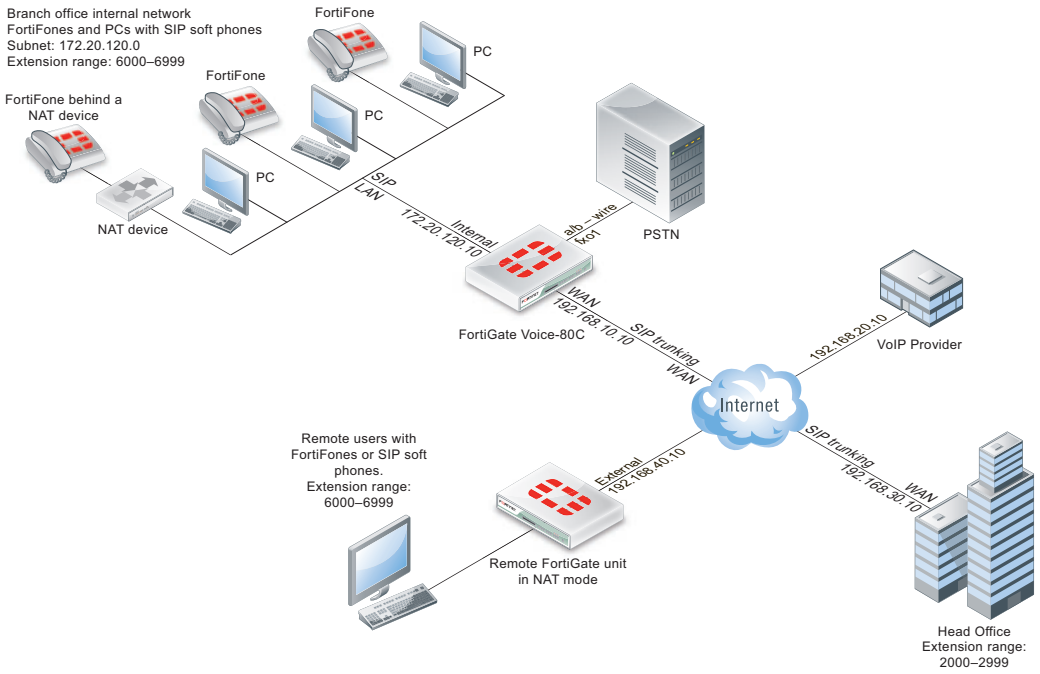
In this example the FortiGate Voice-80C unit provides:

- Internet connectivity, networking, and UTM features for the PCs on the branch office internal network.
- A single line a/b wire connection between the FortiGate Voice-80C fxo1 interface and a public switched telephone network (PSTN) line so that branch office phones can call the PSTN or receive calls from the PSTN.
- VoIP PBX services for FortiFones and SIP soft phones connected to the branch office internal network. PBX features include:
  - Extensions to the FortiFones and SIP soft phones in the internal network. The branch office phones use four digit numeric extensions that begin with the number 6. Example valid extensions are 6123, 6456, and 6899.
  - Extensions for phones behind NAT devices on the internal network.
  - Extensions for phones behind NAT devices on a remote network.
  - To collect voicemail the branch office phones dial *97.
  - Configure the Voice Menu to program the IP phone keys for various things such as recording a custom welcome message, providing access to company directory and adding a shortcut for checking voicemail.
  - SIP trunking to a VoIP provider for calling the head office.
  - To call a phone number on the PSTN from a branch office phone, dial 9 followed by the phone number. PSTN support includes:
    - Dialing 911 for emergencies
    - Support for dialing international calls
    - Support for dialing toll-free calls
    - Support for long distance calls
  - The FortiGate Voice unit sends email notifications to users when they receive voicemail.
  - To call the head office, the branch office phones dial a head office extension directly. The head office extension range is 2000-2999.

This configuration example describes configuring the FortiGate Voice-80C unit to support these services and where required also provides configuration steps for other devices such as the FortiFones and the remote FortiGate unit operating in NAT mode.

Details about the PSTN connection requirements, SIP trunking for the VoIP provider and the Head Office SIP configuration are not described.

Figure 291: Example Branch Office network configuration



This section describes:

- General configuration steps
- Connecting the FortiGate Voice unit
- Configuring basic FortiGate Voice network and UTM settings
- Configuring network settings for the devices on the Internal network
- Configuring the FortiGate Voice PSTN and PBX settings
- Configuring the FortiFones on the internal network
- Adding extensions and configuring FortiFones for users behind a NAT device
- FortiGate Voice IVR configuration
- Providing access to the company directory
- Adding a shortcut for checking voicemail

General configuration steps

1. Connect the FortiGate Voice unit to the Internet, the internal network and the PSTN.
2. Configure FortiGate Voice unit network and UTM settings.

   The network configuration includes enabling the *SIP Traffic* option on the internal and wan1 interfaces. You must enable SIP traffic on these interfaces to accept and process SIP calls. No other special network configuration, firewall policies, or routing is required for the FortiGate Voice to accept and process SIP calls.

You do not have to add SIP firewall policies to enable SIP traffic for the FortiGate Voice unit to function as a PBX. Also, with PBX functionality enabled, you cannot apply FortiGate SIP application control features to SIP traffic received by FortiGate Voice interfaces for which you have enabled the *SIP Traffic* option.

This example also describes how to configure the FortiGate Voice as a DHCP server and DNS server for the branch office internal network. As a DHCP server, the FortiGate Voice unit can supply network configuration settings for the PCs and FortiFones on the internal network.

3 Configure network settings for the PCs on the internal network.

4 Configure the FortiGate Voice PSTN and PBX settings.

5 Configure the FortiFones on the internal network.

6 Configure the FortiGate Voice unit to SIP phone users behind a remote NAT device.

Connecting the FortiGate Voice unit

The following procedure describes how to connect the FortiGate Voice unit to the Internet, the branch office internal network, and the PSTN (supported by some FortiGate Voice models).

To connect the FortiGate Voice unit

1 Use an Ethernet cable to connect the FortiGate Voice wan1 interface to the device that connects the branch office to the Internet.

The device could be a cable or DSL modem or other device depending on how the Branch Office connects to the Internet.

2 Use Ethernet cables to connect the PCs and FortiFones on the internal network to the FortiGate Voice internal interface switch connectors.

You can connect up to 8 PCs and FortiFones directly to the FortiGate Voice Internal interface switch connectors. To connect more devices, add Ethernet switches to your network as required.

3 Use an RJ-45 telephone cable to connect the FortiGate Voice fxo1 port to the branch office PSTN phone line supplied by your local telephone service provider.

Configuring basic FortiGate Voice network and UTM settings

The following procedures describe how to configure a FortiGate Voice to provide basic Internet connectivity, network services, and UTM services for the branch office internal network. Network services include configuring the FortiGate Voice to be the DHCP server and DNS server for the internal network.

As part of the FortiGate Voice network interface configuration you must enable *SIP Traffic* on the internal and wan1 interfaces so that the FortiGate Voice unit accepts SIP sessions received by these interfaces. No other special network configuration, firewall policies, or routing is required for the FortiGate Voice to accept SIP sessions from configured extensions.

To configure basic network settings

1 Connect to the FortiGate Voice web-based manager.

2 Go to *System* > *Network* > *Interface*.

3 Edit the *internal* interface and configure the following settings:

Addressing Mode	Manual
IP/Netmask	172.20.120.10/255.255.255.0
Enable DNS Query	Select *Enable DNS Query* then select *recursive* from the drop-down menu.
SIP Traffic	Select Enable

Configure other network interface settings as required and select OK.

The procedure "To configure the FortiGate Voice to be a DHCP server for the internal network" on page 2606 describes how to configure the FortiGate DHCP server to configure PCs on the internal network to use the FortiGate Voice internal interface as a DNS server.

4 Edit the *wan1* interface and configure the following settings:

Addressing Mode	Manual
IP/Netmask	192.168.10.10/255.255.255.0
SIP Traffic	Select Enable

Configure other network interface settings as required and select OK.

You can also set the *Addressing mode* to *DHCP* or *PPPoE* for the wan1 interface depending on the requirements of your ISP. In the example the wan1 interface has a static IP address.

5 Go to *System* > *Network* > *Options*.

6 Add the IP addresses of the primary and secondary DNS servers used by the branch office provided by your ISP.

7 Select Apply.

8 Go to *Router* > *Static* > *Static Route*.

9 Edit the default static route and configure the following settings:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	wan1
Gateway	Enter the IP address of the default gateway provided by your ISP.
Distance	10

10 Select OK.

To configure the FortiGate Voice to be a DHCP server for the internal network

Use this procedure to add a new DHCP server for the internal network or to change the configuration of the default FortiGateVoice DHCP server. The DHCP server will give PCs on the Internal network IP addresses in the range 172.20.120.110 to 172.20.120.210 and set their default gateway and DNS server to the IP address of the FortiGate Voice internal interface.

1 Go to *System* > *DHCP* > *Service*.

2 Select the *Create New*.

If a DHCP server has already been added for the internal interface, select the Edit icon to change its configuration.

3 Configure the following settings.

Interface Name	internal
Mode	Server
Enable	Select
Type	Regular
IP Range	172.20.120.110 - 172.20.120.210
Network Mask	255.255.255.0
Default Gateway	172.20.120.10
DNS Service	Specify
DNS Server 0	172.20.120.10

4 Change other settings if required and select OK.

To configure FortiGuard services for the FortiGate Voice unit

Use the following procedure to configure the FortiGate Voice unit to connect to the FortiGuard Distribution Network (FDN) to update the antivirus, antispam and IPS attack definitions. Before you can begin receiving updates, you must register the FortiGate Voice unit from the Fortinet Support web site. For more information, see "Registering your Fortinet product" on page 3040.

1 Go to *System* > *Maintenance* > *FortiGuard*.

2 Select the expand arrow for *AntiVirus and IPS Options* to expand the options.

3 Select *Update Now* to update the FortiGuard services and definitions.

If the connection to the FDN is successful, the web-based manager displays a message similar to the following:

```
Your update request has been sent. Your database will be updated
   in a few minutes. Please check your update page for the
   status of the update.
```

After a few minutes, if an update is available, the FortiGuard page lists new version information for the FortiGate services and definitions. The system dashboard license information widget also displays new dates and version numbers for the FortiGuard definitions. Messages are recorded to the event log indicating whether the update was successful or not.

To configure basic Internet access and UTM features

This procedure describes how to add a firewall policy that allows users on the internal network to connect to the Internet with antivirus protection. This configuration is not required for VoIP support. It just provides users on the internal network with UTM-protected access to the Internet.

1 Go to *Firewall* > *Policy* and select *Create New* to add a new firewall policy.

2 Configure the following settings.

Source Interface/Zone	internal
Source Address	all

Destination Interface/Zone	wan1
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT

3 Select UTM and Select Enable Antivirus.

4 Select Create New from the drop-down menu.

5 Customize the antivirus profile and select OK to apply UTM virus scanning to the traffic accepted by the firewall policy.

6 Select OK to save the firewall policy.

Configuring network settings for the devices on the Internal network

You can configure the PCs and other devices on the internal network to get their network configuration automatically using DHCP. If required you can also configure devices on the internal network with static IP addresses on the 172.20.120.0 subnet but outside the range awarded by the FortiGate Voice DHCP server. Example static TCP/IP configuration:

IP Address	172.20.120.20
Subnet Mask	255.255.255.0
Default Gateway	172.20.120.10
DNS Server	172.20.120.10

You can also use the same network configuration for the SIP phones on the internal network.

Configuring the FortiGate Voice PSTN and PBX settings

The procedures in this section describe how to configure the FortiGate Voice unit as the PBX for SIP phones on the branch office internal network. These procedures describe how to configure many of the FortiGate Voice PSTN and PBX features. PSTN features are supported on some FortiGate Voice models. The following procedures are included:

- To configure the fxo1 PSTN interface
- To configure basic PBX system and voicemail notification settings
- To add a VoIP provider
- To add a dial plan for dialing the PSTN and the main office
- To add the extensions that are on the branch office internal network

To configure the fxo1 PSTN interface

This procedure describes how to configure the FortiGate Voice fxo1 PSTN interface to connect the FortiGate Voice unit to one PSTN phone line. If you have more PSTN phone lines you can connect and configure more fxo interfaces. Skip this procedure if your FortiGate Voice unit does not include PSTN interfaces.

1 Go to *PBX* > *Service Providers* > *PSTN Interface* and edit the fxo1 interface.

2 Configure the following settings.

Phone Number	Enter the phone number of the PSTN phone line as provided by your phone service provider. The phone number is used for caller ID for calls from the FortiGate Voice unit to the PSTN. It can be any number, but is usually the actual phone number of the PSTN line connected to the fxo1 interface. Area code and country codes are optional.
Display Name	This name is used for caller ID for calls from the FortiGate Voice unit to the PSTN. It can be any name, such as a company name, that identifies the branch office.
Caller ID Options	Configure the following options to support caller ID functions for calls from the internal network to the PSTN.
Catch Caller ID	Select to enable the FortiGate Voice unit to receive caller ID information from calls originating on the PSTN and send the caller ID information to the extension that answers the call.
Caller ID Protocol	Select the caller ID protocol required by PSTN line that the fxo interface is connected to. Contact your service provider for the name of the protocol to use.
Caller ID Indicator	Select the caller ID indicator required by the PSTN line. Contact your service provider for details.
Ring #	Set the number of rings to wait before receiving caller ID information. In most cases, enter 1 to send caller ID information between the first and second ring. Contact your service provider for details.
Hang-up Options	Configure the following options to configure how the FortiGate Voice unit hangs up calls from the PSTN.
Hang up on Polarity Reversal	Select if the PSTN line uses polarity reversal to indicate a call has been hung up. Contact your service provider for details.
Hang up on Busy Tone	Select if you want the FortiGate Voice unit to hang up automatically when it receives a busy tone when attempting to dial a number on the PSTN.
Busy Tone Detection #	The number of busy tones that the FortiGate Voice receives before hanging up if *Hang up on Busy Tone* is selected.

Busy Tone Duration	Tune the FortiGate Voice unit to accurately detect busy tones on this PSTN line. You can change the default settings if busy tones are not accurately detected.
Busy Tone Interval	
Administrative Status	Set to *Up* if the fxo interface is connected to the PSTN and you want to be able to receive and send calls on this PSTN interface.

3 Select OK.

To configure basic PBX system and voicemail notification settings

Use the following procedure to configure PBX system settings and voicemail notification email settings that affect the overall performance of the PBX service and all of the users of it. Usually you would configure these settings once and rarely thereafter.

1 Go to *PBX* > *Calling Rules* > *Setting*.

2 Configure the following settings.

Extension Pattern	Select *Other* and enter 6XXX The example extension range means that every extension added to the FortiGate Voice unit must be a four digit number starting with a 6.
Country/Area	Select the country from the drop-down menu.
Country Code	Enter the international country calling code for the country or region in which you are installing the FortiGate Voice unit.
Local Area Code	Enter the local area code for the country or region in which you are installing the FortiGate Voice unit.
Voicemail Access	*97 Phone users on the internal network can dial *97 to get their voicemail.
Outgoing Prefix	9 Phone users must dial 9 to get an outside line. The outgoing prefix should not be the same as the first number of the extension range.
Max Voicemail Duration	60 seconds Limits a single voicemail message to 60 seconds.

3 Select Apply to save the changes.

4 Go to *Log&Report* > *Log Config* > *Alert E-mail*.

5 Configure the following settings.

SMTP Server	The name or IP address of an email server that the FortiGate Voice unit can send email notifications to when PBX users receive a voicemail. For example: *mail.example.com*. You can optionally create an email account on the email server for the FortiGate Voice unit.
Email from	Enter the email address that the alert email messages will come from.

Email to	Enter up to three email address recipients for alert email message.
Authentication	Select if the email server requires authentication.
SMTP User	Enter a valid username for an account on the email server.
Password	Enter the password for the account on the email sever.

6 Select Apply to save the changes.

To add a VoIP provider

Use the following procedure to add the information required by the FortiGate Voice unit to use a VoIP provider for routing SIP calls on the main office. In the example, the organization uses a third-party VoIP provider to handle VoIP calls between the head office and the branch office.

1 Go to *PBX* > *Service Providers* > *SIP Trunk*.

2 Select *Create New*.

3 Configure the following settings.

Name	VoIP_Provider_1 A name for the VoIP provider. This can be any name.
Domain	192.168.20.10 The VoIP provider's IP address. This could also be the VoIP providers domain name (for example, voip.example.com).
User Name	Enter a valid user name for an account on the VoIP provider's server. This could also be a phone number including area code, depending on the requirements of the VoIP provider.
Password	Enter the password for the account on the VoIP provider's SIP sever.
Authorization User Name	Enter a valid authorization user name for an account on the VoIP provider's server if required by the VoIP provider.
Display User Name	Enter a valid display user name for an account on the VoIP provider's server if required by the VoIP provider.
Account Type	Select Static or Dynamic depending on the account with the VoIP provider.
Registration Interval	If this is a dynamic account with the VoIP provider, enter the registration interval as required by the VoIP provider. After each registration interval the FortiGate Voice renews the registration of the account with the VoIP provider.
DTMF Method	Auto Auto means the VoIP provider's server and the FortiGate Voice unit will negotiate to select a DTMF method. You could also select a specific DTMF method if required.

4 Select OK to add the VoIP provider.

To add a dial plan for dialing the PSTN and the main office

Dial plans are used to route calls made from an extension to an external phone system. The external phone system can be the PSTN or a VoIP provider. To route calls to an external phone system you add dial plan rules that include a dial pattern and list of outgoing destinations. When the FortiGate Voice unit receives a call from an extension and the number dialed matches a pattern in a dial plan rule, the FortiGate Voice unit routes the call to the outgoing destination added to the dial plan.

In addition to PSTN and head office support, the dial plan must also support emergency, international, toll free and long distance dialing.

Use the following steps to add a dial plan with the following dial plan rules:

- Allows the branch office to call the PSTN
  - Dialing 911 for emergencies
  - Dialing 9 followed by a country code for international calls
  - Dialing 9 followed by 18 for toll free calls
  - Dialing 9 followed by 1 for long distance calls
  - Dialing 9 for all other PSTN calls
- Allows the branch office to dial head office extensions directly. The dial plan rule sends calls starting with 2 to the VoIP provider where they are routed to the head office. This dial plan does not include any other settings because users dial the head office extension number directly without a prefix.

1 Go to *PBX* > *Calling Rules* > *Dial Plan* and select *Create New*.

2 Add a name for the new dial plan, for example, *Dial_Plan_1*.

3 Select OK.

4 Select *Create New* to add the dial plan rule for dialing 911 for emergencies.

Name	Emergency
Use Default Outgoing Prefix (“9”)	Not selected
Phone number Begin with	911
Action	Allow
Outgoing Selected	PSTN - fxo1

5 Select *Create New* to add the dial plan rule for dialing 9 followed by a country code for international calls.

Name	International
Use Default Outgoing Prefix (“9”)	Selected
Phone number Begin with	011
Action	Block

6 Select *Create New* to add the dial plan rule for dialing 9 followed by 18 for toll free calls.

Name	Toll_Free
Use Default Outgoing Prefix (“9”)	Selected
Phone number Begin with	18
Action	Allow
Outgoing Selected	PSTN - fxo1

7 Select *Create New* to add the dial plan rule for dialing 9 followed by 1 for long distance calls.

Name	Long_Distance
Use Default Outgoing Prefix (“9”)	Selected
Phone number Begin with	1
Action	Allow
Outgoing Selected	PSTN - fxo2

8 Select *Create New* to add the dial plan rule for dialing 9 for all other PSTN calls.

Name	Other_PSTN_Numbers
Use Default Outgoing Prefix (“9”)	Selected
Action	Allow
Outgoing Selected	Move *PSTN - fxo1* to the *Selected* list to send calls to the PSTN out the fxo1 interface.

9 Select *Create New* to add the dial plan rule for dialing the Head Office.

Name	Head_Office_Dial_Rule
Use Default Outgoing Prefix (“9”)	Deselect.
Phone number Begin with	2 Indicates that outgoing calls to the Head Office must start with a 2.
Action	Allow
Outgoing	Move *VoIP - VoIP_Provider_1* to the *Selected* list to send calls to the PSTN out the fxo1 interface.

10 Select OK.

To add the extensions that are on the branch office internal network

Use the following steps to add extensions to the FortiGate Voice unit for the IP phones that are to be connected to the internal network. You add identifying information to each extension entry. The IP phone must be configured with identifying information that matches an entry in the extension list in order to get an extension from the FortiGate Voice unit. Extension numbers are independent of the IP address of the IP phone.

1 Go to *PBX* > *Extension* > *Extension* and select *Create New*.

2 Configure the following settings to add extension 6001.

Extension	6001
Password	The SIP phone user password for the phone assigned to this extension. For a FortiFone on the internal network to be able to register with the FortiGate Voice unit to get this extension, the FortiFone *Register Name* must consist of the extension *First Name* followed by the *Last Name* separated by one space. The FortiFone must also be configured with this *Password* and the IP address of the FortiGate Voice internal interface. The password must be 8 or more characters, must contain at least an uppercase character, a lowercase character and a number, non-alphanumeric characters, like (- $, are not supported in the password field.
Type	SIP Phone
First Name	The first name assigned to this extension. Usually a person's first name.
Last Name	The last name assigned to this extension. Usually a person's last name. When this extension calls another phone the caller ID displayed on the called phone consists of the extension *First Name* followed by the *Last Name*.
Email	The email address of the person assigned to this extension. The FortiGate Voice unit sends voicemail notifications for the extension to this email address.
MAC Address	Enter the MAC address of the SIP phone.
Dial Plan	Dial_Plan_1
Voicemail	Select
Voicemail Password	Enter the numeric password that the SIP user must enter to get voicemail. The password can contain numbers only.
Email Notification	Select
Voicemail to Email Attachment	Select to attach a recording of the user's voicemail message to the voicemail notification email.
Maximum Message #	50 The FortiGate Voice unit keeps up to 50 voicemail messages for this extension.

3 Select OK to add the extension.
4 Repeat to add more extensions.

Configuring the FortiFones on the internal network

This section contains high-level instructions for installing and configuring FortiFones for the example configuration. For more detailed information see the FortiFone documentation.

To configure FortiFones on the internal network

The following steps describe how to configure a FortiFone on the internal network with extension number 6001. This procedure would also apply to configuring a FortiFone for most networks. See the documentation supplied with the FortiFone for details.

1 Connect and power on the FortiFone handset.
2 Connect to the handset web configuration interface.

The default web configuration interface address is http://192.168.0.1. To connect to this address from a PC, your PC should have an IP address on the 192.168.0.0 subnet, for example: 192.168.0.10/255.255.255.0.

The default Username is root. No password is required.

3 Go to *Network* > *LAN Settings* and set the *IP Type* to DHCP Client and select Submit.
4 Select Save & Reboot to save the IP addressing change.
5 Log into the FortiFone using the IP address it acquired from the DHCP server.
6 Go to *SIP Settings* > *Service Domain* and add the following configuration information:

Active	On
Display Name	The name to be displayed on the phone. This name is only displayed on this phone. When this phone calls another phone the name displayed is the *First Name* and *Last Name* added to the FortiGate Voice *Extension* configuration.
User Name	6001 This is actually the Line Number or Extension Number and must match the Extension Number added to the FortiGate Voice Extension configuration for this phone.
Register Name	6001 The Register Name is used to authenticate the FortiFone and must match the Extension Number added to the FortiGate Voice Extension configuration for this phone. Both the User Name and Register Name are required.
Register Password	The *Password* added to the FortiGate Voice Extension configuration for this phone. The Register Name and Register Password are used to authenticate the phone with the FortiGate Voice unit.
Domain Server	Leave this field blank. Not required since the configuration uses the FortiGate Voice unit as a SIP proxy. This field is only used to add the phone to a SIP service domain.

Proxy Server	172.20.120.10 The IP address of the FortiGate Voice internal interface.
Outbound Proxy	Leave this field blank.

7 Select Submit.

8 Select Save & Reboot to save the service domain information.

9 If the FortiFone can successfully connect to and register with the FortiGate Voice unit the *Status* of the FortiFone changes to *Registered*.

If *Status* does not change to *Registered* you should verify the *Register Name* or re-enter the *Password*. You should also confirm that the *Domain Server* and *Proxy Server* IP addresses are correct

If you manually configure FortiFone registration settings, set register interval to 60 seconds where it applies. Refer to FortiFone documentation for more information about FortiFone configuration.

Adding extensions and configuring FortiFones for users behind a NAT device

When adding an extension for any SIP phone with a NAT device between the phone and the FortiGate Voice unit you must enable NAT in the FortiGate Voice extension configuration for the phone. You can enable NAT only from the CLI. This applies whether the phone is on a remote network behind a NAT device or behind a NAT device on the internal network.

To add an extension for a SIP phone behind a NAT device

The following procedure describes adding the extension from the FortiGate Voice CLI because you must use the CLI to enable NAT. You could add the extension from the web-based manager and then edit the extension from the CLI to enable NAT.

The following configuration is the same whether the phone is behind a NAT device on the internal network or on a remote network,

1 Connect to the FortiGate CLI.

2 Enter the following command to add extension 6010.

The command includes setting `nat` to `yes` to enable NAT.

```
config pbx extension
  edit 6010
    set first-name <first_name_str>
    set last-name <last_name_str>
    set email <email_str>
    set secret <password_str>
    set dialplan Dial_Plan_1
    set vm-secret <voicemail_password_str>
    set email-notify enable
    set attach enable
    set nat yes
    set macaddress <mac_address>
  end
```

To configure FortiFones behind a NAT device on the internal network

The configuration for FortiFones behind a NAT device on the internal network is the same as for FortiFones directly on the Internal network. See "To configure FortiFones on the internal network" on page 2615.

You may have to configure the NAT device to allow SIP sessions between the FortiFone and the FortiGate Voice unit.

To configure FortiFones behind a NAT device on a remote network

The following steps describe how to configure a FortiFone on the remote network with extension number 6010.

1 Connect and power on the FortiFone handset.

2 Connect to the handset web configuration interface.

The default web configuration interface address is http://192.168.0.1. To connect to this address from a PC, your PC should have an IP address on the 192.168.0.0 subnet, for example: 192.168.0.10/255.255.255.0.

The default Username is root. No password is required.

3 Go to *Network* > *LAN Settings* and set the *IP Type* to DHCP Client and select Submit.

4 Select Save & Reboot to save the IP addressing change.

5 Log into the FortiFone using the IP address it acquired from the DHCP server.

6 Go to *SIP Settings* > *Service Domain* and add the following configuration information:

Active	On
Display Name	The name to be displayed on the phone. This name is only displayed on this phone. When this phone calls another phone the name displayed is the *First Name* and *Last Name* added to the FortiGate Voice *Extension* configuration.
User Name	6010 This is actually the Line Number or Extension Number and must match the Extension Number added to the FortiGate Voice Extension configuration for this phone.
Register Name	6010 The Register Name is used to authenticate the FortiFone and must match the Extension Number added to the FortiGate Voice Extension configuration for this phone. Both the User Name and Register Name are required.
Register Password	The *Password* added to the FortiGate Voice Extension configuration for this phone. The Register Name and Register Password are used to authenticate the phone with the FortiGate Voice unit.
Domain Server	Leave this field blank. Not required since the configuration uses the FortiGate Voice unit as a SIP proxy. This field is only used to add the phone to a SIP service domain.

Proxy Server	172.20.120.10 The IP address of the FortiGate Voice internal interface.
Outbound Proxy	Leave this field blank.

7 If the FortiFone can successfully connect to and register with the FortiGate Voice unit the *Status* of the FortiFone changes to *Registered*.

If *Status* does not change to *Registered* you should verify the *Register Name* or re-enter the *Password*. You should also confirm that the *Domain Server* and *Proxy Server* IP addresses are correct.

To configure the remote FortiGate unit in NAT mode

The remote FortiGate unit in NAT mode must be configured to allow SIP sessions between the remote users on the remote network and the FortiGate Voice external interface. To do this you need to:

- Add an internal to external firewall policy that allows SIP sessions so that the remote users can start SIP sessions with the FortiGate Voice unit
- Add a virtual IP and an external to internal firewall policy that allows SIP sessions from the FortiGate Voice wan1 interface to connect to the phones in the remote network

For higher security, you could configure IPSec tunneling between the branch office network and the remote network and send SIP traffic over the IPSec tunnel.

FortiGate Voice IVR configuration

By default, when callers call into the FortiGate Voice PBX from a remote system such as the PSTN, the call is picked up by the PBX system which plays a default message asking the caller to dial the extension number that they want to reach or to dial 0 for assistance. If the caller dials 0 they can use the number keys on their phone to spell out the *First Name* or *Last Name* of an extension to connect with that extension.

You can use the following procedure to add a custom welcome message.

To add a custom welcome message

1 Log into the FortiGate Voice web-based manager.

2 Go to *PBX* > *Calling Rules*> *Voice Menu*.

3 Enter a *Recorder Extension*.

4 Enter a *Password for Recording*.

The password should include numbers only.

5 Select OK.

6 From a SIP phone that is registered with the FortiGate Voice unit, dial the Extension added in step 3.

7 Follow the prompts to record a new welcome message.

Providing access to the company directory

Use the following procedure to allow phone users to dial 3 to access the FortiGate Voice PBX directory. Phone users can use the directory to call an extension by using the number keys on their phone to spell out the *First Name* or *Last Name* of an extension to connect with that extension.

To provide access to the company directory from any extension

1 Log into the FortiGate Voice web-based manager.
2 Go to *PBX* > *Calling Rules* > *Voice Menu.*
3 Select the Edit icon for Key 3.
You can select any available key, but this example uses 3.
4 Set Action to *Go to Company Directory* and select OK.

Adding a shortcut for checking voicemail

Use the following procedure to allow phone users to dial 7 to access their voicemail.

To provide access to the company directory form any extension

1 Log into the FortiGate Voice web-based manager.
2 Go to *PBX* > *Calling Rules* > *Voice Menu.*
3 Select the Edit icon for Key 7.
You can select any available key, but this example uses 7.
4 Set Action to *Check Voicemail* and select OK.

Checking voicemail

Once users connect to their voicemail using the *Voicemail Access* number configured from *PBX* > *Calling Rules* > *Setting* or by pressing the configured voicemail key they can follow the prompts to listen to, store, and delete messages. Users can also change their voicemail password.

FortiGate Voice web-based manager configuration reference

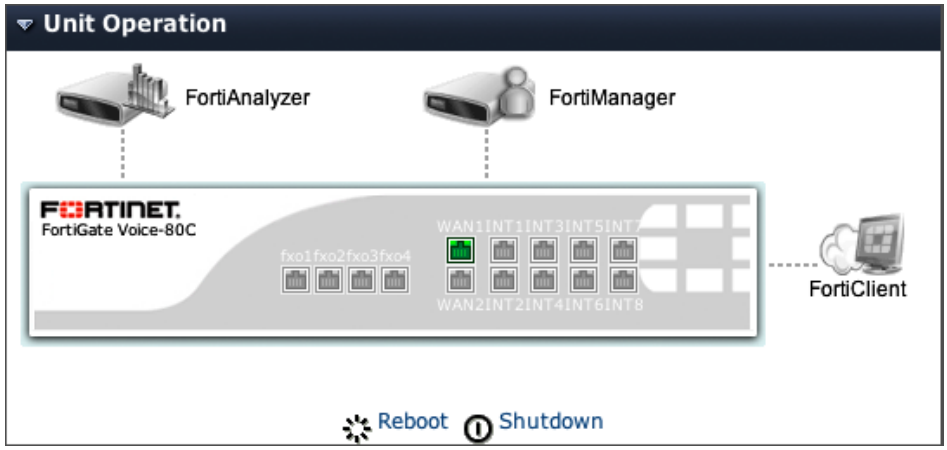
This section describes the following FortiGate Voice web-based manager configuration settings.

- Unit operation dashboard widget
- Configuring interface settings to support VoIP PBX features
- PBX configuration
- Logging of PBX activities

Unit operation dashboard widget

Go to *System* > *Dashboard* > *Status* and view the *Unit Operation* widget to see the status of the FortiGate Voice unit and its Ethernet and fxo interfaces. The fxo interfaces appear if your FortiGate Voice unit includes PSTN interfaces.

Figure 292: FortiGate Voice-80C Unit operation widget



Configuring interface settings to support VoIP PBX features

You can configure the following options on one or more FortiGate Voice ethernet interfaces to support PBX functionality for FortiGate Voice PBX users:

- Configuring an interface to accept SIP traffic
- Enabling access to the PBX user web portal

- SIP phone auto-provisioning

These options may compromise the security of the FortiGate Voice unit interface on which they are enabled (for example by opening a TCP or UDP port). The best practice is to only enable them on an interface connected to a secure network. Use caution when enabling them on an interface that is connected to an unsecure network such as the Internet.

Configuring an interface to accept SIP traffic

For PBX users to access the PBX features of a FortiGate Voice unit, you must configure the FortiGate Voice interface that PBX users connect to accept SIP traffic.

This option allows the FortiGate Voice interface to accept SIP traffic on UDP port 5060. The best practice is to enable this option on an interface connected to a secure network. Use caution when enabling this option on an interface that is connected to an unsecure network such as the Internet.

To enable SIP traffic on a FortiGate Voice interface

1 Go to *System* > *Network* > *Interface*.
2 Select the interface that you want to configure VoIP settings for.
The interface connected to the network containing SIP phones.
3 Select the *SIP* check box to enable SIP traffic.
4 Select *OK*.

Enabling access to the PBX user web portal

PBX users can log into the FortiGate Voice PBX user web portal using their PBX extension and password. The connection to the web portal is secured using HTTPS. From the portal, users can view their PBX configuration, change some configuration settings such as their password, listen to their voicemail, configure call forwarding, access conference calls, and listen to recorded conference calls.

This option allows users to log into the FortiGate Voice unit using an HTTPS connection to the configured port (8443 by default). The best practice is to enable this option only on an interface connected to a secure network. If you enable this option on an interface that is connected to an unsecure network such as the Internet make sure the extensions have secure passwords.

For information about how to log into and use the PBX user web portal, see “Using the PBX user web portal” on page 2649.

To allow access to the FortiGate Voice PBX user web portal

You can configure one or more FortiGate Voice interfaces to accept connections to the PBX user web portal.

1 Go to *System* > *Network* > *Interface* and edit an interface.
2 Enable the *PBX User Portal* for this interface.

To log into the PBX user web portal

1 Browse to the following address:

`https://<interface_address>:8443`

where:

`<interface_address>` is the IP address or domain name of a FortiGate Voice interface on which you have enabled the PBX user portal.

`8443` is the default port that users must browse to connect to the portal.

SIP phone auto-provisioning

You can configure the FortiGate Voice unit to auto-provision SIP phones on your network. The SIP phones must support auto-provisioning using TFTP. See the FortiGate Voice release notes for a list of supported SIP phones.

With auto-provisioning configured, when a supported SIP phone is connected to the network and powered on it automatically receives all of its PBX setup information from the FortiGate Voice unit. In most cases the administrator does not have to make configuration changes to the SIP phone itself.

To configure FortiGate Voice auto-provisioning you need to enable *Phone Auto-Provision* for the FortiGate Voice interface connected to the same network as the SIP phones to be auto-provisioned.

Enabling Phone Auto-Provision on a FortiGate Voice interface opens UDP port 69 (the TFTP port) on that interface. You should only enable phone auto-provisioning on a secure network.

You must also configure a DHCP server on this interface. In the DHCP server configuration, select DHCP option 66 (an advanced option on the web-based manager) and include the IP address of this FortiGate Voice interface.

DHCP server option 66 identifies a TFTP server and includes the IP address of the TFTP server and downloads the TFTP server identity to the device that gets an IP address from the DHCP server. DHCP option 66 is defined in RFC 2132.

The address must be input in hexadecimal ASCII format. In this format, each ASCII character in the dotted decimal IP address (including periods) is represented by a 2-digit hexadecimal number that maps to the corresponding ASCII character. For example, for the FortiGate Voice default configuration, the IP address of the FortiGate Voice internal interface (192.168.1.99) is input in hexadecimal format as follows:

Hexadecimal	31	39	32	2E	31	36	38	2E	31	2E	39	39
IPv4	1	9	2	.	1	6	8	.	1	.	9	9

For a hexadecimal representation of all ASCII characters, see the ASCII printable characters list on Wikipedia.

With this configuration in place, when a SIP phone that supports auto-provisioning with TFTP receives its IP address via DHCP from the FortiGate Voice unit, it also receives the TFTP server address. The SIP phone then downloads its PBX configuration from TFTP server running on the FortiGate Voice unit.

The FortiGate Voice unit identifies the SIP phone by its MAC address. When you add an extension for the phone to the PBX configuration you include its MAC address. The FortiGate Voice unit uses this MAC address to identify the SIP phone and match it with its extension in the PBX configuration. In most cases the MAC address is available from a sticker attached to the phone or its packaging.

Default FortiGate Voice auto-provisioning configuration

By default the FortiGate Voice unit enables auto-provisioning on the Internal interface for SIP phones attached to the internal network. The default IP address of the internal interface is 192.168.1.99. The FortiGate Voice default configuration also includes a DHCP server for the Internal interface that provides IP addresses in the range of 192.168.1.110 to 192.168.1.210. You can configure all of the devices on your internal network (including PCs and SIP phones and so on) to use DHCP to automatically get their IP addresses from the FortiGate Voice unit DHCP server. SIP phones that support auto-provisioning can also get their PBX configuration if an extension for the SIP phone's MAC address has been added to the FortiGate Voice PBX configuration.

If you want to configure the network connected to the FortiGate Voice internal interface to use a different subnet but still support auto-provisioning, you must:

- Change the IP address of the FortiGate Voice internal interface.
- Change the IP addresses that the DHCP server provides.
- Change the TFTP server IP address added to the DHCP server option 66.

Configuring SIP phones for auto-provisioning

Before you begin, make sure your FortiGate Voice unit is set up for auto-provisioning and the configuration meets the following:

- A DHCP server set up as described.
- A PBX extension set up with SIP phone's MAC address.

This section describes how to configure auto-provisioning for the following phones:

- FortiFone-110
- FortiFone-210
- Polycom
- Aastra

To configure a FortiFone-110 phone for auto-provisioning

1. Connect the FortiFone-110 phone to the VoIP network.

   Refer to the phone's documentation for instructions for connecting the phone.
2. Reset the phone to its factory default settings by selecting *Menu* > *Phone Settings* > *Reset to Factory*.
3. Set DHCP IP client as WAN port option by selecting *Menu* > *Network* > *WAN Port Option* > *DHCP IP Client*.

   The FortiFone-110 phone reboots and starts acquiring an IP address and PBX extension settings from the FortiGate Voice unit. During this time ***invalid account*** followed by ***Updating configuration, please wait*** appears on the screen. After a few minutes, the phone reboots one last time. The phone extension settings appear on the screen, the IP address and the other connection details can be found by navigating through the phone's menu.

To configure a FortiFone-210 phone for auto-provisioning

1. Connect the FortiFone-210 phone to the VoIP network.

   Refer to the phone's documentation for instructions for connecting the phone.

2 Reset the phone to its factory default settings.

Refer to the phone's documentation.

The FortiFone-210 phone reboots and starts acquiring an IP address and PBX extension settings from the FortiGate Voice unit.

To configure Polycom phones for auto-provisioning

1 Connect the Polycom phone to the VoIP network.

Refer to the phone's documentation for instructions for connecting the phone.

2 Select *Setup* on the screen.

3 Enter the administrator password.

The default password is 456.

4 Set the server type to Trivial FTP by selecting *V* > *Server Menu* > *Server Type* > *Trivial FTP*.

5 Select *Exit*.

The Polycom phone reboots and starts acquiring an IP address and PBX extension settings from the FortiGate Voice unit.

To configure Aastra phones for auto-provisioning

1 Connect the Aastra phone to the VoIP network.

Refer to phone's documentation for instructions for connecting the phone.

2 Reset the phone to its factory default settings.

Refer to the phone's documentation.

The Astra phone reboots and starts acquiring an IP address and PBX extension settings from the FortiGate Voice unit.

If you manually configure any FortiFone's registration settings, set register interval to 60 seconds where it applies. Refer to FortiFone documentation for more information about FortiFone configuration.

PBX configuration

The following explains how to configure PBX settings for your network environment. These settings include, adding extensions to your PBX, voicemail notification settings, configuring the FortiGuard Voice service, configuring other VoIP providers, as well as system settings such as a voicemail access code and a maximum voicemail duration time limit.

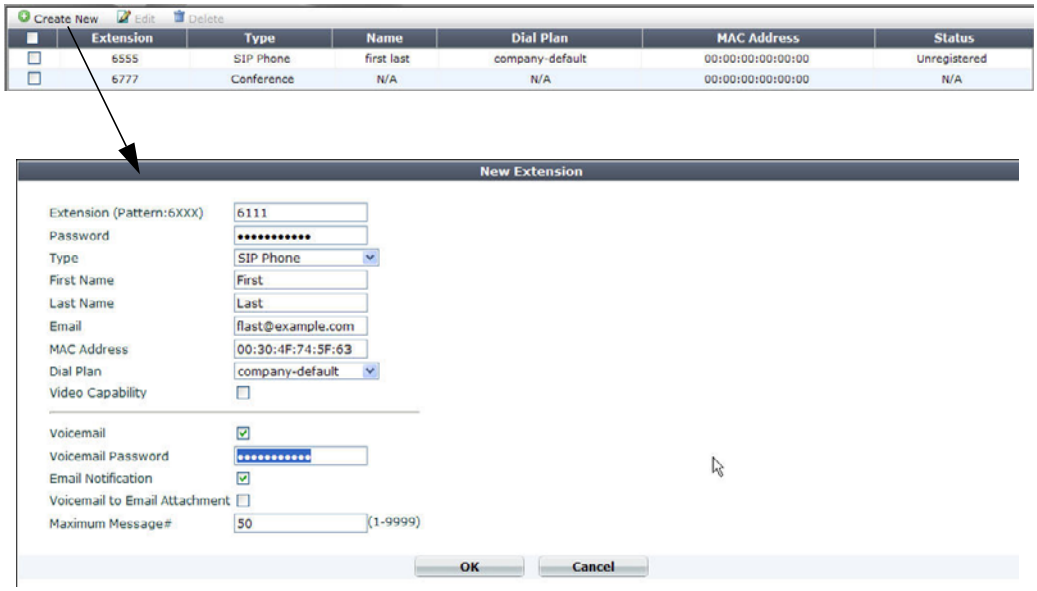
Configuring extensions

Add PBX extensions to configure the settings for the SIP phones that the FortiGate Voice unit supplies PBX services for. Each extension configuration includes the extension number, the name and email address of the person assigned to the extension, the MAC address of the device to be used for the extension (to support auto-provisioning), whether the device includes video calling, and voicemail settings. You can also use the extension settings to add conference bridges.

To add a new extension, go to *PBX* > *Extension* > *Extension*, select *Create New*, enter the information and then select *OK.*

FortiGate Voice unit uses the alertmail settings to access an SMTP server and send email notifications. Alertmail is configured in *Log&Report* > *Log Config* > *Alert E-mail*.

Figure 293: Configuring extensions



General extension settings	
Create New	Select to create an extension.
Extension	The extension number.
Type	The type of extension the number is. Type can be: • SIP Phone to configure a SIP phone extension • Conference to configure a conference bridge. For the Conference extension you can add an extension number and a password. PBX users can call this extension number and enter the password to join a conference call.
Name	The name of the extension.
Dial Plan	The dial plan that will be used for that extension.
Extension configuration settings	
Extension	Enter the extension number. The web-based manager shows the pattern that the extension number must follow. For example, *(Pattern: XXX)* means the extension must consist of three numbers.

Password	Enter a password for the extension. The password is used to log into the PBX user web portal. The password cannot be blank, must be 8 or more characters, must contain at least one uppercase character, one lowercase character and one number. Non-alphanumeric characters, like (- $, are not supported in the password field. If you are entering a password for a conference bridge, the password cannot be blank and must contain only numbers. This becomes the conference PIN number.
Type	Select the type of extension. You can choose from SIP Phone or Conference. If you select SIP phone you can add a SIP extension to the PBX configuration. If you select Conference you can add a conference bridge to the PBX configuration. To configure a conference bridge you specify the conference bridge extension, password, conference host, host pin, video capability, and whether conferences can be recorded.
Conference Host	The name of the PBX extension that can host conference calls using this conference bridge. The user of the conference host extension can manage the conference bridge from the PBX user web portal. The conference host user can change the conference password and host pin and change the video and recordable settings for the conference bridge.
Host PIN	Enter the number to be entered by the conference host to be able to host a conference call.
Conference Recordable	Select to enable recording of conference calls that use this conference bridge. You cannot select this option if the conference bridge supports video calls.
First Name	Enter the first name of the person that will be using this extension.
Last Name	Enter the surname of the person that will be using this extension.
Email	Enter the email address of the person that will be using this extension.
MAC Address	The MAC address of the SIP phone to be used for this extension. The MAC address is required if the SIP is to be configured using auto-provisioning. See “SIP phone auto-provisioning” on page 2623.
Video Capability	Select if the SIP phone can display video and handle video calls.
Dial Plan	Select the dial plan that will be used with this extension from the drop-down list.
Voicemail	Select if you want to have voicemail available for this extension.
Voicemail Password	Enter a voicemail password for accessing the voicemail.
Email Notification	Select to have an email sent to the email address given in the Email field so that the person is notified when a voicemail message is in their voicemail message inbox.

Voicemail to Email Attachment	Select to attach the actual voicemail message to the notification email.
Maximum Message #	Enter a number for the maximum number of messages that can be stored in the extension's voicemail inbox before automatically deleting the oldest messages.

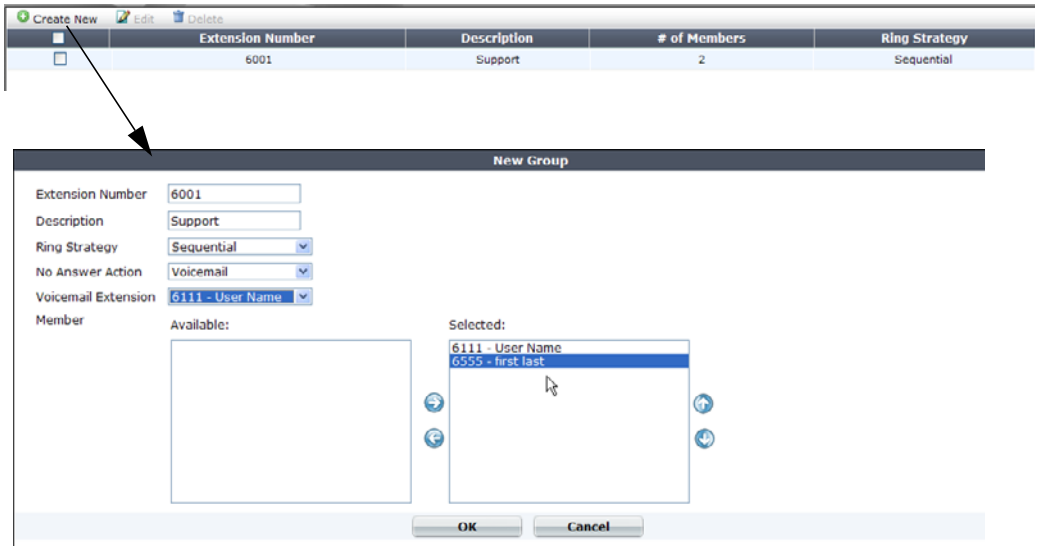
Configuring extension groups (ring groups)

Extension groups (also called ring groups) are a group of extensions that can be called using one number. The extension group can be used to call all the extensions in the group at the same time or to call the extensions one at a time until someone answers.

The order in which the members are added to the ring group does not match the order in which the FortiGate Voice unit calls them.

To add an extension group, go to *PBX* > *Extension* > *Group*, select *Create New*, enter the information, and then select *OK*.

Figure 294: Configuring extension groups



Extension Number	The number to call to reach extension group. This number must be a valid extension number for the FortiGate Voice configuration.
Description	A description of the extension group.
# of Members	The number of extensions in the extension group.
Ring Strategy	Select a type from the drop-down list. You can choose either Sequential or Ring All.
No Answer Action	Select the action to take when there is no answer for the incoming caller. You can select Voicemail, which routes the caller to voicemail, IVR, or Hangup. If you select Voicemail, the Voicemail Extension list appears and you need to select the voicemail extension number.

Voicemail Extension	Select the voicemail extension number from the drop-down list. This option appears only when Voicemail is selected in No Answer Action.
Member	Select an extension in the Available column and then use the -> arrow to move it to the Selected column. To remove an extension from the Selected column, select the extension and use the <- arrow to move it back to the Available column.

Configuring service providers (the FortiGuard Voice service)

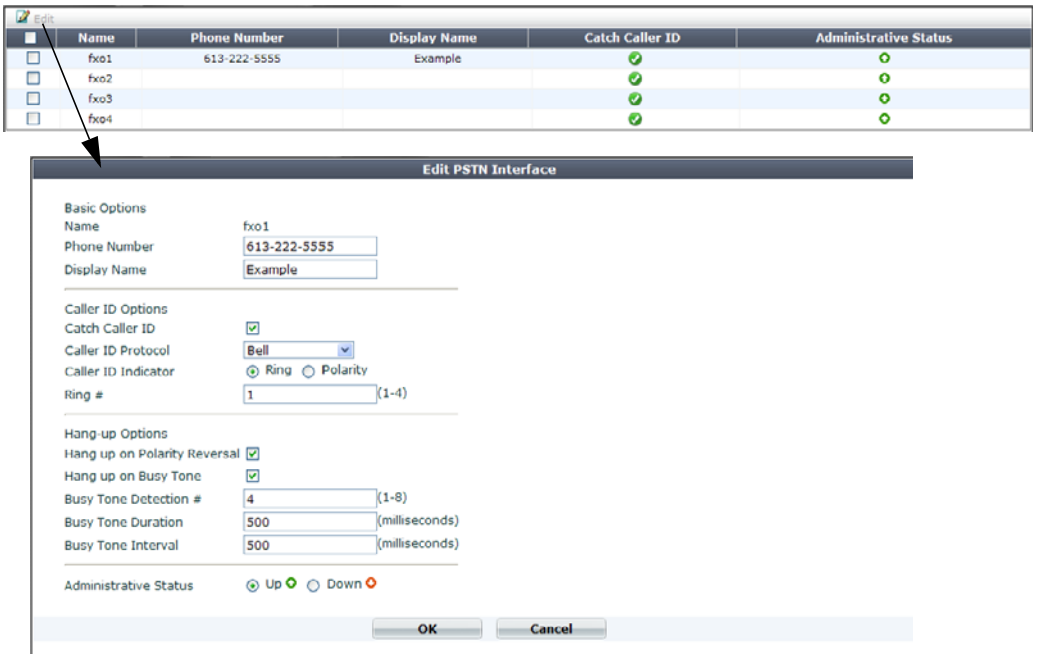
If your FortiGate Voice unit is installed in North America and the Country Code is set to 1 then you can use the FortiGuard Voice service as your SIP service provider. (The default Country Code is 1 and is set from *PBX* > *Calling Rules* > *Setting*.) The FortiGuard Voice service is supported only in North America. If you install the FortiGate Voice unit elsewhere in the world and change the Country Code, the FortiGuard Voice Service configuration is not available.

Configuring PSTN interfaces

Some FortiGate Voice models include public switched telephone network (PSTN) interfaces that you can use to connect the FortiGate Voice PBX to your local public telephone network. Using these interfaces you can route calls from your FortiGate Voice network to the public telephone network. The PSTN interfaces are named fxo1, fxo2, and so on.

To configure the PSTN interfaces, go to *PBX* > *Service Providers* > *PSTN Interface*, configure settings for the fxo interface and then select *OK*.

Figure 295: Configuring PSTN interfaces



General PSTN interface settings	
Name	The name of the PSTN interface.
Phone Number	The phone number that is associated with that PSTN interface.
Display Name	The name that displays on the phone's LCD.
Catch Caller ID	If enabled, a green checkmark appears. If Catch Caller ID is disabled, a gray X appears.
Administrative Status	Status of the PSTN interface. A red down arrow indicates that the interface is down; a green up arrow indicates that the interface is up.
PSTN interface configuration settings	
Basic Options	The basic options for the interface.
Name	The name of the PSTN interface.
Phone Number	Enter the phone number of the PSTN phone line as provided by your phone service provider. The phone number is used for caller ID for calls from the FortiGate Voice unit to the PSTN. It can be any number, but is usually the actual phone number of the PSTN line connected to the fxo1 interface. Area code and country codes are optional.
Display Name	This name is used for caller ID for calls from the FortiGate Voice unit to the PSTN. It can be any name, such as a company name, that identifies the branch office.

Caller ID Options	Configure the following options to support caller ID functions for calls from the internal network to the PSTN.
Catch Caller ID	Select to enable the FortiGate Voice unit to receive caller ID information from calls originating on the PSTN and send the caller ID information to the extension that answers the call.
Caller ID Protocol	Select the caller ID protocol required by PSTN line that the fxo interface is connected to. Contact your service provider for the name of the protocol to use.
Caller ID Indicator	Select the caller ID indicator required by the PSTN line. Contact your service provider for details.
Ring #	Set the number of rings to wait before receiving caller ID information. In most cases, enter 1 to send caller ID information between the first and second ring.Contact your service provider for details.
Hang-up Options	Configure the following options to configure how the FortiGate Voice unit hangs up calls from the PSTN.
Hang up on Polarity Reversal	Select if the PSTN line uses polarity reversal to indicate a call has been hung up. Contact your service provider for details.
Hang up on Busy Tone	Select if you want the FortiGate Voice unit to hang up automatically when it receives a busy tone when attempting to dial a number on the PSTN.
Busy Tone Detection #	The number of busy tones that the FortiGate Voice receives before hanging up if *Hang up on Busy Tone* is selected.
Busy Tone Duration	Tune the FortiGate Voice unit to accurately detect busy tones on this PSTN line. You can change the default settings if busy tones are not accurately detected.
Busy Tone Interval	
Administrative Status	Set to *Up* if the fxo interface is connected to the PSTN and you want to be able to receive and send calls on this PSTN interface.

Configuring the FortiGuard Voice service

The FortiGuard Voice service is a SIP trunking or SIP VoIP service provided by Fortinet. The FortiGuard Voice service includes the following features in addition to the being able to make calls from the FortiGate Voice unit to other VoIP providers and to the PSTN:

- Direct inward dial numbers
- FortiFAX eFAX service (see “FortiFAX service” on page 2644)
- Toll free numbers
- Different calling card packages and credit levels

The FortiGuard Voice service is currently available only in North America. To use the FortiGuard Voice service the FortiGate Voice unit Country Code must be set to 1 and the FortiGate Voice unit must have a valid static public Internet IP address.

You can connect your FortiGate Voice unit to the FortiGuard Voice service by purchasing a subscription for your FortiGate Voice unit. Once you have purchased a subscription, if your FortiGate Voice unit meets the above criteria and is connected to the Internet it is also automatically connected to the FortiGuard Voice service network.

You can also go to the License Information dashboard widget or to *PBX* > *Service Providers* > *FortiGuard Voice Service* to subscribe to the FortiGuard Voice service. If you have already subscribed to but have not activated the service you can select *Activate Now* from either of these locations to activate the service.

To activate the service you must fill out the following fields:

- Area Code: The local area code used by the FortiGate Voice unit.
- Company Name: Name of the company.
- Directory List Address: Local number to call for directory listings, for example 411.
- E911 Emergency Address: Local emergency number, for example 911.

When you activate the service, FortiGuard sends the direct inward dial, EFax number, and toll free number settings assigned to the FortiGuard Voice service license assigned to the FortiGate Voice unit.

When the FortiGuard Voice service is active it is integrated into your FortiGate Voice default configuration, the company-default dial plan sends all outgoing calls to the FortiGuard Voice service.

To view the status of your FortiGuard Voice service subscription find the *Voice Service* entry in the License Information dashboard widget. You can also go to *System* > *Maintenance* > *FortiGuard* and view the status of the Voice Service entry in the FortiGuard Subscription Services list. The status of the FortiGuard Voice service should indicate that the FortiGate Voice unit is licensed for the service.

Viewing FortiGuard Voice service status

You can also view more detailed status information about the FortiGuard Voice service by going to *PBX* > *Service Providers* > *FortiGuard Voice Service*. You can view the overall status of your FortiGuard Voice service account as well as details about the service that you have purchased.

Figure 296: FortiGuard Voice service status

Subscription	The status of the FortiGuard Voice service subscription for the FortiGate Voice unit. Status should be *Yes* if everything is properly configured.
Account Status	The status of the FortiGuard Voice service account used by the FortiGate Voice unit. If account status is active the FortiGate Voice unit can receive and send calls from and to the FortiGuard Voice service.

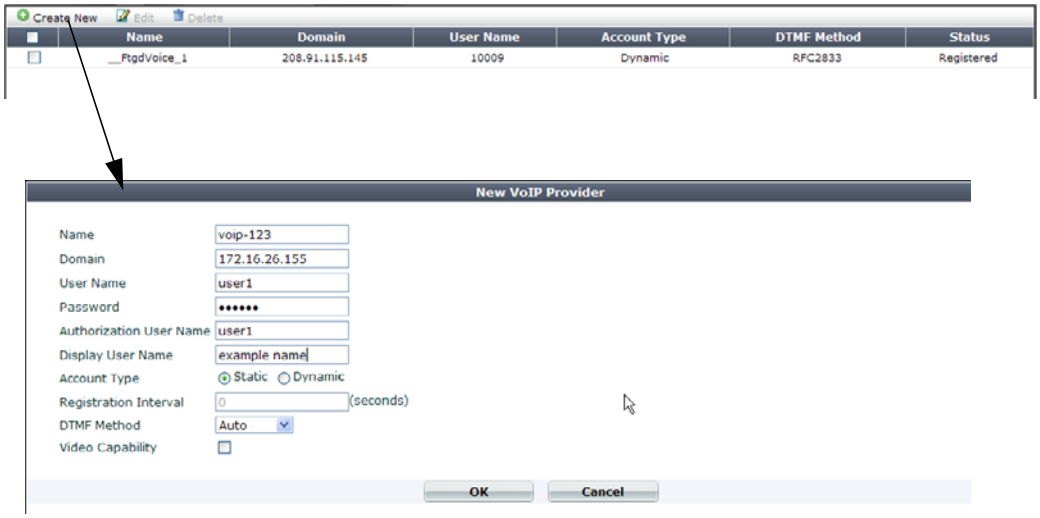
DIDs	The direct inward dial numbers available from FortiGuard Voice service. DID allows the FortiGate Voice unit to direct calls from external callers directly to PBX extensions. For more information about DID, see "Configuring direct inward dialing" on page 2640.
FortiFAX	The FortiGate Voice unit's FortiFAX eFax number if this is part of the FortiGuard Voice service license for the FortiGate Voice unit. Third parties can send faxes to the FortiGate Voice unit using this number.
Toll Frees	The FortiGate Voice unit's toll free number if this is part of the FortiGuard Voice service license for the FortiGate Voice unit. Third parties can call this number toll free to reach extensions connected to the FortiGate Voice unit.
Packages	Information about additional packages that are part of the FortiGuard Voice services purchased for the FortiGate Voice unit.
Package Type	The package type depends on the FortiGuard Voice services that have been purchased. Multiple packages are available with different features.
Calling Card Credit Left	The amount of money available for making phone calls to the FortiGuard Voice service from the FortiGate Voice unit for each package.
Calling Card Credit Used	The amount of money spent for making phone calls to the FortiGuard Voice service from the FortiGate Voice unit for each package.
Expiration Date	The date on which the package expires. When the package expires all unused calling card credit is lost.
SIP Status	An indicator of the SIP status of the FortiGate Voice service. If it is operating normally the status should show a green check mark icon.

Adding SIP trunks

You can configure multiple VoIP providers for your PBX configuration.

To configure VoIP providers, go to *PBX* > *Service Providers* > *SIP Trunk*, select *Create New*, configure the settings and then select *OK*.

Figure 297: VoIP Provider



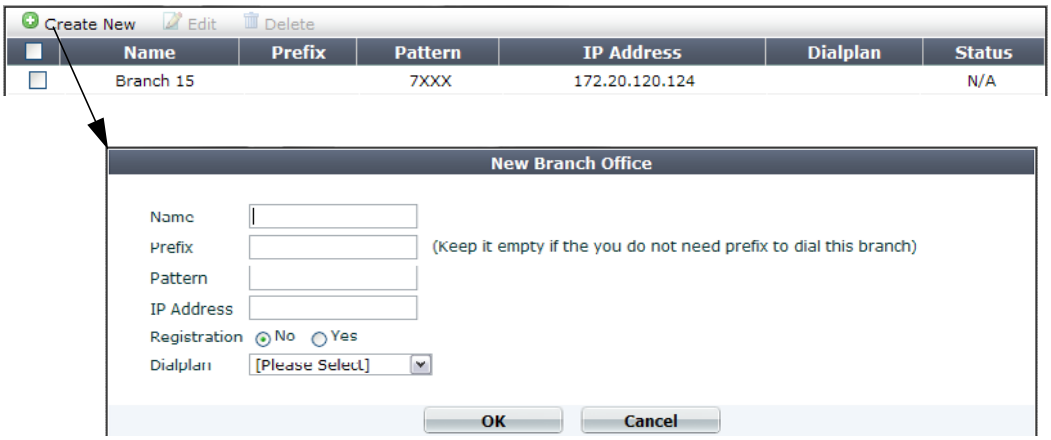
Name	Enter the name for the VoIP provider configuration. This can be any name.
Domain	The VoIP provider's domain name or IP address. For example, 172.20.120.11 or voip.example.com.
User Name	Enter a valid user name for an account on the VoIP provider's server. This could also be a phone number including area code, depending on the requirements of the VoIP provider.
Password	Enter the password for the account on the VoIP provider's SIP sever.
Authorization User Name	Enter a valid authorization user name for an account on the VoIP provider's server if required by the VoIP provider.
Display User Name	Enter a valid display user name for an account on the VoIP provider's server if required by the VoIP provider.
Account Type	Select Static or Dynamic depending on the account with the VoIP provider.
Registration Interval	If this is a dynamic account with the VoIP provider, enter the registration interval as required by the VoIP provider. After each registration interval the FortiGate Voice renews the registration of the account with the VoIP provider.
DTMF Method	Select the DTMF method used by the VoIP provider. Options are RFC2833, Inband, Info, and Auto. Auto means the VoIP provider's server and the FortiGate Voice unit will negotiate to select a DTMF method. You could also select a specific DTMF method if required.
Video Capability	Select if the SIP service provider supports video calling over SIP.

Branch Office

The branch office feature allows you to easily configure communication between two FortiGate Voice phone systems. A common application is the easy linking of branch offices in separate locations.

To configure Branch Office, go to *PBX* > *Service Providers* > *Branch Office*, select *Create New*, configure the settings and then select *OK*.

Figure 298: Branch office



Name	The name for the branch office configuration. This can be any name.
Prefix	The prefix required to dial an extension to the branch office. If there is no overlap between the extensions in your office and the branch office, no prefix is required. If no prefix is specified, extensions in the branch office are dialed exactly as local extensions.
Pattern	The extension number pattern of the branch office. For example, XXXX is any four digit number while 7XXX is a four digit number that always starts with 7.
IP Address	The IP address of the branch office FortiGate Voice unit.
Registration	The registration determines the means by which a caller from another branch is authenticated. The *No* setting uses authentication by IP address. This is the preferred method because it is simple and convenient. The *Yes* setting requires extension and extension password for authentication. This option is provided for compatibility with equipment that does not support IP address authentication.
Dialplan	Specify a dialplan to allow a user to call out of a branch office. The user calls will be routed as specified in the dial plan. If no dial plan is selected, users will be able to dial only branch extensions.

Configuring dial plans

Dial plans route calls made from a FortiGate Voice extension to an external phone system. The external phone system can be one or more PSTN lines if your FortiGate Voice unit includes PSTN interfaces, or a VoIP service provider. To route calls to an external phone system you add dial plan rules that define the extra digits that extension users must dial to call out of the PBX. The rules also control how the FortiGate Voice unit handles these calls including whether to block or allow the call, the destinations the calls are routed to and whether to add digits to the beginning of the dialed number (called prepending).

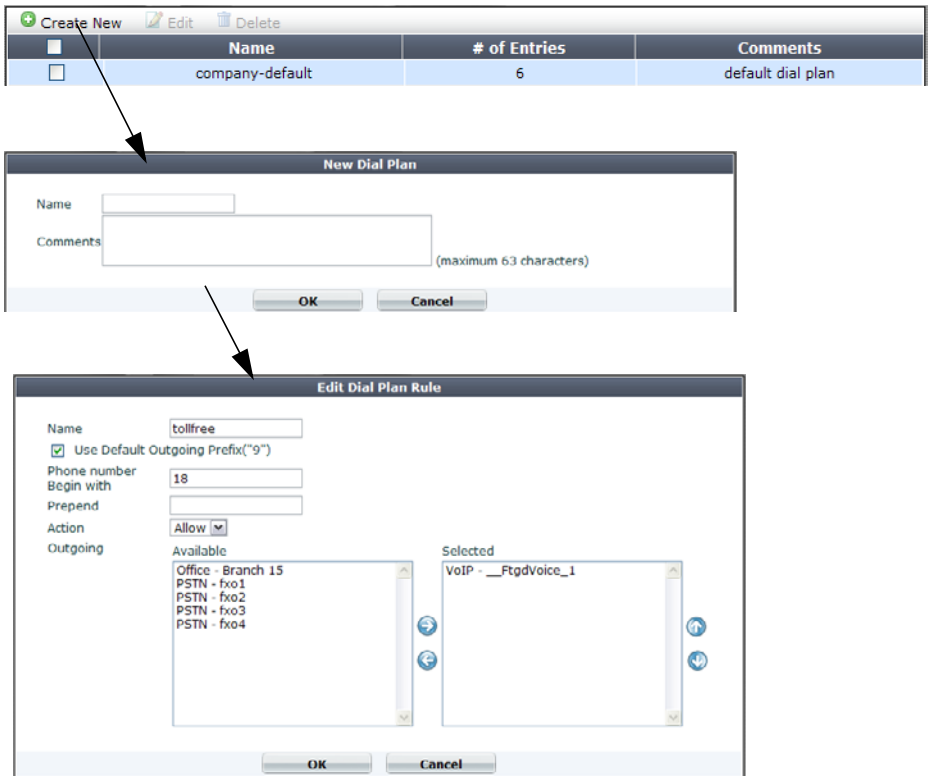
For example, if PBX users should be able to dial 911 for emergencies you should include a dial plan rule that sends all calls that begin with 911 to an external phone system. This rule should also override the default outgoing prefix so that users can dial 911 without having to dial 9 first.

You can also use dial plan rules to block some calls. For example, if you want to block extensions from making international calls you can add dial plan rule that blocks calls that start with the default outgoing prefix followed by 011.

When the FortiGate Voice unit receives a call from an extension that does not match the FortiGate Voice unit's extension range, the call is processed according to the dial plan added to the extension. (If the extension does not have a dial plan the call is blocked). To process the call, the FortiGate Voice unit selects the dial plan rule that best matches the dialed numbers and processes the call using the settings in the dial plan rule. For example, the emergency dial plan rule could route calls out a local PSTN line (if your FortiGate Voice unit includes them) or to a remote VoIP provider.

To configure dial plan, go to *PBX* > *Calling Rules* > *Dial Plan*, select *Create New*, configure the settings and then select *OK*.

Figure 299: Configuring a dial plan



General dial plan list settings	
Create New	Select to configure a dial plan. You can add multiple dial plans and assign them to different extensions. For example, you might want to have a dial plan that allows long distance calls and a dial plan that does not.
Name	The name of the dial plan.
# of Entries	The number of entries in each dial plan.
Comments	An optional description of the dial plan.
Dial plan rule configuration settings	
Name	Enter a descriptive name for the dial plan rule.
Use Default Outgoing Prefix("9")	Select this checkbox if the dial plan rule should use the default outgoing prefix (usually 9).
Outgoing Prefix	If you clear the Use Default Outgoing Prefix checkbox you can enter a different outgoing prefix for this dial plan.

Phone number Begin with	Enter the leading digits of the phone number that this dial plan rule should match with. For example, a dial plan rule for toll free numbers in North America should begin with 18. The FortiGate Voice uses a best match to match a dialed number with a dial plan. So each dial plan should have a different Phone number Begin with setting. But you should plan your dial plan to make sure that unexpected matches do not occur.
Prepend	Add digits that should be prepended or added to the beginning of the dialed number before the call is forwarded to its destination. You can prepend digits at the beginning of a call of special dialing is required to reach and external phone system.
Action	Set the action to Allow if this dial plan rule should allow a call. Set the action to Block if the dial plan should block a call. For example, if you want to block international calls you could set the Phone Number begin with to 011 and set the action to block.
Outgoing	In the *Available* column, select one or more PSTN interfaces (if your FortiGate Voice unit includes them) and/or VoIP service providers that the calls matching this dial plan should be routed to and use the arrow to move to them to the *Selected* column. If you need to remove a PSTN interface or VoIP provider from the *Selected* list, select the item and use the arrow to move it back to the *Available* column list. The FortiGate Voice unit uses the PSTN interfaces and VoIP providers in the *Selected* list in the order in which they are arranged in the list. You can arrange the PSTN interfaces and VoIP providers in the *Selected* column using the up and down arrows beside the Selected column. Select a PSTN interface or VoIP provider and then use the arrows to arrange them in the list.

Example dial plan

This simplified example dial plan is similar the default FortiGate Voice dial plan. The default dial plan that routes all external calls to the FortiGuard Voice service. The following example includes 5 dial plan rules that:

- Routes emergency calls (dialing 911) to the fxo1 PSTN interface
- Blocks international calls (the phone number begins with 011)
- Routes Toll Free calls (beginning with 18) to the FortiGuard Voice service
- Routes non-international long distance calls (beginning with 1) to the FortiGuard Voice service
- Routes all other external calls to the fxo2 and fxo3 PSTN interfaces

In this example, all outgoing calls are routed to the PSTN and not to other VoIP service providers. On a FortiGate Voice unit without PSTN interfaces, the dial plan would route all calls to the FortiGuard Voice service or to one or more VoIP service providers.

Table 145: Rule 1: emergency calls using 911

Name	Emergency
Use Default Outgoing Prefix ("9")	Not selected
Phone number Begin with	911
Action	Allow
Outgoing Selected	PSTN - fxo1

Table 146: Rule 2: international calls beginning with 011

Name	International
Use Default Outgoing Prefix ("9")	Selected
Phone number Begin with	011
Action	Block

Table 147: Rule 3: Toll free calls starting with 18

Name	Toll_Free
Use Default Outgoing Prefix ("9")	Selected
Phone number Begin with	18
Action	Allow
Outgoing Selected	VoIP - __FtgdVoice_1

Table 148: Rule 4: Long Distance calls starting with 1

Name	Long_Distance
Use Default Outgoing Prefix ("9")	Selected
Phone number Begin with	1
Action	Allow
Outgoing Selected	VoIP - __FtgdVoice_1

Table 149: Rule 5: Other outgoing calls

Name	Other_PSTN_Numbers
Use Default Outgoing Prefix ("9")	Selected
Phone number Begin with	
Action	Allow
Outgoing Selected	PSTN - fxo2, PSTN - fxo3

Configuring voice menu options

The operator voice mail message can be accessed and reprogrammed by configuring recorder extension. To configure a recorder extension, go to *PBX* > *Calling rules* > *Voice Menu* and enter an extension number and a password. The recorder extension can be dialed from any PBX extension and used for recording a new operator voice mail message.

Configure voice menu options to provide PBX users with shortcuts to PBX functions such as accessing their voice mail, finding numbers in the company directory, or dialing a ring group.

To access voice menu functions PBX users dial a single number on their phones and wait a few seconds for the PBX to respond. For example, you can use voice menu options to allow PBX users to simply dial 3 to access their voicemail.

To configure voice menu options

1 Go to *PBX* > *Calling Rules* > *Voice Menu*.

2 Edit the row of the key that you want to configure voice menu options for.

3 In the *Action* drop-down list, select one of the following:

None	No action will be taken when a caller dial this number.
Ring Group	The PBX user calls a ring group. Select the ring group to call. A ring group is also called an extension group. To add ring groups, see "Configuring extension groups (ring groups)" on page 2628.
Check Voicemail	Provides direct access to the PBX user's voice mail inbox.
Go to Company Directory	Provides direct access to the PBX company phone directory.

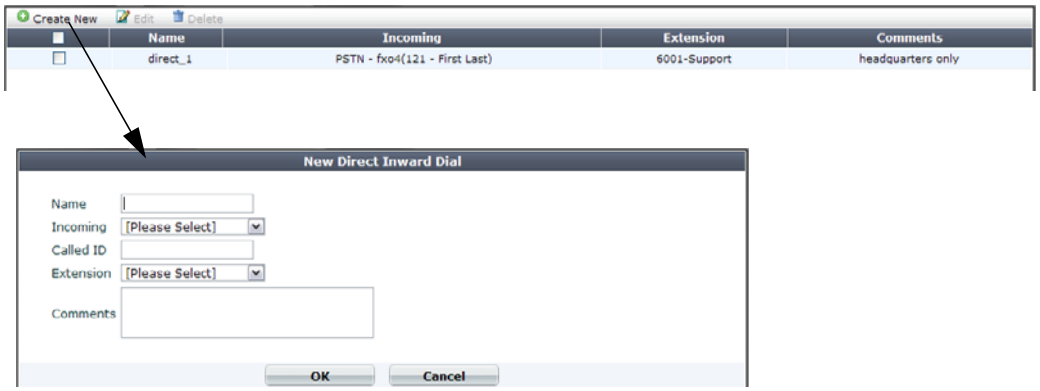
4 Select *OK*.

Configuring direct inward dialing

You can configure direct inward dialing (DID) for calls. DID allows the FortiGate Voice unit to direct calls from external callers directly to PBX extensions. For example, you could set up DID so that external users call 555-1234 and DID directs the call to extension 1234. Using the FortiGate Voice unit direct inward dial settings you associate an incoming PSTN interface (if supported by your FortiGate Voice unit), the FortiGuard Voice service, or VoIP service provider with a PBX extension. When an incoming call is received from one of these sources, if the last digits of the dialed number match the selected extension number the FortiGate Voice unit directs the call directly to the extension. For this to work you must obtain an external phone number with the last digits matching the selected extension.

To configure direct inward dialing, go to *PBX* > *Calling Rules* > *Direct Inward Dial*, enter the information, and then select *OK*.

Figure 300: Direct inward dialing



Name	A name for the DID configuration.
Incoming	Select a PSTN interface, the FortiGuard Voice service, or VoIP service provider from which to accept calls to this DID number.
Called ID	Enter the ID displayed on the callers phone when they dial this DID number.
Extension	Select an extension from the drop-down list.
Comments	Enter a description, if applicable, for the direct inward dialing configuration.

From the CLI you can use the `cid-number` option of the `config pbx did` command to specify the number called from an external line that is re-directed to the selected extension. Use this option if the extension number cannot be matched with the external number. In the following example, DID sends calls received on the fxo1 PSTN interface that end with 5555 to extension 1234.

```
config pbx did
  edit did_example
    set external-line fxo1
    set cid-number 5555
    set extension 1234
  end
end
```

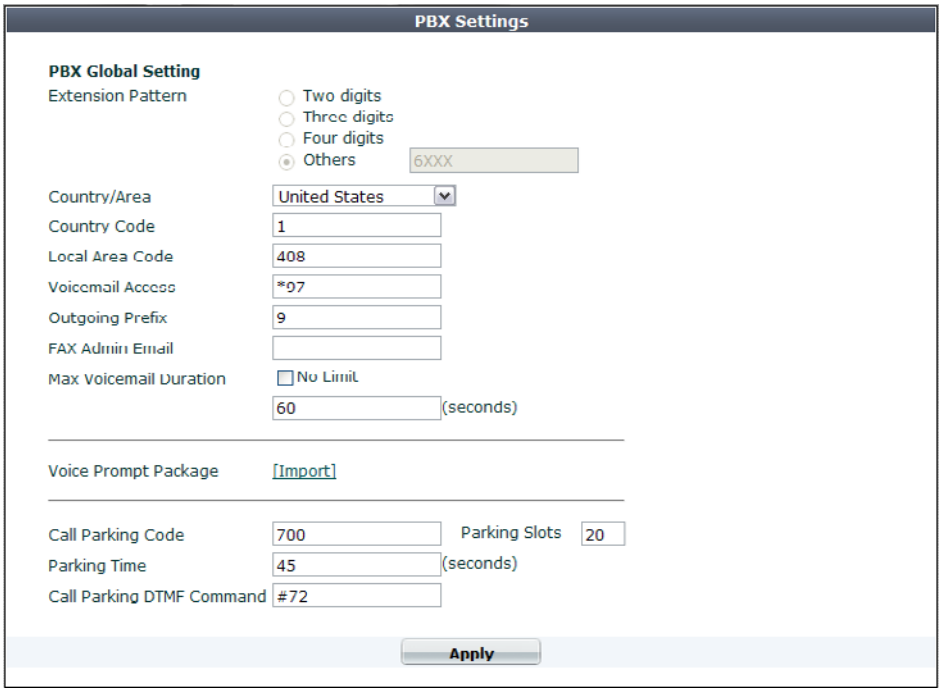
Configuring PBX global settings

Configure PBX global settings that affect the overall performance of the PBX service and all of the users of it. Settings include the extension pattern for the PBX, information about the country or area in which the FortiGate Voice unit is installed, and the outgoing dial prefix. Usually you would configure these settings once and rarely thereafter.

The Country Code must be set to 1 to use the FortiGuard Voice service. This service is available only in North America.

To configure PBX settings group, go to *PBX* > *Calling Rules* > *Setting*, make configuration changes as required and then select Apply.

Figure 301: Configuring PBX settings



PBX Global Settings	
Extension Pattern	Select two, three, or four digit extensions, or choose *Others* to specify an extension pattern. An extension pattern of two, three, or four digits allows you to choose any extension number of the selected length. Other allows you to enter a pattern that defines the valid extensions that can be added to the FortiGate Voice configuration. The pattern can include numbers that must be in every extension and upper case Xs to indicate the number of digits. The extension range can only contain numbers and the letter X. • If you add numbers to the extension range, all extensions added to this FortiGate Voice unit must include the same numbers in the same location in the extension number. For example, if you include a 6 as the first digit, all extensions added this FortiGate Voice unit must begin with the number 6. • The Xs indicate the number of digits in addition to the required number that each extension must have. For example, 6XXX indicates the extensions must start with the number 6 and be followed by any three numbers. Usually you would add one or two numbers to the start of the extension range to identify the extensions for this PBX and follow this with enough Xs to be able to add the required number of extensions. The extension range should not begin with the same number as the outgoing prefix.
Country/Area	Select the country or region in which the FortiGate Voice unit is installed.

Country Code	Enter the international country calling code for the country or region in which you are installing the FortiGate Voice unit.
Local Area Code	Enter the local area code for the location in which you are installing the FortiGate Voice unit.
Voicemail Access	Enter the exact pattern that PBX users dial to get their voicemail. For example, for users to dial *99 to get their voice mail, enter *99.
Outgoing Prefix	The number that PBX users must dial to get an outside line. For example, if users should dial 9 to get an outside line, add 9 to this field. The outgoing prefix should not be the same as the first number of the extension range.
FAX Admin Email	Enter the email address of the fax administrator.
Max Voicemail Duration	Select *No Limit* if you don't want to limit the voice mail duration. Otherwise enter a maximum time in seconds for voice mail recordings.
Voice Prompt Package	Select *Import* to import a new voice prompt file. The new file replaces the current voice prompt. See "Importing a new voice prompt file" on page 2643.
Call Parking Code	Enter the extension number used as the transfer destination for parking calls.
Parking Slots	Enter the number of parking slots.
Parking Time	Enter the maximum parking time, in seconds. If a call is left parked for the parking time duration, the call will ring to the originally dialed extension.
Call Parking DTMF Command	Enter the command used to park a call.

Importing a new voice prompt file

You can replace the default voice prompt by importing a new voice prompt file. You can create your own voice prompt file or you can obtain one in a different language from Fortinet. The new file overwrites the current voice prompt when imported.

To import a new pbx voice prompt file go to *PBX* > *Calling Rules* > *Setting* then select *Import*. The voice prompt file should be added to a tar file and zipped. This file would usually have the extension tgz.

Parking calls

Parking a call is similar to putting the caller on hold, except that the call can then be picked up from any extension.

For example, if an urgent call came in to an office for the manager, the receptionist may call the manager's office to make sure he is present to take the call rather than blindly transferring the call and possibly sending the caller to voicemail. If the manager is not in his office, the receptionist can park the call and use the PA system to inform the manager of the call and the number to dial to receive it. He can then use the nearest extension to dial the number and take the call. Further, if the call is not taken within 45 seconds, it will ring back to the extension from which it was parked.

Without call parking, the receptionist must put the caller on hold and then determine where the manager is, direct him to a nearby extension, and finally forward the call to the extension.

To configure call parking, go to *PBX* > *Calling Rules* > *Setting*.

FortiFAX service

The FortiFAX service is available as part of the FortiGuard Voice service for sending and receiving faxes. If your FortiGuard Voice service includes FortiFAX, the FortiGate Voice unit stores and then forwards faxes sent to and received from the FortiGuard Voice service. You can go to *PBX* > *FortiFAX* > *Received Fax* to view faxes received from the FortiGuard Voice service. You can go to *PBX FortiFAX* > *Sent Fax* to view faxes sent from a FAX device connected to the FortiGate Voice unit to the FortiGuard Voice service. For all faxes sent and received you can view information about the sender and receiver of the fax, the date and time the fax was received and the status of the fax. You can also download or delete any listed fax.

Incoming faxes are received and stored by the FortiGate Voice unit. PBX users can view their faxes from the FortiGate Voice user portal. See "Using the PBX user web portal" on page 2649. The FortiGate Voice unit sends email notifications to the PBX user's email address when a fax is received for them.

Users upload outgoing faxes to the FortiGate Voice unit using the FortiGate Voice user portal. The FortiGate Voice unit sends the faxes to their destination and records the result of sending the fax. If the fax cannot be sent right away the FortiGate Voice unit continues polling and will send the fax when possible. When the fax is sent the FortiGate Voice unit sends an email to the PBX user's email address.

Monitoring calls

You can monitor incoming and outgoing calls from *PBX* > *Monitor* > *Active Call*.

You can view information for all active calls including the originator of the call (From) the destination of the call (To), how long the call has been active (Duration), the codec used for transmitting voice packets, and the status of the call.

Monitoring recorded conference calls

You can view a list of recorded conference calls from *PBX* > *Monitor* > *Recorded Conference*.

You can view information for all recorded conference calls including the host of the call, the recording time of the conference and the size of the recorded file. You can also download recordings and delete them from the FortiGate Voice unit.

All recorded conference calls are saved on the FortiGate Voice hard disk. Recordings are also available on the user portal.

Monitoring voice mail storage

You can view information about each PBX user's stored voicemail messages from *PBX* > *Monitor* > *Voice Mail Storage*.

The information displayed includes each extension's voicemail status and amount of disk space used for recorded voice messages. You can delete voice mail for any or all extensions to recover disk space.

All recorded voice messages are saved on the FortiGate Voice hard disk. Recordings are also available on the user portal.

Monitoring active phones

You can view information about each active phone from *PBX* > *Monitor* > *Phone*.

The information displayed includes each phone's status, IP address, MAC address, and VCI.

Logging of PBX activities

After configuring PBX settings, you can configure logging of PBX activities and events. In addition to configuring required FortiGate logging settings you can also configure logging of PBX events.

To configure logging of PBX settings

1 Go to *Log&Report* > *Log Config* > *Log Setting*.

2 Select the check box beside *Enable* to make the other event log options available.

3 Select the check box beside *PBX event*.

Viewing log messages

You can view the PBX activities and events from *Log&Report* > *Log & Archive Access*. The log messages can be filtered so that you are viewing specific information, or you can display them in Raw format. Raw format is the format of what a log message actually appears in the log file.

Example PBX log messages

The following log message indicates that the phone with FortiGate Voice extension number 6005 called 914036085000 and the call was routed to the skype-088adb08 service provider. The call was answered and lasted for 1869 seconds.

2010-03-12 12:53:27 log_id=0162043782 type=event subtype=pbx pri=information fwver=040000 vd=root action=PBX-call clid="6005", src="6005" dst="914036085000"channel="SIP/6005-088a7c08" dstchannel="SIP/skype-088adb08" duration=1869 start="Fri Mar 12 12:22:18 2010 " end="Fri Mar 12 12:53:27 2010 " disposition="ANSWERED"msg="call from 6005=>914036085000, ANSWERED, for 1869 seconds"

The following log message indicates that the phone with FortiGate Voice extension number 6012 with caller ID Example Caller called extension 6036. And that the call was answered and lasted for 23 seconds.

2010-03-12 01:12:42 log_id=0162043782 type=event subtype=pbx pri=information fwver=040000 vd=root action=PBX-call clid=""Example Caller" <6012>", src="6012" dst="6036"channel="SIP/6012-084a9aa0" dstchannel="SIP/6036-08464150" duration=23 start="Fri Mar 12 01:12:19 2010 " end="Fri Mar 12 01:12:42 2010 " disposition="ANSWERED"msg="call from 6012=>6036, ANSWERED, for 23 seconds"

VoIP interface reference

The unit can effectively secure VoIP solutions since it supports VoIP protocols and associates state at the signaling layer with packet flows at the media layer. By using SIP ALG controls, the unit can interpret the VoIP signaling protocols used in the network and dynamically open and close ports (pinholes) for each specific VoIP call to maintain security.

In *UTM Profiles* > *VoIP* > *Profile*, you can configure multiple profiles for applying to firewall policies that concern only VoIP protocols.

Profile

The Profile menu allows you to configure VoIP profiles for applying to firewall policies. A profile is specific information that defines how the traffic within a policy is examined and what action may be taken based on the examination.

VoIP profile configuration settings

The following are VoIP profile configuration settings in *UTM Profiles* > *VoIP* > *Profile*. If the VoIP option does not appear, use this CLI command to enable it.

```
config system global
  set gui-voip-profile enable
end
```

Profile page	
Lists the profiles that you created for SIP and SCCP protocols. On this page, you can edit, delete or create a new profile for VoIP protocols. You are redirected to this page when you select *View List* on the Edit VoIP Profile page.	
Create New	Creates a new VoIP profile. When you select *Create New*, you are automatically redirected to the New VoIP Profile page.
Edit	Modifies settings within a VoIP profile. When you select *Edit*, you are automatically redirected to the Edit VoIP Profile page.
Delete	Removes a VoIP profile from the list on the Profile page. To remove multiple VoIP profiles from within the list, on the Profile page, in each of the rows of the profiles you want removed, select the check box and then select *Delete*. To remove all VoIP profiles from the list, on the Profile page, select the check box in the check box column and then select *Delete*.
Name	The name of the profile.
Comments	A description about the profile. This is an optional setting.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a firewall policy; on the Profile page (*UTM Profiles* > *Antivirus* > *Profile*), 1 appears in *Ref.* To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy, and that firewall policy's settings appear within the table.

New VoIP Profile page	
Provides settings for configuring SIP and SCCP options within the profile. This page appears when you select *Create New* on the Edit VoIP Profile page. If you are on the Profile page, and you select *Create New*, you will be redirected to the New VoIP Profile page.	
Name	Enter a name for the profile.
Comments	Enter a description about the profile. This is optional.
SIP	Configuration settings for SIP protocols.
Limit REGISTER requests	Enter a number for limiting the time it takes to register requests.
Limit INVITE requests	Enter a number to limit invitation requests.
SCCP	Configuration settings for SCCP protocols.
Limit Call Setup	Enter a number to limit call setup time.

Using the PBX user web portal

This section describes how to log into and use the FortiGate Voice PBX portal. FortiGate Voice PBX users can use the PBX web user portal to configure some of their extension's PBX settings, retrieve their voicemail, configure call forwarding for their extension, and review conference calls and conference call recordings.

Logging into and out of the FortiGate Voice PBX user web portal

FortiGate Voice PBX users use their extension number and password to log in to the PBX user web portal.

To log into the PBX user web portal

1 Open any web browser and browse to the following address:

`https://<interface_address>:8443`

where:

`<interface_address>` is the IP address or domain name of a FortiGate Voice interface from which users can access the FortiGate Voice PBX user web portal.

`8443` is the default port that users must browse to connect to the portal. FortiGate Voice system administrators can change this port number.

2 On the login form enter your extension number and extension password as provided by your system administrator and select Login.

If you successfully log in the user portal web-based manager is displayed.

To log out of the PBX user web portal

1 Select the Logout icon that appears at the top of every PBX user web portal page.

Configuring PBX extension settings

Go to *Configuration* > *Setting* to view your extension settings and to change your PBX user web portal password, and voicemail password and other PBX settings.

Extension	The extension number used to log into the portal (view only).
First Name **Last Name**	The first and last names assigned to this extension number (view only).
Email	The email address assigned to this extension number (view only).

Password	The password used to log into the portal. You can change the password by entering a new password into this field. When you start typing the new password a *Repeat Password* field appears. Re-type the new password and select OK to change the password. The next time you log into the portal you must use this password. The password cannot be blank, must be 8 or more characters, must contain at least one uppercase character, one lowercase character and one number. Non-alphanumeric characters, like (- $, are not supported in the password field.
Voicemail	Indicates whether or not this extension includes voicemail (ready only).
Voicemail password	The password used to retrieve your voicemail using your SIP phone. This password can only contain numbers. You can change the password by entering a new password into this field. When you start typing the new password a *Repeat Password* field appears. Re-type the new password and select OK to change the password. The next time you retrieve voicemail into the portal you must use this password. The password cannot be blank. Using a secure password is a best practice.
Email Notification	Select to receive email notifications from the FortiGate Voice unit when a caller leaves you a voicemail.
Voicemail to Email Attachment	Select to have the FortiGate Voice unit attach the voicemail messages to the notification email as an audio file. When you receive an email notification of a voicemail you can listen to the voicemail by playing the audio file.
Maximum Message#	Shows the number of saved voicemail messages that can be saved for this extension.

Voicemail

You can view lists of your extension's voicemail messages. Any message can be downloaded to be listened to or deleted. You can also save voicemail messages. Saved messages appear on the saved message list. If you have listened to voicemail messages from your SIP phone but not saved them they are added to the Old Message list.

To download or delete a message, select the message and select Download or Delete.

Configuring call forwarding

Use call forwarding options to configure forward your calls. The following options are available. Select and option and select OK to save the change.

None	Disable or turn off call forwarding.
Forward Calls to VoiceMail Box	Send all calls directly to your voicemail. The caller hears your welcome message and can leave a message for your voicemail. The extension does not ring.

Forward All Calls	Forward all calls to a different phone number. This can be a different extension or an external phone number (for example, your cell phone number). In the Forward Number field, enter the number that the call is forwarded to. Include the area code, country code etc. if required.
Forward Unanswer Calls	Forward calls to a different phone number if you don't answer the phone. The call is forwarded to the external number instead of to voice mail after the same number of rings. This can be a different extension or an external phone number (for example, your cell phone number). In the Forward Number field, enter the number that the call is forwarded to. Include the area code, country code etc. if required.

Sending a Fax using FortiFAX

To send a fax, create a pdf file containing the pages that you want to send. Use the following instructions to upload the pdf to the FortiGate Voice PBX and send it as a fax.

FortiFAX is only available via active FortiGuard Voice Service subscriptions that include FortiFAX service.

To send a fax, go to *FortiFAX* > *Fax Document Upload*. Enter the fax number that you want to send a fax message to. Select *Browse* to upload the pdf file that you want to send. You can also type in the file location manually into the File to Fax field. Select OK to send the fax. A message appears to confirm that the fax has been sent.

The FortiGate Voice PBX stores a copy of the pdf file, which is only viewable by a system administrator.

Conference calls

If the PBX administrator has made your extension a conference bridge host you can view the conference bridges that you can host, change their configuration, and see lists of the participants in an active conference call using your conference bridges. You can also manage conference call recordings for your conference bridges.

To change your conference bridge settings, log into the PBX user web portal and go to *Conference* > *Conference List* and edit the conference bridge.

Conference ID	The number that participants dial to call into a conference using this conference bridge (view only).
Password	Change the password for this conference bridge. The password cannot be blank and must contain only numbers. This becomes the conference PIN number.
Host	The extension number of the conference bridge host, which is your extension number (view only).
Host Pin	Change the host pin for this conference bridge. The pin only contain numbers.

Video	Select if the conference bridge can display video and handle video calls.
Recordable	Select to enable recording of conference calls that use this conference bridge. You cannot select this option if the conference bridge supports video calls.

Conference call recordings are saved on the FortiGate Voice hard disk. You can go to *Conference* > *Recorded Conference* to download and delete conference call recordings.

Managing conference calls

The conference bridge host must dial into the conference bridge and enter the host pin for the conference call to start. During the call the host can also can also do the following from the phone used to start the conference call:

- Press * to hear a conference bridge menu
- Press 8 to start recording the conference call
- Press 9 to stop recording the conference call

Conference call recordings are saved on the FortiGate Voice hard disk. After the recording has been stopped and the call ended the host can log into the FortiGate Voice PBX user web portal and download or delete conference call recordings.

FortiGate Voice VoIP, PBX, and PSTN CLI Reference

This section describes FortiGate Voice VoIP, PBX, and PSTN configuration settings. PSTN interfaces are not available on all FortiGate Voice models. For information about other FortiGate Voice CLI commands see the *FortiGate CLI Reference*.

This section describes:

config pbx dialplan

Use this command to add a dial plan and add rules to the dial plan. A dial plan rule indicates an outgoing destination to send calls to. You can add multiple rules to a dial plan. You add dial plans to extensions to control how to handle outgoing calls from the extension.

Syntax

```
config pbx dialplan
  edit <pbx_dialplan_name>
    set comments <comment_string>
      config rule
        edit <rule_name_str>
          set action {allow | block}
          set callthrough {fxo1 | fxo2 | fxo3 | fx04 |
             <voip_providers>}
          set outgoing-prefix <pattern_str>
          set phone-no-beginwith <patern_str>
          set prepend <pattern_str>
```

```
            set use-global-outgoing-prefix {no | yes}
        end
    end
```

Variables	Description	Default
edit <pbx_dialplan_name>	Enter the name for the dial plan. If you entering an existing dial plan, select Tab to get to the dial plan that you want to edit.	No default
comments <comment_string>	Optionally enter a description of the dial plan.	No default
config rule	Configure a new dial plan rule.	No default
edit <rule_name_str>	Enter the name of the dial plan rule to configure.	No default
action {allow | block}	Set the action to allow if this dial plan rule should allow a call. Set the action to block if the dial plan should block a call. For example, if you want to block international calls you could set the Phone Number begin with to 011 and set the action to block.	No default
callthrough {fxo1 | fxo2 | fxo3 | fx04 | <voip_providers>}	Select one or more destinations that the dial plan rule sends outgoing calls to. fxo1, fxo2, fxo3, and fx04 are the 4 PSTN interfaces. <voip_providers> are the VoIP providers added to the FortiGate Voice. A dial plan rule can send calls to one or more destinations.	No default
outgoing-prefix <pattern_str>	If you set use-global-outgoing-prefix to no you can enter a different outgoing prefix for this dial plan.	null
phone-no-beginwith <patern_str>	Enter the leading digits of the phone number that this dial plan rule should match with. For example, a dial plan rule for toll free numbers in North America should begin with 18. The FortiGate Voice uses a best match to match a dialed number with a dial plan. So each dial plan should have a different Phone number Begin with setting. But you should plan your dial plan to make sure that unexpected matches do not occur.	null
prepend <pattern_str>	Add digits that should be prepended or added to the beginning of the dialed number before the call is forwarded to its destination. You can prepend digits at the beginning of a call of special dialing is required to reach and external phone system.	null
use-global-outgoing-prefix {no | yes}	Select yes if the dial plan rule should use the default outgoing prefix (usually 9). Select no to add a different outgoing-prefix.	yes

config pbx did

Use this command to configure Direct Inward Dialing (DID). DID allows calls from external phone systems to dial directly to extensions added to the FortiGate Voice unit.

Syntax

```
config pbx did
  edit <pbx_did_name>
    set external-line {fxo1 | fxo2 | fxo3 | fx04 |
       <voip_providers>}
    set cid-number <phone_number>
    set extension <extension_number>
    set comment <comment_string>
end
```

Variables	Description	Default
edit <pbx_did_name>	Enter the name for the Direct Inward Dial.	No default
external-line {fxo1 | fxo2 | fxo3 | fx04 | <voip_providers>}	Select one external system that can dial directly to an extension. fxo1, fxo2, fxo3, and fx04 are the 4 PSTN interfaces. <voip_providers> are the VoIP providers added to the FortiGate Voice.	null
cid-number <phone_number>	Enter the phone number dialed by a caller on the external system.	null
extension <extension_number>	Enter the FortiGate Voice extension number the call is directed to.	null
comment <comment_string>	Enter a description, if applicable, about the direct inward dial configuration.	null

config pbx extension

Use this command to add SIP phone extensions to the FortiGate Voice unit. You can add new extensions or reconfigure the existing ones. For example, you can label an extension by user name, or you can add an extension and set it as a host for conference calls, or you can get FortiGate Voice unit to send email notifications to the users when they receive new voicemail messages.

FortiGate Voice uses the alertmail settings to access an SMTP server and send email notifications. Alertmail can be configured through config system alertmail command. For more information about alertmail CLI command configuration refer to FortiGate CLI Reference.

Syntax

```
config pbx extension
  edit <extension_number>
    set attach {enable | disable}
    set auto-delete {enable | disable}
    set conference-host <extension_number>
    set dialplan <dialplan_name>
```

```
    set email <user_email>
    set email-notify {enable | disable}
    set first-name <first_name>
    set host-pin <host_password>
    set last-name <surname_name>
    set macaddress <mac_address>
    set max-msg <max_messages_ allowed>
    set nat {no | yes}
    set recordable-flag {enable | disable}
    set secret <user_password>
    set type {conference | sip-phone}
    set video {enable | disable}
    set vm-secret <user_password>
    set voicemail {enable | disable}
end
```

Variables	Description	Default
edit <extension_number>	Enter the extension number. The extension number has to match the config pbx global extension pattern.	No default
attach {enable | disable}	Enable the voicemail message as an attachment in an email.	disable
auto-delete {enable | disable}	Enable to automatically delete voice mail.	disable
conference-host <extension_number>	Enter the extension number that will host the conference.	null
dialplan <dialplan_name>	Enter the dial plan that you want to use for the extension.	null
email <user_email>	Enter the user's email address. This email address can be used to notify the user when they have a new voicemail message.	null
email-notify {enable | disable}	Enable email notification. When email notification is enabled the user gets notified of each new voicemail messages.	disable
first-name <first_name>	Enter the person's first name.	null
host-pin <host_password>	Enter the password for the conference call. The password must contain only numbers. The users need to enter this password to join the conference call.	
last-name <surname_name>	Enter the surname of the person.	null
macaddress <mac_address>	Enter the MAC address of the SIP phone for the current extension. A typical MAC address consists of six double digit alpha-numeric characters separated by colons. Colons must be used when entering the MAC address.	00:00:00:00:00:00

Variables	Description	Default
max-msg <max_messages_allowed>	Enter the maximum number of voicemail messages that are allowed in a user's voicemail inbox.	50
nat {no | yes}	Enter to indicate that the phone is behind a NAT device.	no
recordable-flag {enable | disable}	Enable conference recording. When enabled the conference call are recorded on FortiGate Voice unit's hard drive.	disable
secret <user_password>	Enter the user's password for voicemail.	No default
type {conference | sip-phone}	Enter the type of extension to configure. • sip-phone to configure a SIP phone extension • conference to add a conference bridge. Multiple users can call the conference bridge extension number enter the secret and have a conference call. A conference bridge only requires an extension number and a secret.	sip-phone
video {enable | disable}	Enable video conferencing.	disable
vm-secret <user_password>	Enter the user's password for accessing their voicemail inbox.	No default
voicemail {enable | disable}	Enable the extension to have voicemail.	enable

config pbx global

Use this command to configure voicemail settings such as limiting the length of voicemail messages, as well as the country and the extension pattern of the user.

Syntax

```
config pbx global
  set atxfer-dtmf <str>
  set blindxfer-dtmf <str>
  set block-blacklist {enable | disable}
  set code-callpark <str>
  set country-area <country_name>
  set country-code <country_code>
  set dtmf-callpark <str>
  set efax-check-interval <integer>
  set extension-pattern <extension_pattern>
  set fax-admin-email <email_address>
  set ftgd-voice-server <server_address>
  set local-area-code <code_string>
  set max-voicemail <max_length_seconds>
  set outgoing-prefix <pattern_str>
  set parking-slots <int>
  set parking-time <int>
  set ring-timeout <time_int>
  set rtp-hold-timeout <time_int>
```

```
    set rtp-timeout <time_int>
    set voicemail-extension <access_number>
  end
```

Variables	Description	Default
atxfer-dtmf <str>	The DTMF command to trigger an attended transfer.	*2
blindxfer-dtmf <str>	The DTMF command to trigger a blind transfer.	#1
block-blacklist {enable | disable}	Enable to block blacklist IP addresses.	enable
code-callpark <str>	Enter this numeric code to park the current call.	700
country-area <country_name>	Enter the name of the country in which the FortiGate Voice unit is installed.	USA
country-code <country_code>	Enter the country code in which the FortiGate Voice unit is installed.	1
dtmf-callpark <str>	The DTMF command to trigger a call park.	#72
efax-check-interval <integer>	Enter the efax polling interval from FortiGuard fax server. The value range is 5 to 120 in minutes.	5
extension-pattern <extension_pattern>	Enter a pattern that defines the valid extensions that can be added to the FortiGate Voice configuration. The pattern can include numbers that must be in every extension and upper case Xs to indicate the number of digits. The extension range can only contain numbers and the letter X. • If you add numbers to the extension range, all extensions added to this FortiGate Voice unit must include the same numbers in the same location in the extension number. For example, if you include a 6 as the first digit, all extensions added this FortiGate Voice unit must begin with the number 6. • The Xs indicate the number of digits in addition to the required number that each extension must have. For example, 6XXX indicates the extensions must start with the number 6 and be followed by any three numbers. Usually you would add one or two numbers to the start of the extension range to identify the extensions for this PBX and follow this with enough Xs to be able to add the required number of extensions. The extension range should not begin with the same number as the outgoing prefix.	null

Variables	Description	Default
fax-admin-email <email_address>	Enter the email address of the fax administrator.	null
ftgd-voice-server <server_address>	Enter the FortiGuard voice server address. Default: service.fortivoice.com	
local-area-code <code_string>	Enter the local area code for the country or region in which you are installing the FortiGate Voice unit.	408
max-voicemail <max_length_seconds>	Limit the length of voicemail messages in seconds. Set to 0 for no limit.	60
outgoing-prefix <pattern_str>	The number that PBX users must dial to get an outside line. For example, if users should dial 9 to get an outside line, add 9 to this field. The outgoing prefix should not be the same as the first number of the extension range.	9
parking-slots <int>	The maximum number of calls that can be parked at the same time.	20
parking-time <int>	The length of time, in seconds, a call can be parked. If this time expires without the call being answered, the parked call will ring back to the extension from which it was parked.	45
ring-timeout <time_int>	The number of seconds that an extension should be allowed to ring before going to voicemail.	20
rtp-hold-timeout <time_int>	The amount of time in seconds that the extension will wait on hold for RTP packets before hanging up the call. 0 means no time limit.	0
rtp-timeout <time_int>	The amount of time in seconds during an active call that the extension will wait for RTP packets before hanging up the call. 0 means no time limit.	60
voicemail-extension <access_number>	Enter the voicemail extension number that a user will use to access their voicemail inbox.	*97

config pbx ringgrp

Use this command to add and configure the extension groups. An extension group here is referred to a ring group and is a group of extensions that can be called using one number. You can configure the ring group to call all of the extensions in the group at the same time or to call the extensions one at a time until someone answers.

The order in which the members are added to the ring group does not match the order in which the FortiGate Voice unit calls them.

Syntax

```
config pbx ringgrp
  edit <ring_group_name>
    set description <description_str>
    set member <acd_group_member>
    set no-answer-action {hangup | ivr | voicemail}
    set strategy {ring-all | sequential}
    set voicemail-of-extension <extension_number>
end
```

Variables	Description	Default
`edit <ring_group_name>`	Enter the name for the group.	No default.
`description <description_str>`	A description of the extension group.	null
`member <acd_group_member>`	Enter the ACD member for the group.	No default
`no-answer-action {hangup | ivr | voicemail}`	Enter the action that will be taken when none of the extensions in the ring group answers. • `hangup` hand up and end the call. • `ivr` return the caller to the attendant where they can try another extension. • `voicemail` the caller is directed to the voicemail system where they can leave a message.	`voicemail`
`strategy {ring-all | sequential}`	Control how the extensions in the group are called by the ring group. • `ring-all` calls all of the extensions in the group at the same time. • `sequential` calls the extensions in the group one at a time in the order in which they have been added to the group.	`sequential`
`voicemail-of-extension <extension_number>`	Enter the extension number to use for voicemail if no one answers the call and `no-answer-action` is set to `voicemail`.	null

config pbx voice-menu

Use this command to configure the menu that callers will access when they call. The variable `config press-<number>` configures the settings for the type of ring group and the type of group associated with that number.

Syntax

```
config pbx voice-menu
  set comment <comment_string>
  set password <ext_password>
  set recorder-exten <extension_str>
    config [press-0 | press-1 | press-2 | press-3 | press-4 |
       press-5 | press-6 | press-7 | press-8 | press-9]
      set type {directory | none | ring-group | voicemail}
```

```
        set ring-group <group_string>
    end
end
```

Variables	Description	Default
comment <comment_string>	Enter a description of the voice-menu settings, if applicable.	No default
password <ext_password>	Enter the password to access recording a new IVR message.	null
recorder-exten <extension_str>	Enter the extension number for recording a new IVR message.	*30
config [press-0 | press-1 | press-2 | press-3 | press-4 | press-5 | press-6 | press-7 | press-8 | press-9]	Use this command when configuring what action each number on the phone's keypad will take. For example, you want the personnel directory to come up every time someone presses 1; config press-1 variable would have the type directory selected in type.	No default
type {directory | none | ring-group | voicemail}	Enter the type of action that is associated with the specific number on the phone's keypad. For example, the office phone directory is heard when a caller presses 0 because config press-0 has directory as its type.	No default
ring-group <group_string>	Enter to include a specific ring-group if you have select ring-group in type. This variable appears only when ring-group is selected in type.	null

config pbx sip-trunk

Use this command to configure SIP server providers for the PBX. If your FortiGate Voice unit is installed in North America and the Country Code is set to 1 then you can use the FortiGuard Voice service as your SIP service provider. (The default Country Code is 1, see "config pbx global" on page 2657 for changing county code.) The FortiGuard Voice service is supported only in North America. If you install the FortiGate Voice unit elsewhere in the world and change the Country Code, the FortiGuard Voice Service configuration is replaced by the SIP trunk configuration. You can use the SIP trunk configuration to add one or more SIP service providers to the FortiGate Voice configuration.

Syntax

```
config pbx voip-provider
  edit <provider_name>
    set user <user_name>
    set domain {<VoIP_provider_address_ipv4> |
       <VoIP_provider_domain> }
    set secret <password>
    set authuser <authuser>
    set display-name <display_name>
    set reigstration-interval <refresh_interval>
```

```
        set account-type {static | dynamic}
        set dtmf-metod {auto | inband | info | rfc2833}
        set codec {alaw | g729 |none | ulaw}
        set codec1 {alaw | g729 |none | ulaw}
        set codec2 {alaw | g729 |none | ulaw}
        set video {enable | disable}
    end
```

Variables	Description	Default
edit <provider_name>	Enter the VoIP provider's name.	No default
user <user_name>	Enter the user name for the provider. You can enter the phone number registered with this provider instead.	No default
secret <password>	Enter the password associated with the provider.	No default
domain {<VoIP_provider_address_ipv4> | <VoIP_provider_domain>}	The VoIP provider's domain name or IP address. For example, 172.20.120.11 or voip.example.com.	No default
authuser <authuser>	Enter the authentication user for the account.	No default
display-name <display_name>	Enter the name that will be used as the caller ID name if the provider supports this feature.	No default
reigstration-interval <refresh_interval>	Enter a number for the refresh interval.	No default
account-type {static | dynamic}	Enter to define the type of account.	No default.
dtmf-metod {auto | inband | info | rfc2833}	Enter the DTMF method that will be used.	No default
codec {alaw | g729 |none | ulaw}	Enter the most preferred Codec for the VoIP provider.	ulaw
codec1 {alaw | g729 |none | ulaw}	Enter the second most preferred Codec for the VoIP provider.	none
codec2 {alaw | g729 |none | ulaw}	Enter the third most preferred Codec for the VoIP provider.	none
video {enable | disable}	Enable video capability if the provider supports this feature.	disable

config system pstn

Use this command to configure the PSTN interfaces. PSTN interfaces are available on some FortiGate Voice models.

Syntax

```
config system pstn
  edit <fxo_name>
    set cid-name <caller_name>
    set cid-number <caller_name>
    set status {enable | disable}
    set use-callerid {enable | disable}
    set cid-signalling {bell | dtmf | v23 | v23-jp}
    set cid-start {polarity | ring}
    set send-callerid-after <integer>
    set hangup-on-polarity-reversal {enable | disable}
    set hangup-on-zero-voltage {enable | disable}
    set hangup-on-busy-tone {enable | disable}
    set busycount <integer>
    set busy-tone-length <integer>
    set busy-quiet-length <integer>
    set codec {alaw | ulaw}
end
```

Variables	Description	Default
edit <fxo_name>	Enter the name of the FXO.	No default
cid-name <caller_name>	This name is used for caller ID for calls from the FortiGate Voice unit to the PSTN. It can be any name, such as a company name, that identifies the branch office.	No default
cid-number <caller_name>	Enter the phone number of the PSTN phone line as provided by your phone service provider.	No default
status {enable | disable}	Enable the status of the port.	enable
use-callerid {enable | disable}	Enable to catch the caller ID.	enable
cid-signalling {bell | dtmf | v23 | v23-jp}	Enter the caller ID protocol. The protocol v23-jp is the v23 protocol for Japan.	bell
cid-start {polarity | ring}	Enter to start transmitting the caller ID.	ring
send-callerid-after <integer>	Enter a number for the number of rings after that the caller ID began to transmit.	1
hangup-on-polarity-reversal {enable | disable}	Enable to have the phone hang up when there is polarity reversal.	enable

Variables	Description	Default
`hangup-on-zero-voltage {enable | disable}`	Enable to have the phone hang up when there is zero voltage.	`disable`
`hangup-on-busy-tone {enable | disable}`	Enable to have the phone hang up when a busy tone is detected.	`enable`
`busycount <integer>`	Enter a number for the accurate number of busy tones that are detected.	`4`
`busy-tone-length <integer>`	Enter a number that determines how logn the busy tone is on in milliseconds.	`500`
`busy-quiet-length <integer>`	Enter a number that determines how long the busy tone is off in milliseconds.	`500`
`codec {alaw | ulaw}`	Enter the Codec preference type based on the country.	`ulaw`
`ring detect {ring-cross-threshold | ring-full-wave | ring-half-wave | ring-validate}`	Enter the appropriate ring detection method for your phone system.	`ring-validate`
`ring-timeout {128ms | 256ms | 384ms | 512ms | 640ms | 768ms | 896ms | 1024ms | 1152ms | 1280ms | 1408ms | 1536ms | 1664ms | 1792ms | 1920ms}`	Enter the appropriate ring time-out for your phone system.	`640ms`
`ring-threshold {level-1 | level-2 | level-3}`	Enter the appropriate ring threshold for your phone system. The ring-threshold is based on voltage: • level-1: 13.5V to 16.5V • level-2: 19.35V to 23.65V • level-3: 40.5V to 49.5V	`level-1`
`ring-delay-time {256ms | 512ms | 768ms | 1024ms | 1280ms |1536ms | 1792ms}`	Enter the appropriate ring delay time for your phone system.	`512ms`
`ring-confirm-time {100ms | 150ms | 200ms | 256ms | 384ms | 512ms | 640ms 1024ms}`	Enter the appropriate ring confirmation time for your phone system.	`512ms`
`ring-max-assertion-count <int>`	Enter the appropriate ring maximum assertion count for your phone system.	`22`
`ring-assertion-time <int>`	Enter the appropriate ring assertion time for your phone system.	`25`

Variables	Description	Default
tx-gain <int>	Enter the gain for the transmitted signal, in dB, from -15 to 12.	0
rx-gain <int>	Enter the gain for the received signal, in dB, from -15 to 12.	0

config system interface

Use this command to allow traffic for the VoIP protocol, SIP, to flow on a specific interface. You can also allow users to access PBX user portal and enable auto-provisioning for SIP phone configuration on the same interface.

Syntax

```
config system interface
  edit <interface_name>
    set pbx-user-portal {enable | disable}
    set phone-auto-provision {enable | disable}
    set voip {enable | disable}
  end
```

Variables	Description	Default
edit <interface_name>	Enter the interface that you want to allow SIP traffic on.	No default
pbx-user-portal {enable | disable}	Enable PBX user portal on the interface.	disable
phone-auto-provision {enable | disable}	Enable SIP phone auto-provisioning on the interface.	disable
voip {enable | disable}	Enable the VoIP SIP protocol for allowing SIP traffic on the interface.	disable

execute pbx

Use this command to view active channels and to delete, list or upload music files for when music is playing while a caller is on hold.

Syntax

```
execute pbx active-call <list>
execute pbx extension <list>
execute pbx ftgd-voice-pkg {sip-trunk}
execute pbx music-on-hold {delete | list | upload}
execute pbx prompt upload ftp <file.tgz>
   <ftp_server_address>[:port] [<username>] [password>]
execute pbx prompt upload tftp <file.tgz>
   <ftp_server_address>[:port] [<username>] [password>]
execute pbx prompt upload usb <file.tgz>
   <ftp_server_address>[:port] [<username>] [password>]
execute pbx restore-default-prompts
```

```
execute pbx sip-trunk list
```

Variables	Description
active-call <list>	Enter to display a list of the active calls being processed by the FortiGate Voice unit.
extension <list>	Enter to display the status of all extensions with SIP phones that have connected to the FortiGate Voice unit.
ftgd-voice-pkg {sip-trunk}	Enter to retrieve FortiGuard voice package sip trunk information.
music-on-hold {delete | list | upload}	Enter to either delete, list or upload music on hold files. You can upload music on hold files using FTP, TFTP, or from a USB drive plugged into the FortiGate Voice unit.
prompt upload ftp <file.tgz> <ftp_server_address> [:port] [<username>] [password>]	Upload new pbx voice prompt files using FTP. The voice prompt files should be added to a tar file and zipped. This file would usually have the extension tgz. You must include the filename, FTP server address (domain name of IPv4 address) and if required the username and password for the server.
prompt upload tftp <file.tgz> <ftp_server_address> [:port] [<username>] [password>]	Upload new pbx voice prompt files using TFTP. The voice prompt files should be added to a tar file and zipped. This file would usually have the extension tgz. You must include the filename and TFTP server IP address.
prompt upload usb <file.tgz> <ftp_server_address> [:port] [<username>] [password>]	Upload new pbx voice prompt files from a USB drive plugged into the FortiGate Voice unit. The voice prompt files should be added to a tar file and zipped. This file would usually have the extension tgz. You must include the filename.
restore-default-prompts	Restore default English voicemail and other PBX system prompts. Use this command if you have changed the default prompts and want to restore the default settings.
sip-trunk list	Enter to display the status of all SIP trunks that have been added to the FortiGate Voice configuration.

Example command output

Enter the following command to view active calls:

```
execute pbx active-call

Call-From    Call-To    Durationed
6016         6006       00:00:46
```

Enter the following command to display the status of all extensions

```
execute pbx extension list
  Extension  Host                Dialplan
  6052       Unregister          company-default
  6051       Unregister          company-default
  6050       Unregister          company-default
  6022       Unregister          company-default
  6021/6021  172.30.63.34        company-default
```

```
    6020      Unregister          company-default
```

Enter the following command to display the status of all SIP trunks

```
  execute pbx sip-trunk list
Name        Host          Username     Account-Type    State
Provider_1  192.169.20.1  +5555555     Static           N/A
```

get pbx branch-office

Use this command to list the configured branch offices.

Syntax

```
get pbx branch-office
```

Example output

```
== [ Branch 15 ]
name: Branch 15
== [ Branch 12 ]
name: Branch 12
```

get pbx dialplan

Use this command to list the configured dial plans.

Syntax

```
get pbx dialplan
```

Example output

```
== [ company-default ]
name: company-default
== [ inbound ]
name: inbound
```

get pbx did

Use this command to list the configured direct inward dial (DID) numbers.

Syntax

```
get pbx did
```

Example output

```
== [ Operator ]
name: Operator
== [ Emergency ]
name: Emergency
```

get pbx extension

Use this command to list the configured extensions.

Syntax

```
get pbx extension
```

Example output

```
== [ 6555 ]
extension: 6555
== [ 6777 ]
extension: 6777
== [ 6111 ]
extension: 6111
```

get pbx ftgd-voice-pkg

Use this command to display the current FortiGate Voice service package status.

Syntax

```
get pbx ftgd-voice-pkg status
```

Example output

```
Status: Activated
Total 1 Packages:
Package Type: B, Credit Left: 50.00, Credit Used: 0.00,
Expiration Date: 2011-01-01 12:00:00

Total 1 Dids:
12345678901
Total 1 Efaxs:
12345678902
Total 0 Tollfrees:
```

get pbx global

Use this command to display the current global pbx settings.

Syntax

```
get pbx global
```

Example output

```
block-blacklist     : enable
country-area        : USA
country-code        : 1
efax-check-interval : 5
extension-pattern   : 6XXX
fax-admin-email     : faxad@example.com
ftgd-voice-server   : service.fortivoice.com
local-area-code     : 408
max-voicemail       : 60
outgoing-prefix     : 9
ring-timeout        : 20
rtp-hold-timeout    : 0
rtp-timeout         : 60
```

```
voicemail-extension : *97
```

get pbx ringgrp

Use this command to display the currently configured ring groups.

Syntax

```
get pbx ringgrp
```

Example output

```
== [ 6001 ]
name: 6001
== [ 6002 ]
name: 6002
```

get pbx sip-trunk

Use this command to display the currently configured SIP trunks.

Syntax

```
get pbx sip-trunk
```

Example output

```
== [ __FtgdVoice_1 ]
name: __FtgdVoice_1
```

get pbx voice-menu

Use this command to display the current voice menu and recorder extension configuration.

Syntax

```
get pbx voice-menu
```

Example output

```
comment             : general
password            : *
press-0:
    ring-group          : 6001
    type                : ring-group
press-1:
    type                : voicemail
press-2:
    type                : directory
press-3:
    type                : none
press-4:
    type                : none
press-5:
    type                : none
press-6:
    type                : none
```

```
press-7:
    type                : none
press-8:

press-9:
    type                : none
recorder-exten      : *30
```

diagnose pbx restart

Use this diagnose command to restart the FortiGate Voice PBX daemon.

```
diagnose pbx restart
```

Chapter 17 WAN Optimization, Web Cache, Explicit Proxy, and WCCP

The FortiOS Handbook chapter contains the following sections:

WAN optimization, web cache, explicit proxy, and WCCP concepts: Provides an overview of FortiGate WAN optimization best practices and technologies and some of the concepts and rules for using them. We recommend that you begin with this chapter before attempting to configure your FortiGate unit to use WAN optimization.

WAN optimization and Web cache storage: Describes how to configure WAN optimization storage settings to control how data is stored for web caching and byte caching.

WAN optimization peers and authentication groups: Describes how to use WAN optimization peers and authentication groups to control access to WAN optimization tunnels.

Configuring WAN optimization rules: Provides basic configuration for WAN optimization rules, including adding rules, organizing rules in the rule list and using WAN optimization addresses. This chapter also explains how WAN optimization accepts sessions, as well as how and when you can apply UTM features to WAN optimization traffic.

WAN optimization configuration examples: Describes basic active-passive and peer-to-peer WAN optimization configuration examples. This chapter is a good place to start learning how to put an actual WAN optimization network together.

Web caching: Describes how WAN optimization web caching works to cache different session types, including HTTPS, and includes web caching configuration examples.

Advanced configuration example: Provides a configuration example that combines WAN optimization, web caching, out-of-path WAN optimization, and the use of multiple VDOMs to apply UTM features to sessions being optimized.

SSL offloading for WAN optimization and web caching: Describes how to offload SSL processing from web sites to FortiGate units to improve WAN performance for SSL-protected web sites on a WAN.

FortiClient WAN optimization: Describes how FortiGate and FortiClient WAN optimization work together and includes an example configuration.

The FortiGate explicit web proxy: Describes how to configure the FortiGate explicit web proxy, how users connect to the explicit web proxy, and how to add web caching to the explicit web proxy.

The FortiGate explicit FTP proxy: Describes how to configure the FortiGate explicit FTP proxy and how users connect to the explicit FTP proxy.

FortiGate WCCP: Describes FortiGate WCCP and how to configure WCCP and the WCCP client.

WAN optimization, web cache, explicit proxy and WCCP get and diagnose commands: describes get and diagnose commands available for troubleshooting WAN optimization, web cache, and WCCP.

WAN optimization, web cache, explicit proxy, and WCCP concepts

FortiGate WAN optimization consists of a number of techniques that you can apply to improve the efficiency of communication across your WAN. These techniques include protocol optimization, byte caching, web caching, SSL offloading, and secure tunnelling. Protocol optimization can improve the efficiency of traffic that uses the CIFS, FTP, HTTP, or MAPI protocol, as well as general TCP traffic. Byte caching caches files and other data on FortiGate units to reduce the amount of data transmitted across the WAN. Web caching stores web pages on FortiGate units to reduce latency and delays between the WAN and web servers. SSL offloading offloads SSL decryption and encryption from web servers onto FortiGate SSL acceleration hardware. Secure tunnelling secures traffic as it crosses the WAN.

You can apply different combinations of these WAN optimization techniques to a single traffic stream depending on the traffic type. For example, you can apply byte caching and secure tunneling to any TCP traffic. For HTTP and HTTPS traffic, you can also apply protocol optimization and web caching.

You can configure a FortiGate unit to be an explicit web proxy server and an explicit FTP proxy server. Users on your internal network can browse the Internet through the explicit web proxy server or connect to FTP servers through the explicit FTP proxy server. You can also configure these proxies to protect access to web or FTP servers behind the FortiGate unit using a reverse proxy configuration.

FortiGate units that support WAN optimization can also be configured to support web caching. Both WAN optimization and web caching require that the FortiGate unit include a hard disk. Either an internal hard disk or AMC or other hard disk module. Web caching can be applied to any HTTP, this includes HTTP traffic accepted by a security policy, explicit web proxy traffic, and HTTP and HTTPS WAN optimization traffic.

You can also configure a FortiGate unit to operate as a Web Cache Communication Protocol (WCCP) client or server. WCCP provides the ability to offload web caching to one or more redundant web caching servers.

This chapter describes:

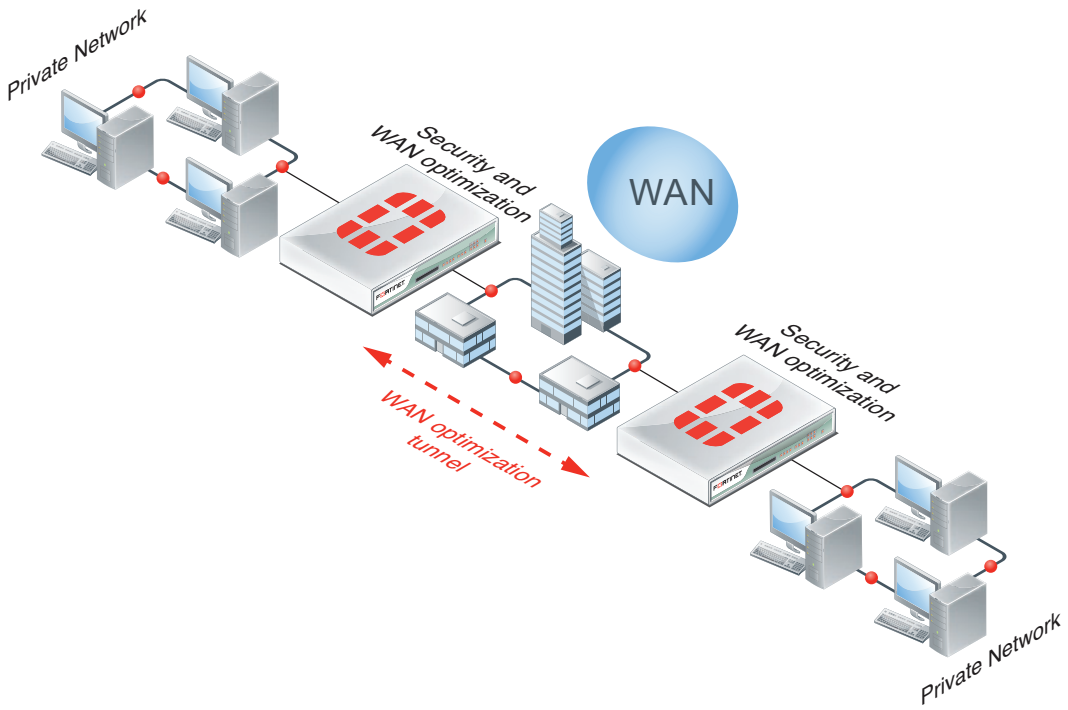
WAN optimization topologies

This section describes some common WAN optimization topologies:

Basic WAN optimization topologies

The basic FortiGate WAN optimization topology consists of two FortiGate units operating as WAN optimization peers intercepting and optimizing traffic crossing the WAN between the private networks.

Figure 302: Security device and WAN optimization topology



As shown in Figure 302, the FortiGate units can be deployed as security devices that protect private networks connected to the WAN and also perform WAN optimization. In this configuration, the FortiGate units are configured as typical security devices for the private networks and are also configured for WAN optimization. The WAN optimization configuration intercepts traffic to be optimized as it passes through the FortiGate unit and uses a WAN optimization tunnel with another FortiGate unit to optimize the traffic that crosses the WAN.

As shown in Figure 303, you can also deploy WAN optimization on single-purpose FortiGate units that only perform WAN optimization. In Figure 303, the WAN optimization FortiGate units are located on the WAN outside of the private networks. You can also install the WAN optimization FortiGate units behind the security devices on the private networks.

The WAN optimization configuration is the same for FortiGate units deployed as security devices and for single-purpose WAN optimization FortiGate units. The only differences would result from the different network topologies.

Out-of-path topology

In an out-of-path topology, one or both of the FortiGate units configured for WAN optimization are not directly in the main data path. Instead, the out-of-path FortiGate unit is connected to a device on the data path, and the device is configured to redirect sessions to be optimized to the out-of-path FortiGate unit.

Figure 303: Single-purpose WAN optimization topology

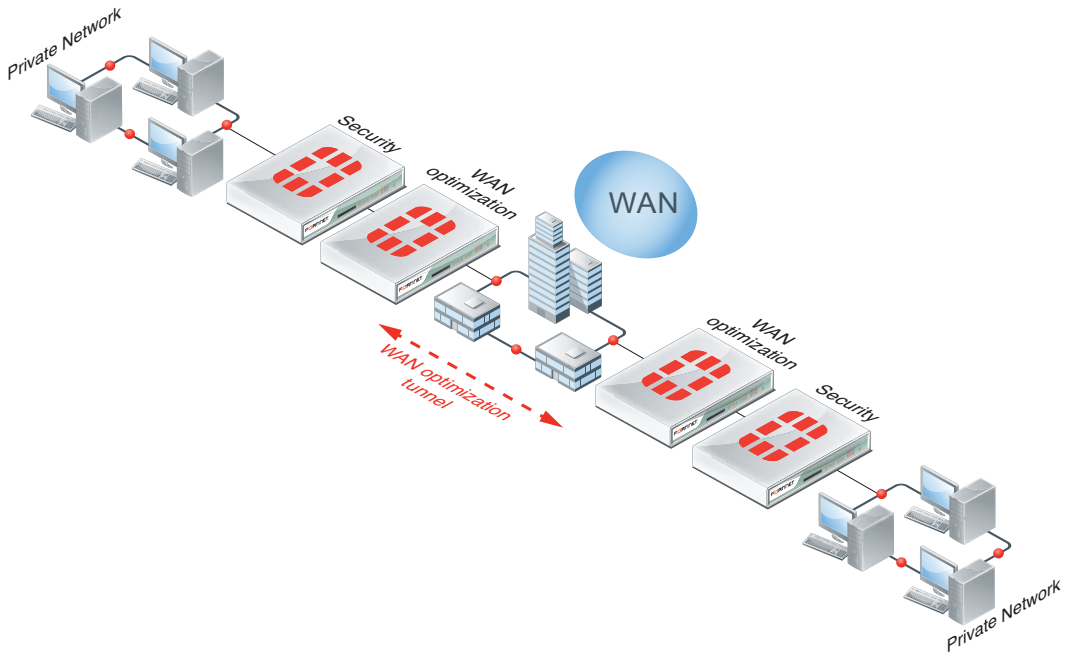


Figure 304 shows out-of-path FortiGate units configured for WAN optimization and connected directly to FortiGate units in the data path. The FortiGate units in the data path use a method such as policy routing to redirect traffic to be optimized to the out-of-path FortiGate units. The out-of-path FortiGate units establish a WAN optimization tunnel between each other and optimize the redirected traffic.

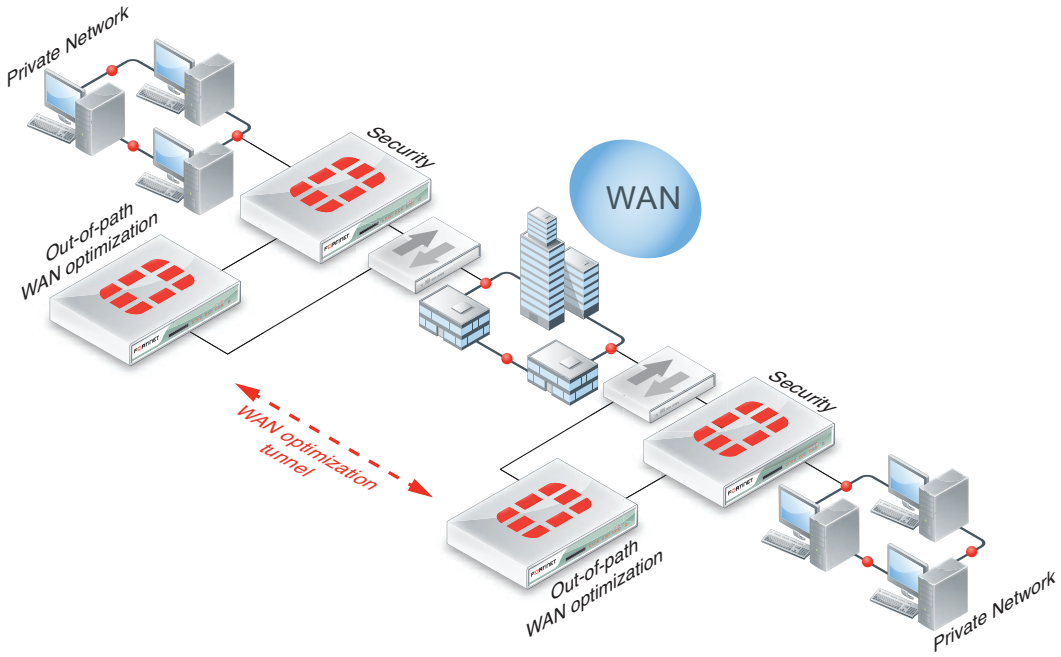
Figure 304: Out-of-path WAN optimization



One of the benefits of out-of-path WAN optimization is that out-of-path FortiGate units only perform WAN optimization and do not have to process other traffic. An in-path FortiGate unit configured for WAN optimization also has to process other non-optimized traffic on the data path.

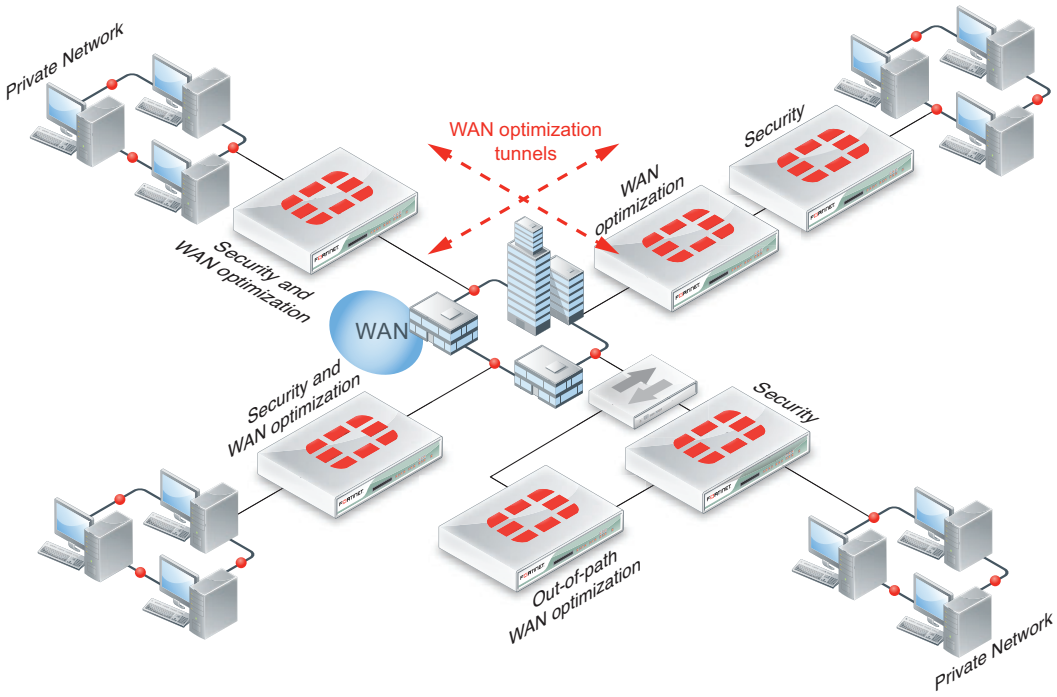
The out-of-path FortiGate units can operate in NAT/Route or Transparent mode.

Other out-of-path topologies are also possible. For example, you can install the out-of-path FortiGate units on the private networks instead of on the WAN. Also, the out-of-path FortiGate units can have one connection to the network instead of two. In a one-arm configuration such as this, security policies and routing have to be configured to send the WAN optimization tunnel out the same interface as the one that received the traffic.

Topology for multiple networks

As shown in Figure 305, you can create multiple WAN optimization configurations between many private networks. Whenever WAN optimization occurs, it is always between two FortiGate units, but you can configure any FortiGate unit to perform WAN optimization with any of the other FortiGate units that are part of your WAN.

Figure 305: WAN optimization among multiple networks

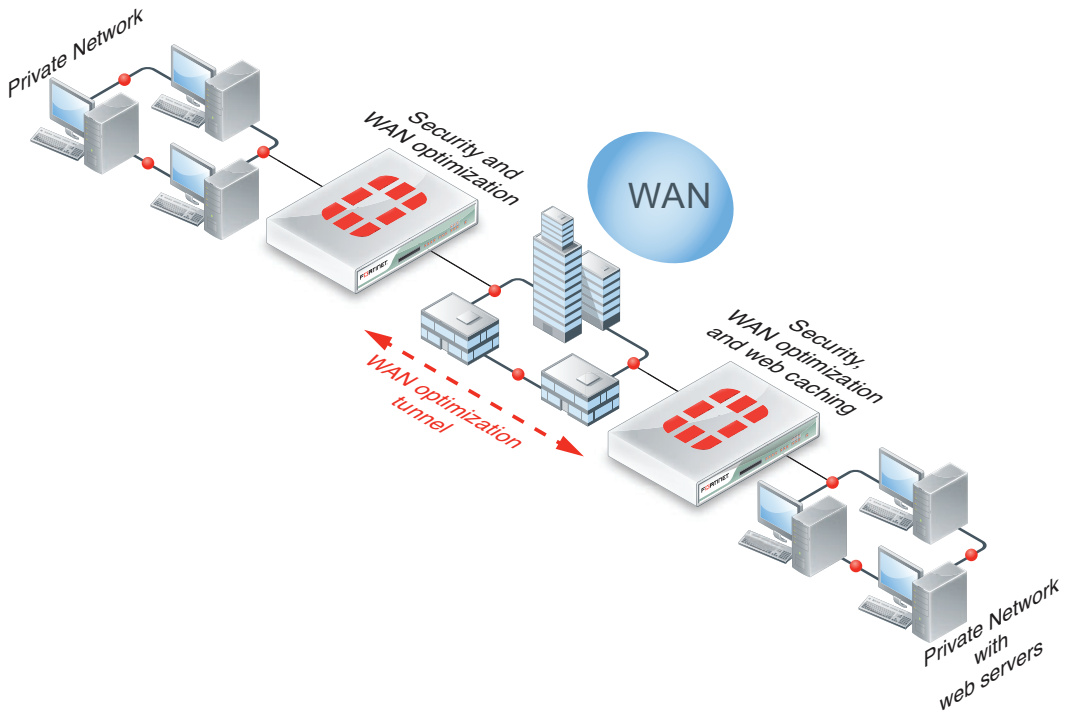


You can also configure WAN optimization between FortiGate units with different roles on the WAN. FortiGate units configured as security devices and for WAN optimization can perform WAN optimization as if they are single-purpose FortiGate units just configured for WAN optimization.

WAN optimization with web caching

You can add web caching to a WAN optimization topology when users on a private network communicate with web servers located across the WAN on another private network.

Figure 306: WAN optimization with web caching topology

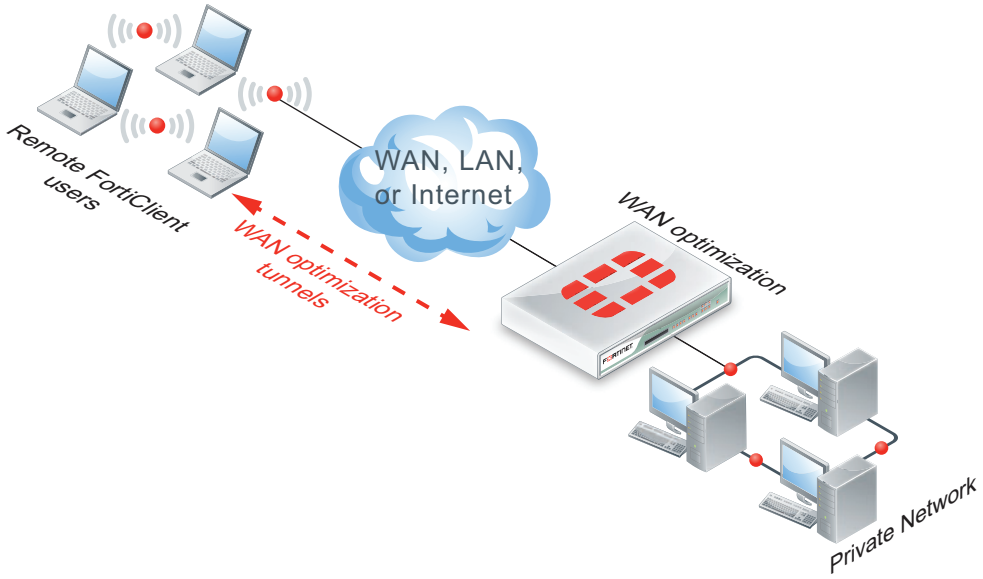


The topology in Figure 306 is the same as that of Figure 302 on page 2674 with the addition of web caching to the FortiGate unit in front of the private network that includes the web servers. In a similar way, you can add web caching to all of the topologies shown in "WAN optimization topologies" on page 2674.

WAN optimization and web caching with FortiClient peers

FortiClient WAN optimization works with FortiGate WAN optimization to accelerate remote user access to the private networks behind FortiGate units. The FortiClient application requires a simple WAN optimization configuration to automatically detect if WAN optimization is enabled on the FortiGate unit. Once WAN optimization is enabled, the FortiClient application transparently makes use of the WAN optimization and web caching features available.

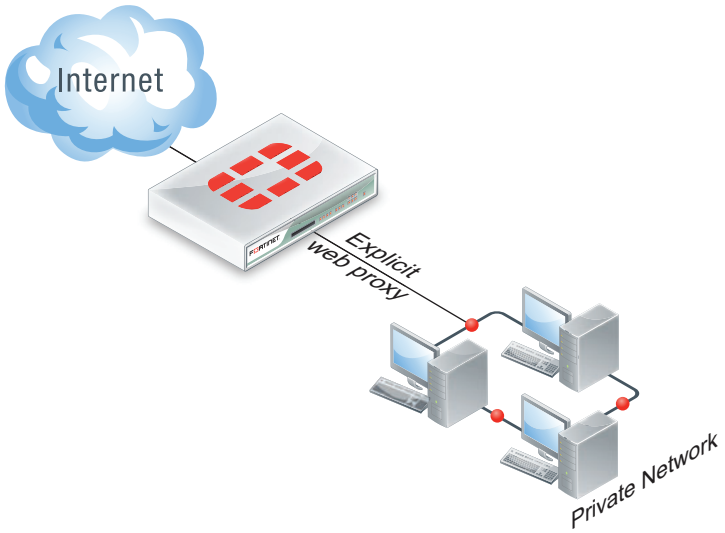
Figure 307: FortiClient WAN optimization topology



Explicit Web proxy topologies

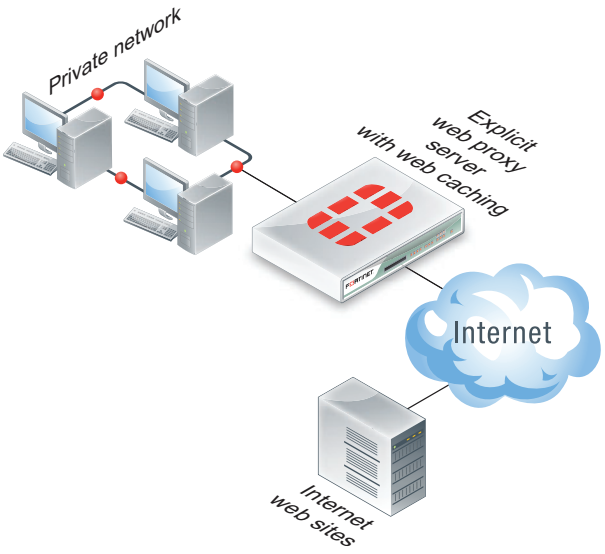
You can configure a FortiGate unit to be an explicit web proxy server for Internet web browsing. To use the explicit web proxy, users must add the IP address of the FortiGate interface configured for the explicit web proxy to their web browser proxy configuration.

Figure 308: Explicit web proxy topology



If the FortiGate unit supports web caching, you can also add web caching to the security policy that accepts explicit web proxy sessions The FortiGate unit then caches Internet web pages on a hard disk to improve web browsing performance.

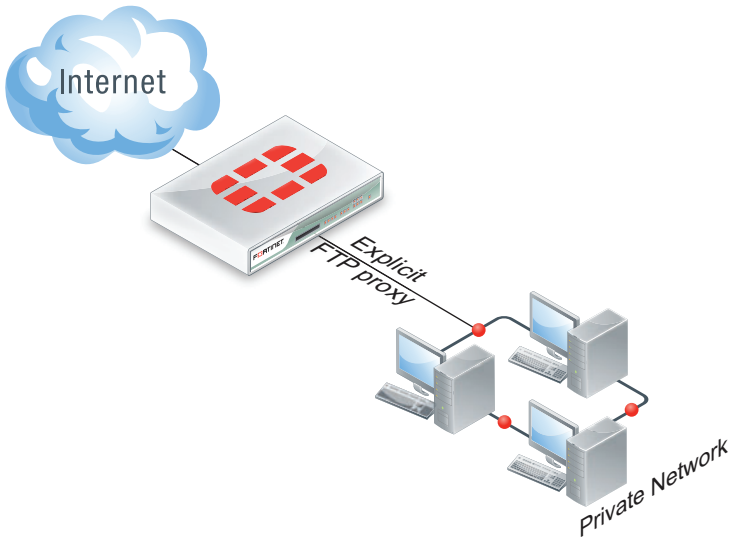
Figure 309: Explicit web proxy with web caching topology



Explicit FTP proxy topologies

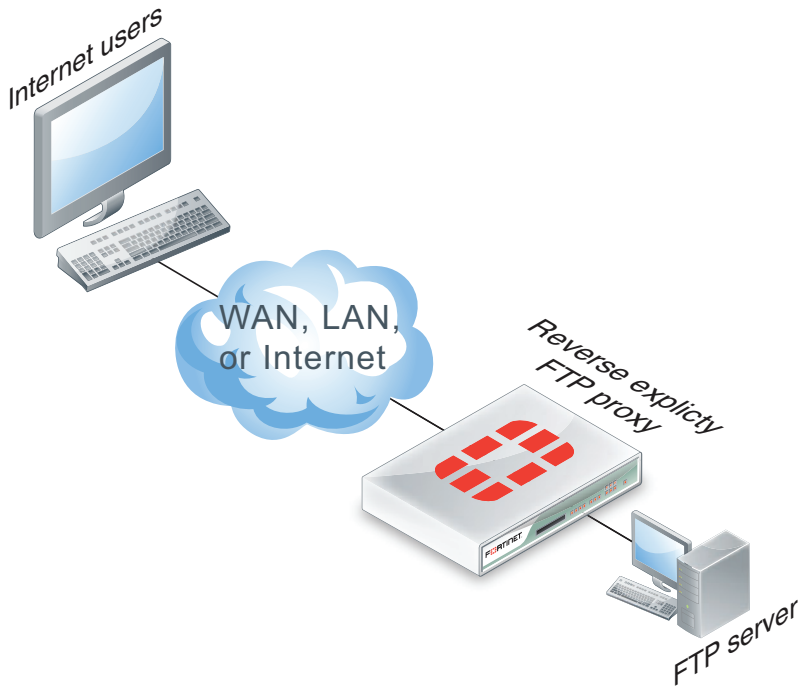
You can configure a FortiGate unit to be an explicit FTP proxy server for FTP users. To use the explicit web proxy, FTP users must connect to and authenticate with the explicit FTP proxy before connecting to an FTP server.

Figure 310: Explicit FTP proxy topology



You can also configure reverse explicit FTP proxy (Figure 311). In this configuration, users on the Internet connect to the explicit web proxy before connecting to an FTP server installed behind a FortiGate unit.

Figure 311: Reverse explicit FTP proxy topology

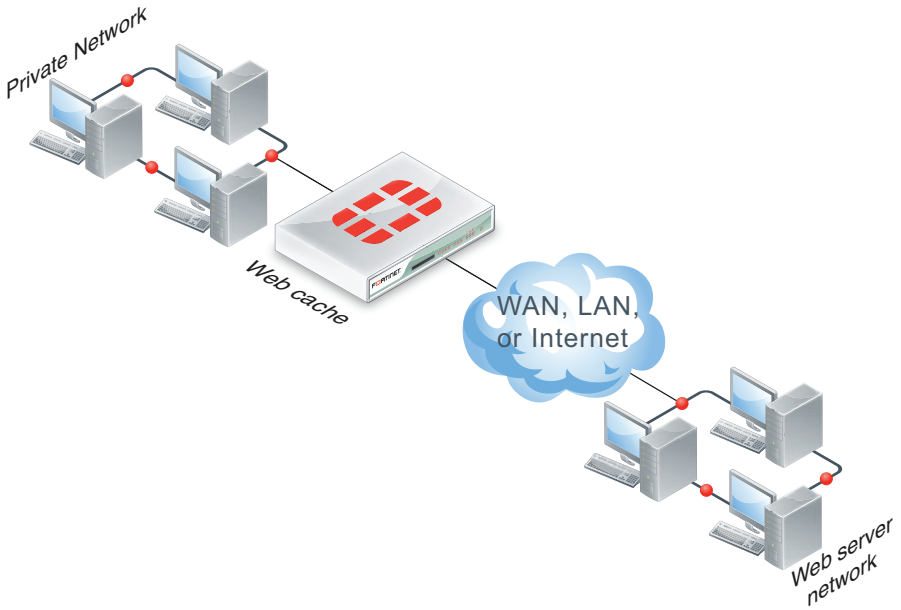


Web caching topologies

FortiGate web caching can be added to any security policy and any HTTP or HTTPS traffic accepted by that security policy can be cached on the FortiGate unit hard disk. You can also add web caching explicit web proxy security policies to cache explicit web proxy traffic. You can also created web caching only WAN optimization rules. The network topologies for all of these scenarios are very similar. They involved a FortiGate unit installed between users and web servers with web caching enabled.

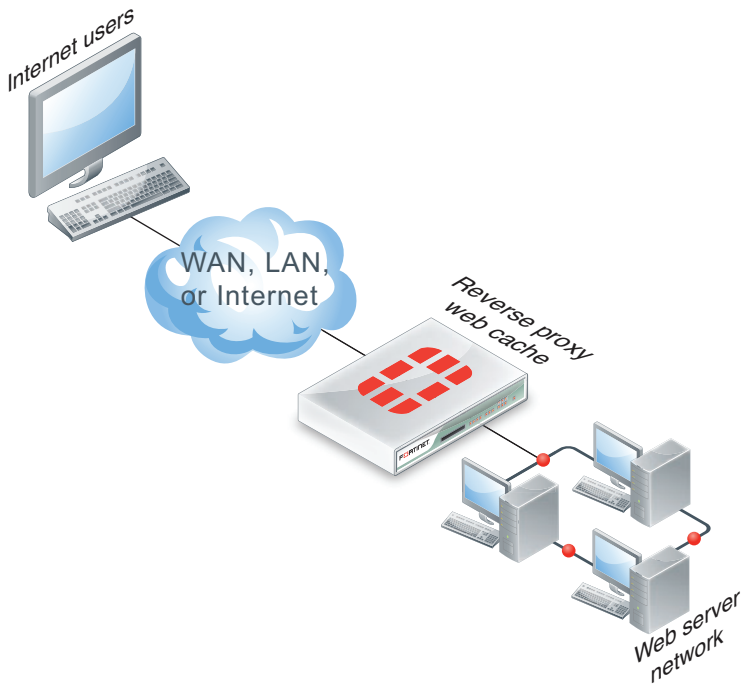
A typical web-caching topology includes one FortiGate unit that acts as a web cache server (Figure 312). Web caching is enabled in a security policy and the FortiGate unit intercepts web page requests accepted by the security policy, requests web pages from the web servers, caches the web page contents, and returns the web page contents to the users. When the FortiGate unit intercepts subsequent requests for cached web pages, the FortiGate unit contacts the destination web server just to check for changes.

Figure 312: Web caching topology



You can also configure reverse proxy web-caching (Figure 313). In this configuration, users on the Internet browse to a web server installed behind a FortiGate unit. The FortiGate unit intercepts the web traffic (HTTP and HTTPS) and caches pages from the web server. Reverse proxy web caching on the FortiGate unit reduces the number of requests that the web server must handle, leaving it free to process new requests that it has not serviced before.

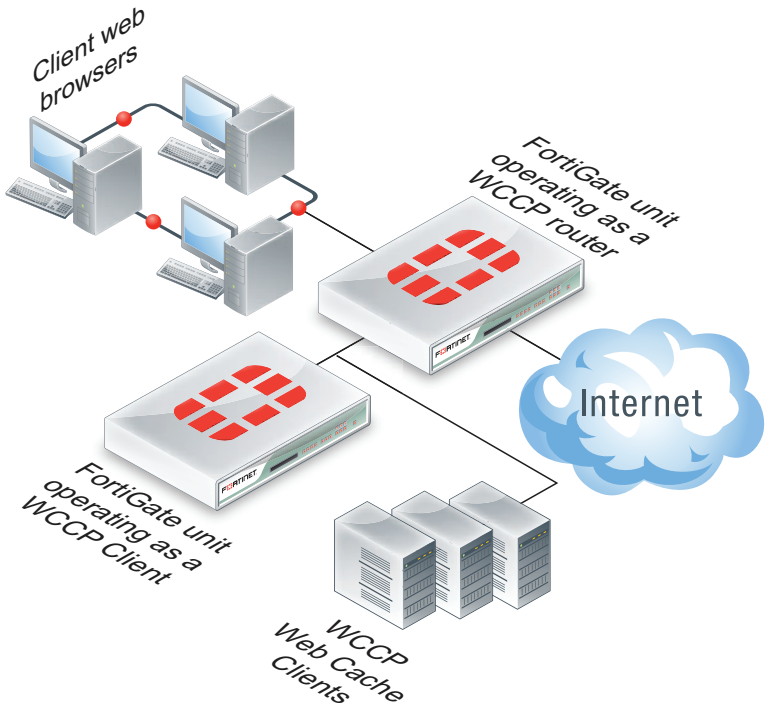
Figure 313: Reverse proxy web caching topology



WCCP topologies

You can operate a FortiGate unit as a Web Cache Communication Protocol (WCCP) router or cache engine. As a router, the FortiGate unit intercepts web browsing requests from client web browsers and forwards them to a WCCP cache engine. The cache engine returns the required cached content to the client web browser. If the cache server does not have the required content it accesses the content, caches it and returns the content to the client web browser.

Figure 314: WCCP topology



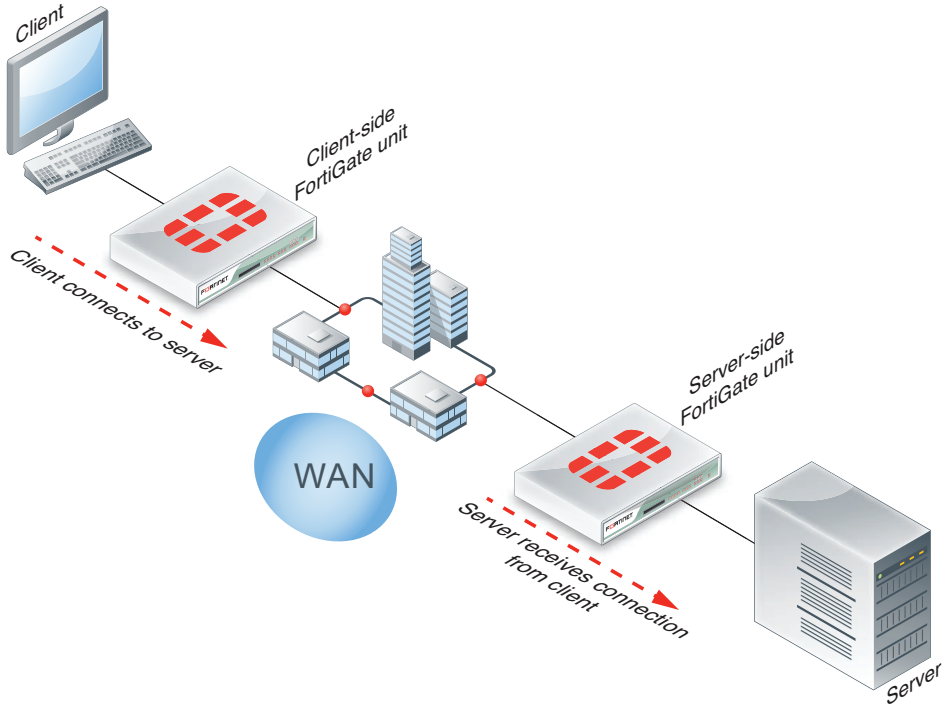
FortiGate units can also operate as WCCP cache servers, communicating with WCCP routers, caching web content and providing it to client web browsers as required.

WCCP is transparent to client web browsers. The web browsers do not have to be configured to use a web proxy.

WAN optimization client/server architecture

Traffic across a WAN typically consists of clients on a client network communicating across a WAN with a remote server network. The clients do this by starting communication sessions from the client network to the server network. To optimize these sessions, you add security policies to the client-side FortiGate unit (which is located between the client network and the WAN, see Figure 315) to accept sessions from the client network that are destined for the server network. To apply WAN optimization to these sessions, you must also add WAN optimization rules to the client-side FortiGate unit. The WAN optimization rules intercept sessions accepted by security policies and apply WAN optimization to them.

Figure 315: Client/server architecture



When a client-side FortiGate unit matches a session with a WAN optimization rule, it uses the information in the rule to attempt to start a WAN optimization tunnel with a server-side FortiGate unit installed in front of the server network. The client-side and server side FortiGate units must be able to identify each other. To do this the client-side FortiGate unit configuration must include the IP address and peer host ID of the server-side FortiGate unit and the configuration of the server-side FortiGate unit must include the IP address and peer host ID of the client-side FortiGate unit. With this information available, when the client-side FortiGate unit attempts to contact the server-side FortiGate unit, the two units share their IP addresses and peer host IDs and confirm that they can create a WAN optimization tunnel between each other.

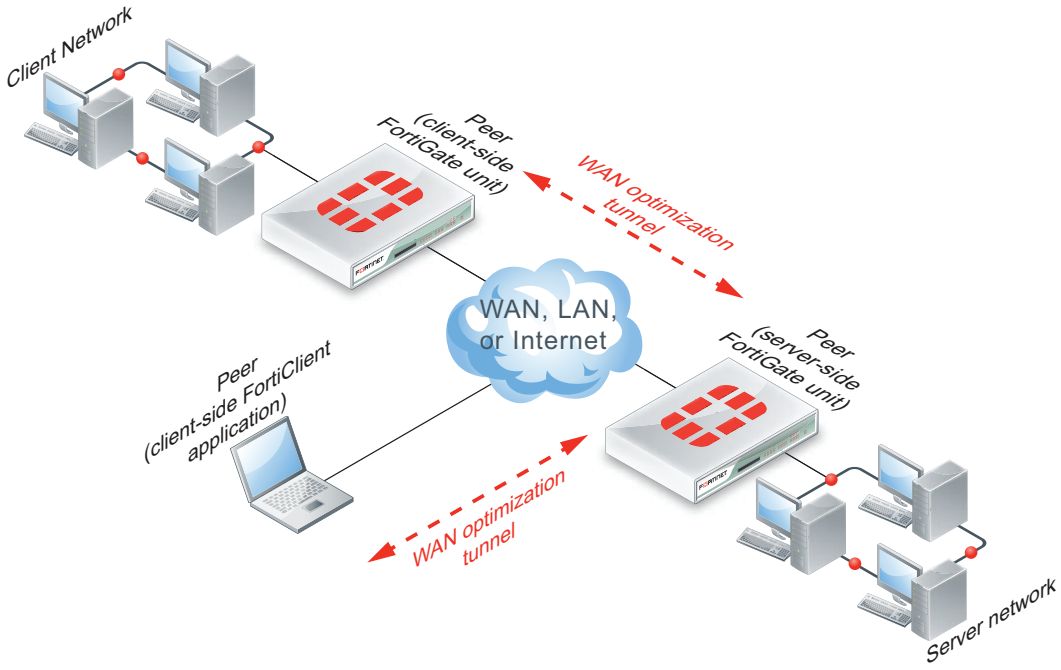
Security policies are not required for WAN optimization on the server-side FortiGate unit. Sessions from the client-side to the server-side FortiGate unit are WAN optimization tunnel requests. As long as the client-side and server-side FortiGate units can identify each other according to peer host ID and IP address the server-side FortiGate unit will accept WAN optimization tunnel requests from the client-side FortiGate unit.

In addition to basic identification by peer host ID and IP address you can configure authentication options to impose authentication using certificates and pre-shared keys. In addition to you can configure FortiGate units involved in WAN optimization to accept connections from any identified peer or restrict connections to specific peers.

WAN optimization peers

The client-side and server-side FortiGate units are called WAN optimization peers (see Figure 316) because all of the FortiGate units in a WAN optimization network have the same peer relationship with each other. The client and server roles just relate to how a session is started. Any FortiGate unit configured for WAN optimization can be a client-side and a server-side FortiGate unit at the same time, depending on the direction of the traffic. Client-side FortiGate units initiate WAN optimization sessions and server-side FortiGate units respond to the session requests. Any FortiGate unit can simultaneously be a client-side FortiGate unit for some sessions and a server-side FortiGate unit for others.

Figure 316: WAN optimization peer and tunnel architecture



To identify all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with, you add host IDs and IP addresses of all of the peers to the FortiGate unit configuration. The peer IP address is actually the IP address of the peer unit interface that communicates with the FortiGate unit.

Peer-to-peer and active-passive WAN optimization

You can create peer-to-peer and active-passive WAN optimization configurations. Peer-to-peer configurations are less complex because they only require the creation of a WAN optimization rule in the client side FortiGate unit. Active-passive WAN optimization configurations require an active rule on the client side FortiGate unit and a passive rule on the server-side FortiGate unit. For more details about peer to peer and active-passive WAN optimization, see “Configuring WAN optimization rules” on page 2705.

WAN optimization and the FortiClient application

PCs running the FortiClient application are client-side peers that initiate WAN optimization tunnels with server-side peer FortiGate units. However, you can have an ever-changing number of FortiClient peers with IP addresses that also change regularly. To avoid maintaining a list of such peers, you can instead configure WAN optimization to accept any peer and use authentication to identify FortiClient peers.

Together, the WAN optimization peers apply the WAN optimization features to optimize the traffic flow over the WAN between the clients and servers. WAN optimization reduces bandwidth requirements, increases throughput, reduces latency, offloads SSL encryption/decryption and improves privacy for traffic on the WAN.

Operating modes and VDOMs

To use WAN optimization, the FortiGate units can operate in either NAT/Route or Transparent mode. The client-side and server-side FortiGate units do not have to be operating in the same mode.

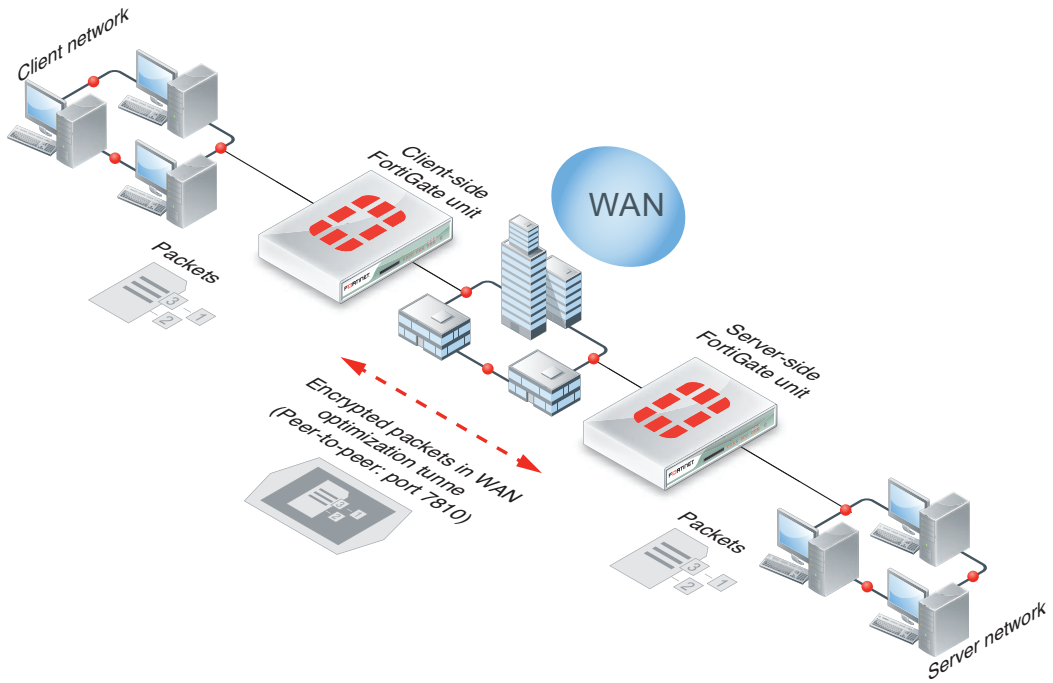
As well, the FortiGate units can be configured for multiple virtual domain (VDOM) operation. You configure WAN optimization for each VDOM and configure one or both of the units to operate with multiple VDOMs enabled.

If a FortiGate unit or VDOM is operating in Transparent mode with WAN optimization enabled, WAN optimization uses the management IP address as the peer IP address of the FortiGate unit instead of the address of an interface.

WAN optimization tunnels

All optimized traffic passes between the FortiGate units or between a FortiClient peer and a FortiGate unit over a WAN optimization tunnel. Traffic in the tunnel can be sent in plain text or encrypted using AES-128bit-CBC SSL.

Figure 317: WAN optimization tunnels



Both plain text and the encrypted peer-to-peer tunnels use TCP destination port 7810.

Before a tunnel can be started, the peers must be configured to authenticate with each other and to agree on the tunnel configuration. Then, the client-side peer attempts to start a WAN optimization tunnel with the server-side peer. Once the peers authenticate with each other, they bring up the tunnel and WAN optimization communication over the tunnel starts. After a tunnel has been established, multiple WAN optimization sessions can start and stop between peers without restarting the tunnel.

Tunnel sharing

You can use the `tunnel-sharing` WAN optimization rule CLI keyword to configure tunnel sharing for WAN optimization rules with `auto-detect` set to `off`. Tunnel sharing means multiple WAN optimization sessions share the same WAN optimization tunnel. Tunnel sharing can improve WAN performance by reducing the number of WAN optimization tunnels between FortiGate units. Having fewer tunnels means less data to manage. Also, tunnel setup requires more than one exchange of information between the ends of the tunnel. Once the tunnel is set up, each new session that shares the tunnel avoids tunnel setup delays.

Tunnel sharing also uses bandwidth more efficiently by reducing the chances that small packets will be sent down the tunnel. Processing small packets reduces network throughput, so reducing the number of small packets improves performance. A shared tunnel can combine all the data from the sessions being processed by the tunnel and send the data together. For example, suppose a FortiGate unit is processing five WAN optimization sessions and each session has 100 bytes to send. If these sessions use a shared tunnel, WAN optimization combines the packets from all five sessions into one 500-byte packet. If each session uses its own private tunnel, five 100-byte packets will be sent instead. Each packet also requires a TCP ACK reply. The combined packet in the shared tunnel requires one TCP ACK packet. The separate packets in the private tunnels require five.

Tunnel sharing is not always recommended and may not always be the best practice. Aggressive and non-aggressive protocols should not share the same tunnel. An aggressive protocol can be defined as a protocol that is able to get more bandwidth than a non-aggressive protocol. (The aggressive protocols can “starve” the non-aggressive protocols.) HTTP and FTP are considered aggressive protocols. If aggressive and non-aggressive protocols share the same tunnel, the aggressive protocols may take all of the available bandwidth. As a result, the performance of less aggressive protocols could be reduced. To avoid this problem, rules for HTTP and FTP traffic should have their own tunnel. To do this, set `tunnel-sharing` to `private` for WAN optimization rules that accept HTTP or FTP traffic.

It is also useful to set `tunnel-sharing` to `express-sharing` for applications, such as Telnet, that are very interactive but not aggressive. Express sharing optimizes tunnel sharing for Telnet and other interactive applications where latency or delays would seriously affect the user’s experience with the protocol.

Set `tunnel-sharing` to `sharing` for applications that are not aggressive and are not sensitive to latency or delays. WAN optimization rules set to `sharing` and `express-sharing` can share the same tunnel.

Protocol optimization

Protocol optimization techniques optimize bandwidth use across the WAN. These techniques can improve the efficiency of communication across the WAN optimization tunnel by reducing the amount of traffic required by communication protocols. You can apply protocol optimization to Common Internet File System (CIFS), FTP, HTTP, MAPI, and general TCP sessions. You can apply general TCP optimization to MAPI sessions.

For example, CIFS provides file access, record locking, read/write privileges, change notification, server name resolution, request batching, and server authentication. CIFS is a fairly “chatty” protocol, requiring many background transactions to successfully transfer a single file. This is usually not a problem across a LAN. However, across a WAN, latency and bandwidth reduction can slow down CIFS performance.

When you set *Protocol* to *CIFS* in a WAN optimization rule, the FortiGate units at both ends of the WAN optimization tunnel use a number of techniques to reduce the number of background transactions that occur over the WAN for CIFS traffic.

You can select only one protocol in a WAN optimization rule. For best performance, you should separate the traffic by protocol by creating different WAN optimization rules for each protocol. For example, to optimize HTTP traffic, you should set *Port* to 80 so that only HTTP traffic is accepted by this WAN optimization rule. For an example configuration that uses multiple rules for different protocols, see “Example: Active-passive WAN optimization” on page 2721.

If the WAN optimization accepts a range of different types of traffic, you can set *Protocol* to *TCP* to apply general optimization techniques to TCP traffic. However, applying this TCP optimization to a range of different types of traffic is not as effective as applying more protocol-specific optimization to specific types of traffic. TCP protocol optimization uses techniques such as TCP SACK support, TCP window scaling and window size adjustment, and TCP connection pooling to remove TCP bottlenecks.

Protocol optimization and MAPI

By default the MAPI service uses port number 135 for RPC port mapping and may use random ports for MAPI messages. The random ports are negotiated through sessions using port 135. The FortiOS DCE-RPC session helper leans these ports and opens pinholes for the messages. WAN optimization is also aware of these ports and attempts to apply protocol optimization to MAPI messages that use them. However, to configure protocol optimization for MAPI you should set the WAN optimization rule to a single port number (usually port 135). Specifying a range of ports may reduce performance.

Byte caching

Byte caching breaks large units of application data (for example, a file being downloaded from a web page) into small chunks of data, labelling each chunk of data with a hash of the chunk and storing those chunks and their hashes in a database. The database is stored on a WAN optimization storage device. Then, instead of sending the actual data over the WAN tunnel, the FortiGate unit sends the hashes. The FortiGate unit at the other end of the tunnel receives the hashes and compares them with the hashes in its local byte caching database. If any hashes match, that data does not have to be transmitted over the WAN optimization tunnel. The data for any hashes that does not match is transferred over the tunnel and added to that byte caching database. Then the unit of application data (the file being downloaded) is reassembled and sent to its destination.

The stored byte caches are not application specific. Byte caches from a file in an email can be used to optimize downloading that same file or a similar file from a web page.

The result is less data transmitted over the WAN. Initially, byte caching may reduce performance until a large enough byte caching database is built up.

To enable byte caching, you select *Enable Byte Cache* in a WAN optimization rule. The *Protocol* setting does not affect byte caching. Data is byte cached when it is processed by a WAN optimization rule that includes byte caching.

Byte caching cannot determine whether or not a file is compressed (for example a zip file), and caches compressed and non-compressed versions of the same file separately.

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended best practice HA configuration for WAN optimization is active-passive mode. When the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions.

You can also form a WAN optimization tunnel between a cluster and a standalone FortiGate unit or between two clusters.

In a cluster, the primary unit stores only web cache and byte cache databases. These databases are not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its web and byte caches.

Rebuilding the byte caches can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGate units that it is participating with in WAN optimization tunnels.

WAN optimization, web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency FortiOS WAN optimization and web caching uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, WAN optimization and web cache require a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When WAN optimization and web caching are enabled you will see a reduction in available memory. The amount of reduction will increase when more WAN optimization and web cache sessions are being processed. If you are thinking of enabling WAN optimization or web caching on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods before you enable these features.

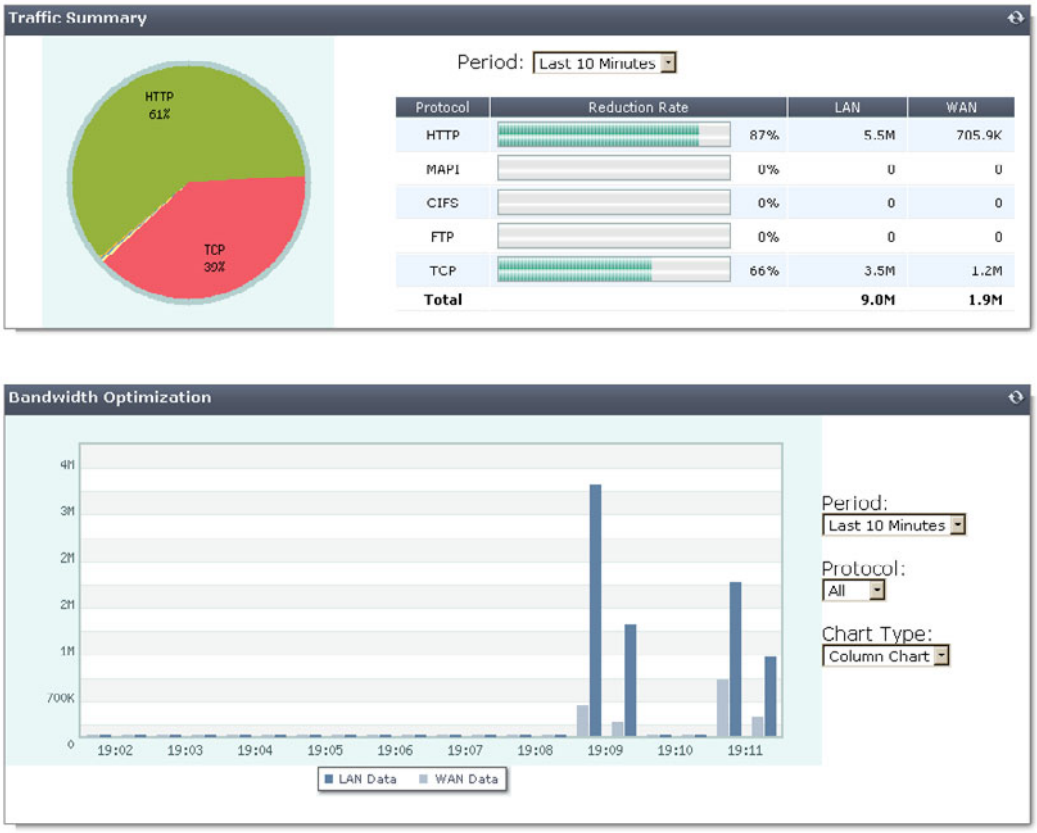
In addition to using the system dashboard to see the current memory usage you can use the `get test wad 1` command to see how much memory is currently being used by WAN optimization and web caching. See “get test {wa_cs | wa_dbd | wad | wad_diskd | wccpd} <test_level>” on page 2859 for more information.

Monitoring WAN optimization performance

Using WAN optimization monitoring, you can confirm that a FortiGate unit is optimizing traffic and view estimates of the amount of bandwidth saved. The WAN optimization monitor presents collected log information in a graphical format to show network traffic summary and bandwidth optimization information.

To view the WAN optimization monitor, go to *WAN Opt. & Cache* > *Monitor* > *WAN Opt Monitor*.

Figure 318: WAN optimization monitor



Traffic Summary

The traffic summary shows how WAN optimization is reducing the amount of traffic on the WAN for each WAN optimization protocol by showing the traffic reduction rate as a percentage of the total traffic. The traffic summary also shows the amount of WAN and LAN traffic. If WAN optimization is being effective the amount of WAN traffic should be lower than the amount of LAN traffic.

You can use the refresh icon to update the traffic summary display at any time. You can also set the amount of time for which the traffic summary shows data. The time period can vary from the last 10 minutes to the last month.

Bandwidth Optimization

This section shows network bandwidth optimization per time period. A line or column chart compares an application's pre-optimized size (LAN data) with its optimized size (WAN data). You can select the chart type, the monitoring time period, and the protocol for which to display data. If WAN optimization is being effective the WAN bandwidth should be lower than the LAN bandwidth.

Configuring WAN optimization traffic usage logs

Use the following command to generate WAN optimization traffic log messages for each WAN optimization protocol. WAN optimization traffic logs are required to generate WAN optimization usage reports. By default WAN optimization traffic log messages are not generated:

```
config wanopt settings
  set log-traffic {cifs | ftp | http | mapi | tcp}
end
```

For example, to enable WAN optimization traffic logging for CIFS and HTTP traffic enter:

```
config wanopt settings
  set log-traffic cifs http
end
```

You must also enable traffic logging in security policies that accept the traffic to be optimized.

As a result of this configuration, traffic log messages with a sub type of `wanopt-traffic` are generated by the FortiGate unit.

You can review, filter, and analyze these messages in the same way as other traffic log messages. For example, to view WAN optimization traffic log messages, go to *Log&Report* > *Log & Archive Access* > *Traffic Log* and configure a filter to view all log messages with a sub type of `wanopt-traffic`.

You can also use the following commands to enable or disable sending WAN optimization traffic logs to memory, FortiAnalyzer, or to a remote syslog server. These are all enabled by default.

```
config log memory filter
  set wanopt-traffic enable
end
config log fortianalyzer filter
  set wanopt-traffic enable
end
config log syslogd filter
  set wanopt-traffic enable
end
```

WAN optimization best practices

This is a short list of WAN optimization and explicit proxy best practices.

- WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic. However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel. See “Tunnel sharing” on page 2688.
- Active-passive HA is the recommended HA configuration for WAN optimization. See “Tunnel sharing” on page 2688.
- Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure. See “Accepting any peers” on page 2697.
- Set the explicit HTTP proxy *Default Policy Action* to *Deny*. This means that a security policy is required to use the explicit web proxy. See “Explicit web proxy configuration overview” on page 2809.
- Set the explicit FTP proxy *Default Policy Action* to *Deny*. This means that a security policy is required to use the explicit FTP proxy. See “Explicit FTP proxy configuration overview” on page 2834.

WAN optimization and Web cache storage

WAN optimization storage is used for storing the byte cache and web cache databases. In most cases, you can accept the default WAN optimization storage configuration because all of the disk space available on the FortiGate unit is in one partition. By default WAN optimization and logging and archiving are configured to use this partition.

You only have to configure WAN optimization storage if you have more than one possible storage location. This can happen if you have multiple partitions that you can use for storage locations. If you have more than one storage location you can move WAN optimization storage to it. You can also configure WAN optimization to use multiple storage locations.

You can also optionally configure WAN optimization storage if you want to adjust the relative amounts of disk space available for byte caching and web caching.

This chapter contains the following topics:

Formatting the hard disk

In most cases the hard disks on your FortiGate unit should be formatted with one partition that is used for WAN optimization and Logging and Archiving. If for some reason the hard disk is not formatted you can use the following information to format it. In some cases you might also want to use the following options to erase all data from the hard disk by reformatting it.

From the web-based manager go to *System* > *Config* > *Advanced* > *Disk Management* to display information about the hard disk or disks available to the FortiGate unit. To format a hard disk, select the format icon. The hard disk format takes a few minutes and the FortiGate unit restarts after formatting is complete.

Fro this web-based manager page you can also view and change the WAN optimization and Web Cache Storage size and view how much of the WAN optimization and web cache storage has been used.

From the CLI you can use the following command to view the current disk format and partition status. See the following example for a FortiGate-51B unit.

```
execute disk list

Device I1           29.9 GB      ref: 256 SUPER TALENT (IDE)
  partition 1       29.9 GB      ref: 257 label: 2B6375792136C707
```

You can use the following command to reformat the hard disk. Use this command if for some reason the disk is not formatted correctly. The command includes the device partition reference number (256) so formats the entire disk and not just the partition.

```
execute disk format 256
```

You can use the following command to reformat the partition. The command includes the partition reference number so formats the partition, removing add data from it. You can use this command to delete all data from the partition and to fix partition errors.

```
execute disk format 257
```

Configuring WAN optimization and Web cache storage

You can use the following command to add multiple WAN optimization storage locations if your FortiGate unit has multiple disk partitions and you want to use more than one for WAN optimization storage:

```
config system storage
```

Enter `get` to see the name of the default storage location. You cannot edit this storage location, but you can add new ones:

```
config system storage
  edit new_storage
    set partition <partition_number>
end
```

Where `<partition_number>` is the number of the partition to create a storage location in. This cannot be the same as the partition added to the default storage location. This command automatically adds a WAN optimization storage location with the name `new_storage`.

Changing the amount of space allocated for WAN optimization and Web cache storage

From the web-based manager you can go to *System* > *Config* > *Advanced* > *Disk Management* to edit the WAN optimization & Web Cache storage and change the allocation size to limit the amount of storage available for WAN optimization byte caching and web caching. The size is in Mbytes.

You can use the following command to change the size of any WAN optimization storage location. For example, in the FortiGate-51B the default WAN optimization storage is `Internal`. Use the following command to limit the amount of space allocated for WAN optimization to 20 Gbytes

```
config wanopt storage
  edit Internal
    set size 20000
end
```

Adjusting the relative amount of disk space available for byte caching and web caching

By default the `config wanopt storage` command allocates the same amount disk for byte caching and for web caching. In some cases you may want to adjust the relative amounts of disk space available for these two uses. For example, if you have not implemented web caching you may want to reduce the amount of disk space used for web caching and increase the amount of space used for byte caching.

You can adjust the relative amount of disk space used for byte caching using the `webcache-storage-percentage` option of the `config wanopt storage` command. This option adjusts the percentage in the range of 0 to 100. The default percentage is 50.

To reduce the percentage of space allocated on the Internal disk for web caching to 10% (resulting in the amount of space for byte caching increasing to 90%) enter:

```
config wanopt storage
  edit Internal
    set webcache-storage-percentage 10
end
```

You can enter this command at any time without disrupting web caching or byte caching performance. Data may be lost from the cache that is reduced in size.

WAN optimization peers and authentication groups

All communication between WAN optimization peers begins with one WAN optimization peer (or client-side FortiGate unit) sending a WAN optimization tunnel request to another peer (or server-side FortiGate unit). During this process, the WAN optimization peers identify and optionally authenticate each other.

This chapter describes:

Basic WAN optimization peer requirements

WAN optimization requires the following configuration on each peer. For information about configuring local and peer host IDs, see "Configuring peers" on page 2699.

- The peer must have a unique host ID.

  Unless authentication groups are used, peers authenticate each other using host ID values. Do not leave the local host ID at its default value.
- The peer must know the host IDs and IP addresses of all of the other peers that it can start WAN optimization tunnels with. This does not apply if you use authentication groups that accept all peers.

  All peers must have the same local certificate installed on their FortiGate units if the units authenticate by local certificate (see "Certificate-based authentication" on page 1263). Similarly, if the units authenticate by pre-shared key (password), administrators must know the password. The type of authentication is selected in the authentication group. This applies only if you use authentication groups.

Accepting any peers

Strictly speaking, you do not need to add peers. Instead you can configure authentication groups that accept any peer. However, for this to work, both peers must have the same authentication group (with the same name) and both peers must have the same certificate or pre-shared key.

Accepting any peer is useful if you have many peers or if peer IP addresses change. For example, you could have many travelling FortiClient peers with IP addresses that are always changing as the users travel to different customer sites. This configuration is also useful if you have FortiGate units with dynamic external IP addresses (using DHCP or PPPoE). For most other situations, this method is not recommended and is not a best practice as it is less secure than accepting defined peers or a single peer. For more information, see "Configuring authentication groups" on page 2700.

How FortiGate units process tunnel requests for peer authentication

When a client-side FortiGate unit attempts to start a WAN optimization tunnel with a peer server-side FortiGate unit, the tunnel request includes the following information:

- the client-side local host ID
- the name of an authentication group, if included in the rule that initiates the tunnel
- if an authentication group is used, the authentication method it specifies: pre-shared key or certificate
- the type of tunnel (secure or not).

For information about configuring the local host ID, peers and authentication groups, see "Configuring peers" on page 2699 and "Configuring authentication groups" on page 2700.

The authentication group is optional unless the tunnel is a secure tunnel. For more information, see "Secure tunneling" on page 2702.

If the tunnel request includes an authentication group, the authentication will be based on the settings of this group as follows:

- The server-side FortiGate unit searches its own configuration for the name of the authentication group in the tunnel request. If no match is found, the authentication fails.
- If a match is found, the server-side FortiGate unit compares the authentication method in the client and server authentication groups. If the methods do not match, the authentication fails.
- If the authentication methods match, the server-side FortiGate unit tests the peer acceptance settings in its copy of the authentication group.
  - If the setting is *Accept Any Peer*, the authentication is successful.
  - If the setting is *Specify Peer*, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the peer name in the server-side authentication group. If the names match, authentication is successful. If a match is not found, authentication fails.
  - If the setting is *Accept Defined Peers*, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the server-side peer list. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the tunnel request does not include an authentication group, authentication will be based on the client-side local host ID in the tunnel request. The server-side FortiGate unit searches its peer list to match the client-side local host ID in the tunnel request. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the server-side FortiGate unit successfully authenticates the tunnel request, the server-side FortiGate unit sends back a tunnel setup response message. This message includes the server-side local host ID and the authentication group that matches the one in the tunnel request.

The client-side FortiGate unit then performs the same authentication procedure as the server-side FortiGate unit did. If both sides succeed, tunnel setup continues.

Configuring peers

When you configure peers, you first need to add the local host ID that identifies the FortiGate unit for WAN optimization and then add the peer host ID and IP address of each FortiGate unit with which a FortiGate unit can create WAN optimization tunnels.

To configure WAN optimization peers - web-based manager

1 Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Peer*.

2 For *Local Host ID*, enter the local host ID of ***this*** FortiGate unit and select *Apply*. If you add this FortiGate unit as a peer to another FortiGate unit, use this ID as its ***peer*** host ID.

The local or host ID can contain up to 25 characters and can include spaces.

3 Select *Create New* to add a new peer.

4 For *Peer Host ID*, enter the peer host ID of the peer FortiGate unit. This is the local host ID added to the peer FortiGate unit.

5 For *IP Address*, add the IP address of the peer FortiGate unit. This is the source IP address of tunnel requests sent by the peer, usually the IP address of the FortiGate interface connected to the WAN.

6 Select *OK*.

To configure WAN optimization peers - CLI

In this example, the local host ID is named `HQ_Peer` and has an IP address of `172.20.120.100`. Three peers are added, but you can add any number of peers that are on the WAN.

1 Enter the following command to set the local host ID to `HQ_Peer`.

```
config wanopt settings
  set host-id HQ_peer
end
```

2 Enter the following commands to add three peers.

```
config wanopt peer
  edit Wan_opt_peer_1
    set ip 172.20.120.100
  next
  edit Wan_opt_peer_2
    set ip 172.30.120.100
  next
  edit Wan_opt_peer_3
    set ip 172.40.120.100
  end
```

Configuring authentication groups

You need to add authentication groups to support authentication and secure tunneling between WAN optimization peers.

To perform authentication, WAN optimization peers use a certificate or a pre-shared key added to an authentication group so they can identify each other before forming a WAN optimization tunnel. Both peers must have an authentication group with the same name and settings. You add the authentication group to a peer-to-peer or active rule on the client-side FortiGate unit. When the server-side FortiGate unit receives a tunnel start request from the client-side FortiGate unit that includes an authentication group, the server-side FortiGate unit finds an authentication group in its configuration with the same name. If both authentication groups have the same certificate or pre-shared key, the peers can authenticate and set up the tunnel.

Authentication groups are also required for secure tunneling. See "Secure tunneling" on page 2702.

To add authentication groups, go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group*.

To add an authentication group - web-based manager

Use the following steps to add any kind of authentication group. It is assumed that if you are using a local certificate to authenticate, it is already added to the FortiGate unit. For more information about FortiGate units and certificates, see the *FortiGate Certificate Management Guide*.

1. Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group*.
2. Select *Create New*.
3. Add a *Name* for the authentication group.

   You will select this name when you add the authentication group to a WAN optimization rule.
4. Select the *Authentication Method*.

   Select *Certificate* if you want to use a certificate to authenticate and encrypt WAN optimization tunnels. You must select a local certificate that has been added to this FortiGate unit. (To add a local certificate, go to *System* > *Certificates* > *Local Certificates*.) Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and certificate.

   Select *Pre-shared key* if you want to use a pre-shared key or password to authenticate and encrypt WAN optimization tunnels. You must add the *Password* (or pre-shared key) used by the authentication group. Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and password. The password must contain at least 6 printable characters and should be known only by network administrators. For optimum protection against currently known attacks, the key should consist of a minimum of 16 randomly chosen alphanumeric characters.

5 Configure *Peer Acceptance* for the authentication group.

Select *Accept Any Peer* if you do not know the peer host IDs or IP addresses of the peers that will use this authentication group. This setting is most often used for WAN optimization with the FortiClient application or with FortiGate units that do not have static IP addresses, for example units that use DHCP.

Select *Accept Defined Peers* if you want to authenticate with peers added to the peer list only.

Select *Specify Peer* and select one of the peers added to the peer list to authenticate with the selected peer only.

For more information, see "Configuring peers" on page 2699.

6 Select *OK*.

7 Add the authentication group to a WAN optimization rule to apply the authentication settings in the authentication group to the rule.

For more information, see "Configuring WAN optimization rules" on page 2710.

To add an authentication group that uses a certificate- CLI

Enter the following command to add an authentication group that uses a certificate and can authenticate all peers added to the FortiGate unit configuration.

In this example, the authentication group is named `auth_grp_1` and uses a certificate named `Example_Cert`.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert Example_Cert
    set peer-accept defined
  end
```

To add an authentication group that uses a pre-shared key - CLI

Enter the following command to add an authentication group that uses a pre-shared key and can authenticate only the peer added to the authentication group.

In this example, the authentication group is named `auth_peer`, the peer that the group can authenticate is named `Server_net`, and the authentication group uses `123456` as the pre-shared key. In practice you should use a more secure pre-shared key.

```
config wanopt auth-group
  edit auth_peer
    set auth-method psk
    set psk 123456
    set peer-accept one
    set peer Server_net
  end
```

To add an authentication group that accepts WAN optimization connections from any peer - web-based manager

Add an authentication group that accepts any peer for situations where you do not have the *Peer Host IDs* or *IP Addresses* of the peers that you want to perform WAN optimization with. This setting is most often used for WAN optimization with the FortiClient application or with FortiGate units that do not have static IP addresses, for example units that use DHCP. An authentication group that accepts any peer is less secure than an authentication group that accepts defined peers or a single peer.

The example below sets the authentication method to *Pre-shared key*. You must add the same password to all FortiGate units using this authentication group.

1 Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group*.

2 Select *Create New* to add a new authentication group.

3 Configure the authentication group:

Name	Specify any name.
Authentication Method	Pre-shared key
Password	Enter a pre-shared key.
Peer Acceptance	Accept Any Peer

To add an authentication group that accepts WAN optimization connections from any peer - CLI

In this example, the authentication group is named `auth_grp_1`. It uses a certificate named `WAN_Cert` and accepts any peer.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert WAN_Cert
    set peer-accept any
  end
```

Secure tunneling

You can configure WAN optimization rules to use AES-128bit-CBC SSL to encrypt the traffic in the WAN optimization tunnel. WAN optimization uses FortiASIC acceleration to accelerate SSL decryption and encryption of the secure tunnel. Peer-to-peer secure tunnels use the same TCP port as non-secure peer-to-peer tunnels (TCP port 7810).

To use secure tunneling, you must select *Enable Secure Tunnel* in a WAN optimization rule and add an authentication group. The authentication group specifies the certificate or pre-shared key used to set up the secure tunnel. The *Peer Acceptance* setting of the authentication group does not affect secure tunneling.

The FortiGate units at each end of the secure tunnel must have the same authentication group with the same name and the same configuration, including the same pre-shared key or certificate. To use certificates you must install the same certificate on both FortiGate units.

For active-passive WAN optimization you can select *Enable Secure Tunnel* only in the active rule. In peer-to-peer WAN optimization you select *Enable Secure Tunnel* in the WAN optimization rule on both FortiGate units. For information about active-passive and peer-to-peer WAN optimization, see “Configuring WAN optimization rules” on page 2705.

For a secure tunneling configuration example, see “Example: Adding secure tunneling to an active-passive WAN optimization configuration” on page 2728. Secure tunneling is also used in the configuration example: “Example: SSL offloading for a WAN optimization tunnel” on page 2786.

Monitoring WAN optimization peer performance

The WAN optimization peer monitor lists all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with. These include peers manually added to the configuration as well as discovered peers.

The monitor lists each peer's name, IP address, and peer type. The peer type indicates whether the peer was manually added or discovered. To show WAN optimization performance, for each peer the monitor lists the percent of traffic reduced by the peer in client-side WAN optimization configurations and in server-side configurations (also called gateway configurations).

To view the peer monitor, go to *WAN Opt. & Cache* > *Monitor* > *Peer Monitor*.

Configuring WAN optimization rules

To configure WAN optimization, you add WAN optimization rules. Similar to security policies, when a FortiGate unit receives a connection packet, it analyzes the packet's source address, destination address, and service (by destination port number), and attempts to locate a matching WAN optimization rule that decides how to optimize the traffic over the WAN. WAN optimization rules also apply features such as byte-caching and protocol optimization to optimized traffic.

You can add one of two types of WAN optimization rules: peer-to-peer and active-passive.

A ***peer-to-peer WAN optimization*** rule includes a peer host ID. WAN optimization sessions matched by a client-side peer-to-peer rule can only connect to the named server-side peer. When the client-side peer unit initiates a tunnel with the server-side peer, the packets that initiate the tunnel include extra information so that the server-side peer can determine that it is a peer-to-peer tunnel request. This extra information is required because the server-side peer does not require a WAN optimization rule; you just need to add the client peer host ID and IP address to the server-side FortiGate unit peer list. Peer to peer WAN optimization tunnels use port 7810.

For ***active-passive WAN optimization***, you add active rules to client-side FortiGate units and passive rules to server-side FortiGate units. A single passive rule can accept tunnel requests from multiple active rules. The configuration of the active rule enables WAN optimization features. The passive rule uses the configuration of the active rules. The one exception is web caching, which is enabled in passive rules.

This chapter describes:

WAN optimization rules, security policies, and UTM protection

The FortiGate unit applies security policies to communication sessions before WAN optimization rules. A WAN optimization rule can be applied to a packet only after the packet is accepted by a security policy. WAN optimization processes all sessions accepted by a security policy that also match a WAN optimization rule. However, if the security policy includes any UTM features, communication sessions accepted by the policy are processed by the UTM engine and not by WAN optimization. Before you add WAN optimization rules, you must add security policies to accept the traffic that you want to optimize.

To apply WAN optimization to traffic that is accepted by a security policy containing UTM features, you can use multiple FortiGate units or multiple VDOMs. You apply the UTM features in the first FortiGate unit or VDOM and then apply WAN optimization in the second FortiGate unit or VDOM. You also add inter-VDOM links between the VDOMs. See the configuration example "Out-of-path WAN optimization with inter-VDOM routing" on page 2757.

WAN optimization does not apply source and destination NAT settings included in security policies. This means that selecting NAT or adding virtual IPs in a security policy does not affect WAN optimized traffic. WAN optimization is also not compatible with firewall load balancing. However, traffic accepted by these policies that is not WAN optimized is processed as expected.

WAN optimization is compatible with identity-based security policies. If a session is allowed after authentication and if the identity-based policy that allows the session does not include UTM features, the session can be processed by matching WAN optimization rules.

traffic shaping is compatible with client/server (active-passive) transparent mode WAN optimization rules. Traffic shaping is ignored for peer-to-peer WAN optimization and for client/server WAN optimization not operating in transparent mode.

WAN optimization transparent mode

WAN optimization is transparent to users. This means that with WAN optimization in place, clients connect to servers in the same way as they would without WAN optimization. However, servers receiving packets after WAN optimization "see" different source addresses depending on whether or not transparent mode is selected for WAN optimization. If transparent mode is selected, WAN optimization keeps the original source address of the packets, so servers appear to receive traffic directly from clients. Routing on the server network should be configured to route traffic with client source IP addresses from the server-side FortiGate unit to the server and back to the server-side FortiGate unit.

Some protocols, for example CIFS, may not function as expected if transparent mode is ***not*** selected. In most cases, for CIFS WAN optimization you should select transparent mode and make sure the server network can route traffic as described to support transparent mode.

If transparent mode is not selected, the source address of the packets received by servers is changed to the address of the server-side FortiGate unit interface that sends the packets to the servers. So servers appear to receive packets from the server FortiGate unit. Routing on the server network is simpler in this case because client addresses are not involved. All traffic appears to come from the server FortiGate unit and not from individual clients.

Do not confuse WAN optimization transparent mode with FortiGate transparent mode. WAN optimization transparent mode is configured in individual WAN optimization rules. FortiGate Transparent mode is a system setting that controls how the FortiGate unit (or a VDOM) processes traffic.

WAN optimization rule list

The WAN optimization rule list displays WAN optimization rules in their order of matching precedence. WAN optimization rule order affects rule matching. For details about arranging rules in the rule list, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

For information about WAN optimization rules and security policies, see "WAN optimization rules, security policies, and UTM protection" on page 2705.

Then you add WAN optimization rules that:

- match WAN traffic to be optimized that is accepted by a security policy according to source and destination addresses and destination port of the traffic
- add the WAN optimization techniques to be applied to the traffic.

To view the WAN optimization rule list, go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule*.

Create New	Add a new WAN optimization rule. New rules are added to the bottom of the list.
Status	Select to enable a rule or clear to disable a rule. A disabled rule is out of service.
ID	The rule identifier. Rules are numbered in the order they are added to the rule list.
Source	The source address or address range that the rule matches. For more information, see "WAN optimization address formats" on page 2709.
Destination	The destination address or address range that the rule matches. For more information, see "WAN optimization address formats" on page 2709.
Port	The destination port number or port number range that the rule matches.
Method	Indicates whether you have selected byte caching in the WAN optimization rule.
Auto-Detect	Indicates whether the rule is an active (client) rule, a passive (server) rule or if auto-detect is off. If auto-detect is off, the rule can be peer-to-peer or Web Cache Only.
Protocol	The protocol optimization WAN optimization technique applied by the rule. For more information, see "Protocol optimization" on page 2689.
Peer	For a peer-to-peer rule, the name of the peer WAN optimizer at the other end of the link.
Mode	Indicates whether the rule applies Full Optimization or Web Cache Only.
SSL	Indicates whether the rule is configured for SSL offloading.
Secure Tunnel	Indicates whether the rule is configured to used a WAN optimization tunnel.
Delete icon	Delete a rule from the list.
Edit icon	Edit a rule.

Insert WAN Optimization Rule Before icon	Add a new rule above the corresponding rule.
Move To icon	Move the corresponding rule before or after another rule in the list. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

How list order affects rule matching

Similar to security policies, you add WAN optimization rules to the WAN optimization rule list. The FortiGate unit uses the first-matching technique to select the WAN optimization rule to apply to a communication session.

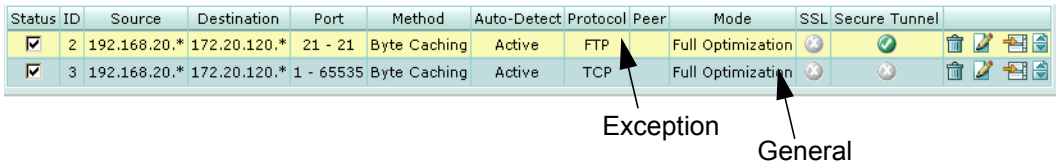
When WAN optimization rules have been added, each time the FortiGate security accepts a communication session, it then searches the WAN optimization rule list for a matching rule. Matching rules are determined by comparing the rule with the session source and destination addresses and destination port.The search begins at the top of the rule list and progresses in order towards the bottom. Each rule in the rule list is compared with the communication session until a match is found. When the FortiGate unit finds the first matching rule, it applies that rule's specified WAN optimization features to the session and disregards subsequent rules.

If no WAN optimization rule matches, the session is processed according to the security policy that originally accepted the session.

As a general rule, you should order the WAN optimization rule list from most specific to most general because of the order in which rules are evaluated for a match, and because only the ***first*** matching rule is applied to a session. Subsequent possible matches are not considered or applied. Ordering rules from most specific to most general prevents rules that match a wide range of traffic from superseding and effectively masking rules that match exceptions.

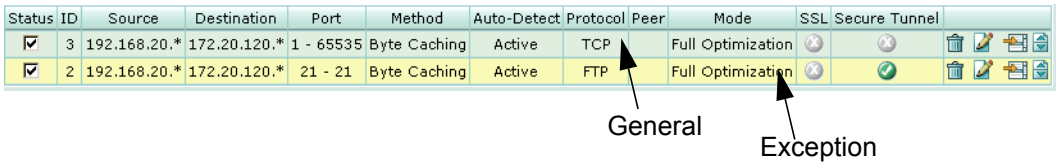
For example, you might have a general WAN optimization rule that applies WAN optimization features but does not apply secure tunneling to most WAN traffic. However, you want to apply secure tunneling to FTP traffic (FTP traffic uses port 21). In this case, you would add a rule that creates a secure tunnel for FTP sessions above the general rule.

Figure 319: Example: secure tunneling for FTP — correct rule order



FTP sessions (using port 21) would immediately match the secure tunnel rule. Other kinds of services would not match the FTP rule, so rule evaluation would continue until the search reaches the matching general rule. This rule order has the intended effect. But if you reversed the order of the two rules, positioning the general rule before the FTP rule, all session, including FTP, would immediately match the general rule, and the rule to secure FTP would never be applied. This rule order would not have the intended effect.

Figure 320: Example: secure tunneling for FTP — incorrect rule order



Similarly, if specific traffic requires exceptional WAN optimization rule settings, you would position those rules above other potential matches in the rule list. Otherwise, the other matching rules would take precedence, and the required exceptional settings might never be used.

Moving a rule to a different position in the rule list

When more than one rule has been defined, the first matching rule is applied to the traffic session. You can arrange the WAN optimization rule list to influence the order in which rules are evaluated for matches with incoming traffic. For more information, see "How list order affects rule matching" on page 2708.

Moving a rule in the rule list does not change its ID, which only indicates the order in which the rule was created.

To move a rule in the WAN optimization rule list - web-based manager

1 Go to *WAN Opt & Cache* > *WAN Opt. Rule* > *Rule*.
2 In the rule list, note the ID of a rule that is before or after your intended destination.
3 In the row corresponding to the rule that you want to move, select the *Move To* icon.
4 Select *Before* or *After*, and enter the ID of the rule that is before or after your intended destination. This specifies the rule's new position in the WAN optimization rule list.
5 Select *OK*.

To move a rule in the WAN optimization rule list - CLI

1 Use the following command to move a WAN optimization rule with ID 34 above the rule in the rule list with ID 10.

```
config wanopt rule
  move 34 before 10
end
```

2 Use the following command to move a WAN optimization rule with ID 5 after the rule in the rule list with ID 1.

```
config wanopt rule
  move 5 after 1
end
```

WAN optimization address formats

A WAN optimization source or destination address can contain one or more network addresses. Network addresses can be represented by an IP address with a netmask or an IP address range.

When representing hosts by an IP address with a netmask, the IP address can represent one or more hosts. For example, a source or destination address can be:

- a single computer, for example, `192.45.46.45`
- a subnetwork, for example, `192.168.1.*` for a class C subnet

- `0.0.0.0`, matches any IP address.

The netmask corresponds to the subnet class of the address being added, and can be represented in either dotted decimal or CIDR format. The FortiGate unit automatically converts CIDR-formatted netmasks to dotted decimal format. Example formats:

- netmask for a single computer: `255.255.255.255`, or `/32`
- netmask for a class A subnet: `255.0.0.0`, or `/8`
- netmask for a class B subnet: `255.255.0.0`, or `/16`
- netmask for a class C subnet: `255.255.255.0`, or `/24`
- netmask including all IP addresses: `0.0.0.0`

Valid IP address and netmask formats include:

- x.x.x.x/x.x.x.x, such as `192.168.1.0/255.255.255.0`
- x.x.x.x/x, such as `192.168.1.0/24`

An IP address `0.0.0.0` with netmask `255.255.255.255` is not a valid source or destination address.

When representing hosts by an IP range, the range indicates hosts with continuous IP addresses in a subnet, such as `192.168.1.[2-10]`, or `192.168.1.*` to indicate the complete range of hosts on that subnet. You can also indicate the complete range of hosts on a subnet by entering 192.168.1.[0-255] or 192.168.1.0-192.168.1.255. Valid IP range formats include:

- x.x.x.x-x.x.x.x, for example, `192.168.110.100-192.168.110.120`
- x.x.x.[x-x], for example, `192.168.110.[100-120]`
- x.x.x.*, for a complete subnet, for example: `192.168.110.*`
- x.x.x.[0-255] for a complete subnet, such as `192.168.110.[0-255]`
- x.x.x.0 -x.x.x.255 for a complete subnet, such as `192.168.110.0 - 192.168.110.255`

You cannot use square brackets [ ] or asterisks * when adding addresses to the CLI. Instead you must enter the start and end addresses of the subnet range separated by a dash -. For example, 192.168.20.0-192.168.20.255 for a complete subnet and 192.168.10.10-192.168.10.100 for a range of addresses.

Configuring WAN optimization rules

This section describes all the details that you can configure for the WAN optimization rules. The options available depend on how you configure a specific rule. The conditions are noted.

To add a WAN optimization rule - web-based manager

1 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New.*

2 Configure the WAN optimization rule, using the guidance in the following table, and select *OK*.

Mode	Select *Full Optimization* to add a rule that can apply all WAN optimization features. Select *Web Cache Only* to add a rule that just applies web caching. If you select *Web Cache Only*, you can configure the source and destination address and port for the rule. You can also select *Transparent Mode* and *Enable SSL*.
Source	Enter an IP address, followed by a forward slash (/), then subnet mask, or enter an IP address range separated by a hyphen. For more information, see "WAN optimization address formats" on page 2709. Only packets whose source address header contains an IP address matching this IP address or address range will be accepted by and subject to this rule. For a passive rule, the server (passive) source address range should be compatible with the source addresses of the matching client (active) rule. To match one passive rule with many active rules, the passive rule source address range should include the source addresses of all of the active rules.
Destination	Enter an IP address, followed by a forward slash (/), then subnet mask, or enter an IP address range separated by a hyphen. For more information, see "WAN optimization address formats" on page 2709. Only a packet whose destination address header contains an IP address matching this IP address or address range will be accepted by and subject to this rule. For a Web Cache Only rule, if you set *Destination* to 0.0.0.0, the rule caches web pages on the Internet or any network. For a passive rule, the server (passive) destination address range should be compatible with the destination addresses of the matching client (active) rule. To match one passive rule with many active rules, the passive rule destination address range should include the destination addresses of all of the active rules.
Port	Enter a single port number or port number range. Only packets whose destination port number matches this port number or port number range will be accepted by and subject to this rule. For a passive rule, the server (passive) port range should be compatible with the port range of the matching client (active) rule. To match one passive rule with many active rules, the passive rule port range should include the port ranges of all of the active rules.

Auto-Detect	Available only if *Mode* is set to *Full Optimization*. Specify whether the rule is *Active* (client), *Passive* (server) or if *Auto-Detect* is *Off*. If *Auto-Detect* is *Off*, the rule is a peer-to-peer rule. For an *Active* (client) rule, you must select all of the WAN optimization features to be applied by the rule. You can select the protocol to optimize, transparent mode, byte caching, SSL offloading, secure tunneling, and an authentication group. A *Passive* (server) rule uses the settings in the active rule on the client FortiGate unit to apply WAN optimization settings. You can also select web caching for a passive rule. If *Auto-Detect* is *Off*, the rule must include all required WAN optimization features and you must select a *Peer* for the rule. Select this option to configure peer-to-peer WAN optimization where this rule can start a WAN optimization tunnel with this peer only.
Protocol	Available only if *Mode* is set to *Full Optimization*, and *Auto-Detect* is set to *Off* or *Active*. Select CIFS, FTP, HTTP or MAPI to apply protocol optimization for one of these protocols. For information about protocol optimization, see "Protocol optimization" on page 2689. Select TCP if the WAN optimization tunnel accepts sessions that use more than one protocol or that do not use the CIFS, FTP, HTTP, or MAPI protocol.
Peer	Available only if *Mode* is set to *Full Optimization*, and *Auto-Detect* is set to *Off*. Select the peer host ID of the peer that this peer-to-peer WAN optimization rule will start a WAN optimization tunnel with. You can also select *[Create New...]* from the list to add a new peer.
Enable Web Cache	Available only if *Mode* is set to *Full Optimization*, and *Auto-Detect* is set to *Off* or *Passive*. If *Auto-Detect* is set to *Off*, then *Protocol* must be set to *HTTP*. Select to apply WAN optimization web caching to the sessions accepted by this rule. For more information, see "Web caching" on page 2735.
Transparent Mode	Available only if *Mode* is set to *Full Optimization* and *Auto-Detect* is set to *Active* or *Off*, or if *Mode* is set to *Web Cache Only.* Servers receiving packets after WAN optimization "see" different source addresses depending on whether or not you select *Transparent Mode*. For more information, see "WAN optimization transparent mode" on page 2706.
Enable Byte Caching	Available only if *Mode* is set to *Full Optimization*, and *Auto-Detect* is set to *Off* or *Active*. Select to apply WAN optimization byte caching to the sessions accepted by this rule. For more information, see "Byte caching" on page 2689.

Enable SSL	Available only if *Auto-Detect* is set to *Active* or *Off*. Select to apply SSL offloading for HTTPS traffic. You can use SSL offloading to offload SSL encryption and decryption from one or more HTTP servers to the FortiGate unit. If you enable this option, you must configure the rule to accept SSL-encrypted traffic. For example, you can configure the rule to accept HTTPS traffic by setting *Port* to 443. If you enable SSL offloading, you must also use the CLI command `config wanopt ssl-server` to add an SSL server for each HTTP server that you want to offload SSL encryption/decryption for. For more information, see "SSL offloading for WAN optimization and web caching" on page 2781.
Enable Secure Tunnel	Available only if *Mode* is set to *Full Optimization*, and *Auto-Detect* is set to *Active* or *Off*. If you select *Enable Secure Tunnel*, the WAN optimization tunnel is encrypted using SSL encryption. You must also add an authentication group to the rule. For more information, see "Secure tunneling" on page 2702.
Authentication Group	Available only if *Mode* is set to *Full Optimization*, and *Auto-Detect* is set to *Active* or *Off*. Select this option and select an authentication group from the list if you want groups of FortiGate units to authenticate with each other before starting the WAN optimization tunnel. You must also select an authentication group if you select *Enable Secure Tunnel*. You must add identical authentication groups to both of the FortiGate units that will participate in the WAN optimization tunnel started by the rule. For more information, see "Configuring authentication groups" on page 2700.

To add a WAN optimization rule - CLI

Using the guidance in the previous table, enter the following commands. For more information, see the `wanopt` and `rules` listings in the *FortiGate CLI Reference*.

```
config wanopt rule
  edit <index_int>
    set auth-group <auth_group_name>
    set auto-detect {active | off | passive}
    set byte-caching {disable | enable}
    set dst-ip <address_ipv4>[-<address-ipv4>]
    set mode {full | webcache-only}
    set peer <peer_name>
    set port <port_int>[-<port-int>]
    set proto {cifs | ftp | http | mapi | tcp}
    set secure-tunnel {disable | enable}
    set src-ip <address_ipv4>[-<address-ipv4>]
    set ssl {disable | enable}
    set status {disable | enable}
    set transparent {disable | enable}
    set tunnel-non-http {disable | enable}
    set tunnel-sharing {express-shared | private | shared}
    set unknown-http-version {best-effort | reject | tunnel}
    set webcache {disable | enable}
  end
```

Processing non-HTTP sessions accepted by an HTTP rule

From the CLI, use the `tunnel-non-http` keyword of the `config wanopt rule` command to configure how to process non-HTTP sessions when a rule configured to accept and optimize HTTP traffic accepts a non-HTTP session. This can occur if an application sends non-HTTP sessions using an HTTP destination port.

To drop non-HTTP sessions accepted by the rule set `tunnel-non-http` to `disable`, or set it to `enable` to pass non-HTTP sessions through the tunnel without applying protocol optimization, byte-caching, or web caching. In this case, the FortiGate unit applies TCP protocol optimization to non-HTTP sessions.

Processing unknown HTTP sessions

Unknown HTTP sessions are HTTP sessions that do not comply with HTTP 0.9, 1.0, or 1.1. From the CLI, use the `unknown-http-version` keyword of the `config wanopt rule` command to specify how a rule handles such HTTP sessions.

To assume that all HTTP sessions accepted by the rule comply with HTTP 0.9, 1.0, or 1.1, select `best-effort`. If a session uses a different HTTP version, WAN optimization may not parse it correctly. As a result, the FortiGate unit may stop forwarding the session and the connection may be lost. To reject HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, select `reject`.

To pass HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, but without applying HTTP protocol optimization, byte-caching, or web caching, you can also select `tunnel`. TCP protocol optimization is applied to these HTTP sessions.

WAN optimization configuration examples

This chapter provides the following basic examples to illustrate WAN optimization configurations introduced in the previous chapters:

- Example: Basic peer-to-peer WAN optimization configuration
- Example: Active-passive WAN optimization
- Example: Adding secure tunneling to an active-passive WAN optimization configuration

Example: Basic peer-to-peer WAN optimization configuration

Peer-to-peer WAN optimization is the simplest WAN optimization configuration. In a peer to peer configuration the WAN optimization tunnel can be set up only between one client-side FortiGate unit and one server-side FortiGate unit named in the WAN optimization rule added to the client-side FortiGate unit. When the client-side FortiGate unit initiates a tunnel with the server-side FortiGate unit, the packets that initiate the tunnel include extra information so that this server-side FortiGate unit can determine that it is a peer-to-peer tunnel request. This extra information is required because the server-side FortiGate unit does not require a WAN optimization rule; you just need to add the client peer host ID and IP address to the server-side FortiGate unit peer list.

The extra information in the communication session plus the peer list entry allow the server-side FortiGate unit to set up the WAN optimization tunnel with the client-side FortiGate unit by using only the settings on the client-side WAN optimization rule.

Traffic shaping is ignored for peer-to-peer WAN optimization.

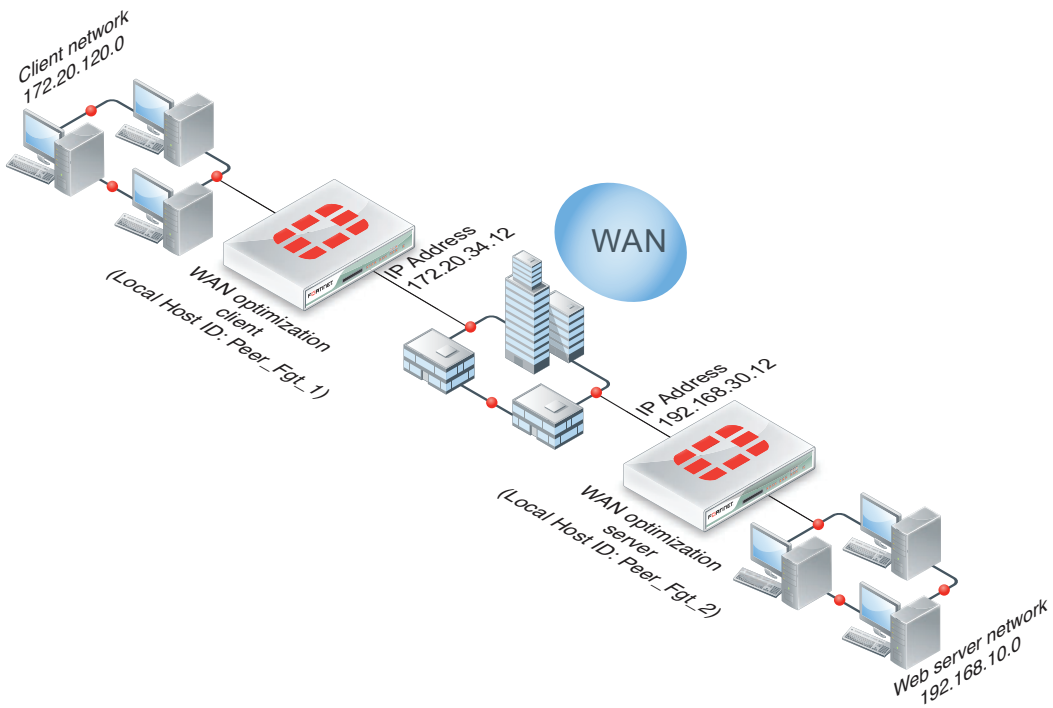
In a peer-to-peer WAN optimization configuration you create a peer-to-peer WAN optimization rule on the client-side FortiGate unit with *Auto-Detect* to *Off* and include the peer host ID of the server-side FortiGate unit. Using this rule, the client-side FortiGate unit can create a WAN optimization tunnel only with the peer that is added to the rule.

You do not have to add a rule to the server-side FortiGate unit. But the server-side FortiGate unit peer list must include the Peer Host ID and IP address of the client FortiGate unit. The server-side FortiGate unit uses the WAN optimization settings in the client-side rule.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Peer_Fgt_1 with a WAN IP address of 172.20.34.12. This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Peer_Fgt_2 with a WAN IP address of 192.168.30.12. This unit is in front of a web server network with IP address 192.168.10.0.

Figure 321: Example peer-to-peer topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1 Configure the client-side FortiGate unit by adding peers and a security policy that accepts traffic to be optimized.

2 Configure the server-side FortiGate unit.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuring basic peer-to-peer WAN optimization - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

To configure the client-side FortiGate unit and security policy

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the client-side FortiGate unit:

Local Host ID	Peer_Fgt_1

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the server-side FortiGate unit:

Peer Host ID	Peer_Fgt_2
IP Address	192.168.30.12

4 Select *OK*.

5 Go to *Policy* > *Policy* > *Policy* and add a security policy to the client-side FortiGate unit that accepts traffic to be optimized:

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	port2
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT

6 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New*.

7 Configure the rule:

Mode	Full Optimization
Source	172.20.120.*
Destination	192.168.10.*
Port	135
Auto-Detect	Off
Protocol	MAPI
Peer	Peer_Fgt_2
Transparent Mode	Select
Enable Byte Caching	Select

8 Select *OK*.

The rule is added to the bottom of the WAN optimization list.

9 If required, move the rule to a different position in the list so that the rule accepts the required MAPI sessions that use port 135. Depending on your rule list configuration, this may involve moving the rule above more general rules that would also match MAPI traffic.

For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the server-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate unit:

Local Host ID	Peer_Fgt_2

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the peer side FortiGate unit:

Peer Host ID	Peer_Fgt_1
IP Address	172.20.34.12

4 Select *OK*.

Configuring basic peer-to-peer WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit and security policy

1 Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id Peer_Fgt_1
end
```

2 Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Peer_Fgt_2
  set ip 192.168.30.12
end
```

3 Add a security policy to the client-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
  edit 23
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  end
end
```

4 Add the following peer-to-peer rule:

```
config wanopt rule
  edit 2
    set src-ip 172.20.120.0-172.20.120.255
    set dst-ip 192.168.10.0-192.168.10.255
    set port 135
    set proto mapi
    set peer Peer_Fgt_2
  end
```

Accept default settings for `auto-detect` (`off`), `transparent` (`enable`), `status` (`enable`), `mode` (`full`), `byte-caching` (`enable`), `ssl` (`disable`), `secure-tunnel` (`disable`), `auth-group` (`null`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

5 If required, move the rule to a different position in the list.

For more information, see "Moving a rule to a different position in the rule list" on page 2709.

6 If required, use the `move` command to change the order of the rules in the list so that the rule accepts the required MAPI sessions that use port 135. Depending on your rule list configuration, this may involve moving the rule above more general rules that would also match MAPI traffic.

For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the server-side FortiGate unit

1 Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
  set host-id Peer_Fgt_2
end
```

2 Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
  edit Peer_Fgt_1
  set ip 192.168.30.12
end
```

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the user network and the web server network. For example, from a PC on the user network browse to the IP address of a web server on the web server network, for example http://192.168.10.100. Even though this address is not on the user network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring (go to *WAN Opt. & Cache* > *Monitor* > *Monitor*). If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the Client-Side FortiGate unit is accepting traffic for the 192.168.10.0 network and that this security policy does not include UTM options. You can do this by checking the FortiGate session table from the dashboard. Look for sessions that use the policy ID of this policy
- Check routing on the FortiGate units and on the user and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the user network must allow packets destined for the web server network to be received by the client side FortiGate unit, and packets from the server side FortiGate unit must be able to reach the web servers etc.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating

Enter the following command on the client-side FortiGate unit to display WAN optimization tunnel protocol statistics. The http tunnel and tcp tunnel parts of the command output below shows that WAN optimization has been processing HTTP and TCP packets.

```
get test wad 11
wad tunnel protocol stats:
  http tunnel
    bytes_in=1751767 bytes_out=325468
  ftp tunnel
    bytes_in=0 bytes_out=0
  cifs tunnel
    bytes_in=0 bytes_out=0
  mapi tunnel
    bytes_in=0 bytes_out=0
```

```
  tcp tunnel
    bytes_in=3182253 bytes_out=200702
  maintenance tunnel
    bytes_in=11800 bytes_out=15052
```

Enter the following command to display the current WAN optimization peers. You can use this command to make sure all peers are configured correctly. The command output for the client side FortiGate unit shows one peer with IP address 192.168.20.1, peer name `Web_servers`, and with 10 active tunnels.

```
get test wad 26
peer name=Web_servers ip=192.168.20.1 vd=0 version=1
   tunnels(active/connecting/failover)=10/0/0
     sessions=0 n_retries=0 version_valid=true
```

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output for the client-side FortiGate unit shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=100 ip=192.168.30.12
    SSL-secured-tunnel=no auth-grp=
    bytes_in=348 bytes_out=384

Tunnel: id=99 type=manual
    vd=0 shared=no uses=0 state=3

    bytes_in=1228 bytes_out=1264

Tunnels total=10 manual=10 auto=0
```

Example: Active-passive WAN optimization

In active-passive WAN optimization you add active WAN optimization rules on the client-side FortiGate unit by setting WAN optimization *Auto-Detect* to *Active*. You configure passive WAN optimization rules on the server-side FortiGate unit by setting WAN optimization *Auto-Detect* to *Passive*.

You can add multiple active rules for one passive rule to optimize different protocols. Since you do not configure the protocol in the passive rule, one passive rule can be used for each of the active rules. Adding fewer passive rules simplifies the WAN optimization configuration.

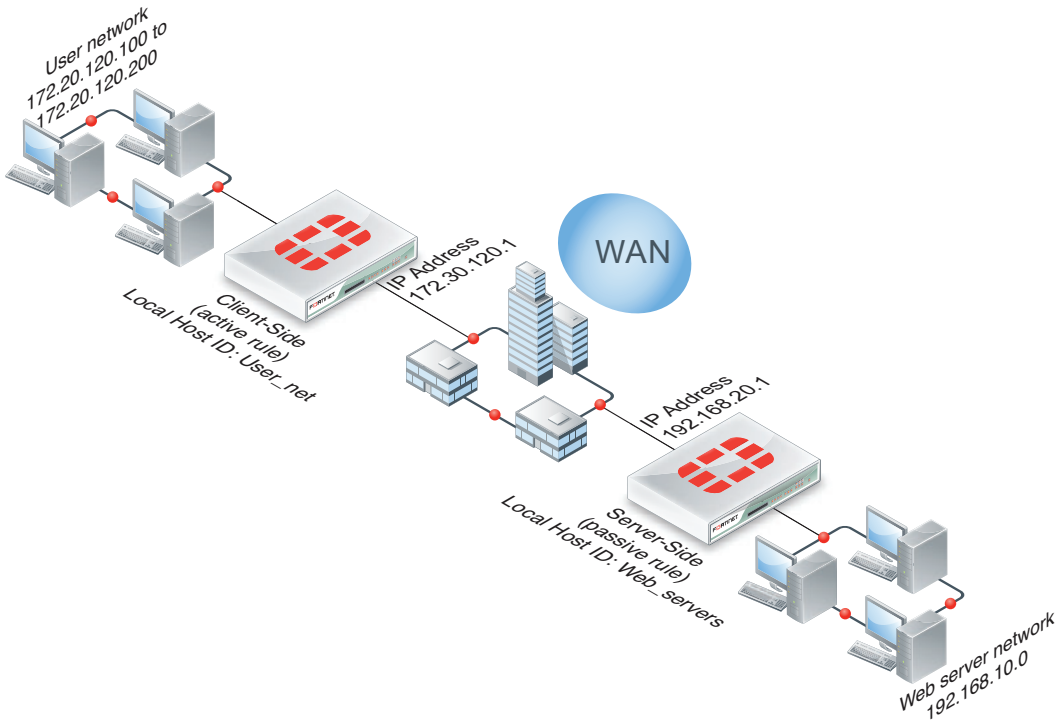
Network topology and assumptions

This example configuration includes three active rules on the client-side FortiGate unit and one passive rule in the server-side FortiGate unit. The active rules do the following:

- optimize CIFS traffic from IP addresses 172.20.120.100 to 172.20.120.200
- optimize HTTP traffic from IP addresses 172.20.120.100 to 172.20.120.150
- optimize FTP traffic from IP addresses 172.20.120.151 172.20.120.200.

You can do this by adding three active WAN optimization rules to the client-side FortiGate unit, one for each protocol—with port set to 80 for the HTTP rule, 21 for the FTP rule and 1-65535 for the CIFS rule. Then you arrange the rules in the WAN optimization rule list with the CIFS rule last because the HTTP and FTP rules include single port numbers.

Figure 322: Example active-passive WAN optimization topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1 Configure the client-side FortiGate unit by adding peers and a security policy that accepts traffic to be optimized.

2 Add WAN optimization rules to the FortiGate unit.

3 Configure the server-side FortiGate unit.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuring basic active-passive WAN optimization - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

To configure peers on the client-side FortiGate unit and add a security policy

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the client-side FortiGate unit:

Local Host ID	User_net

2 Select *Apply* to save your setting.

3 Select *Create New* and add a Peer Host ID and the *IP Address* for the server-side FortiGate unit:

Peer Host ID	Web_servers
IP Address	192.168.20.1

4 Select *OK*.

5 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy to the client-side FortiGate unit to accept the traffic to be optimized:

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	port2
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT

To add the active rules to the client-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule*.

2 Select *Create New* to add the active rule to optimize CIFS traffic from IP addresses 172.20.120.100 to 172.20.120.200:

Mode	Full Optimization
Source	172.20.120.[100-200]
Destination	192.168.10.*
Port	1 - 65535
Auto-Detect	Active
Protocol	CIFS
Transparent Mode	Select
Enable Byte Caching	Select

3 Select *OK*.

4 Select *Create New* to add the active rule to optimize HTTP traffic for IP addresses 172.20.120.100 to 172.20.120.150:

Mode	Full Optimization
Source	172.20.120.[100-150]
Destination	192.168.10.*
Port	80
Auto-Detect	Active
Protocol	HTTP
Transparent Mode	Select
Enable Byte Caching	Select

5 Select *OK*.

6 Select *Create New* to add the active rule to optimize FTP traffic from IP addresses 172.20.120.151 172.20.120.200:

Mode	Full Optimization
Source	172.20.120.[151-200]
Destination	192.168.10.*
Port	21
Auto-Detect	Active
Protocol	FTP
Transparent Mode	Select
Enable Byte Caching	Select

7 Select *OK*.

8 If required, use the *Move To* icon to change the order of the rules in the list so that the HTTP and FTP rules are above the CIFS rule in the list. You may need to do this if you have other WAN optimization rules in the list.

For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the server-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate unit:

Local Host ID	Web_servers

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the client-side FortiGate unit:

Peer Host ID	User_net
IP Address	172.30.120.1

4 Select *OK*.

5 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New*.

6 Add the passive rule. The source address matches the 172.20.120.100 to 172.20.120.200 IP address range and the 1-65535 port range. You can also enable web caching for the HTTP traffic:

Mode	Full Optimization
Source	172.20.120.[100-200]
Destination	192.168.10.*
Port	1-65535
Auto-Detect	Passive
Enable Web Cache	Select

7 Select *OK*.

The rule is added to the bottom of the rule list.

8 If required, move the rule to a different position in the list so that the tunnel request from the client-side FortiGate unit matches with this rule.

For more information, see "Moving a rule to a different position in the rule list" on page 2709.

Configuring basic active-passive WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure peers on the client-side FortiGate unit and add a security policy

1 Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id User_net
end
```

2 Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Web_servers
  set ip 192.168.20.1
end
```

3 Add a security policy to the client-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
  edit 20
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  end
end
```

To add the active rules to the client-side FortiGate unit

1 Add the following active rule to optimize CIFS traffic for IP addresses 172.20.120.100 to 172.20.120.200:

```
config wanopt rule
  edit 2
    set auto-detect active
    set src-ip 172.20.120.100-172.20.120.200
    set dst-ip 192.168.10.0-192.168.10.255
    set port 1-65535
    set proto cifs
  end
```

Accept default settings for `transparent` (`enable`), `status` (`enable`), `mode` (`full`), `byte-caching` (`enable`), `ssl` (`disable`), `secure-tunnel` (`disable`), `auth-group` (`null`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

2 Add the following active rule to optimize HTTP traffic for IP addresses 172.20.120.100 to 172.20.120.150:

```
config wanopt rule
  edit 3
    set auto-detect active
    set src-ip 172.20.120.100-172.20.120.150
    set dst-ip 192.168.10.0-192.168.10.255
    set port 80
  end
```

Accept default settings for `transparent` (`enable`), `proto` (`http`), `status` (`enable`), `mode` (`full`), `byte-caching` (`enable`), `ssl` (`disable`), `secure-tunnel` (`disable`), `auth-group` (`null`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

3 Add the following active rule to optimize FTP traffic from IP addresses 172.20.120.151 172.20.120.200:

```
config wanopt rule
  edit 4
    set auto-detect active
    set src-ip 172.20.120.151-172.20.120.200
    set dst-ip 192.168.10.0-192.168.10.255
    set port 21
    set proto ftp
  end
```

Accept default settings for `transparent` (`enable`), `status` (`enable`), `mode` (`full`), `byte-caching` (`enable`), `ssl` (`disable`), `secure-tunnel` (`disable`), `auth-group` (`null`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

4 If required, use the `move` command to change the order of the rules in the list so that the HTTP and FTP rules are above the CIFS rule in the list. You may need to do this if you have other WAN optimization rules in the list.

For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the server-side FortiGate unit

1 Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
  set host-id Web_servers
end
```

2 Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
  edit User_net
  set ip 172.20.120.1
end
```

3 Add the following passive rule to the server-side FortiGate unit:

```
config wanopt rule
  edit 5
    set auto-detect passive
    set src-ip 172.20.120.[100-200]
    set dst-ip 192.168.10.0-192.168.10.255
    set port 1-65535
    set webcache enable
```

```
end
```

Accept default settings for `status` (`enable`) and `mode` (`full`).

4 If required, use the `move` command to move the rule to a different position in the list so that the tunnel request from the client-side FortiGate unit matches with this rule.

For more information, see "Moving a rule to a different position in the rule list" on page 2709.

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the user network and the web server network. For example, from a PC on the user network browse to the IP address of a web server on the web server network, for example http://192.168.10.100. Even though this address is not on the user network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring (go to *WAN Opt. & Cache* > *Monitor* > *Monitor*). If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the Client-Side FortiGate unit is accepting traffic for the 192.168.10.0 network and that this security policy does not include UTM options. You can do this by checking the FortiGate session table from the dashboard. Look for sessions that use the policy ID of this policy
- Check routing on the FortiGate units and on the user and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the user network must allow packets destined for the web server network to be received by the client side FortiGate unit, and packets from the server side FortiGate unit must be able to reach the web servers etc.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating

Enter the following command to display WAN optimization tunnel protocol statistics. The http tunnel and tcp tunnel parts of the command output below shows that WAN optimization has been processing HTTP and TCP packets.

```
get test wad 11
wad tunnel protocol stats:
  http tunnel
    bytes_in=1751767 bytes_out=325468
  ftp tunnel
    bytes_in=0 bytes_out=0
  cifs tunnel
    bytes_in=0 bytes_out=0
  mapi tunnel
    bytes_in=0 bytes_out=0
  tcp tunnel
    bytes_in=3182253 bytes_out=200702
  maintenance tunnel
    bytes_in=11800 bytes_out=15052
```

Enter the following command to display the current WAN optimization peers. You can use this command to make sure all peers are configured correctly. The command output for the client side FortiGate unit shows one peer with IP address 192.168.20.1, peer name `Web_servers`, and with 10 active tunnels.

```
get test wad 26
peer name=Web_servers ip=192.168.20.1 vd=0 version=1
   tunnels(active/connecting/failover)=10/0/0
      sessions=0 n_retries=0 version_valid=true
```

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 3 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to on).

```
diagnose wad tunnel list

Tunnel: id=139 type=auto
    vd=0 shared=no uses=0 state=1
    peer name= id=0 ip=unknown
    SSL-secured-tunnel=no auth-grp=test
    bytes_in=744 bytes_out=76

Tunnel: id=141 type=auto
    vd=0 shared=no uses=0 state=1
    peer name= id=0 ip=unknown
    SSL-secured-tunnel=no auth-grp=test
    bytes_in=727 bytes_out=76

Tunnel: id=142 type=auto
    vd=0 shared=no uses=0 state=1
    peer name= id=0 ip=unknown
    SSL-secured-tunnel=no auth-grp=test
    bytes_in=727 bytes_out=76

Tunnels total=3 manual=0 auto=3
```

Example: Adding secure tunneling to an active-passive WAN optimization configuration

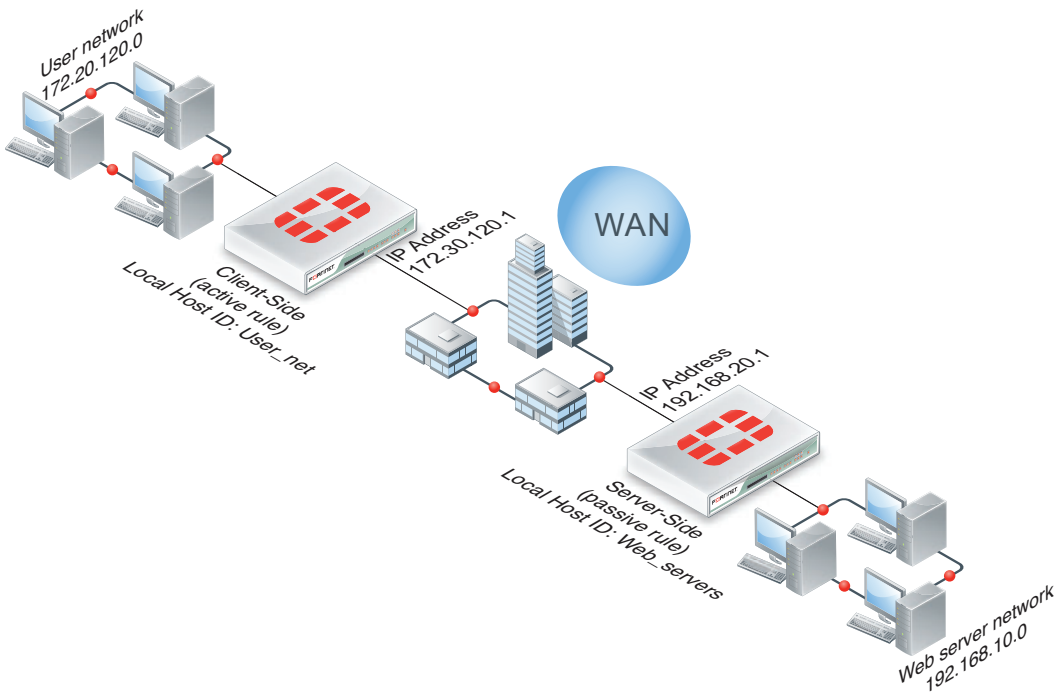
This example shows how to configure two FortiGate units for active-passive WAN optimization with secure tunneling. The same authentication group is added to both FortiGate units. The authentication group includes a password (or pre-shared key) and has *Peer Acceptance* set to *Accept any Peer*. An active rule is added to the client-side FortiGate unit and a passive rule to the server-side FortiGate unit. The active rule uses secure tunneling, optimizes HTTP traffic, and uses Transparent Mode and byte caching.

The authentication group is named *Auth_Secure_Tunnel* and the password for the pre-shared key is *2345678*. The topology for this example is shown in Figure 323. This example includes web-based manager configuration steps followed by equivalent CLI configuration steps. For information about secure tunneling, see “Secure tunneling” on page 2702.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called User_net with a WAN IP address of 172.30.120.1.This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Web_servers and has a WAN IP address of 192.168.20.1. This unit is in front of a web server network with IP address 192.168.10.0.

Figure 323: Example active-passive WAN optimization and secure tunneling topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit by adding peers and a security policy that accepts traffic to be optimized.
2. Add an authentication group and WAN optimization rule to the client-side FortiGate unit.
3. Configure peers on the server-side FortiGate unit.
4. Add the same authentication group and add a WAN optimization rule to the server-side FortiGate unit.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuring WAN optimization with secure tunneling - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

To configure peers on the client-side FortiGate unit and add a security policy

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the client-side FortiGate unit:

Local Host ID	User_net

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the server-side FortiGate unit:

Peer Host ID	Web_servers
IP Address	192.168.20.1

4 Select *OK*.

5 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy to the client-side FortiGate unit to accept the traffic to be optimized:

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	port2
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT

To add the authentication group and WAN optimization rule to the client-side FortiGate unit

1 Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group*.

2 Select *Create New* to add a new authentication group to be used for secure tunneling:

Name	Auth_Secure_Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

3 Select *OK*.

4 Go to *Wan Opt. & Cache* > *WAN Opt. Rule* > *Rule*.

5 Select *Create New* to add an active rule that enables secure tunneling and includes the authentication group:

Mode	Full Optimization
Source	172.20.120.[100-200]
Destination	192.168.10.*
Port	80
Auto-Detect	Active
Protocol	HTTP

Transparent Mode	Select
Enable Byte Caching	Select
Enable Secure Tunnel	Select
Authentication Group	Auth_Secure_Tunnel

6 Select *OK*.

To configure peers on the server-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate unit:

Local Host ID	Web_servers

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the client-side FortiGate unit:

Peer Host ID	User_net
IP Address	172.30.120.1

4 Select *OK*.

To add the authentication group and WAN optimization rule to the server-side FortiGate unit

1 Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group*.

2 Select *Create New* and add a new authentication group to be used for secure tunneling:

Name	Auth_Secure_Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

3 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New*.

4 Add the passive rule. The source address matches the 172.20.120.100 to 172.20.120.200 IP address range and the 1-65535 port range. You can also enable web caching for HTTP traffic:

Mode	Full Optimization
Source	172.20.120.[100-200]
Destination	192.168.10.*
Port	1-65535
Auto-Detect	Passive
Enable Web Cache	Select

5 Select *OK*.

Configuring WAN optimization with secure tunneling - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure peers on the client-side FortiGate unit and add a security policy

1 Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id User_net
end
```

2 Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Web_servers
  set ip 192.168.20.1
end
```

3 Add a security policy to the server-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
  edit 20
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  end
end
```

To add the authentication group and WAN optimization rule to the client-side FortiGate unit

1 Add a new authentication group to be used for secure tunneling:

```
config wanopt auth-group
  edit Auth_Secure_Tunnel
    set auth-method psk
    set psk 2345678
  end
```

Leave `peer-accept` at its default value.

2 Add the following active rule to optimize HTTP traffic for IP addresses 172.20.120.100 to 172.20.120.200:

```
config wanopt rule
  edit 1
    set auto-detect active
    set src-ip 172.20.120.100-172.20.120.200
    set dst-ip 192.168.10.0-192.168.10.255
    set port 80
    set proto http
    set secure-tunnel enable
    set auth-group Auth_Secure_Tunnel
  end
```

Leave the rest of the settings at their default values.

To configure peers on the server-side FortiGate unit

1 Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
  set host-id Web_servers
end
```

2 Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
  edit User_net
  set ip 172.20.120.1
end
```

To add the authentication group and WAN optimization rule to the server-side FortiGate unit

1 Add a new authentication group to be used for secure tunneling:

```
config wanopt auth-group
  edit Auth_Secure_Tunnel
    set auth-method psk
    set psk 2345678
  end
```

Leave `peer-accept` at its default value.

2 Add the following passive rule to the server-side FortiGate unit:

```
config wanopt rule
  edit 5
    set auto-detect passive
    set src-ip 172.20.120.[100-200]
    set dst-ip 192.168.10.0-192.168.10.255
    set port 1-65535
    set webcache enable
  end
```

Leave `status` (`enable`) and `mode` (`full`) at their default values.

Web caching

FortiGate web caching is a form of object caching that accelerates web applications and web servers by reducing bandwidth usage, server load, and perceived latency. Web caching supports caching of HTTP 1.0 and HTTP 1.1 web sites. Web caching can also support caching HTTPS sessions provided that you import the correct certificate. See RFC 2616 for information about web caching for HTTP 1.1. Web caching does not cache audio and video streams including Flash videos and streaming content.

Web caching involves storing HTML pages, images, servlet responses and other web-based objects for later retrieval. These objects are stored in the web cache storage location defined by the `config wanopt storage` command. You can also go to *System* > *Config* > *Advanced* > *Disk Management* to view the storage locations on the FortiGate unit hard disks.

There are three significant advantages to using web caching to improve HTTP and WAN performance:

- reduced bandwidth consumption because fewer requests and responses go over the WAN or Internet.
- reduced web server load because there are fewer requests for web servers to handle.
- reduced latency because responses for cached requests are available from a local FortiGate unit instead of from across the WAN or Internet.

You can use web caching to cache any web traffic that passes through the FortiGate unit, including web pages from web servers on a LAN, WAN or on the Internet. You apply web caching by enabling the web caching option in any security policy and WAN optimization rule. When enabled in a security policy, web caching is applied to all HTTP sessions accepted by the security policy. If the security policy is an explicit web proxy security policy, the FortiGate unit caches explicit web proxy sessions.

When enabled in a WAN optimization rule, the FortiGate unit caches HTTP traffic processed by that WAN optimization rule. You can add WAN optimization rules that only apply web caching. You can also add web caching to WAN optimization rules for HTTP traffic that also include byte caching, protocol optimization, and other WAN optimization features.

Web caching caches compressed and non-compressed versions of the same file separately. If the HTTP protocol considers the compressed and uncompressed versions of a file the same object, only the compressed or uncompressed file will be cached.

This section contains the following topics:

Web caching in security policies

Web caching can be applied to any HTTP traffic, including explicit web proxy traffic, accepted by any security policy by enabling web caching in that security policy.

Enabling web caching in a security policy cannot apply web caching to HTTPS traffic. To apply web caching to HTTPS traffic you need to create a WAN optimization rule.

Web Caching in a security policy takes place before web caching in a WAN Optimization rule. So traffic accepted by a security policy that includes web caching will not be cached by the WAN optimization rule.

By default FortiOS assumes HTTP traffic uses TCP port 80. So web caching in a security policy caches all HTTP traffic accepted by the policy on TCP port 80. If you want to cache HTTP traffic on other ports, you can enable UTM for the security policy and configure a protocol options profile to that looks for HTTP traffic on other TCP ports or on multiple ports.

If you set the HTTP port to 0 (for auto detection) in a protocol options profile, FortiOS looks for HTTP traffic on any port. In this case, HTTP traffic is detected by the IPS. Setting the HTTP port to 0 in a protocol options profile is not compatible with web caching. If you set the HTTP port to 0, web caching only caches HTTP traffic on port 80.

You can add web caching to a security policy to:

- Cache Internet HTTP traffic for users on an internal network to reduce Internet bandwidth use. Do this by selecting the web cache option for security policies that allow users on the internal network to browse web sites on the Internet.
- Reduce the requirements of a public facing web server by caching objects on the FortiGate unit to offload processing from the web server. A reverse proxy with web caching configuration. Do this by selecting the web cache option for security policy that allows users on the Internet to connect to the web server.
- Cache outgoing explicit web proxy traffic when the explicit proxy is used to proxy users in an internal network who are connecting to the web servers on the Internet. Do this by selecting the web cache option for explicit web proxy security policies that allow users on the internal network to browse web sites on the Internet.

Example: Web caching of Internet content for users on an internal network

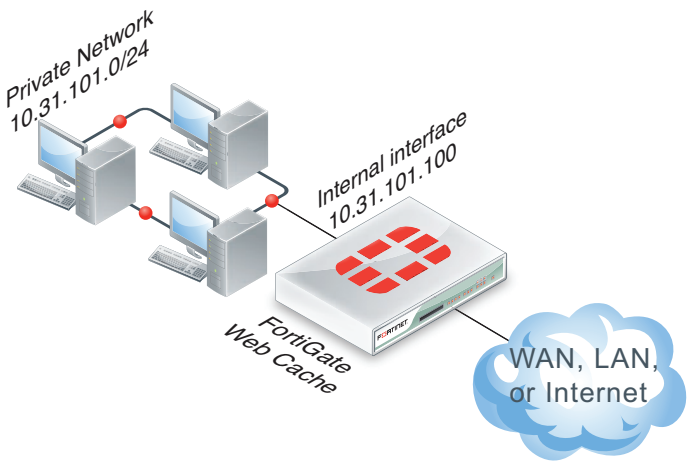
This example describes how to configure web caching for users on a private network connecting to the Internet. This example uses web caching in a security policy to cache HTTP traffic.

Network topology and assumptions

This example includes a client network with subnet address 10.31.101.0 connecting to web servers on the Internet (Figure 324). In this basic example, all of the users on the private network access the Internet though a single general security policy on the FortiGate unit that accepts all sessions connecting to the Internet. Web caching is just added to this security policy.

Initially, UTM is not selected so the example caches all HTTP traffic on TCP port 80. The example also describes how to configure the security policy to cache HTTP traffic on port 80 and 8080 by added a protocol options profile that looks for HTTP traffic on TCP ports 80 and 8080.

Figure 324: Example web caching topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1 Add web caching to the security policy that all users on the private network use to connect to the Internet.

2 Add a protocol options profile to look for HTTP traffic on ports 80 and 8080 and add this protocol options profile to the security policy to enable web caching HTTP traffic on ports 80 and 8080.

If you perform any additional actions between procedures, your configuration may have different results.

Configuration Steps - web-based manager

Use the following steps to configure the example configuration from the FortiGate web-based manager.

To add web caching to a security policy

1 Go to *Policy* > *Policy* > *Policy* and add a security policy that allows all users on the internal network to access the Internet.

Source Interface/Zone	Internal
Source Address	all
Destination Interface/Zone	wan1
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT
Enable web cache	Select
NAT	Enable NAT

2 Select OK to save the security policy.

3 If required, adjust the position of the security policy in the internal > wan1 policy list to make sure all outgoing connections to the Internet use this policy

To cache HTTP traffic on port 80 and 8080

1 Go to *Policy* > *Policy* > *Protocol Options* and either add a new a new protocol options profile or edit the default profile.

2 Change the HTTP settings of the protocol options profile to look for HTTP traffic on ports 80 and 8080:

Port	80, 8080

Adjust other settings as required or leave them as the defaults.

3 Edit the security policy created in the previous procedure. Select UTM and set Protocol Options to the protocol options profile you added or changed.

Configuration Steps - CLI

Use the following steps to configure the example configuration from the FortiGate CLI.

To add web caching to a security policy

1 Enter the following command to add a security policy that allows all users on the internal network to access the Internet.

```
config firewall policy
  edit 0
    set srcintf internal
    set srcaddr all
    set dstintf wan1
    set distinf all
    set schedule always
    set service ANY
    set action accept
    set webcache enable
    set nat enable
end
```

2 If required, adjust the position of the security policy in the internal > wan1 policy list to make sure all outgoing connections to the Internet use this policy

To cache HTTP traffic on port 80 and 8080

1 Go to *Policy* > *Policy* > *Protocol Options* and either add a new a new protocol options profile or edit the default profile.

1 Enter the following command to add a protocol option profile that looks for HTTP traffic on ports 80 and 8080.

```
config firewall profile-protocol-options
  edit custom-HTTP-proto
    config http
      set port 80 8080
    end
end
```

2 Enter the following command to add the protocol options profile to the security policy:

```
config firewall policy
  edit 1
    set utm-status enable
    set profile-protocol-options custom-HTTP-proto
end
```

Web Caching only WAN optimization

You can use Web Cache Only WAN optimization to cache web pages from any web server. In a Web Cache Only configuration, only one FortiGate unit is involved. All traffic between a client network and one or more web servers is intercepted by a Web Cache Only WAN optimization rule. This rule causes the FortiGate unit to cache pages from the web servers on the FortiGate unit and makes the cached pages available to users on the client network. Web cache only WAN optimization can be configured for standard and reverse web caching.

In a standard web caching configuration, the FortiGate unit caches pages for users on a client network. The FortiGate unit is installed between the client network and the WAN or Internet, and the web server or servers are located elsewhere on the WAN or Internet. See "Example: Web Cache Only WAN optimization" on page 2739 for an example of this configuration.

You can also create a reverse proxy web caching configuration where the FortiGate unit is dedicated to providing web caching for a single web server or server farm. In this second configuration, the FortiGate unit is installed between the server network and the WAN or Internet, and users are located elsewhere on the WAN or Internet. See "Example: SSL offloading and reverse proxy web caching for an Internet web server using static one-to-one virtual IPs" on page 2789 for an example of this configuration.

WAN optimization rule order affects Web Cache Only rules in the same way as other WAN optimization rules. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

Since only one FortiGate unit is involved in a Web Cache Only configuration, you do not need to change the WAN optimization peer configuration.

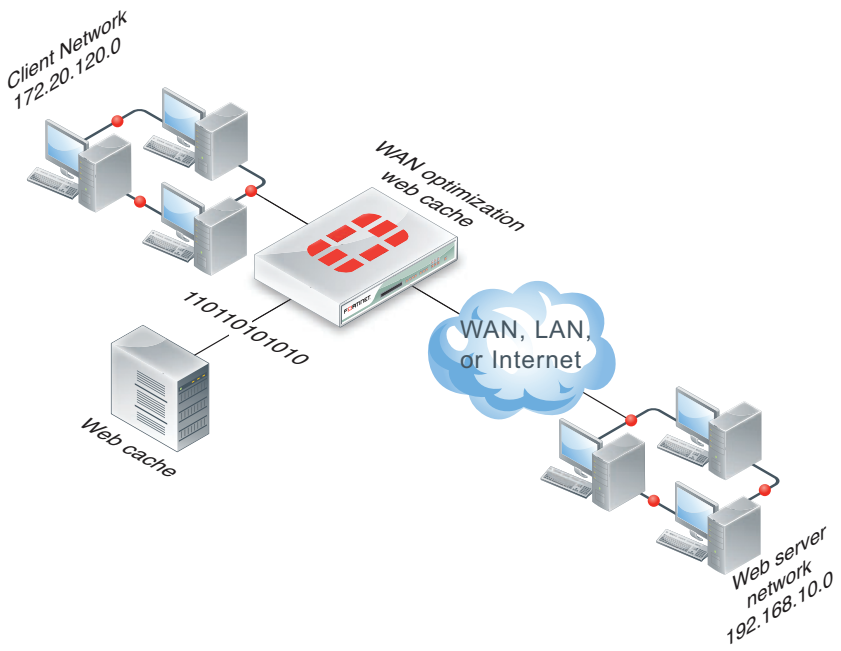
Example: Web Cache Only WAN optimization

This example describes how to configure web caching for users in a client network connecting to a web server network across a WAN.

Network topology and assumptions

This example includes a client network with subnet address 172.20.120.0 connecting to web servers on a network with subnet address 192.168.10.0. Only the communication between the client network and the web server network using Port 80 is to be cached, so the Web Cache Only WAN optimization rule includes the IP addresses of the networks and the *Port* is set to 80. As well, the security policy used in this example includes the addresses of the client and sever subnets instead of more general security addresses.

Figure 325: Example Web Cache Only topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1 Add firewall addresses and a security policy that accepts traffic to be optimized to the FortiGate unit.

2 Add a Web Cache Only WAN optimization rule to the FortiGate unit.

If you perform any additional actions between procedures, your configuration may have different results.

Configuring Web Cache Only WAN optimization - web-based manager

Use the following steps to configure the example WAN optimization configuration from the FortiGate unit web-based manager.

To add the firewall addresses and security policy

1 Go to *Firewall Objects* > *Address* > *Address* and select *Create New* to add the firewall address for the client network:

Address Name	Client_Net
Type	Subnet/IP Range
Subnet / IP Range	172.20.120.*
Interface	Any

2 Add the firewall address for the web server network:

Address Name	Web_Server_Net
Type	Subnet/IP Range

Subnet / IP Range	192.168.10.*
Interface	Any

3 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy that accepts traffic to be web cached:

Source Interface/Zone	port1
Source Address	Client_Net
Destination Interface/Zone	port2
Destination Address	Web_Server_Net
Schedule	always
Service	HTTP
Action	ACCEPT

To add a Web Cache Only WAN optimization rule

1 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New*.

2 Select *Web Cache Only*.

3 Configure the Web Cache Only rule:

Mode	Web Cache Only
Source	172.20.120.*
Destination	192.168.10.*
Port	80 Usually you would set the port to 80 to cache normal HTTP traffic. But you can change the Port to a different number (for example 8080) or to a port number range so that the FortiGate unit provides web caching for HTTP traffic using other ports.
Transparent Mode	Select Transparent Mode
Enable SSL	Do not select Enable SSL. In this example SSL offloading is disabled. For an example of a reverse proxy Web Cache Only configuration that also includes SSL offloading, see “Example: SSL offloading for a WAN optimization tunnel” on page 2786.

4 Select *OK*.

The rule is added to the bottom of the WAN optimization list.

5 If required, use the *Move To* icon to move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see “How list order affects rule matching” on page 2708 and “Moving a rule to a different position in the rule list” on page 2709.

Configuring Web Cache Only WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the FortiGate unit CLI.

To add the firewall addresses and security policy

1 Add the firewall address for the client network:

```
config firewall address
  edit Client_Net
    set type iprange
    set start-ip 172.20.120.0
    set end-ip 172.20.120.255
end
```

2 Add the firewall address for the web server network:

```
config firewall address
  edit Web_Server_Net
    set type iprange
    set start-ip 192.168.10.0
    set end-ip 192.168.10.255
end
```

3 Add a security policy that accepts traffic to be web cached:

```
config firewall policy
  edit 2
    set srcintf port1
    set dstintf port2
    set srcaddr Client_Net
    set dstaddr Web_Server_Net
    set action accept
    set service HTTP
    set schedule always
  end
end
```

To add a Web Cache Only WAN optimization rule

1 Add the following Web Cache Only rule:

```
config wanopt rule
  edit 2
    set mode webcache-only
    set src-ip 172.20.120.0-172.20.120.255
    set dst-ip 192.168.10.0-192.168.10.255
    set port 80
    set peer Peer_Fgt_2
  end
```

Accept default settings for `transparent` (`enable`), `status` (`enable`), `ssl` (`disable`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

In this example, SSL offloading is disabled. For an example of a reverse proxy Web Cache Only configuration that also includes SSL offloading, see "Example: SSL offloading for a WAN optimization tunnel" on page 2786.

2 If required, use the `move` command to move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

Testing and troubleshooting the configuration

To test the configuration, attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network, browse to the IP address of a web server on the web server network, for example http://192.168.10.100. Even though this address is not on the user network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring in *WAN Opt. & Cache* > *Monitor* > *Monitor*. If WAN optimization has been forwarding the traffic, the WAN optimization monitor should show the HTTP protocol that has been optimized and the reduction rate in WAN bandwidth usage.

If you cannot connect, try the following to diagnose the problem:

- Review your configuration and make sure all details, such as address ranges, peer names and IP addresses, are correct.
- Confirm that the security policy on the Client-Side FortiGate unit is accepting traffic for the 192.168.10.0 network and that this security policy does not include UTM options. You can do this by checking the FortiGate session table from the dashboard. Look for sessions that use the policy ID of this policy
- Check routing on the FortiGate units and on the user and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the user network must allow packets destined for the web server network to be received by the client side FortiGate unit, and packets from the server side FortiGate unit must be able to reach the web servers etc.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating

Enter the following command on the client-side FortiGate unit to display WAN optimization tunnel protocol statistics. The `http tunnel` and `tcp tunnel` parts of the command output below shows that WAN optimization has been processing HTTP packets. If the http bytes in and bytes out fields are zero, then WAN optimization is not accepting HTTP packets.

```
get test wad 11
wad tunnel protocol stats:
  http tunnel
    bytes_in=1749865 bytes_out=25926
  ftp tunnel
    bytes_in=0 bytes_out=0
  cifs tunnel
    bytes_in=0 bytes_out=0
  mapi tunnel
    bytes_in=0 bytes_out=0
  tcp tunnel
    bytes_in=0 bytes_out=0
  maintenance tunnel
    bytes_in=0 bytes_out=0
```

You can use the following command to display information about the WAN optimization web cache daemon. The command will only display information if the web cache daemon is running and the statistics displayed show the number of open connections and other indications of activity:

```
diagnose wacs stats
Disk 0 /Internal-2B6375792136C707/wa_cs
```

```
        Current number of open connections: 2
        Number of terminated connections: 7
        Number of requests -- Adds: 206 (0 repetitive keys),
    Lookups: 860, Conflict incidents: 0
        Percentage of missed lookups: 88.49
        Communication is blocked for 0 client(s)
        Disk usage: 5196 KB (11%)
```

Web caching for active-passive WAN optimization

You add web caching support to the passive or server side of an active-passive WAN optimization configuration. Web pages are cached on the server-side FortiGate unit so you should also select *Enable Byte Caching* for optimum WAN optimization performance.

For web caching to work, the WAN optimization tunnel must accept HTTP (and optionally HTTPS) traffic. To do this, the active rule on the client side must include the ports used for HTTP (and HTTPS) traffic. Set *Protocol* to *HTTP* to perform protocol optimization of the HTTP traffic. You can also enable SSL offloading and secure tunneling, as well as add an authentication group.

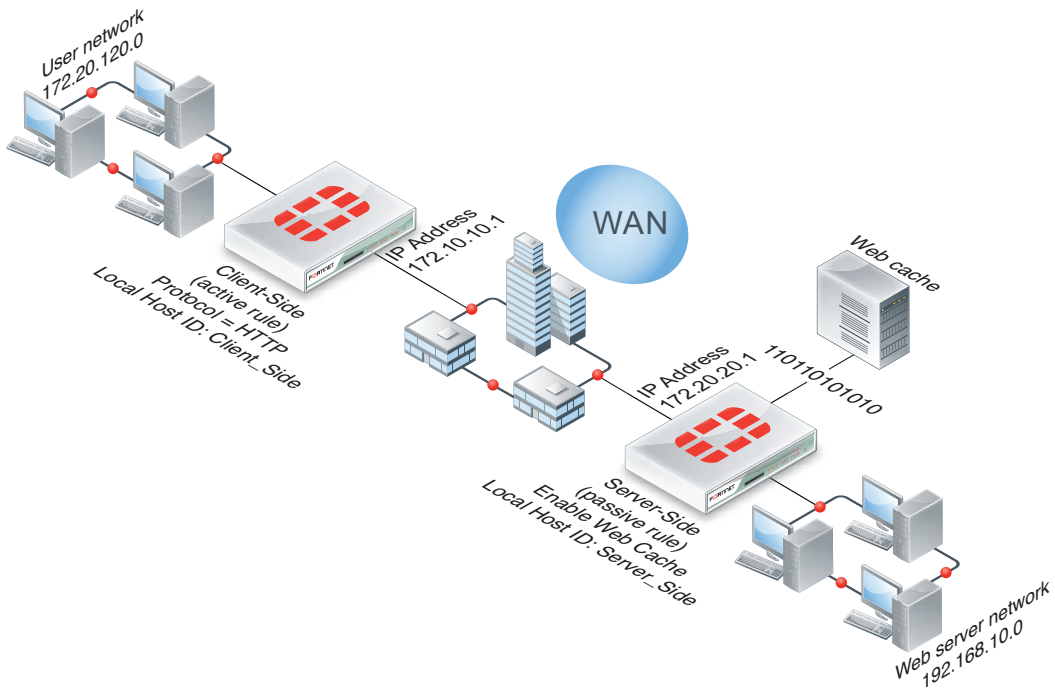
Example: Active-passive Web Caching

This example describes how to configure active-passive web caching for users in a client network connecting to a web server network across a WAN.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client_Side with a WAN IP address of 172.10.10.1 in front of a user network with IP address 172.20.120.0. The server-side FortiGate unit is called Server_Side and has a WAN IP address of 172.20.20.1. This server-side unit is in front of a web server network with IP address 192.168.10.0. Web caching is enabled on the server-side FortiGate unit.

Figure 326: Example active-passive web cache topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1 Configure the client-side FortiGate unit by adding peers, a security policy that accepts traffic to be optimized, and an active WAN optimization rule.

2 Configure the server-side FortiGate unit by adding peers and a passive WAN optimization rule that includes web caching.

If you perform any additional actions between procedures, your configuration may have different results.

Configuring active-passive web caching - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

To configure the client-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the client FortiGate unit:

Local Host ID	Client_Side

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the server-side FortiGate unit:

Peer Host ID	Server_Side
IP Address	172.20.20.1

4 Select *OK*.

5 Go to *Policy* > *Policy* > *Policy* and add a security policy that accepts traffic to be web cached:

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	port2
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT

6 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New*.

7 Configure the rule:

Mode	Full Optimization
Source	172.20.120.*
Destination	192.168.10.*
Port	1-65535
Auto-Detect	Active
Protocol	HTTP
Transparent Mode	Select Transparent Mode
Enable Byte Caching	Select Enable Byte Caching

8 Select *OK*.

The rule is added to the bottom of the WAN optimization list.

9 If required, use the *Move To* icon to move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the server-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate unit:

Local Host ID	Server_Side

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the client-side FortiGate unit:

Peer Host ID	Client_Side
IP Address	172.10.10.1

4 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New*.

5 Configure the passive web cache rule:

Mode	Full Optimization
Source	172.20.120.*
Destination	192.168.10.*
Port	1-65535
Auto-Detect	Passive
Enable Web Cache	Select

6 Select *OK*.

The rule is added to the bottom of the WAN optimization rule list.

7 If required, use the *Move To* icon to move the rule to a different position in the list.

For more information, see "Moving a rule to a different position in the rule list" on page 2709.

Configuring active-passive web caching - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1 Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id Client_Side
end
```

2 Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Server_Side
  set ip 172.20.20.1
end
```

3 Add a security policy to the server-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
  edit 23
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  end
end
```

4 Configure the following active rule:

```
config wanopt rule
  edit 2
    set auto-detect active
    set src-ip 172.20.120.0-172.20.120.255
    set dst-ip 192.168.10.0-192.168.10.255
    set port 1-65535
```

```
    set proto http
  end
```

Accept default settings for `transparent` (`enable`), `status` (`enable`), `mode` (`full`), `byte-caching` (`enable`), `ssl` (`disable`), `secure-tunnel` (`disable`), `auth-group` (`null`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

5 If required, use the `move` command to move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the server-side FortiGate unit

1 Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
  set host-id Server_Side
end
```

2 Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
  edit Client_Side
  set ip 172.10.10.1
end
```

3 Add the following passive web cache rule:

```
config wanopt rule
  edit 5
    set auto-detect passive
    set src-ip 172.20.120.0-172.20.120.255
    set dst-ip 192.168.10.0-192.168.10.255
    set port 1-65535
    set webcache enable
  end
```

Accept default settings for `status` (`enable`) and `mode` (`full`).

4 If required, use the `move` command to move the rule to a different position in the list so that the tunnel request from the client-side FortiGate unit matches with this rule.

For more information, see "Moving a rule to a different position in the rule list" on page 2709.

Web caching for peer-to-peer WAN optimization

In a peer-to-peer web caching configuration, you create a peer-to-peer WAN optimization rule on the client-side FortiGate unit and include the peer host ID of the server-side FortiGate unit. In the rule, you set *Auto-Detect* to *Off* and select *Enable Web Cache*. By using this rule, the client-side FortiGate unit can create a WAN optimization tunnel only with the peer that is added to the rule.

In a peer-to-peer configuration, you do not have to add a rule to the server-side FortiGate unit. If the server-side FortiGate unit peer list contains the client FortiGate unit, the server FortiGate unit accepts WAN optimization tunnel connections from the client FortiGate unit and the two units can form a WAN optimization tunnel. The server-side FortiGate unit uses the settings in the rule added to the client-side FortiGate unit.

For web caching to work, the WAN optimization tunnel must allow HTTP (and optionally HTTPS) traffic. To do this, the WAN optimization rule must include the ports used for HTTP (and HTTPS) traffic. Set *Protocol* to *HTTP* to perform protocol optimization of the HTTP traffic. You can also enable WAN optimization transparent mode, byte caching, SSL offloading, and secure tunneling, as well as add an authentication group.

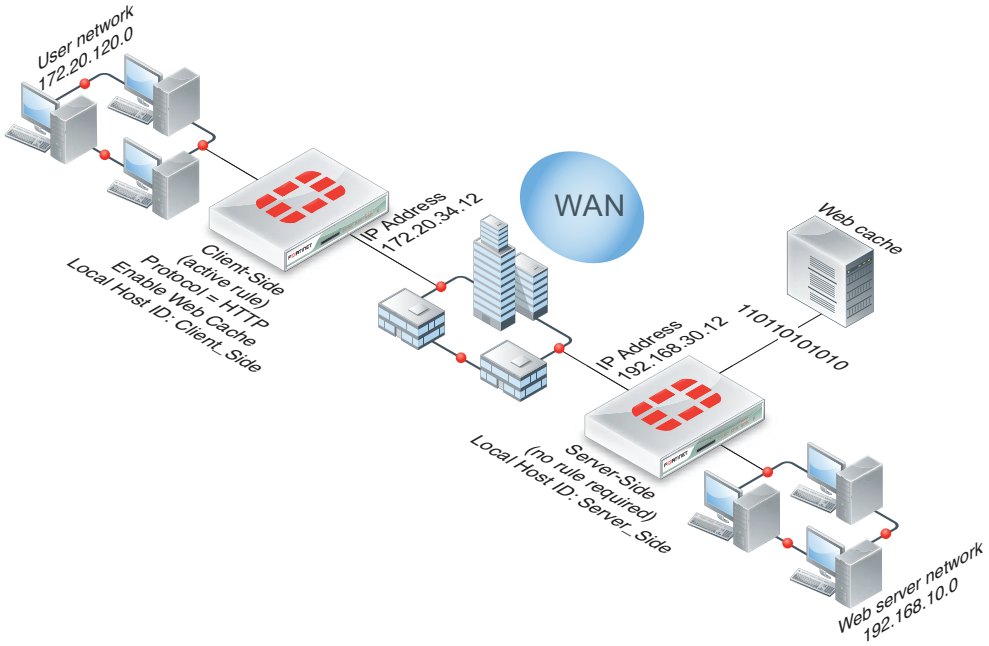
Example: Peer-to-peer web caching

This example describes how to configure peer-to-peer web caching for users in a client network connecting to a web server network across a WAN.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client_Side with a WAN IP address of 172.10.10.1 in front of a user network with IP address 172.20.120.0 The server-side FortiGate unit is called Server_Side and has a WAN IP address of 172.20.20.1. This server-side unit is in front of a web server network with IP address 192.168.10.0. Web caching is enabled on the server-side FortiGate unit.

Figure 327: Example peer-to-peer web cache topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit by adding peers, a security policy that accepts traffic to be optimized, and a peer-to-peer WAN optimization rule that includes web caching.
2. Configure the server-side FortiGate unit.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuring peer-to-peer web caching - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

To configure the client-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the client FortiGate unit:

Local Host ID	Client_Side

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the server-side FortiGate unit:

Peer Host ID	Server_Side
IP Address	192.168.30.12

4 Select *OK*.

5 Go to *Policy* > *Policy* > *Policy* and add a security policy that accepts traffic to be web cached:

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	port2
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT

6 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New*.

7 Configure the rule:

Mode	Full Optimization
Source	172.20.120.*
Destination	192.168.10.*
Port	80
Auto-Detect	Off
Protocol	HTTP
Peer	Server_Side
Enable Web Cache	Select
Transparent Mode	Select
Enable Byte Caching	Select

8 Select *OK*.

The rule is added to the bottom of the WAN optimization list.

9 If required, use the *Move To* icon to move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the server-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server FortiGate unit:

Local Host ID	Server_Side

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the client-side FortiGate unit:

Peer Host ID	Client_Side
IP Address	172.20.34.12

4 Select *OK*.

Configuring peer-to-peer web caching - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1 Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id Client_Side
end
```

2 Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Server_Side
  set ip 192.168.30.12
end
```

3 Add a security policy to the server-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
  edit 23
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  end
end
```

4 Configure the following active rule:

```
config wanopt rule
  edit 5
    set auto-detect off
    set src-ip 172.20.120.*
    set dst-ip 192.168.10.*
    set port 80
    set proto http
    set peer Server_Side
    set web cache enable
```

```
  end
```

Accept default settings for `transparent` (`enable`), `status` (`enable`), `mode` (`full`), `byte-caching` (`enable`), `ssl` (`disable`), `secure-tunnel` (`disable`), `auth-group` (`null`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

5 If required, use the `move` command to the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the server-side FortiGate unit

1 Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
  set host-id Server_Side
end
```

2 Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
  edit Client_Side
  set ip 172.20.34.12
end
```

Exempting web sites from web caching

You may want to exempt some URLs from web caching for a number of reasons. For example, if your users access websites that are not compatible with FortiGate web caching you can add the URLs of these web sites to the web caching exempt list. All traffic accepted by WAN optimization and the explicit web proxy for these websites will not be cached. You can add URLs and numeric IP addresses to the web cache exempt list. When enabled the web cache exempt list applies to web caching in security policies and in WAN optimization rules.

Enter the following command to add www.example.com to the web cache exempt list.

```
config wanopt webcache
  set cache-exemption enable
    config cache-exemption-list
      edit 1
        set url-pattern www.example.com
        set status enable
    end
end
```

Enter the following command to enable the web cache exempt list and add two IP address URLs and a web page URL to the list.

```
config wanopt webcache
  set explicit enable
  set cache-exemption enable
    config cache-exemption-list
      edit 1
        set url-pattern "192.168.1.121"
      next
      edit 2
        set url-pattern "google.com/test123/321"
```

```
        next
        edit 3
          set url-pattern "1.1.1.1"
        next
    end
end
```

You can also add URLs to the web cache exempt list by going to *WAN Opt. & Cache* > *Cache* > *Exempt List*. However, the web cache exempt feature must be enabled from the CLI.

Changing web cache settings

In most cases, the default settings for the WAN optimization web cache are acceptable. However, you may want to change them to improve performance or optimize the cache for your configuration. To change these settings, go to *WAN Opt. & Cache* > *Cache* > *Settings.*

From the FortiGate CLI, you can use the `config wanopt webcache` command to change these WAN optimization web cache settings.

For more information about many of these web cache settings, see RFC 2616.

Always revalidate

Select to always revalidate requested cached objects with content on the server before serving them to the client.

Max cache object size

Set the maximum size of objects (files) that are cached. The default size is 512000 KB and the range is 1 to 4294967 KB. This setting determines the maximum object size to store in the web cache. Objects that are larger than this size are still delivered to the client but are not stored in the FortiGate web cache.

Negative response duration

Set how long in minutes that the FortiGate unit caches error responses from web servers. If error responses are cached, then subsequent requests to the web cache from users will receive the error responses regardless of the actual object status.

The default is 0, meaning error responses are not cached. The content server might send a client error code (4xx HTTP response) or a server error code (5xx HTTP response) as a response to some requests. If the web cache is configured to cache these negative responses, it returns that response in subsequent requests for that page or image for the specified number of minutes.

Fresh factor

Set the fresh factor as a percentage. The default is 100, and the range is 1 to 100%. For cached objects that do not have an expiry time, the web cache periodically checks the server to see if the objects have expired. The higher the *Fresh Factor* the less often the checks occur.

For example, if you set the *Max TTL* value and *Default TTL* to 7200 minutes (5 days) and set the *Fresh Factor* to 20, the web cache check the cached objects 5 times before they expire, but if you set the *Fresh Factor* to 100, the web cache will check once.

Max TTL

The maximum amount of time (Time to Live) an object can stay in the web cache without the cache checking to see if it has expired on the server. The default is 7200 minutes (120 hours or 5 days) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Min TTL

The minimum amount of time an object can stay in the web cache before the web cache checks to see if it has expired on the server. The default is 5 minutes and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Default TTL

The default expiry time for objects that do not have an expiry time set by the web server. The default expiry time is 1440 minutes (24 hours) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Proxy FQDN

The fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP request length

The maximum length of an HTTP request that can be cached. Larger requests will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP message length

The maximum length of an HTTP message that can be cached. Larger messages will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Ignore

Select the following options to ignore some web caching features.

- If-modified-since

  By default, if the time specified by the if-modified-since (IMS) header in the client's conditional request is greater than the last modified time of the object in the cache, it is a strong indication that the copy in the cache is stale. If so, HTTP does a conditional GET to the Overlay Caching Scheme (OCS), based on the last modified time of the cached object.

  Enable ignoring if-modified-since to override this behavior.

- HTTP 1.1 conditionals

  HTTP 1.1 provides additional controls to the client over the behavior of caches toward stale objects. Depending on various cache-control headers, the FortiGate unit can be forced to consult the OCS before serving the object from the cache. For more information about the behavior of cache-control header values, see RFC 2616.

  Enable ignoring HTTP 1.1 Conditionals to override this behavior.

- Pragma-no-cache

  Typically, if a client sends an HTTP GET request with a pragma no-cache (PNC) or cache-control no-cache header, a cache must consult the OCS before serving the content. This means that the FortiGate unit always re-fetches the entire object from the OCS, even if the cached copy of the object is fresh.

  Because of this behavior, PNC requests can degrade performance and increase server-side bandwidth utilization. However, if you enable ignoring Pragma-no-cache, then the PNC header from the client request is ignored. The FortiGate unit treats the request as if the PNC header is not present.

- IE Reload

  Some versions of Internet Explorer issue Accept / header instead of Pragma no-cache header when you select *Refresh*. When an Accept header has only the / value, the FortiGate unit treats it as a PNC header if it is a type-N object.

  Enable ignoring IE reload to cause the FortiGate unit to ignore the PNC interpretation of the Accept / header.

Cache Expired Objects

Applies only to type-1 objects. When this option is selected, expired type-1 objects are cached (if all other conditions make the object cacheable).

Revalidated Pragma-no-cache

The pragma-no-cache (PNC) header in a client's request can affect how efficiently the FortiGate unit uses bandwidth. If you do not want to completely ignore PNC in client requests (which you can do by selecting to ignore Pragma-no-cache, above), you can nonetheless lower the impact on bandwidth usage by selecting *Revalidate Pragma-no-cache*.

When you select *Revalidate Pragma-no-cache*, a client's non-conditional PNC-GET request results in a conditional GET request sent to the OCS if the object is already in the cache. This gives the OCS a chance to return the 304 Not Modified response, which consumes less server-side bandwidth, because the OCS has not been forced to otherwise return full content.

By default, *Revalidate Pragma-no-cache* is disabled and is not affected by changes in the top-level profile.

Most download managers make byte-range requests with a PNC header. To serve such requests from the cache, you should also configure byte-range support when you configure the *Revalidate pragma-no-cache* option.

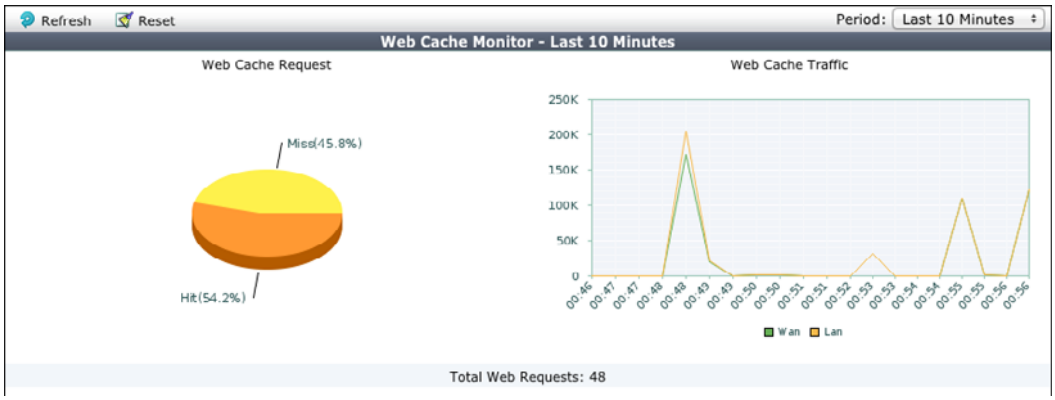
Monitoring Web caching performance

The web cache monitor shows the percentage of web cache requests that retrieved content from the cache (hits) and the percentage that did not receive content from the cache (misses). A higher the number of hits usually indicates that the web cache is being more effective at reducing WAN traffic.

The web cache monitor also shows a graph of web traffic on the WAN and LAN. A lower WAN line on the graph indicates the web cache is reducing traffic on the WAN. The web cache monitor also displays the total number of web requests processed by the web cache.

To view the web cache monitor, go to *WAN Opt. & Cache* > *Monitor* > *Cache Monitor*.

Figure 328: Web cache monitor



Advanced configuration example

This chapter contains an advanced WAN optimization configuration example that combines many of the concepts described in the previous chapters of this document. The configuration example described here includes active-passive rules, web caching, policy routes for out-of-path WAN optimization, and multiple VDOMs with inter-VDOM routing to apply virus scanning (and optionally other UTM features) to traffic before it is optimized.

Out-of-path WAN optimization with inter-VDOM routing

This example describes how to configure out-of-path WAN optimization to optimize web browsing and FTP file transfers between a client network and a server network.

Network topology and assumptions

The client network connects to the Internet through a FortiGate-300A unit, and the server network connects to the Internet through a cluster of two FortiGate-1000A units.

Adding in-path WAN optimization requires replacing these FortiGate units with models that support WAN optimization or adding new FortiGate units in the data path. In either of these in-path configurations, the optimizing FortiGate units would also be required to support all traffic on the data path plus provide WAN optimization.

The out-of-path topology shown in Figure offloads WAN optimization to out-of-path FortiGate units that only process sessions to be optimized. The topology includes a FortiGate-311B unit installed at the client network and a single FortiGate-620B unit installed at the server network.

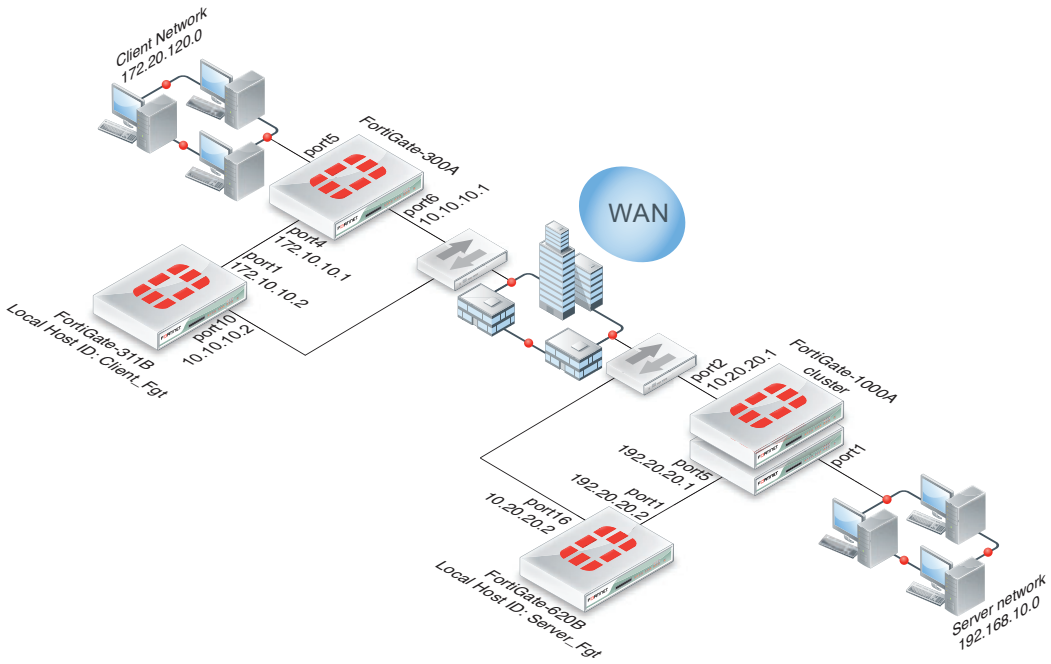
The FortiGate-620B unit is installed at the server network because other client networks also use it for WAN optimization. The configuration for those other client networks is not described in this example.

The client-side FortiGate-300A unit uses policy routing to offload WAN optimization of HTTP and FTP sessions by re-directing all HTTP and FTP sessions to the FortiGate-311B unit. The FortiGate-311B and 620B units work together to apply web caching, byte caching, and HTTP and FTP protocol optimization to HTTP and FTP sessions. The WAN optimization tunnel between the 311B and the 620B operates in Transparent mode. The FortiGate-311B unit also web caches all Internet HTTP traffic from the client network.

The client-side FortiGate-311B unit also applies virus scanning (and optionally other UTM features) to the HTTP and FTP traffic. To do this, the FortiGate-311B unit is configured for multiple VDOM operation. A new VDOM named Wanopt is added to the FortiGate-311B. HTTP and FTP sessions are received by the “root” VDOM. Security policies in the root VDOM accept HTTP and FTP sessions and apply virus scanning (and optionally other UTM features) to them. To preserve the source addresses of the HTTP and FTP sessions, NAT is not enabled for these policies.

The sessions are then routed through an inter-VDOM link to the Wanopt VDOM. The Wanopt VDOM includes security policies that accept the HTTP and FTP sessions and WAN optimization rules that apply WAN optimization and web caching to the sessions.

Figure 329: Out-of-path WAN optimization



The server-side FortiGate-620B unit includes a passive WAN optimization rule that accepts WAN optimization tunnel requests from the FortiGate-311B unit. Only one passive rule is required on the FortiGate-620B unit. The FortiGate-620B unit also forwards sessions to the server-side FortiGate-1000A cluster which forwards them to the server network.

WAN optimization is operating in Transparent mode, so the packets from the client network include their client network source IP addresses. To preserve these source IP addresses, the security policies on the FortiGate-1000A cluster that accept the sessions from the FortiGate- 620B unit should not apply NAT. If the security policies were to apply NAT, the client network addresses would be replaced with the port1 IP address of the FortiGate-1000A cluster and the client network source IP addresses would be lost.

The optimizing FortiGate units operate in NAT/Route mode and are directly connected to the Internet. This configuration requires two Internet connections and two Internet IP addresses for each network. (Reminder: All of the example IP addresses shown in Figure are private IP addresses because all Fortinet documentation examples use only private IP addresses.) If these extra Internet IP addresses are not available, you can install a router between the WAN and the FortiGate units or install the optimizing FortiGate units out of path on the private networks and configure routing on the private networks to route HTTP and FTP sessions to the optimizing FortiGate units.

Configuration steps

This example is divided into client-side and the server-side steps, as configured through the web-based manager and the CLI. Use either method, but for best results, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

This example includes the following sections:

- “Client-side configuration steps - web-based manager” on page 2759
- “Server-side configuration steps - web-based manager” on page 2766

- "Client-side configuration steps - CLI" on page 2769
- "Server-side configuration steps - CLI" on page 2776

Client-side configuration steps - web-based manager

This section describes the configuration steps required to redirect HTTP and FTP sessions from the client-side FortiGate-300A unit and to configure the client-side FortiGate-311B unit to optimize HTTP and FTP sessions to the server network and to apply web caching to all other HTTP sessions from the client network.

The section breaks down the client-side configuration into smaller procedures. For best results, follow the procedures in the order given:

1 Configure the FortiGate-300A unit to redirect all HTTP and FTP sessions to the FortiGate-311B unit.

2 Configure the FortiGate-311B unit for multiple VDOM operation and add an inter-VDOM link.

3 Configure routing for the FortiGate-311B root VDOM.

4 Add security policies to the FortiGate-311B root VDOM to accept HTTP and FTP sessions received at port1 and destined for Vlink0, and apply virus scanning (and optionally other UTM features).

5 Configure routing for the FortiGate-311B Wanopt VDOM.

6 Add security policies to the FortiGate-311B Wanopt VDOM to accept HTTP and FTP sessions received at the Vlink1 interface of the inter-VDOM link and destined for port10.

7 Configure peers for the FortiGate-311B Wanopt VDOM.

8 Add WAN optimization rules for HTTP and FTP to the FortiGate-311B Wanopt VDOM.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

To configure the FortiGate-300A unit to redirect all HTTP and FTP sessions to the FortiGate-311B unit

1 Go to *System* > *Network* > *Interface*, edit *port4*, and set the port4 IP address to 172.10.10.1/24.

2 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy that allows all port5 to port4 HTTP sessions:

Source Interface/Zone	port5
Source Address	all
Destination Interface/Zone	port4
Destination Address	all
Schedule	always
Service	HTTP
Action	ACCEPT
NAT	Select

Configure other policy settings that you may require.

3 Select *Create New* to add a security policy that allows all port5 to port4 FTP sessions:

Source Interface/Zone	port5
Source Address	all
Destination Interface/Zone	port4
Destination Address	all
Schedule	always
Service	FTP
Action	ACCEPT
NAT	Select

Configure other policy settings that you may require.

4 Select *OK*.

5 If required, use the *Move To* icon to change the order of the security policies.

Follow the normal rules for ordering security policies in the policy list. For example, move specific rules above general rules.

6 Go to *Router* > *Static* > *Policy Route* and select *Create New* to add a policy route to redirect HTTP traffic received at port5 to exit the FortiGate unit using port4. Set the gateway address of the route to 172.10.10.2 so that the HTTP sessions are directed to the FortiGate-311B port1 interface. For HTTP traffic, the protocol is 6 (TCP) and the destination port is 80:

Protocol	6
Incoming interface	port5
Source address / mask	0.0.0.0/0.0.0.0
Destination address / mask	0.0.0.0/0.0.0.0
Destination Ports	From 80 to 80
Type of Service	bit pattern: 00 (hex) bit mask: 00 (hex)
Outgoing interface	port4
Gateway Address	172.10.10.2

7 Select *OK*.

8 Select *Create New* to add a policy route to redirect FTP traffic received at port5 to exit the FortiGate unit using port4. Set the gateway address of the route to 172.10.10.2 so that the HTTP sessions are directed to the FortiGate-311B port1 interface. For FTP traffic, the protocol is 6 (TCP) and the destination port is 21:

Protocol	6
Incoming interface	port5
Source address / mask	0.0.0.0/0.0.0.0
Destination address / mask	0.0.0.0/0.0.0.0
Destination Ports	From 21 to 21
Type of Service	bit pattern: 00 (hex) bit mask: 00 (hex)

Outgoing interface	port4
Gateway Address	172.10.10.2

9 Select *OK*.

To configure the FortiGate-311B unit for multiple VDOM operation and add an inter-VDOM link

1 Go to *System* > *Status* > *Dashboard*.

2 In the *System Information* widget, select *Enable* beside *Virtual Domain* to enable multiple VDOM operation and log back in to the web-based manager.

3 Go to *System* > *VDOM* and select *Create New* to add a new virtual domain named *Wanopt*.

4 Select *OK* twice to add the *Wanopt* VDOM with default resource limits.

5 Go to *System* > *Network*, edit the *port10* interface, and configure the following settings to add the port10 interface to the Wanopt VDOM:

Virtual Domain	Wanopt
Addressing Mode	Manual
IP/Netmask	10.10.10.2/24

Configure other settings that you may require.

6 Select *OK*.

7 Select *Create New* > *VDOM Link* and add an inter-VDOM link with the following settings:

Name		Vlink
Interface #0		
	Virtual Domain	root
	IP/Netmask	172.1.1.1/24
Interface #1		
	Virtual Domain	Wanopt
	IP/Netmask	172.1.1.2/24

8 Select *OK*.

To configure routing for the FortiGate-311B root VDOM

1 Log in to the root VDOM.

2 Go to *Router* > *Static* and select *Create New* to add a default route. The destination of the default route is the inter-VDOM link interface in the root VDOM. The gateway of the default route is the IP address of the inter-VDOM link interface in the Wanopt VDOM. The result is the default route sends all traffic out the inter-VDOM link and into the Wanopt VDOM:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	Vlink0
Gateway	172.1.1.2
Distance	10

3 Select *OK*.

4 Select *Create New* to add a route to send return traffic from the server network destined for the client network out the port1 interface to the port4 interface of the FortiGate-300A which has IP address 172.10.10.1:

Destination IP/Mask	172.20.120.0/24
Device	port1
Gateway	172.10.10.1
Distance	10

5 Select *OK*.

To add security policies to the FortiGate-311B root VDOM to accept HTTP and FTP sessions received at port1 destined for Vlink0 and apply virus scanning (and optionally other UTM features)

1 Log in to the root VDOM.

2 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy that accepts HTTP sessions received at port1 destined for Vlink0 and applies virus scanning and other UTM features:

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	Vlink0
Destination Address	all
Schedule	always
Service	HTTP
Action	ACCEPT
NAT	Do not select. To preserve the source addresses of the HTTP sessions, NAT should not be enabled for this policy.
UTM	Select UTM, select a protocol options profile and select an antivirus profile. Optionally select other UTM profiles.

Configure other policy settings that you may require. You can also use more specific security addresses or add one security policy that accepts both FTP and HTTP traffic.

3 Select *OK*.

4 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy that accepts FTP sessions received at port1 and destined for Vlink0 and applies virus scanning and other UTM features to them:

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	Vlink0
Destination Address	all
Schedule	always
Service	FTP
Action	ACCEPT
NAT	Do not select. To preserve the source addresses of the FTP sessions, NAT should not be enabled for this policy.
UTM	Select UTM, select a protocol options profile and select an antivirus profile. Optionally select other UTM profiles.

Configure other policy settings that you may require. You can also use more specific security addresses or add one security policy that accepts both FTP and HTTP traffic.

5 Select *OK*.

To configure routing for the FortiGate-311B Wanopt VDOM

1 Log in to the Wanopt VDOM.

2 Go to *Router* > *Static* and select *Create New* to add a default route. The destination of the default route is the port10 interface. The gateway of the default route is the next hop router that the port10 interface connects with:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port10
Gateway	(next hop router IP address)
Distance	10

3 Select *OK*.

4 Select *Create New* to add a route to send return traffic from the server network destined for the client network out the Vlink1 interface to the Vlink0 interface in the root VDOM, which has the IP address 172.1.1.2:

Destination IP/Mask	172.20.120.0/24
Device	Vlink1
Gateway	172.1.1.2
Distance	10

5 Select *OK*.

To add security policies to the FortiGate-311B Wanopt VDOM to accept HTTP and FTP sessions received at the Vlink1 interface of the inter-VDOM link and destined for port10

1 Log in to the Wanopt VDOM.

2 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy that accepts HTTP sessions received at Vlink1 and destined for port10:

Source Interface/Zone	Vlink1
Source Address	all
Destination Interface/Zone	port10
Destination Address	all
Schedule	always
Service	HTTP
Action	ACCEPT
NAT	Select NAT is ignored for all HTTP sessions for the server network because these sessions are intercepted by a full optimization WAN optimization rule. However, HTTP sessions for the Internet are intercepted by the Web Cache Only rule, so source NAT is required for replies.
UTM	Do not select. Do not select UTM because you cannot apply UTM and WAN optimization to the same session in the same VDOM. UTM was applied to the session in the root VDOM.

Configure other settings that you may require.

3 Select *OK*.

4 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy that accepts FTP sessions received at Vlink1 and destined for port10:

Source Interface/Zone	Vlink1
Source Address	all
Destination Interface/Zone	port10
Destination Address	all
Schedule	always
Service	FTP
Action	ACCEPT
NAT	Select NAT is ignored for all FTP sessions for the server network because these sessions are intercepted by a full optimization WAN optimization rule. However, FTP sessions for the Internet are allowed to reach their destination, so source NAT is required for replies.
UTM	Do not select. Do not select UTM because you cannot apply UTM and WAN optimization to the same session in the same VDOM. UTM was applied to the session in the root VDOM.

Configure other settings that you may require.

5 Select *OK*.

To configure peers for the FortiGate-311B Wanopt VDOM

1 Log in to the Wanopt VDOM.

2 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the client-side FortiGate-311B unit:

Local Host ID	Client_Fgt

3 Select *Apply* to save your setting.

4 Select *Create New* and add a Peer Host ID and the *IP Address* for the server-side FortiGate-620B unit:

Peer Host ID	Server_Fgt
IP Address	10.20.20.2

5 Select *OK*.

To add WAN optimization rules for HTTP and FTP to the FortiGate-311B Wanopt VDOM

1 Log in to the Wanopt VDOM.

2 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule*.

3 Select *Create New* to add an active rule to optimize HTTP traffic from IP addresses on the Client network (172.20.120.0) with a destination address on the server network (192.168.10.0):

Mode	Full Optimization
Source	172.20.120.*
Destination	192.168.10.*
Port	80
Auto-Detect	Active
Protocol	HTTP
Transparent Mode	Select
Enable Byte Caching	Select
Enable SSL	Do not select.
Enable Secure Tunnel	Do not select. For improved privacy you can select this option and add an authentication group to both optimizing FortiGate units.
Authentication Group	Do not select.

4 Select *OK*.

5 Select *Create New* to add an active rule to optimize FTP traffic from IP addresses on the Client network (172.20.120.0) with a destination address on the server network (192.168.10.0):

Mode	Full Optimization
Source	172.20.120.*
Destination	192.168.10.*
Port	21

Auto-Detect	Active
Protocol	FTP
Transparent Mode	Select
Enable Byte Caching	Select
Enable SSL	Do not select.
Enable Secure Tunnel	Do not select. For improved privacy you can select this option and add an authentication group to both optimizing FortiGate units.
Authentication Group	Do not select.

6 Select *OK*.

7 Select *Create New* to add a rule to web cache HTTP traffic from IP addresses on the Client network (172.20.120.0) with any destination address:

Mode	Web Cache Only
Source	172.20.120.*
Destination	0.0.0.0
Port	80
Transparent Mode	Select
Enable SSL	Do not select.

8 Select *OK*.

9 If required, use the *Move To* icon to move the Web Cache Only rule below the full optimization HTTP and FTP rules in the list. The Web Cache Only rule should be below the full optimization rules because it will match all HTTP traffic and you need HTTP sessions with destination address 192.168.10.0 to match the full optimization HTTP rule.

Server-side configuration steps - web-based manager

This section describes the configuration steps required for the server-side FortiGate-620B unit to perform WAN optimization with the client-side FortiGate-311B unit and to send HTTP and FTP sessions to the server-side FortiGate-1000A cluster. This section also describes how to configure the FortiGate-1000A cluster to forward HTTP and FTP sessions from the client network to the server network.

The section breaks down the client-side configuration into smaller procedures. For best results, follow the procedures in the order given:

1 Configure routing for the FortiGate-620B unit.

2 Configure peers for the server-side FortiGate-620B unit.

3 Add a passive WAN optimization rule to the server-side FortiGate-620B unit.

4 Configure the FortiGate-1000A cluster to accept HTTP and FTP connections at port5 and forward them out port1 to the server network.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

To configure routing for the FortiGate-620B unit

1 Go to *Router* > *Static* and select *Create New* to add a default route. The destination of the default route is the port16 interface. The gateway of the default route is the next hop router that the port16 interface connects with:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port16
Gateway	(next hop router IP address)
Distance	10

2 Select *OK*.

3 Select *Create New* to add a route to send traffic for the server network out port1 to the port5 interface of the FortiGate-1000A cluster, which has the IP address 192.20.20.1:

Destination IP/Mask	192.168.10.0/24
Device	port1
Gateway	192.20.20.1
Distance	10

4 Select *OK*.

To configure peers for the server-side FortiGate-620B unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate-620B unit:

Local Host ID	Server_Fgt

2 Select *Apply* to save your setting.

3 Select *Create New* and add a Peer Host ID and the *IP Address* for the client-side FortiGate-311B unit:

Peer Host ID	Client_Fgt
IP Address	10.10.10.2

4 Select *OK*.

To add a passive WAN optimization rule to the server-side FortiGate-620B unit

You can add one passive WAN optimization rule to the server-side FortiGate-620B unit for both active rules on the FortiGate-311B unit. This rule can also allow the FortiGate-620B to perform WAN optimization with other client-side devices as long as the required Peer Host IDs are added to the FortiGate-620B configuration and to the client-side configurations.

1 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New* to add a passive rule that accepts any WAN optimization tunnel request:

Mode	Full Optimization
Source	0.0.0.0
Destination	192.168.10.*
Port	1-65535 You can also use a narrower port range such as 21-80 or add two rules, one with port set to 80 and one with port set to 21.

Auto-Detect	Passive
Enable Web Cache	Select

2 Select *OK*.

3 If required, use the *Move To* icon to move the rule to a different position in the list so that the tunnel request from the client-side FortiGate unit matches with this rule.

For more information, see "Moving a rule to a different position in the rule list" on page 2709.

To configure the FortiGate-1000A cluster to accept HTTP and FTP connections at port5 and forward them out port1 to the server network

1 Go to *Firewall Objects* > *Address* and select *Create New* to add an address for the server network:

Address Name	Server_Net
Type	Subnet / IP Range
Subnet / IP Range	192.168.10.*
Interface	Any

2 Select *OK*.

3 Go to *Firewall Objects* > *Address* and select *Create New* to add an address for the client network:

Address Name	Client_Net
Type	Subnet / IP Range
Subnet / IP Range	172.20.120.*
Interface	Any

4 Select *OK*.

5 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy that accepts HTTP sessions at port5 destined for port1 and the server network:

Source Interface/Zone	port5
Source Address	Client_Net
Destination Interface/Zone	port1
Destination Address	Server_Net
Schedule	always
Service	HTTP

Action	ACCEPT
NAT	Do not select. WAN optimization is operating in Transparent mode so the packets from the client network include their client network source IP addresses. To preserve these source IP addresses the security policies on the FortiGate-1000A cluster that accept the sessions from the FortiGate- 620B unit should not apply NAT. If the policies were to apply NAT, the client network addresses would be replaced with the port1 IP address of the FortiGate-1000A cluster and the client network source IP addresses would be lost.

6 Select *OK*.

7 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy that accepts FTP sessions at port5 destined for port1 and the server network:

Source Interface/Zone	port5
Source Address	Client_Net
Destination Interface/Zone	port1
Destination Address	Server_Net
Schedule	always
Service	FTP
Action	ACCEPT
NAT	Do not select As described above, selecting NAT would cause the loss of client network source IP addresses.

8 Select *OK*.

Client-side configuration steps - CLI

This section describes the configuration steps required to redirect HTTP and FTP sessions from the client-side FortiGate-300A unit and to configure the client-side FortiGate-311B unit to optimize HTTP and FTP sessions to the server network and to apply web caching to all other HTTP sessions from the client network.

The section breaks down the client-side configuration into smaller procedures. For best results, follow the procedures in the order given:

1 Configure the FortiGate-300A unit to redirect all HTTP and FTP sessions to the FortiGate-311B unit.

2 Configure the FortiGate-311B unit for multiple VDOM operation and add an inter-VDOM link.

3 Configure routing for the FortiGate-311B root VDOM.

4 Add security policies to the FortiGate-311B root VDOM to accept HTTP and FTP sessions received at port1 and destined for Vink0, and apply virus scanning (and optionally other UTM features).

5 Configure routing for the FortiGate-311B Wanopt VDOM.

6 Add security policies to the FortiGate-311B Wanopt VDOM to accept HTTP and FTP sessions received at the Vlink1 interface of the inter-VDOM link and destined for port10.

7 Configure peers for the FortiGate-311B Wanopt VDOM.

8 .Add WAN optimization rules for HTTP and FTP to the FortiGate-311B Wanopt VDOM.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

To configure the FortiGate-300A unit to redirect all HTTP and FTP sessions to the FortiGate-311B unit

1 Set the FortiGate-300A port4 IP address to 172.10.10.1:

```
config system interface
  edit port4
    set ip 172.10.10.1/24
  end
end
```

2 Add a security policy that allows all port5 to port4 HTTP sessions:

```
config firewall policy
  edit 1
    set srcintf port5
    set dstintf port4
    set srcaddr all
    set dstaddr all
    set action accept
    set service HTTP
    set schedule always
    set nat enable
  end
end
```

Configure other policy settings that you may require. For example, you could add virus scanning (and optionally other UTM features).

3 Add a security policy that allows all port5 to port4 FTP sessions:

```
config firewall policy
  edit 2
    set srcintf port5
    set dstintf port4
    set srcaddr all
    set dstaddr all
    set action accept
    set service FTP
    set schedule always
    set nat enable
  end
end
```

Configure other policy settings that you may require.

4 If required, use the `move` command to change the order of the policies in the policy list.

Follow the normal rules for ordering security policies in the policy list. For example, move specific rules above general rules.

5 Add a policy route to redirect HTTP traffic received at port5 to exit the FortiGate unit using port4. Set the gateway address of the route to 172.10.10.2 so that the HTTP sessions are directed to the FortiGate-311B port1 interface. For HTTP traffic, the protocol is 6 (TCP) and the destination port is 80:

```
config router policy
  edit 1
    set protocol 6
    set input-device port5
    set output-device port4
    set src 0.0.0.0/0.0.0.0
    set dst 0.0.0.0/0.0.0.0
    set start-port 80
    set end port 80
    set gateway 172.10.10.2
  end
end
```

Accept default settings for `tos` (`0x00`) and `tos-mask` (`0x00`).

6 Add a policy route to redirect FTP traffic received at port5 to exit the FortiGate unit using port4. Set the gateway address of the route to 172.10.10.2 so that the FTP sessions are directed to the FortiGate-311B port1 interface. For FTP traffic, the protocol is 6 (TCP) and the destination port is 21:

```
config router policy
  edit 1
    set protocol 6
    set input-device port5
    set output-device port4
    set src 0.0.0.0/0.0.0.0
    set dst 0.0.0.0/0.0.0.0
    set start-port 21
    set end port 21
    set gateway 172.10.10.2
  end
end
```

Accept default settings for `tos` (`0x00`) and `tos-mask` (`0x00`).

To configure the FortiGate-311B unit for multiple VDOM operation and add an inter-VDOM link

1 Enable multiple VDOM operation and log back in to the web-based manager:

```
config system global
  set vdom-admin enable
end
```

2 Log back in to the CLI.

3 Add a new virtual domain named Wanopt.

```
config vdom
  edit Wanopt
end
```

4 Add the port10 interface to the Wanopt VDOM:

```
config global
  config system interface
    edit port10
      set vdom Wanopt
```

```
      set IP 10.10.10.2/24
    end
end
```

5 Add an inter-VDOM named Vlink and configure the Vlink0 and Vlink1 interfaces:

```
config global
  config system vdom-link
    edit Vlink
  end
  config system interface
      edit Vlink0
        set vdom root
        set ip 172.1.1.1/24
      next
      edit Vlink1
        set vdom Wanopt
        set ip 172.1.1.2/24
      end
end
```

To configure routing for the FortiGate-311B root VDOM

1 Log in to the root VDOM from the CLI.

2 Add a default route. The destination of the default route is the inter-VDOM link interface in the root VDOM. The gateway of the default route is the IP address of the inter-VDOM link interface in the Wanopt VDOM. The result is the default route sends all traffic out the inter-VDOM link and into the Wanopt VDOM:

```
config router static
  edit 1
    set dst 0.0.0.0/0.0.0.0
    set device Vlink0
    set gateway 172.1.1.2
    set distance 10
end
```

3 Add a route to send return traffic from the server network destined for the client network out the port1 interface to the port4 interface of the FortiGate-300A which has IP address 172.10.10.1:

```
config router static
  edit 2
    set dst 172.20.120.0/24
    set device port1
    set gateway 172.10.10.1
    set distance 10
end
```

To add security policies to the FortiGate-311B root VDOM to accept HTTP and FTP sessions received at port1 and destined for Vlink0 and apply virus scanning and optionally other UTM features)

1 Log in to the root VDOM from the CLI.

2 Add a security policy that accepts HTTP sessions received at port1 and applies virus scanning to them:

```
config firewall policy
  edit 20
```

```
    set srcintf port1
    set dstintf Vlink0
    set srcaddr all
    set dstaddr all
    set action accept
    set service HTTP
    set schedule always
    set utm-status enable
    set profile-protocol-options default
    set av-profile scan
end
```

To preserve the source addresses of the HTTP sessions, NAT should not be enabled for this policy.

Configure other policy settings that you may require. You can also use more specific firewall addresses or add one security policy that accepts both FTP and HTTP traffic.

3 Add a security policy that accepts FTP sessions received at port1 and applies virus scanning to them:

```
config firewall policy
  edit 20
    set srcintf port1
    set dstintf Vlink0
    set srcaddr all
    set dstaddr all
    set action accept
    set service FTP
    set schedule always
    set utm-status enable
    set profile-protocol-options default
    set av-profile scan
end
```

To preserve the source addresses of the HTTP sessions, NAT should not be enabled for this policy.

Configure other policy settings that you may require. You can also use more specific firewall addresses or add one security policy that accepts both FTP and HTTP traffic.

To configure routing for the FortiGate-311B Wanopt VDOM

1 Log in to the Wanopt VDOM from the CLI.

2 Add a default route. The destination of the default route is the port10 interface. The gateway of the default route is the next hop router that the port10 interface connects with:

```
config router static
  edit 1
    set dst 0.0.0.0/0.0.0.0
    set device port10
    set gateway (next hop router IP address)
    set distance 10
end
```

3 Add a route to send return traffic from the server network destined for the client network out the Vlink1 interface to the Vlink0 interface in the root VDOM, which has the IP address 172.1.1.2:

```
config router static
  edit 2
    set dst 172.20.120.0/24
    set device Vlink1
    set gateway 172.1.1.2
    set distance 10
end
```

To add security policies to the FortiGate-311B Wanopt VDOM to accept HTTP and FTP sessions received at the Vlink1 interface of the inter-VDOM link destined for port10

1 Log in to the Wanopt VDOM from the CLI.

2 Add a security policy that accepts HTTP sessions received at Vlink1 and destined for port10:

```
config firewall policy
  edit 20
    set srcintf Vlink1
    set dstintf port10
    set srcaddr all
    set dstaddr all
    set action accept
    set service HTTP
    set schedule always
    set nat enable
end
```

NAT is ignored for all HTTP sessions for the server network because these sessions are intercepted by a full optimization WAN optimization rule. However, HTTP sessions for the Internet are intercepted by the Web Cache Only rule, so source NAT is required for replies.

Do not enable UTM because you cannot apply UTM features and WAN optimization to the same session in the same VDOM. Virus scanning was applied to the session in the root VDOM.

Configure other settings that you may require.

3 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy that accepts FTP sessions received at Vlink1 and destined for port10:

```
config firewall policy
  edit 20
    set srcintf Vlink1
    set dstintf port10
    set srcaddr all
    set dstaddr all
    set action accept
    set service FTP
    set schedule always
    set nat enable
```

```
end
```

NAT is ignored for all HTTP sessions for the server network because these sessions are intercepted by a full optimization WAN optimization rule. However, HTTP sessions for the Internet are intercepted by the Web Cache Only rule, so source NAT is required for replies.

Do not enable UTM because you cannot apply UTM features and WAN optimization to the same session in the same VDOM. Virus scanning was applied to the session in the root VDOM.

Configure other settings that you may require.

To configure peers for the FortiGate-311B Wanopt VDOM

1 Log in to the Wanopt VDOM from the CLI.

2 Add the Local Host ID for the client-side FortiGate-311B unit:

```
config wanopt settings
  set host-id Client_Fgt
end
```

3 Add a Peer Host ID and the IP Address for the server-side FortiGate-620B unit.

```
config wanopt peer
  edit Server_Fgt
  set ip 10.20.20.2
end
```

To add WAN optimization rules for HTTP and FTP to the FortiGate-311B Wanopt VDOM

1 Log in to the Wanopt VDOM from the CLI.

2 Add an active rule to optimize HTTP traffic from IP addresses on the Client network (172.20.120.0) with a destination address on the server network (192.168.10.0):

```
config wanopt rule
  edit 4
    set auto-detect active
    set src-ip 172.20.120.0-172.20.120.255
    set dst-ip 192.168.10.0-192.168.10.255
    set port 80
    set proto http
  end
```

Accept default settings for `transparent` (`enable`), `status` (`enable`), `mode` (`full`), `byte-caching` (`enable`), `ssl` (`disable`), `secure-tunnel` (`disable`), `auth-group` (`null`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

For improved privacy you can enable `secure-tunnel` and add an authentication group to both optimizing FortiGate units.

3 Add an active rule to optimize FTP traffic from IP addresses on the Client network (172.20.120.0) with a destination address on the server network (192.168.10.0):

```
config wanopt rule
  edit 5
```

```
    set auto-detect active
    set src-ip 172.20.120.0-172.20.120.255
    set dst-ip 192.168.10.0-192.168.10.255
    set port 21
    set proto ftp
  end
```

Accept default settings for `transparent` (`enable`), `status` (`enable`), `mode` (`full`), `byte-caching` (`enable`), `ssl` (`disable`), `secure-tunnel` (`disable`), `auth-group` (`null`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

For improved privacy you can enable `secure-tunnel` and add an authentication group to both optimizing FortiGate units.

4 Add a rule to web cache HTTP traffic from IP addresses on the Client network (172.20.120.0) with any destination address:

```
config wanopt rule
  edit 6
    set mode webcache-only
    set src-ip 172.20.120.0-172.20.120.255
    set dst-ip 0.0.0.0
    set port 80
    set proto http
  end
```

Accept default settings for `transparent` (`enable`), `status` (`enable`), `ssl` (`disable`), `unknown-http-version` (`tunnel`), and `tunnel-non-http` (`disable`).

5 If required, use the `move` command to move the Web Cache Only rule below the full optimization HTTP and FTP rules in the list. The Web Cache Only rule should be below the full optimization rules because it will match all HTTP traffic and you need HTTP sessions with destination address 192.168.10.0 to match the full optimization HTTP rule

For more information, see “Moving a rule to a different position in the rule list” on page 2709.

Server-side configuration steps - CLI

This section describes the configuration steps required for the server-side FortiGate-620B unit to perform WAN optimization with the client-side FortiGate-311B unit and to send HTTP and FTP sessions to the server-side FortiGate-1000A cluster. This section also describes how to configure the FortiGate-1000A cluster to forward HTTP and FTP sessions from the client network to the server network.

The section breaks down the client-side configuration into smaller procedures. For best results, follow the procedures in the order given:

1 Configure routing for the FortiGate-620B unit.

2 Configure peers for the server-side FortiGate-620B unit.

3 Add a passive WAN optimization rule to the server-side FortiGate-620B unit.

4 Configure the FortiGate-1000A cluster to accept HTTP and FTP connections at port5 and forward them out port1 to the server network.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

To configure routing for the FortiGate-620B unit

1 Add a default route. The destination of the default route is the port16 interface. The gateway of the default route is the next hop router that the port16 interface connects with:

```
config router static
  edit 1
    set dst 0.0.0.0/0.0.0.0
    set device port16
    set gateway (next hop router IP address)
    set distance 10
end
```

2 Add a route to send traffic for the server network out port1 to the port5 interface of the FortiGate-1000A cluster, which has the IP address 192.20.20.1:

```
config router static
  edit 2
    set dst 192.168.10.0/24
    set device port1
    set gateway 192.20.20.1
    set distance 10
end
```

To configure peers for the server-side FortiGate-620B unit

1 Add the Local Host ID for the server-side FortiGate-620B unit:

```
config wanopt settings
  set host-id Server_Fgt
end
```

2 Add a Peer Host ID and the IP Address for the client-side FortiGate-311B unit:

```
config wanopt peer
  edit Client_Fgt
  set ip 10.10.10.2
end
```

To add a passive WAN optimization rule to the server-side FortiGate-620B unit

You can add one passive WAN optimization rule to the server-side FortiGate-620B unit for both active rules on the FortiGate-311B unit. This rule can also allow the FortiGate-620B to perform WAN optimization with other client-side devices as long as the required Peer Host IDs are added to the FortiGate-620B configuration and to the client-side configurations.

1 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New* to add a passive rule that accepts any WAN optimization tunnel request:

```
config wanopt rule
  edit 5
    set auto-detect passive
    set src-ip 0.0.0.0
    set dst-ip 192.168.10.0-192.168.10.255
    set port 1-65535
    set webcache enable
  end
```

Accept default settings for `status` (`enable`) and `mode` (`full`).

You can also use a narrower `port` range such as 21-80 or add two rules, one with port set to 80 and one with port set to 21.

2 If required, use the `move` command to move the rule to a different position in the list so that the tunnel request from the client-side FortiGate unit matches with this rule.

For more information, see "Moving a rule to a different position in the rule list" on page 2709.

To configure the FortiGate-1000A cluster to accept HTTP and FTP connections at port5 and forward them out port1 to the server network

1 Add a firewall address for the server network:

```
config firewall address
  edit Server_Net
    set type iprange
    set start-ip 192.168.10.0
    set end-ip 192.168.10.255
end
```

2 Add a firewall address for the client network:

```
config firewall address
  edit Client_Net
    set type iprange
    set start-ip 172.20.120.0
    set end-ip 172.20.120.255
end
```

3 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add an security policy that accepts HTTP sessions at port5 destined for port1 and the server network:

```
config firewall policy
  edit 10
    set srcintf port5
    set dstintf port1
    set srcaddr Client_Net
    set dstaddr Server_Net
    set action accept
    set service HTTP
    set schedule always
  end
end
```

WAN optimization is operating in Transparent mode so the packets from the client network include their client network source IP addresses. To preserve these source IP addresses, the security policies on the FortiGate-1000A cluster that accept the sessions from the FortiGate- 620B unit should not apply NAT. If the policies were to apply NAT, the client network addresses would be replaced with the port1 IP address of the FortiGate-1000A cluster and the client network source IP addresses would be lost.

4 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add an security policy that accepts FTP sessions at port5 destined for port1 and the server network:

```
config firewall policy
  edit 11
    set srcintf port5
    set dstintf port1
    set srcaddr Client_Net
    set dstaddr Server_Net
    set action accept
    set service FTP
    set schedule always
  end
end
```

As described above, selecting NAT would cause the loss of the client network source IP addresses.

SSL offloading for WAN optimization and web caching

WAN optimization SSL offloading uses a FortiGate unit's FortiASIC SSL encryption/decryption engine to accelerate SSL performance. Most commonly SSL offloading is used accelerate the performance of a web server that secures communication using the HTTPS protocol. SSL offloading can be applied to WAN optimization configurations and reverse proxy web caching configurations.

In a WAN optimization configuration where clients on a client network use HTTPS to communicate with a web server over a WAN optimization tunnel, you can use SSL offloading to decrypt HTTPS traffic before sending it through the WAN optimization tunnel. Decrypting the HTTPS traffic before it enters the tunnel allows WAN optimization to apply optimization techniques to the in the clear HTTP traffic. These techniques that would not be as effective with encrypted HTTPS traffic. When the optimized traffic leaves the WAN optimization tunnel it can either be forwarded as clear text HTTP traffic or it can be re-encrypted as HTTPS traffic before being sent to its destination. To forward clear text traffic, SSL offloading must be configured in half mode. To forward encrypted traffic, SSL offloading must be configured in full mode.

In a half mode reverse proxy web caching SSL offloading configuration, the FortiGate unit intercepts HTTPS traffic from clients and decrypts it before sending it as HTTP clear text traffic to a web server. The HTTP clear text response from the web server is encrypted by the FortiGate unit and returned to the clients as encrypted HTTPS traffic. SSL offloading improves performance by offloading SSL processing from the web server.

In a full mode reverse proxy web cache SSL offloading configuration, the FortiGate unit decrypts HTTPS traffic, applies web caching, and then re-encrypts the HTTPS traffic before forwarding it to the web server.

You can also combine SSL offloading with other WAN optimization techniques such as HTTP protocol optimization, byte caching, and web caching to further enhance web server performance.

You enable SSL offloading by selecting *Enable SSL* in a WAN optimization rule. You must also add SSL servers to support SSL offloading by using the CLI command `config wanopt ssl-server`.

You must add one SSL server for each web server for which you are configuring SSL offloading. The SSL server configuration must include the destination IP address and port number of the HTTPS packets to be decrypted. The SSL server configuration also includes the SSL mode (full or half), the name of the HTTP server CA certificate used to decrypt and encrypt the traffic, the size of the Diffie-Hellman prime used in DHE-RSA negotiation, the relative strength of the encryption algorithms accepted during negotiation, the SSL/TLS versions to use, and the behavior regarding sending empty fragments to avoid a CBC IV attack.

You load HTTP server CA certificate into the FortiGate unit as a local certificate and then add it to the SSL server configuration using the `ssl-cert` keyword. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

SSL offload does not perform address or port translation. If your configuration requires address translation this must be configured at the security policy level using firewall virtual IPs.

You can configure one WAN optimization rule to offload SSL encryption/decryption for multiple HTTP servers. To do this, you configure the WAN optimization rule source and destination addresses, so that the rule accepts packets destined for all of the HTTP servers for which you want offloading. Then you add one SSL server for each of the HTTP servers.

This chapter describes:

- Example: SSL offloading for a WAN optimization tunnel
- Example: SSL offloading and reverse proxy web caching for an Internet web server using static one-to-one virtual IPs
- Example: SSL offloading and reverse proxy web caching for an Internet web server using a port forwarding virtual IP for HTTPS traffic

About SSL server full and half mode

An SSL server configuration can operate in full mode or half mode. In full mode the SSL server performs both decryption and encryption of the HTTPS traffic. The full mode sequence is:

```
HTTPS -> HTTP -> HTTPS
HTTPS <- HTTP <- HTTPS
```

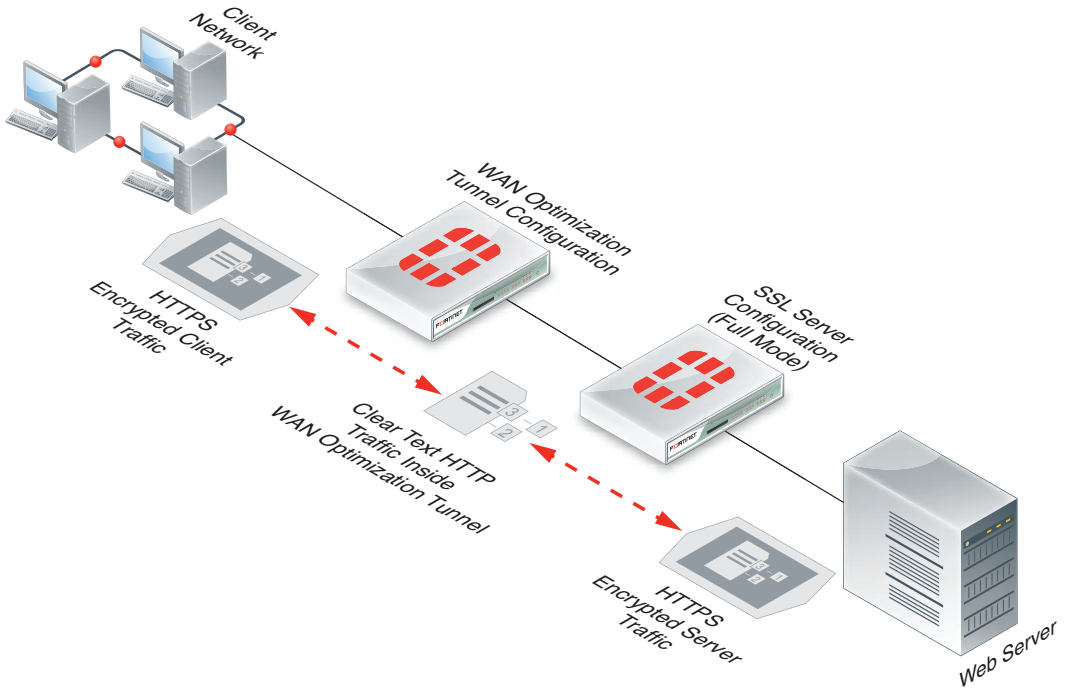
In half mode, the SSL server only performs one encryption or decryption action. If HTTP packets are received, the half mode SSL server encrypts them and converts them to HTTPS packets. If HTTPS packets are received, the SSL server decrypts them and converts them to HTTP packets. The half mode sequence is:

```
HTTPS -> HTTP
HTTPS <- HTTP
```

WAN optimization full mode SSL server configuration

As shown in Figure 330, in a WAN optimization full mode SSL server configuration, encrypted HTTPS packets received from a client network are decrypted into clear text HTTP packets that are sent over the WAN optimization tunnel to a server network. When the packets exit the tunnel they are re-encrypted and sent to the web server as HTTPS packets. HTTPS responses from the server are unencrypted before being sent across the tunnel and then re-encrypted before being returned to the clients.

Figure 330: WAN optimization full mode SSL server configuration

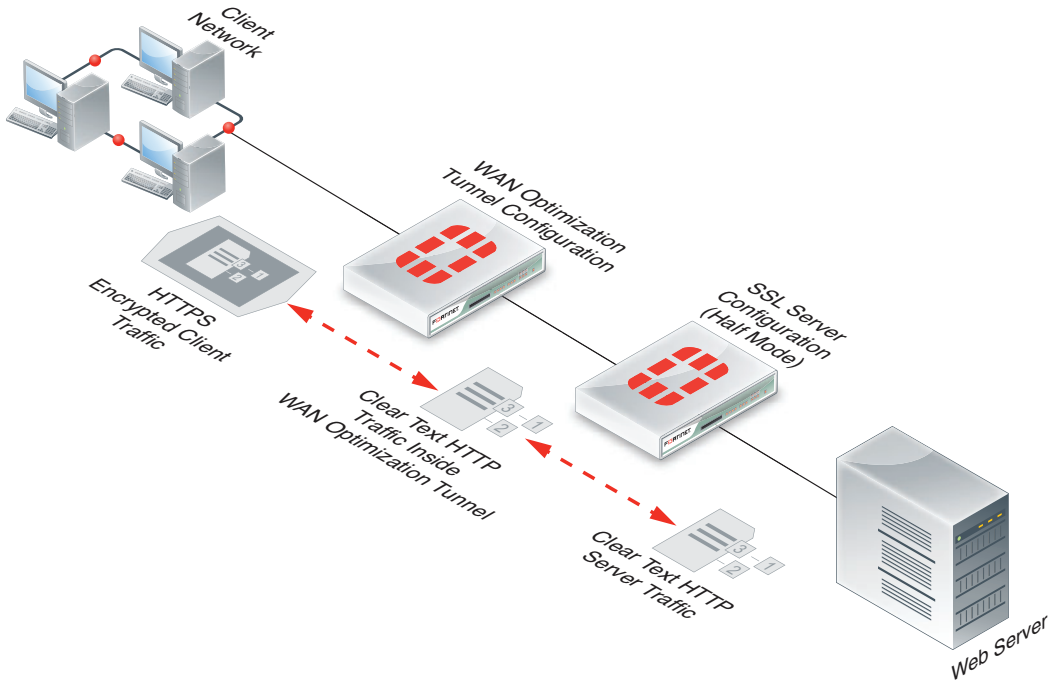


This full mode configuration is used when the traffic on both the client and server networks must be encrypted. This configuration enhances performance by allowing WAN optimization to apply HTTP optimization, byte caching, and web caching to the HTTP traffic in the WAN optimization tunnel.

WAN optimization half mode SSL server configuration

As shown in Figure 331, in a WAN optimization half mode SSL server configuration, encrypted HTTPS packets received from a client network are decrypted into clear text HTTP packets that are sent over the WAN optimization tunnel and forwarded to the server. HTTP responses from the server are sent across the tunnel and then re-encrypted before being returned to the clients.

Figure 331: WAN optimization half mode SSL server configuration

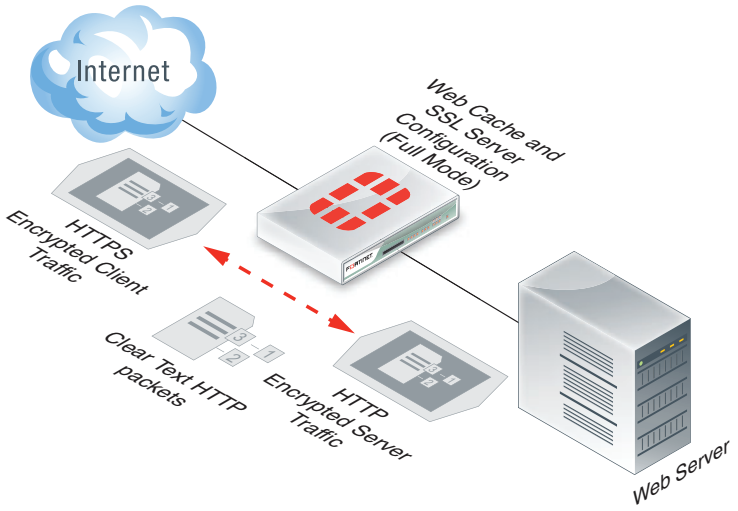


This half mode configuration is used when the traffic on the server network can be in clear text. This configuration enhances performance by accelerating SSL decryption and encryption and by allowing WAN optimization to apply HTTP optimization, byte caching, and web caching to the HTTP traffic in the WAN optimization tunnel.

Reverse proxy web cache full mode SSL server configuration

As shown in Figure 332, in a reverse proxy web cache full mode SSL server configuration, encrypted HTTPS packets received from a client network are decrypted into clear text HTTP packets that are cached and then re-encrypted and sent to the web server as HTTPS packets. HTTPS responses from the server are unencrypted and cached and then re-encrypted before being returned to the clients.

Figure 332: Reverse proxy web cache full mode SSL server configuration

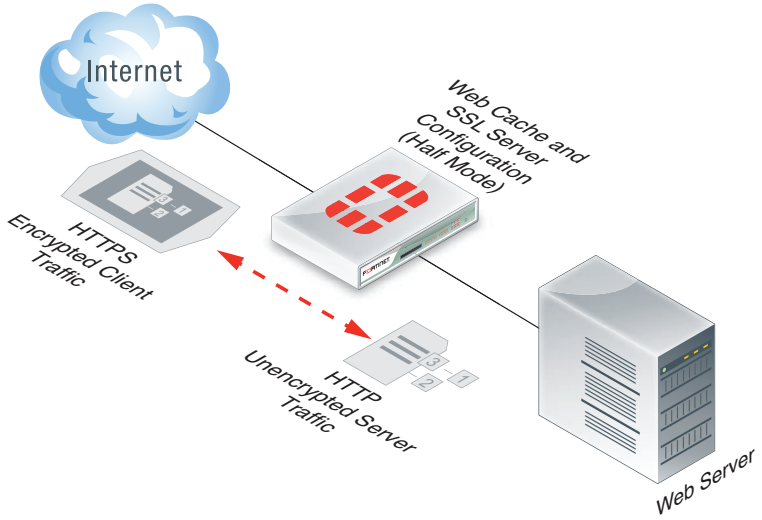


This full mode configuration is used when the traffic on both the client and server networks must be encrypted. This configuration enhances performance by caching HTTP content.

Reverse proxy web cache half mode SSL server configuration

As shown in Figure 333, in a reverse proxy web cache half mode SSL server configuration, encrypted HTTPS packets received from a client network are decrypted into clear text HTTP packets that are cached and forwarded to the server. HTTP responses from the server are cached and then re-encrypted before being returned to the clients.

Figure 333: Reverse proxy web cache half mode SSL server configuration



This half mode configuration is used when the traffic on the server network can be in clear text. This configuration enhances performance by accelerating SSL decryption and encryption and by applying web caching to the HTTP traffic.

Example: SSL offloading for a WAN optimization tunnel

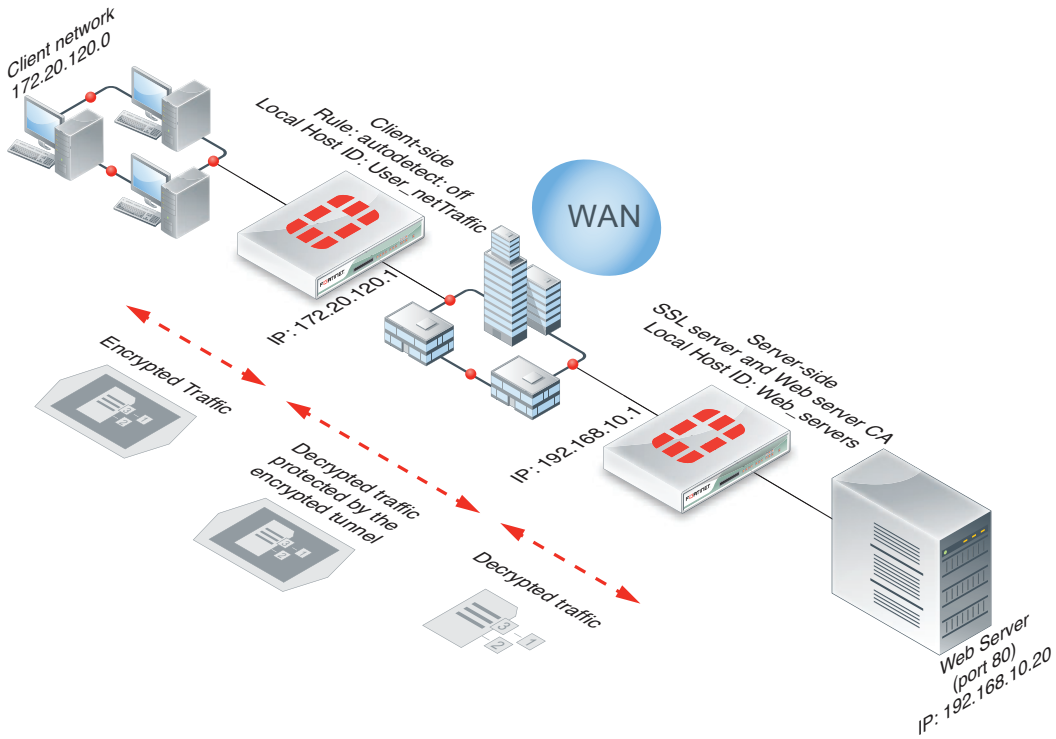
This example shows how to configure basic SSL offloading for a WAN optimization tunnel. This basic SSL offloading configuration can be applied to many network configurations.

Network topology and assumptions

In this example, clients on a client network use https://192.168.10.20 to browse to a web server. A WAN optimization rule with *Auto-Detect* set to *Off* on the client-side FortiGate unit accepts sessions from the clients with source addresses on the 172.20.120.0 network and with a destination address of 192.168.10.0 and a destination port of 443. In this rule, *Enable Secure Tunnel* is selected so that the tunnel is encrypted. To support the encrypted tunnel, the configuration also includes an authentication group with a pre-shared key. Both FortiGate units must have the same authentication group with the same pre-shared key.

The server-side FortiGate unit includes an SSL server configuration with `ip` set to 192.168.10.20 and `port` to 443. The unit also includes the web server CA.

Figure 334: SSL offloading WAN optimization configuration



When the client-side FortiGate unit accepts an HTTPS connection for 192.168.10.20, the SSL server configuration provides the information that the client-side unit needs to decrypt the traffic and send it in clear text across a WAN optimization tunnel to the server-side unit. The server-side unit then forwards the clear text packets to the web server.

The web server CA is not downloaded from the server side to the client-side FortiGate unit. Instead, the client-side FortiGate unit proxies the SSL parameters from the client side to the server side, which returns an SSL key and other required information to the client-side unit so that it can decrypt and encrypt HTTPS traffic.

In this peer-to-peer configuration you do not need to add a WAN optimization rule to the server-side FortiGate unit as long as this server-side unit includes the peer host ID of the client-side FortiGate unit in its peer list. However, you can set *Auto-Detect* to *Active* on the client-side FortiGate unit and then add a passive rule to the server-side unit.

In this example, you do not require the secure tunnel and the authentication group configurations, but they are included to show how to protect the privacy of the WAN optimization tunnel.Alternataively, you could configure a route-based IPsec VPN between the FortiGate units and use IPsec to protect the privacy of the WAN optimization tunnel.

In this example, it is assumed that you have a local CA named Web_Server_Cert_1.crt stored in a file that you will import when you configure the server-side FortiGate unit.

General configuration steps

This example is divided into client-side and server-side steps, as configured through the web-based manager, and with CLI instructions provided for CLI-only steps. For best results, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

You also need access to the CLI to perform CLI-only steps.

Client-side configuration steps

To configure the client-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate unit:

Local Host ID	User_net

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the peer side FortiGate unit:

Peer Host ID	Web_servers
IP Address	192.168.10.1

4 Select *OK*.

5 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group* and select *Create New* to add an authentication group named SSL_auth_grp to the client-side FortiGate unit.

The authentication group includes a pre-shared key and the peer added in step 3. An authentication group with the same name and the same pre-shared key must also be added to the server-side FortiGate unit. This authentication group is required for the secure tunnel:

Name	SSL_auth_grp
Authentication Method	Pre-shared key
Password	<pre-shared_key>
Peer Acceptance	Specify Peer: Web_servers

6 Select *OK*.

7 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New* to add the WAN optimization rule:

Mode	Full Optimization
Source	172.20.120.*
Destination	192.168.10.*
Port	443
Auto-Detect	Off
Protocol	HTTP
Peer	Web_servers
Transparent Mode	Select
Enable Byte Caching	Select
Enable SSL	Select
Enable Secure Tunnel	Select
Authentication Group	SSL_auth_grpa

8 Select *OK*.

The rule is added to the bottom of the WAN optimization list.

9 If required, move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

Server-side configuration steps

To configure the server-side FortiGate unit

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate unit:

Local Host ID	Web_servers

2 Select *Apply* to save your setting.

3 Select *Create New* and add a *Peer Host ID* and the *IP Address* for the peer side FortiGate unit:

Peer Host ID	User_net
IP Address	172.20.120.1

4 Select *OK*.

5 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group* and select *Create New* to add an authentication group named SSL_auth_grp to the server-side FortiGate unit.

The authentication group includes a pre-shared key and the peer added to the server-side FortiGate unit in step 3:

Name	SSL_auth_grp
Authentication Method	Pre-shared key
Password	<pre-shared_key>
Peer Acceptance	Specify Peer: User_net

6 Select *OK*.

7 Go to *System* > *Certificates* > *Local Certificates* and select *Import* to import the web server's CA.

For *Type*, select *Local Certificate*. Select the *Browse* button to locate the file, Web_Server_Cert_1.crt.

The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

8 From the CLI, enter the following command to add the SSL server to the server-side FortiGate unit:

```
config wanopt ssl-server
  edit example_server
    set ip 192.168.10.20
    set port 443
    set ssl-mode half
    set ssl-cert Web_Server_Cert_1
  end
```

Configure other `ssl-server` settings that you may require for your configuration.

Example: SSL offloading and reverse proxy web caching for an Internet web server using static one-to-one virtual IPs

This section describes configuring SSL offloading for a reverse proxy Web Cache Only WAN optimization configuration using a static one-to-one firewall virtual IP (VIP). While the static one-to-one configuration described in this example is valid, its also common to change the destination port of the unencrypted HTTPS traffic to a commonly used HTTP port such as 8080 using a port forwarding virtual IP. For an example of this configuration see "Example: SSL offloading and reverse proxy web caching for an Internet web server using a port forwarding virtual IP for HTTPS traffic" on page 2795.

Network topology and assumptions

In this configuration, clients on the Internet use HTTP and HTTPS to browse to a web server. The FortiGate unit intercepts the HTTP traffic and a Web Cache Only WAN optimization rule forwards the HTTP traffic to the web server. The FortiGate unit intercepts the HTTPS traffic and a different Web Cache Only WAN optimization rule with SSL offloading enabled decrypts the traffic before sending it to the web server. The FortiGate unit also caches HTTP and HTTPS pages from the web server. Replies to HTTPS sessions from the web server are encrypted by the FortiGate unit before returning to the web browsing clients.

In the Web Cache Only rules transparent mode is enabled because the FortiGate unit is performing NAT between the Internet and the HTTP server and the web server network is not configured to route Internet traffic between the FortiGate unit and the web server.

In this configuration, the FortiGate unit is operating as a web cache in reverse proxy mode. Reverse proxy caches can be placed directly in front of a web server. Web caching on the FortiGate unit reduces the number of requests that the web server must handle, therefore leaving it free to process new requests that it has not serviced before.

Using a reverse proxy configuration:

- avoids the capital expense of additional web servers by increasing the capacity of existing servers
- serves more requests for static content from web servers
- serves more requests for dynamic content from web servers
- reduces operating expenses including the cost of bandwidth required to serve content
- accelerates the response time of web servers and of page download times to end users.

When planning a reverse proxy implementation, the web server's content should be written so that it is “cache aware” to take full advantage of the reverse proxy cache.

In reverse proxy mode, the FortiGate unit functions more like a web server for the clients it services. Unlike internal clients, external clients are not reconfigured to access the proxy server. Instead, the site URL routes the client to the FortiGate unit as if it were a web server. Replicated content is delivered from the proxy cache to the external client without exposing the web server or the private network residing safely behind the firewall.

In this example, the site URL translates to IP address 192.168.10.1, which is the port2 IP address of the FortiGate unit. The port2 interface is connected to the Internet.

This example also includes two Web Cache Only rules, one that accepts the HTTP traffic for web caching and one that accepts the HTTPS traffic for SSL offloading and web caching. You could instead add only one rule for both the HTTP and HTTPS traffic.

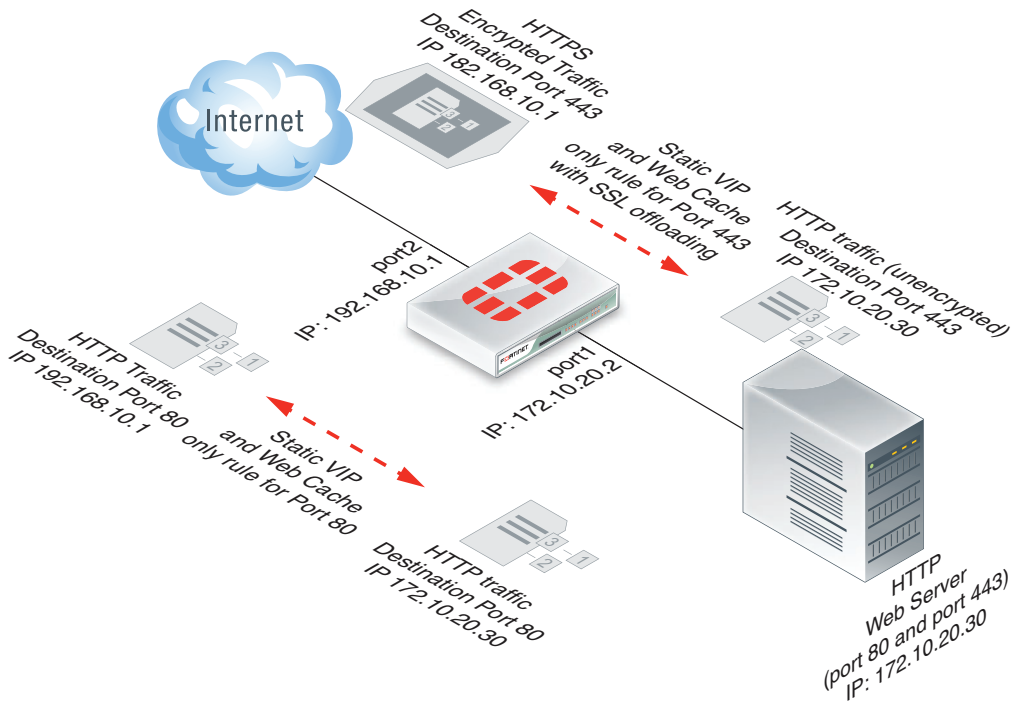
For this example, it is also assumed that all HTTP traffic uses port 80 and all HTTPS traffic uses port 443.

The FortiGate unit includes the web server CA and an SSL server configuration for IP address 172.10.20.30 and port to 443. The name of the file containing the CA is Rev_Proxy_Cert_1.crt.

The destination address of incoming web server requests are translated to the IP address of the web server using a static one-to-one virtual IP that performs destination address translation (DNAT) for the HTTP and HTTPS packets. The DNAT translates the destination address of the packets from 192.168.10.1 to 172.10.20.30 but does not change the destination port number.

WAN optimization receives the packets after the DNAT has occurred so the source address for the reverse proxy WAN optimization rules should be 172.10.20.30.

Figure 335: SSL offloading and reverse proxy web caching for an Internet web server using static one-to-one virtual IPs



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1 Configure the FortiGate unit as a reverse proxy web cache server.

2 Configure the FortiGate unit for SSL offloading of HTTPS traffic.

3 Add an SSL server to offload SSL encryption and decryption for the web server.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuration steps - web-based manager

To configure the FortiGate unit as a reverse proxy web cache server

1 Go to *Firewall Objects* > *Virtual IP* > *Virtual IP* and select *Create New* to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

Name	Reverse_proxy_VIP
External Interface	port2
Type	Static NAT
Source Address Filter	Do not select.
External IP Address/Range	192.168.10.1
Mapped IP Address/Range	172.10.20.30
Port Forwarding	Do not select.

2 Select *OK* to save your settings.

3 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet.

Do not select UTM features. Set the destination address to the virtual IP. You do not have to enable NAT.

Source Interface/Zone	port2
Source Address	all
Destination Interface/Zone	port1
Destination Address	Reverse_proxy_VIP
Schedule	always
Service	HTTP and HTTPS Select *Multiple* to select more than one service.
Action	ACCEPT

4 Select *OK* to save your settings.

5 Go to *WAN Opt. & Cache* > *WAN Opt Rule* > *Rule* and select *Create New* to add a Web Cache Only WAN optimization rule.

Configure the rule to accept the HTTP traffic on port 80 accepted by the security policy:

Mode	Web Cache Only
Source	0.0.0.0
Destination	172.10.20.30 You need to set *Destination* to the translated (DNATed) IP address (172.10.20.30).
Port	80
Transparent Mode	Select
Enable SSL	Do not select

6 Select *OK*.

The rule is added to the bottom of the WAN optimization list.

7 If required, move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the FortiGate unit for SSL offloading of HTTPS traffic

The security policy added in the first procedure accepts HTTPS traffic so you do not have to add another one.

1 Go to *WAN Opt. & Cache* > *WAN Opt Rule* > *Rule* and select *Create New* to add a Web Cache Only WAN optimization rule.

Configure the rule to accept the HTTPS traffic on port 443 accepted by the security policy:

Mode	Web Cache Only
Source	0.0.0.0
Destination	172.10.20.30 You need to set *Destination* to the translated (DNATed) IP address (172.10.20.30).
Port	443
Transparent Mode	Select.
Enable SSL	Select.

2 Select *OK*.

The rule is added to the bottom of the WAN optimization list.

3 If required, move the rule to a different position in the list.

The HTTPS rule can be above or below the HTTP rule.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To add an SSL server to offload SSL encryption and decryption for the web server

1 Go to *System* > *Certificates* > *Local Certificates* and select *Import* to import the web server's CA.

For *Type*, select *Local Certificate*. Select the *Browse* button to locate the file Rev_Proxy_Cert_1.crt.

The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

2 From the CLI, enter the following command to add the SSL server.

The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config wanopt ssl-server
  edit rev_proxy_server
    set ip 172.10.20.30
    set port 443
    set ssl-mode half
    set ssl-cert Rev_Proxy_Cert_1
  end
```

3 Configure other `ssl-server` settings that you may require for your configuration.

Configuration steps - CLI

To configure the FortiGate unit as a reverse proxy web cache server

1 Enter the following command to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

```
config firewall vip
  edit Reverse_proxy_VIP
    set extintf port2
    set type static-nat
    set extip 192.168.10.1
    set mappedip 172.10.20.30
  end
```

2 Enter the following command to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet.

Do not select UTM features. Set the destination address to the virtual IP. You do not have to enable NAT.

```
config firewall policy
  edit 0
    set srcintf port2
    set srcaddr all
    set dstintf port1
    set dstaddr Reverse_proxy_VIP
    set schedule always
    set service HTTP HTTPS
    set action accept
  end
```

3 Enter the following command to add a Web Cache Only WAN optimization rule that accepts the HTTP traffic on port 80 accepted by the security policy.

Set `dst-ip` to the translated (DNATed) IP address (172.10.20.30).

```
config wanopt rule
  edit 0
    set mode webcache-only
    set src-ip 0.0.0.0
    set dst-ip 172.10.20.30
    set port 80
    set transparent enable
    set ssl disable
  end
```

4 If required, move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the FortiGate unit for SSL offloading of HTTPS traffic

The security policy added in the first procedure accepts HTTPS traffic so you do not have to add another one.

1 Enter the following command to add a Web Cache Only WAN optimization rule that accepts the HTTPS traffic on port 443 accepted by the security policy.

Set `dst-ip` to the translated (DNATed) IP address (172.10.20.30).

```
config wanopt rule
  edit 0
    set mode webcache-only
    set src-ip 0.0.0.0
    set dst-ip 172.10.20.30
    set port 443
    set transparent enable
    set ssl enable
  end
```

2 If required, move the rule to a different position in the list.

The HTTPS rule can be above or below the HTTP rule.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To add an SSL server to offload SSL encryption and decryption for the web server

1 Place a copy of the web server's CA (file name Rev_Proxy_Cert_1.crt) in the root folder of a TFTP server.

2 Enter the following command to import the web server's CA from a TFTP server. The IP address of the TFTP server is 10.31.101.30:

```
execute vpn certificate local import tftp Rev_Proxy_Cert_1.crt
   10.31.101.30
```

The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

3 From the CLI, enter the following command to add the SSL server.

The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config wanopt ssl-server
  edit rev_proxy_server
    set ip 172.10.20.30
    set port 443
    set ssl-mode half
    set ssl-cert Rev_Proxy_Cert_1
  end
```

4 Configure other `ssl-server` settings that you may require for your configuration.

Example: SSL offloading and reverse proxy web caching for an Internet web server using a port forwarding virtual IP for HTTPS traffic

This section describes configuring SSL offloading for a reverse proxy Web Cache Only WAN optimization configuration using a static virtual IP (VIP) for HTTP traffic and a port forwarding virtual IP for HTTPS traffic. While the port forwarding configuration described in this example is commonly used, it also possible to use a static virtual IP that does not change the destination port. For an example of this configuration see "Example: SSL offloading and reverse proxy web caching for an Internet web server using static one-to-one virtual IPs" on page 2789.

Network topology and assumptions

In this configuration, clients on the Internet use HTTP (on port 80) and HTTPS (on port 9443) to browse to a web server. The FortiGate unit intercepts the HTTP traffic and a Web Cache Only WAN optimization rule forwards the HTTP traffic to the web server. The FortiGate unit intercepts the HTTPS traffic and a different Web Cache Only WAN optimization rule with SSL offloading enabled decrypts the traffic before sending it to the web server. The FortiGate unit also caches pages from the web server. Replies to HTTPS sessions from the web server are encrypted by the FortiGate unit before returning to the web browsing clients.

In the Web Cache Only WAN optimization rules, transparent mode is enabled because the FortiGate unit is performing NAT between the Internet and the HTTP server and the web server network is not configured to route Internet traffic between the FortiGate unit and the web server.

In this configuration, the FortiGate unit is operating as a web cache in reverse proxy mode. Reverse proxy caches can be placed directly in front of a web server. Web caching on the FortiGate unit reduces the number of requests that the web server must handle, therefore leaving it free to process new requests that it has not serviced before.

Using a reverse proxy configuration:

- avoids the capital expense of additional web servers by increasing the capacity of existing servers
- serves more requests for static content from web servers
- serves more requests for dynamic content from web servers
- reduces operating expenses including the cost of bandwidth required to serve content
- accelerates the response time of web servers and of page download times to end users.

When planning a reverse proxy implementation, the web server's content should be written so that it is “cache aware” to take full advantage of the reverse proxy cache.

In reverse proxy mode, the FortiGate unit functions more like a web server for the clients it services. Unlike internal clients, external clients are not reconfigured to access the proxy server. Instead, the site URL routes the client to the FortiGate unit as if it were a web server. Replicated content is delivered from the proxy cache to the external client without exposing the web server or the private network residing safely behind the firewall.

In this example, the site URL translates to IP address 192.168.10.1, which is the port2 IP address of the FortiGate unit. The port2 interface is connected to the Internet.

This example also includes two Web Cache Only rules, one that accepts the HTTP traffic for web caching and one that accepts the HTTPS traffic for SSL offloading and web caching.

For this example, it is also assumed that all HTTP traffic uses port 80 and all HTTPS traffic uses port 9443. (Since HTTPS traffic is received on the non-standard port of 9443 a security policy that accepts this traffic must have service set to ALL or you must add a custom service that matches traffic on port 9443. The example takes the custom service approach.)

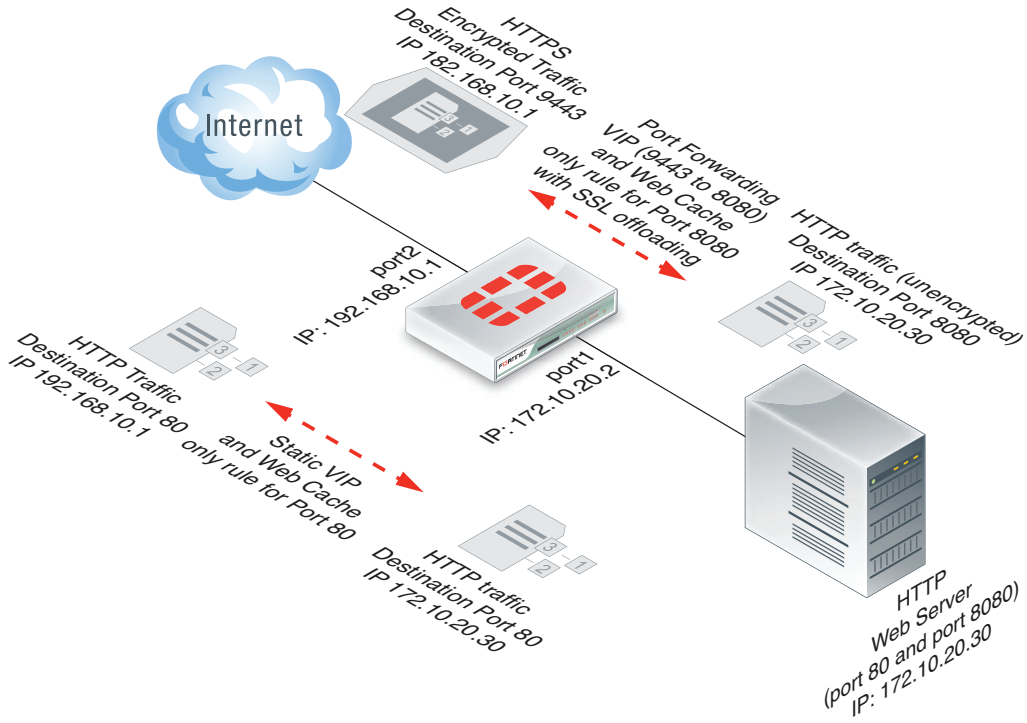
The FortiGate unit includes the web server CA and an SSL server configuration for IP address 172.10.20.30 and port to 8080. The name of the file containing the CA is Rev_Proxy_Cert_1.crt.

The destination address of incoming HTTP requests is translated to the IP address of the web server using a static NAT virtual IP that performs destination address translation (DNAT). The DNAT translates the destination address of the HTTP packets from 192.168.10.1 to 172.10.20.30 but does not change the destination port of the HTTP traffic.

The destination address and port number of incoming HTTPS requests is translated to the IP address of the web server and to port 8080 using a port forwarding virtual IP that performs destination address translation (DNAT) and destination port translation (port forwarding). The DNAT translates the destination address of the packets from 192.168.10.1 to 172.10.20.30. Port forwarding changes the destination port number from 9443 to 8080.

WAN optimization receives the packets after the address and port translation has occurred so the source address for the reverse proxy WAN optimization rules should be 172.10.20.30 and the source port should be 80 for the HTTP traffic and 8080 for the HTTPS traffic.

Figure 336: SSL offloading and reverse proxy web caching for an Internet web server using a static virtual IP for HTTP traffic and a port forwarding virtual IP for HTTPS traffic



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the FortiGate unit as a reverse proxy web cache server for the HTTP traffic (port 80, static DNAT).
2. Configure the FortiGate unit as a reverse proxy web cache server with SSL offloading for HTTPS traffic (DNAT, port forwarding (9443 to 8080), SSL offloading).

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuration steps - web-based manager

To configure the FortiGate unit as a reverse proxy web cache server for the HTTP traffic

1 Go to *Firewall Objects* > *Virtual IP* > *Virtual IP* and select *Create New* to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate the destination port):

Name	Reverse_proxy_http_VIP
External Interface	port2
Type	Static NAT
Source Address Filter	Do not select.
External IP Address/Range	192.168.10.1
Mapped IP Address/Range	172.10.20.30
Port Forwarding	Do not select.

2 Select *OK* to save your settings.

3 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a port2 to port1 security policy that accepts HTTP traffic from the Internet.

Do not select UTM features. Set the destination address to the virtual IP. You do not have to enable NAT.

Source Interface/Zone	port2
Source Address	all
Destination Interface/Zone	port1
Destination Address	Reverse_proxy_http_VIP
Schedule	always
Service	HTTP
Action	ACCEPT

4 Select *OK* to save your settings.

5 Go to *WAN Opt. & Cache* > *WAN Opt Rule* > *Rule* and select *Create New* to add a Web Cache Only WAN optimization rule.

Configure the rule to accept the HTTP traffic on port 80 accepted by the security policy:

Mode	Web Cache Only
Source	0.0.0.0
Destination	172.10.20.30 You need to set *Destination* to the translated (DNATed) IP address (172.10.20.30).
Port	80

Transparent Mode	Select
Enable SSL	Do not select

6 Select *OK*.

The rule is added to the bottom of the WAN optimization list.

7 If required, move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the FortiGate unit as a reverse proxy web cache server for the HTTPS traffic

1 Go to *Firewall Objects* > *Virtual IP* > *Virtual IP* and select *Create New* to add a port forwarding virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 and translates the destination port from 9443 to 8080:

Name	Reverse_proxy_https_VIP
External Interface	port2
Type	Static NAT
Source Address Filter	Do not select.
External IP Address/Range	192.168.10.1
Mapped IP Address/Range	172.10.20.30
Port Forwarding	Select
Protocol	TCP
External Service Port	9443
Map to Port	8080

2 Select *OK* to save your settings.

3 Go to *Firewall Objects* > *Service* > *Custom* and select *Create New* to add a custom service for HTTPS on port 9443:

Name	HTTPS_9443
Protocol Type	TCP/UDP/SCTP
Protocol	TCP
Source Port (Low - High)	1 - 65535
Destination Port (Low - High)	9443 - 9443

4 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a port2 to port1 security policy that uses the custom service and accepts traffic from the Internet.

Do not select UTM features. Set the destination address to the virtual IP. You do not have to enable NAT.

Source Interface/Zone	port2
Source Address	all
Destination Interface/Zone	port1
Destination Address	Reverse_proxy_https_VIP

Schedule	always
Service	HTTPS_9443
Action	ACCEPT

5 Select *OK* to save your settings.

6 Go to *WAN Opt. & Cache* > *WAN Opt Rule* > *Rule* and select *Create New* to add a Web Cache Only WAN optimization rule.

Configure the rule to accept the HTTPS traffic on port 8080, the as translated by the port forwarding virtual IP:

Mode	Web Cache Only
Source	0.0.0.0
Destination	172.10.20.30 You need to set *Destination* to the translated (DNATed) IP address (172.10.20.30).
Port	8080
Transparent Mode	Select
Enable SSL	Select

7 Select *OK*.

The rule is added to the bottom of the WAN optimization list.

8 If required, move the rule to a different position in the list.

The HTTPS rule can be above or below the HTTP rule.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

9 Go to *System* > *Certificates* > *Local Certificates* and select *Import* to import the web server's CA.

For *Type*, select *Local Certificate*. Select the *Browse* button to locate the file Rev_Proxy_Cert_1.crt.

The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

10 From the CLI, enter the following command to add the SSL server.

The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic after being translated by the virtual IP (8080). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config wanopt ssl-server
  edit rev_proxy_server
    set ip 172.10.20.30
    set port 8080
    set ssl-mode half
    set ssl-cert Rev_Proxy_Cert_1
  end
```

11 Configure other `ssl-server` settings that you may require for your configuration.

Configuration steps - CLI

To configure the FortiGate unit as a reverse proxy web cache server for the HTTP traffic

1 Enter the following command to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

```
config firewall vip
  edit Reverse_proxy_http_VIP
    set extintf port2
    set type static-nat
    set extip 192.168.10.1
    set mappedip 172.10.20.30
  end
```

2 Enter the following command to add a port2 to port1 security policy that accepts HTTP traffic from the Internet.

Do not select UTM features. Set the destination address to the virtual IP. You do not have to enable NAT.

```
config firewall policy
  edit 0
    set srcintf port2
    set srcaddr all
    set dstintf port1
    set dstaddr Reverse_proxy_http_VIP
    set schedule always
    set service HTTP
    set action accept
  end
```

3 Enter the following command to add a Web Cache Only WAN optimization rule that accepts the HTTP traffic on port 80 accepted by the security policy.

Set `dst-ip` to the translated (DNATed) IP address (172.10.20.30).

```
config wanopt rule
  edit 0
    set mode webcache-only
    set src-ip 0.0.0.0
    set dst-ip 172.10.20.30
    set port 80
    set transparent enable
    set ssl disable
  end
```

4 If required, move the rule to a different position in the list.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

To configure the FortiGate unit as a reverse proxy web cache server for the HTTPS traffic

1 Enter the following command to add a port forwarding virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 and translates the destination port from 9443 to 8080:

```
config firewall vip
  edit Reverse_proxy_https_VIP
    set extintf port2
    set type static-nat
    set port-forward enable
    set extip 192.168.10.1
    set mappedip 172.10.20.30
    set extport 9443
    set mappedport 8080
  end
```

2 Enter the following command to add a custom service for HTTPS on port 9443:

```
config firewall service custom
  edit HTTPS_9443
    set protocol TCP/UDP/SCTP
    set tcp_portrange 9443
  end
```

3 Enter the following command to add a port2 to port1 security policy that uses the custom service and accepts traffic from the Internet.

Do not select UTM features. Set the destination address to the virtual IP. You do not have to enable NAT.

```
config firewall policy
  edit 0
    set srcintf port2
    set srcaddr all
    set dstintf port1
    set dstaddr Reverse_proxy_https_VIP
    set schedule always
    set service HTTPS_9443
    set action accept
  end
```

4 Enter the following command to add a Web Cache Only WAN optimization rule that accepts the HTTPS traffic on port 443 accepted by the security policy.

Set `dst-ip` to the translated (DNATed) IP address (172.10.20.30) and set `port` to the translated port (8080).

```
config wanopt rule
  edit 0
    set mode webcache-only
    set src-ip 0.0.0.0
    set dst-ip 172.10.20.30
    set port 8080
    set transparent enable
    set ssl enable
  end
```

5 If required, move the rule to a different position in the list.

The HTTPS rule can be above or below the HTTP rule.

The order of the rules in the list significantly affects how the rules are applied. For more information, see "How list order affects rule matching" on page 2708 and "Moving a rule to a different position in the rule list" on page 2709.

6 Place a copy of the web server's CA (file name Rev_Proxy_Cert_1.crt) in the root folder of a TFTP server.

7 Enter the following command to import the web server's CA from a TFTP server. The IP address of the TFTP server is 10.31.101.30:

```
execute vpn certificate local import tftp Rev_Proxy_Cert_1.crt
   10.31.101.30
```

The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

8 From the CLI, enter the following command to add the SSL server.

The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic after being translated by the virtual IP (8080). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config wanopt ssl-server
  edit rev_proxy_server
    set ip 172.10.20.30
    set port 8080
    set ssl-mode half
    set ssl-cert Rev_Proxy_Cert_1
  end
```

9 Configure other `ssl-server` settings that you may require for your configuration.

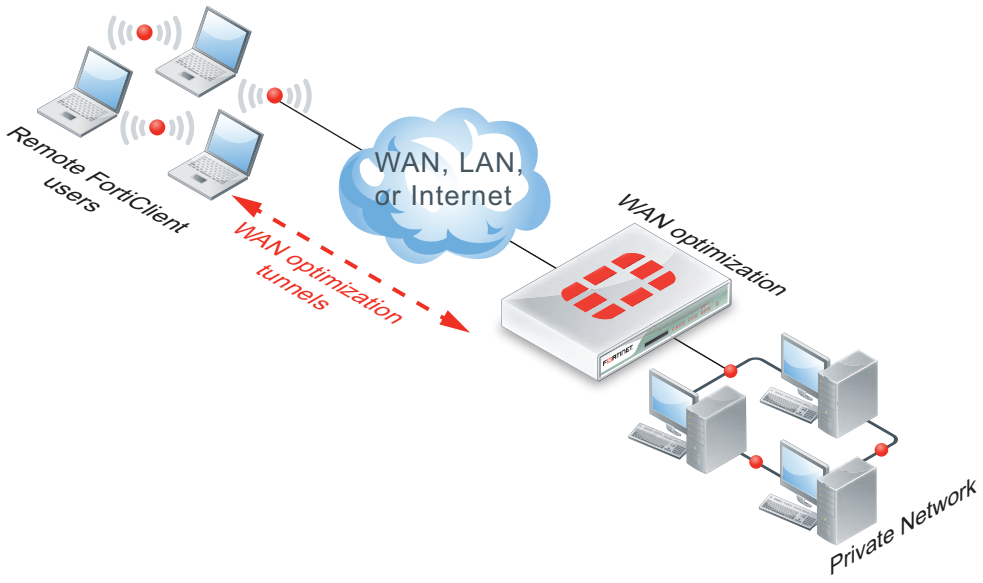
FortiClient WAN optimization

FortiClient WAN optimization works together with WAN optimization on a FortiGate unit to accelerate network traffic between a PC running version 4.0 or greater of the FortiClient application and a network behind a FortiGate unit. When a user of a PC with FortiClient WAN optimization enabled attempts to connect to network resources behind a server-side FortiGate unit, the FortiClient application automatically detects if WAN optimization is enabled on the FortiGate unit. If WAN optimization is detected and the FortiClient application can successfully negotiate a WAN optimization tunnel with the FortiGate unit, a WAN optimization tunnel starts.

FortiClient WAN optimization includes protocol optimization settings selected in the FortiClient application and byte caching (byte caching is enabled by default in the FortiClient application and cannot be disabled). Web caching is applied if selected in the passive rule on the FortiGate unit that accepts FortiClient WAN optimization tunnel requests.

This chapter describes how to configure the FortiClient application for WAN optimization and how to configure a FortiGate unit to accept WAN optimization tunnel requests from the FortiClient application.

Figure 337: FortiClient WAN optimization topology



Configuring FortiClient WAN optimization

Configuring WAN optimization with the FortiClient application consists of enabling WAN optimization for the FortiClient application and configuring the FortiGate unit to accept WAN optimization tunnel requests from the FortiClient application.

FortiClient configuration steps

To configure WAN Optimization for the FortiClient application

1 From the FortiClient user interface, go to *Status* > *WAN Optimization*.

2 Select *Enable WAN Optimization*.

3 Enable the protocols to be optimized: *HTTP* (web browsing), *CIFS* (Windows file sharing), *MAPI* (Microsoft Exchange) and *FTP* (file transfers).

4 Set *Maximum Disk Cache* to 512, 1024, or 2048 MB.

The default is 512 MB. If the PC hard disk can accommodate a larger cache, better optimization performance is possible.

5 Select *Apply*.

FortiGate unit configuration steps

To configure FortiClient WAN Optimization on the FortiGate unit

Because PCs running the FortiClient application can have IP addresses that change often, it is usually not practical to add PCs running the FortiClient application to the WAN optimization peer list. Instead, a FortiGate unit that accepts WAN optimization tunnel requests from the FortiClient application should be configured to accept any peer (see "Accepting any peers" on page 2697) by adding an authentication group named *auth-fc* with *Peer acceptance* set to *Accept Any Peer*.

On the FortiGate unit, you also need to add a passive rule that includes source and destination addresses that will accept connections from the IP addresses of PCs running the FortiClient application. If these PCs can be anywhere on the Internet, the source address for this rule is 0.0.0.0. You can also use a more restrictive address range if the PCs running the FortiClient application have a restricted range of addresses.

You do not need to add security policies to the FortiGate unit because it is on the server side of the WAN optimization tunnel.

1 Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group* and select *Create New*.

2 Configure the authentication group:

Name	auth-fc
Authentication Method	Certificate
Certificate	Fortinet_Firmware
Peer Acceptance	Accept Any Peer

3 Select *OK*.

4 Go to *WAN Opt. & Cache* > *WAN Opt. Rule* > *Rule* and select *Create New*.

5 Configure a rule to accept FortiClient WAN optimization sessions:

Mode	Full Optimization
Source	0.0.0.0
Destination	0.0.0.0
Port	1-65535
Auto-Detect	Passive

6 Select *OK*.

The FortiGate explicit web proxy

You can use the FortiGate explicit web proxy to enable explicit HTTP, and HTTPS proxying on one or more FortiGate interfaces. The explicit web proxy also supports proxying FTP sessions from a web browser and proxy auto-config (PAC) to provide automatic proxy configurations for explicit web proxy users. From the CLI you can also configure the explicit web proxy to support SOCKS sessions from a web browser.

The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

Web proxies are configured for each VDOM when multiple VDOMs are enabled.

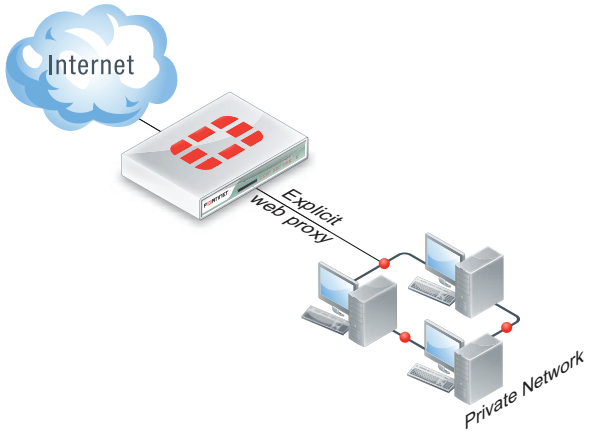
In most cases you would configure the explicit web proxy for users on a network by enabling the explicit web proxy on the FortiGate interface connected to that network. Users on the network would configure their web browsers to use a proxy server for HTTP and HTTPS, FTP, or SOCKS and set the proxy server IP address to the IP address of the FortiGate interface connected to their network. Users could also enter the PAC URL into their web browser PAC configuration to automate their web proxy configuration using a PAC file stored on the FortiGate unit.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in Transparent mode, users would configure their browsers to use a proxy server with the FortiGate unit management IP address.

The web proxy receives web browser sessions to be proxied at FortiGate interfaces with the explicit web proxy enabled. The web proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit web proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in Transparent mode the explicit web proxy changes the source addresses to the management IP address. For more information about explicit web proxy sessions, see “Explicit proxy sessions and user limits” on page 2825.

Figure 338: Example explicit web proxy topology



To allow all explicit web proxy traffic to pass through the FortiGate unit you can set the explicit web proxy default firewall proxy action to accept. However, in most cases you would want to use security policies to control explicit web proxy traffic and apply security features such as access control/authentication, UTM, and traffic logging. You can do this by keeping the default explicit web proxy security policy action to deny and then adding web-proxy security policies.

You can also change the explicit web proxy default security policy action to accept and add explicit web proxy security policies. If you do this, sessions that match web-proxy security policies are processed according to the security policy settings. Connections to the explicit web proxy that do not match a web-proxy security policy are allowed with no restrictions or additional security processing. This configuration is not recommended and is not a best practice.

Web-proxy security policies can selectively allow or deny traffic, apply authentication using identity-based policies, enable traffic logging, and use UTM options to apply virus scanning, web filtering, and DLP to explicit web proxy traffic. There are some limitations to the UTM features that can be applied to explicit web proxy sessions. See “UTM features and the explicit web proxy” on page 2817.

You cannot configure IPsec, SSL VPN, or Traffic shaping for explicit web proxy traffic. Security policies for the web proxy can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to *Any*. (On the web-based manager you must set the interface to *Any*. In the CLI you must `unset` the `associated-interface`.)

Authentication of explicit web proxy sessions uses HTTP authentication and can be based on the user’s source IP address or on cookies from the user’s web browser. For more information, see “Explicit web proxy authentication” on page 2815.

To use the explicit web proxy, users must add the IP address of a FortiGate interface on which the explicit web proxy is enabled and the explicit web proxy port number (default 8080) to the proxy configuration settings of their web browsers.

On FortiGate units that support WAN optimization, you can also enable web caching for explicit web proxy sessions.

This section describes:

- Explicit web proxy configuration overview
- Proxy chaining
- Explicit web proxy authentication
- UTM features and the explicit web proxy

Explicit web proxy configuration overview

You can use the following general steps to configure the explicit web proxy.

To enable the explicit web proxy - web-based manager

1 Go to *System* > *Network* > *Explicit Proxy*. Select *Enable Explicit Web Proxy* to turn on the explicit web proxy for HTTP and HTTPS traffic.

You can also select FTP to enable the web proxy for FTP over HTTP sessions in a web browser (not an FTP client) and PAC to enable automatic proxy configuration.

You can also optionally change the HTTP port that the proxy listens on (the default is 8080) and optionally specify different ports for HTTPS, FTP, and PAC.

2 Select Apply.

The default explicit web proxy configuration has *Default Firewall Policy Action* set to Deny and requires you to add a security policy to allow access to the explicit web proxy. This configuration is recommended as a best practice because you can use security policies to control access to the explicit web proxy and also apply security features such as logging, UTM, and authentication (by adding identity-based policies).

3 Go to *System* > *Network* > *Interface* and select one or more interfaces for which to enable the explicit web proxy. Edit the interface configuration and select Enable Explicit Web Proxy.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

4 Go to *Policy* > *Policy* > *Policy* and select Create New and set the *Source Interface/Zone* to *web-proxy.*

You can add multiple web-proxy security policies.

5 Configure the security policy as required to accept the traffic that you want to be processed by the explicit web proxy.

The source address of the policy should match client source IP addresses. The firewall address selected as the source address cannot be assigned to a FortiGate interface. The Interface field of the firewall address must be blank or it must be set to *Any*.

The destination address of the policy should match the IP addresses of web sites that clients are connecting to. Usually the destination address would be *all* if proxying Internet web browsing.

If *Default Firewall Policy Action* is set to Deny, traffic sent to the explicit web proxy that is not accepted by a web-proxy security policy is dropped. If *Default Firewall Policy Action* is set to Allow then all web-proxy sessions that don't match with a security policy are allowed.

For example the following security policy allows users on an internal network to access the Internet through the wan1 interface of a FortiGate unit.

Source Interface/Zone	web-proxy
Source Address	Internal_subnet
Destination Interface/Zone	wan1
Destination Address	all
Action	ACCEPT

6 You can select other security policy options as required.

For example, you can apply UTM protection to web proxy sessions and log allowed web proxy traffic.

7 You can also select *Enable Identity Based Policy* to apply authentication to explicit web proxy sessions.

8 You can add multiple identity based policies to apply different authentication for different user groups and also apply different UTM and logging settings for different user groups.

To enable the explicit web proxy - CLI

You must use the CLI to enable the explicit web proxy for VLAN interfaces.

1 Enter the following command to turn on the explicit web proxy for HTTP and HTTPS traffic.

```
config web-proxy explicit
  set status enable
end
```

You can also enter the following command to enable the web proxy for FTP sessions in a web browser.

```
config web-proxy explicit
  set ftp-over-http enable
end
```

The default explicit web proxy configuration has `sec-default-action` set to `deny` and requires you to add a security policy to allow access to the explicit web proxy.

2 Enter the following command to enable the explicit web proxy for the internal interface.

```
config system interface
  edit internal
    set explicit-web-proxy enable
  end
end
```

3 Use the following command to add a firewall address that matches the source address of users who connect to the explicit web proxy.

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
  end
```

The source address for a web-proxy security policy cannot be assigned to a FortiGate unit interface.

4 Use the following command to add a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the Internet.

```
config firewall policy
  edit 2
    set srcintf web-proxy
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set identity-based enable
    set schedule always
      config identity-based-policy
        edit 1
          set groups Internal_users
          set utm-status enable
          set profile-protocol-options default
          set av-profile Scan
          set logtraffic enable
          set schedule always
          set service ANY
        end
end
```

The firewall address selected as the source address cannot be assigned to a FortiGate unit interface. Either the field must be blank or it must be set to *Any*.

5 Use the following command to change global web proxy settings, for example to set the maximum request length for the explicit web proxy to 10:

```
config web-proxy global
  set max-request-length 10
end
```

Proxy auto-config (PAC) configuration

A proxy auto-config (PAC) file defines how web browsers can choose a proxy server for receiving HTTP content. PAC files include the FindProxyForURL(url, host) JavaScript function that returns a string with one or more access method specifications. These specifications cause the web browser to use a particular proxy server or to connect directly.

To configure PAC for explicit web proxy users, you can use the port that PAC traffic from client web browsers use to connect to the explicit web proxy. explicit web proxy users must configure their web browser's PAC proxy settings to use the PAC port.

PAC File Content

You can edit the default PAC file from the web-based manager or use the following command to upload a custom PAC file:

```
config web-proxy explicit
  set pac-file-server-status enable
  set pac-file data <pac_file_str>
end
```

Where <pac_file_str> is the contents of the PAC file. Enter the contents of the PAC file. Enclose the PAC file text in quotes. You can copy the contents of a PAC text file and paste the contents into the CLI using this option. Enter the command followed by two sets of quotes then place the cursor between the quotes and paste the file content.

The maximum PAC file size is 256 kbytes. If your FortiGate unit is operating with multiple VDOMs each VDOM has its own PAC file. The total amount of FortiGate memory available to store all of these PAC files 2 MBytes. If this limit is reached you will not be able to load any additional PAC files.

You can use any PAC file syntax that is supported by your users's browsers. The FortiGate unit does not parse the PAC file.

To use PAC, users must add an automatic proxy configuration URL (or PAC URL) to their web browser proxy configuration. The default PAC file URL is:

```
http://<interface_ip>:<PAC_port_int>/<pac_file_str>
```

For example, if the interface with the explicit web proxy has IP address 172.20.120.122, the PAC port is the same as the default HTTP explicit web proxy port (8080) and the PAC file name is proxy.pac the PAC file URL would be:

```
http://172.20.120.122:8080/proxy.pac
```

From the CLI you can use the following command to display the PAC file urls:

```
get web-proxy explicit
```

Unknown HTTP version

You can select the action to take when the proxy server must handle an unknown HTTP version request or message. Set unknown HTTP version to Reject or Best Effort. Best Effort attempts to handle the HTTP traffic as best as it can. Reject treats known HTTP traffic as malformed and drops it. The Reject option is more secure.

Authentication realm

You can enter an authentication realm to identify the explicit web proxy. The realm can be any text string of up to 63 characters. If the realm includes spaces enclose it in quotes. When a user authenticates with the explicit web proxy the HTTP authentication dialog includes the realm so you can use the realm to identify the explicitly web proxy for your users.

Other explicit web proxy options

You can change the following explicit web proxy options as required by your configuration.

HTTP port, HTTPS port, FTP port, PAC port	The TCP port that web browsers use to connect to the explicit proxy for HTTP, HTTPS, FTP and PAC services. The default port is 8080 for all services. By default HTTPS, FTP. and PAC use the same port as HTTP. You can change any of these ports as required. Users configuring their web browsers to use the explicit web proxy should add the same port numbers to their browser configurations.
Proxy FQDN	Enter the fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server.
Max HTTP request length	Enter the maximum length of an HTTP request in Kbytes. Larger requests will be rejected.
Max HTTP message length	Enter the maximum length of an HTTP message in Kbytes. Larger messages will be rejected.
Add headers to Forwarded Requests	The web proxy server will forward HTTP requests to the internal network. You can include the following headers in those requests:
Client IP Header	Enable to include the Client IP Header from the original HTTP request.
Via Header	Enable to include the Via Header from the original HTTP request.
X-forwarded-for Header	Enable to include the X-Forwarded-For (XFF) HTTP header. The XFF HTTP header identifies the originating IP address of a web client or browser that is connecting through an HTTP proxy, and the remote addresses it passed through to this point.
Front-end HTTPS Header	Enable to include the Front-end HTTP Header from the original HTTPS request.

Proxy chaining

For the explicit web proxy you can configure web proxy forwarding servers to use proxy chaining to redirect web proxy sessions to other proxy servers. Proxy chaining can be used to forward web proxy sessions from the FortiGate unit to one or more other proxy servers on your network or on a remote network. You can use proxy chaining to integrate the FortiGate explicit web proxy with an already existing web proxy solution.

A FortiGate unit can forward sessions to most web proxy servers including a remote FortiGate unit with the explicit web proxy enabled. No special configuration of the explicit web proxy on the remote FortiGate unit is required.

You can deploy the explicit web proxy with proxy chaining in an enterprise environment consisting of small satellite offices and a main office. If each office has a FortiGate unit, users at each of the satellite offices can use their local FortiGate unit as an explicit web proxy server. The satellite office FortiGate units can forward explicit web proxy sessions to an explicit web proxy server at the central office. From here the sessions can connect to web servers on the Internet.

FortiGate proxy chaining does not support authenticating with the remote forwarding server.

Adding a web proxy forwarding server

You add forwarding servers from the web-based manager by going to *System* > *Network* > *Explicit Proxy* and adding them. For each server you can define its address as a numeric IP address or fully qualified domain name. You can also specify the TCP port to use to connect to the proxy server.

Use the following CLI command to add a web proxy forwarding server named `fwd-srv` at address `proxy.example.com` and port 8080.

```
config web-proxy forward-server
  edit fwd-srv
    set addr-type fqdn
    set fqdn proxy.example.com
    set port 8080
  end
```

Web proxy forwarding server monitoring and health checking

By default, a FortiGate unit monitors web proxy forwarding server by forwarding a connection to the remote server every 10 seconds. If the remote server does not respond it is assumed to be down. Checking continues and when the server does send a response the server is assumed to be back up. If you configure health checking, every 10 seconds the FortiGate unit attempts to get a response from a web server by connecting through the remote forwarding server.

You can configure health checking for each remote server and specify a different website to check for each one.

If the remote server is found to be down you can configure the FortiGate unit to block sessions until the server comes back up or to allow sessions to connect to their destination, bypassing the remote forwarding server. You cannot configure the FortiGate unit to fail over to another remote forwarding server.

Configure the server down action and enable health monitoring from the web-based manager by going to *System* > *Network* > *Explicit Proxy*, selecting a forwarding server, and changing the server down action and changing the health monitor settings.

Use the following CLI command to enable health checking for a web proxy forwarding server and set the server down option to bypass the forwarding server if it is down.

```
config web-proxy forward-server
  edit fwd-srv
    set healthcheck enable
    set monitor http://example.com
    set server-down-option pass
  end
```

Adding proxy chaining to an explicit web proxy security policy

You enable proxy chaining for web proxy sessions by adding a web proxy forwarding server to an explicit web proxy security policy. In a policy you can select one web proxy forwarding server. All explicit web proxy traffic accepted by this security policy is forwarded to the specified web proxy forwarding server.

To add an explicit web proxy forwarding server - web-based manager

1 Go to *Policy* > *Policy* > *Policy* and select Create New.

2 Configure the security policy:

Source Interface/Zone	web-proxy
Source Address	Internal_subnet
Destination Interface/Zone	wan1
Destination Address	all
Schedule	always
Service	webproxy
Action	ACCEPT
Web Proxy Forwarding Server	Select, fwd-srv

3 Select OK to save the security policy.

To add an explicit web proxy forwarding server - CLI

1 Use the following command to add a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the Internet. The policy forwards web proxy sessions to a remote forwarding server named `fwd-srv`

```
config firewall policy
  edit 2
    set srcintf web-proxy
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set schedule always
    set service webproxy
    set webproxu-forward-server fwd-srv
end
```

Explicit web proxy authentication

You can add identity-based policies to apply authentication to explicit web proxy sessions. You can use authentication to control access to the explicit web proxy. You can also use identity-based policies to identify users and apply different UTM features to different users.

Authentication of web proxy sessions uses HTTP basic and digest authentication as described in RFC 2617 (HTTP Authentication: Basic and Digest Access Authentication) and prompts the user for credentials from the browser allowing individual users to be identified by their web browser instead of IP address. HTTP authentication allows the FortiGate unit to identify multiple users accessing services from a shared IP address. You can also select IP-based authentication to authenticate users according to their source IP address.

IP-Based authentication

IP-based authentication applies authentication by source IP address. Once a user authenticates, all sessions to the explicit web proxy from that IP address are assumed to be from that user and are accepted until the authentication timeout ends or the session times out.

This method of authentication is similar to standard (non-web proxy) firewall authentication and may not produce the desired results if multiple users share IP addresses (such as in a network that uses virtualization solutions or includes a NAT device between the users and the explicit web proxy).

To configure IP-based authentication, add a security policy for the explicit web proxy, set the source interface/zone to web-proxy, select Enable Identify Based Policy, and make sure IP Based is selected before adding identity-based policies. You can also set the authentication method to basic, digest, NTLM or FSAE.

Use the following CLI command to add IP-based authentication to a web proxy security policy. IP-based authentication is selected by setting `ip-based` to `enable`.

```
config firewall policy
  edit 3
    set srcintf web-proxy
    set dstintf port1
    set scraddr User_network
    set dstaddr all
    set action accept
    set identity-based enable
    set ip-based enable
      config identity-based-policy
        edit 1
          set groups Internal_users
          set service ANY
          set schedule always
        end
end
```

Per session authentication

If you don't select *IP Based* the FortiGate unit applies HTTP authentication per session. This authentication is browser-based (see Figure 339 on page 2817). When a user enters a user name and password in their browser to authenticate with the explicit web proxy, this information is stored by the browser in a session cookie. Each new session started by the same web browser uses the session cookie for authentication. When the session cooke expires the user has to re-authenticate. If the user starts another browser on the same PC or closes and then re-opens their browser they have to authenticate again.

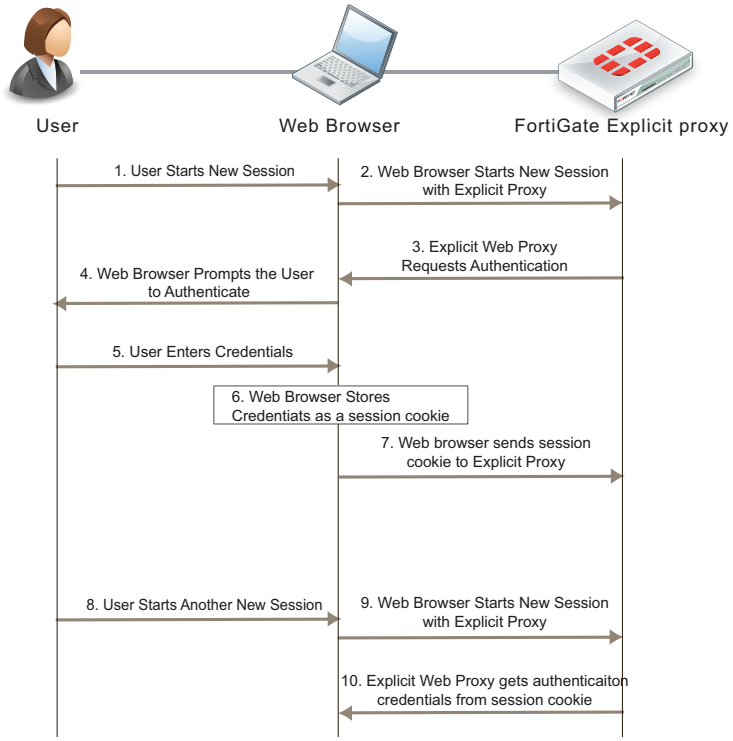
Since the authentication is browser-based, multiple clients with the same IP address can authenticate with the proxy using their own credentials. HTTP authentication provides authentication for multiple user sessions from the same source IP address. This can happen if there is a NAT device between the users and the FortiGate unit. HTTP authentication also supports authentication for other configurations that share one IP address among multiple users. These includes Citrix products and Windows Terminal Server and other similar virtualization solutions.

To configure per session authentication, add a security policy for the explicit web proxy, set the source interface/zone to web-proxy, select Enable Identify Based Policy, and make sure IP Based is not selected before adding identity-based policies. You can also set the authentication method to basic, digest, NTLM or FSAE.

Use the following CLI command to add per session authentication to a security policy. Per session authentication is selected by setting `ip-based` to `disable`.

```
config firewall policy
  edit 5
    set srcintf web-proxy
    set dstintf port1
    set scraddr User_network
    set dstaddr all
    set action accept
    set identity-based enable
    set ip-based disable
      config identity-based-policy
        edit 1
          set groups Internal_users
          set service ANY
          set schedule always
        end
end
```

Figure 339: Per session HTTP authentication



UTM features and the explicit web proxy

You can apply protocol options, antivirus, web filtering, FortiGuard Web Filtering and data leak prevention (DLP) including DLP archiving to explicit web proxy sessions. UTM features are applied by selecting them in a web proxy security policy or an identity based policy in a web proxy security policy. You cannot apply intrusion protection (IPS), email filtering, application control, or VoIP UTM features to explicit web proxy sessions.

To apply intrusion protection to explicit web proxy traffic you can add DoS policies to the FortiGate interfaces that receive and send explicit web proxy traffic. However, you cannot apply application control to explicit web proxy traffic, so you cannot filter explicit web proxy traffic by application and explicit web proxy traffic does not contribute to application control monitoring or reporting.

Explicit web proxy sessions and flow-based scanning

Flow-based scanning cannot be applied to explicit web proxy sessions. This includes:

- IPS
- Application control
- Flow-based virus scanning
- Flow-based web filtering
- Flow-based FortiGuard web filtering
- Flow-based Data leak prevention (DLP)

Explicit web proxy sessions and protocol options

Since the traffic accepted by the explicit web proxy is known to be either HTTP, HTTPS, or FTP over HTTP and since the ports are already known by the proxy, the explicit web proxy does not use the HTTP or HTTPS port protocol options settings.

When adding UTM features to a web proxy security policy, you must select a protocol options profile. In most cases you can select the default protocol options profile. You could also create a custom protocol options profile.

The explicit web proxy supports the following protocol options:

- Enable chunked bypass
- HTTP oversized file action and threshold

The explicit web proxy does not support the following protocol options:

- Client comforting
- Server comforting
- Monitor content information from dashboard. URLs visited by explicit web proxy users are not added to dashboard usage and log and archive statistics widgets.

Explicit web proxy sessions web filtering and FortiGuard web filtering

For explicit web proxy sessions, the FortiGate unit applies web filtering to an HTTP request when it receives the headers of the request. If web filtering allows the HTTP request, it is forwarded to the web server. If web filtering blocks the HTTP request is, the request is dropped and a blocking HTTP response is generated by the FortiGate unit and returned to the client web browser.

The explicit web proxy completely supports all web filtering and FortiGuard web filtering options and their configuration settings.

The web page displayed when FortiGuard Web Filtering blocks a web page through the explicit web proxy may be different than the page displayed through a normal firewall session.

Explicit web proxy sessions and HTTPS deep scanning

HTTPS explicit web proxy sessions are subject to web filtering and FortiGuard web filtering if you select *HTTPS scanning* in the web filtering profile applied to the explicit web proxy HTTPS sessions.

However, HTTPS deep scanning (also called SSL content scanning and inspection) is not supported for explicit web proxy HTTPS sessions. This means that web filtering of HTTPS sessions will only be done based on the URL in the session certificate.

The following features are also not supported for explicit web proxy HTTPS sessions:

- Virus scanning
- Data leak prevention (DLP)
- Enabling deep scanning in a protocol options profile

Explicit web proxy sessions and antivirus

For explicit web proxy sessions, the FortiGate unit applies antivirus scanning to HTTP POST requests and HTTP responses. The FortiGate unit starts virus scanning a file in an HTML session when it receives a file in the body of an HTML request. The explicit web proxy can receive HTTP responses from either the originating web server or the FortiGate web cache module.

Flow-based virus scanning is not available for explicit web proxy sessions. Even if the FortiGate unit is configured to use flow-based antivirus, explicit web proxy sessions use the regular virus database.

Web Proxy Services

Use the Web Proxy Service menu to configure multiple web proxy services for the web proxy feature. Web proxy services can only be selected in a security policy when *web-proxy* is selected as the source interface.

Web proxy services are similar to standard firewall services. You can configure web proxy services to define one or more protocols and port numbers that are associated with each web proxy service. Web proxy services can also be grouped into web proxy service groups.

The following are web proxy service configuration settings in *Firewall Objects* > *Service* > *Web Proxy Service*.

Name	Enter a name for the web proxy service.
Protocol	Select a protocol from the drop-down list.
Source Port	Enter the low and high source ports.
Low	Enter the lowest source port.
High	Enter the highest source port.
Destination Port	Enter the low and high destination ports.
Low	Enter the lowest destination port.
High	Enter the highest destination port.

Web Proxy Service Groups

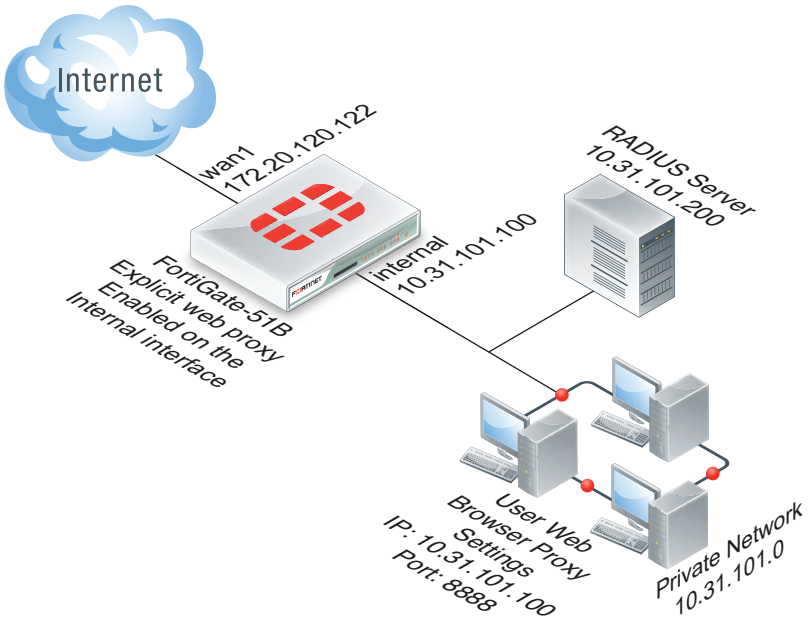
In *Firewall Objects* > *Service* > *Web Proxy Service Group*, you can configure groups of web proxy services. By using service groups, you can efficiently apply several web proxy services to a security policy. This feature is applicable only when *web-proxy* is selected as the source interface in a security policy.

Group Name	Enter the name of the group.
Available Services	The web proxy services that can be members of the group. Select a web proxy service and use the -> arrow to move it to *Members*. Repeat for each service that you want to be a member in the group.
Members	The members of a group. To remove a member from *Members*, select the service and then use the <- arrow to move it back to *Available Services*.

Example: users on an internal network browsing the Internet through the explicit web proxy with web caching, RADIUS authentication, web filtering and virus scanning

This example describes how to configure the explicit web proxy for the example network shown in Figure 340. In this example, users on the internal network connect to the explicit web proxy through the Internal interface of the FortiGate-51B unit. The explicit web proxy is configured to use port 8888 so users must configure their web browser proxy settings to use port 8888 and IP address 10.31.101.100.

Figure 340: Example explicit web proxy network topology



In this example, explicit web proxy users must authenticate with a RADIUS server before getting access to the proxy. To apply authentication, the security policy that accepts explicit web proxy traffic includes an identity based policy that applies per session authentication to explicit web proxy users and includes a user group with the RADIUS server in it. The identity based policy also applies UTM web filtering and virus scanning.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Enable the explicit web proxy for HTTP and HTTPS and change the HTTP and HTTPS ports to 8888.
2. Enable the explicit web proxy on the internal interface.
3. Add a RADIUS server and user group for the explicit web proxy.
4. Add web filtering and antivirus profiles for the explicit web proxy.
5. Add a security policy for the explicit web proxy.

   Enable web caching in the security policy.

   Add an identity based policy to the security policy to support authentication. Enable antivirus, web filter, and DLP UTM features for the identity-based policy.

Configuring the explicit web proxy - web-based manager

Use the following steps to configure the explicit web proxy from FortiGate web-based manager.

To enable and configure the explicit web proxy - web-based manager

1. Go to *System* > *Network* > *Explicit Proxy* and change the following settings:

Enable Explicit Web Proxy	Select *HTTP/HTTPS*.
Listen on Interfaces	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
HTTP Port	8888
HTTPS Port	8888
Realm	You are authenticating with the explicit web proxy.
Default Firewall Policy Action	Deny

2. Select *Apply*.

To enable the explicit web proxy on the Internal interface - web-based manager

1. Go to *System* > *Network* > *Interface*.
2. Edit the internal interface.
3. Select *Enable Explicit Web Proxy.*
4. Select *OK*.

To add a RADIUS server and user group for the explicit web proxy - web-based manager

1. Go to *User* > *Remote* > *RADIUS*.

2 Select Create New to add a new RADIUS server:

Name	RADIUS_1
Type	Query
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

3 Go to *User* > *User Group* > *User Group* and select *Create New*.

Name	Explict_proxy_user_group
Type	Firewall
Members	RADIUS_1

4 Select OK.

To add a security policy for the explicit web proxy - web-based manager

1 Go to *Firewall Objects* > *Address* > *Address* and select Create New.

2 Add a firewall address for the internal network:

Address Name	Internal_subnet
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.[1-255]
Interface	Any

3 Go to *Policy* > *Policy* > *Policy* and select Create New.

4 Configure the explicit web proxy security policy.

Source Interface/Zone	web-proxy
Source Address	Internal_subnet
Destination Interface/Zone	wan1
Destination Address	all
Action	ACCEPT

5 Select *Enable web cache* to enable web caching for the explicit web proxy.

6 Select *Enable Identity Based Policy*, make sure *IP Based* is not selected and *Auth Method* is set to *Basic*.

7 Select Add and configure the following settings for the identity based policy:

User Group	Explicit_policy
Service	webproxy
UTM	Select
Enable Antivirus	default
Enable Web Filter	default
Enable DLP Sensor	default
Protocol Options	default

You can also create custom antivirus, web filter, and DLP profiles instead of using the defaults.

8 Select OK.

Configuring the explicit web proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable the explicit web proxy on the Internal interface - CLI

1 Enter the following command to enable the explicit web proxy on the internal interface.

```
config system interface
  edit internal
    set explicit-web-proxy enable
end
```

To enable and configure the explicit web proxy - CLI

1 Enter the following command to enable the explicit web proxy and set the TCP port that proxy accepts HTTP and HTTPS connections on to 8888.

```
config web-proxy explicit
  set status enable
  set http-incoming-port 8888
  set https-incoming-port 8888
  set realm "You are authenticating with the explicit web
     proxy"
  set sec-default-action deny
end
```

To add a RADIUS server and user group for the explicit web proxy - CLI

1 Enter the following command to add a RADIUS server:

```
config user radius
  edit RADIUS_1
    set server 10.31.101.200
    set secret RADIUS_server_secret
end
```

2 Enter the following command to add a user group for the RADIUS server.

```
config user group
  edit Explicit_proxy_user_group
    set group-type firewall
    set member RADIUS_1
end
```

To add a security policy for the explicit web proxy - CLI

1 Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
end
```

2 Enter the following command to add the explicit web proxy security policy:

```
config firewall policy
  edit 0
    set srcintf web-proxy
```

```
        set dstintf wan1
        set srcaddr Internal_subnet
        set dstaddr all
        set action accept
        set schedule always
        set webcache enable
        set identity-based enable
        set ipbased disable
        set auth-method basic
          config identity-based-policy
            edit 1
              set groups Explicit_Proxy_user_group
              set schedule always
              set service explicit-web
              set utm-status enable
              set av-profile Explicit_av_pro
              set webfilter-profile Explicit_wf_pro
              set dlp-sensor default
              set profile-protocol-options default
        end
    end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit web proxy configuration is working as expected:

To test the explicit web proxy configuration

1. Configure a web browser on the internal subnet to use a web proxy server at IP address 10.31.101.100 and port 8888.
2. Browse to an Internet web page.

   The web browser should pop up an authentication window that includes the phrase that you added to the Realm option.
3. Enter the username and password for an account on the RADIUS server.

   If the account is valid you should be allowed to browse web pages on the Internet.
4. Close the browser and clear its cache and cookies.
5. Restart the browser and connect to the Internet.

   You could also start a second web browser on the same PC. Or you could start a new instance of the same browser as long as the browser asks for a user name and password again.

   You should have to authenticate again because identity-based policies are set to session-based authentication.
6. If this basic functionality does not work, check your FortiGate and web browser configuration settings.
7. Browse to a URL on the URL filter list and confirm that the web page is blocked.
8. Browse to http://eicar.org and attempt to download an anti-malware test file.

   The antivirus configuration should block the file.

   Sessions for web-proxy security policies do not appear on the Top Sessions dashboard widget and the count column for security policies does not display a count for explicit web proxy security policies.

9 You can use the following command to display explicit web proxy sessions

```
get test wad 60
IP based users:

Session based users:
        user:0x9c20778, username:User1, vf_id:0, ref_cnt:9

Total allocated user:1

Total user count:3, shared user quota:50, shared user count:3
```

This command output shows one explicit proxy user with user name `User1` authenticated using session-based authentication.

Explicit proxy sessions and user limits

Web browsers and web servers open and close multiple sessions with the explicit web proxy. Some sessions open and close very quickly. HTTP 1.1 keepalive sessions are persistent and can remain open for long periods of time. Sessions can remain on the explicit web proxy session list after a user has stopped using the proxy (and has, for example, closed their browser). If an explicit web proxy session is idle for more than 3600 seconds it is torn down by the explicit web proxy. See RFC 2616 for information about HTTP keepalive/persistent HTTP sessions.

This section describes proxy sessions and user limits for both the explicit web proxy and the explicit FTP proxy. Session and user limits for the two proxies are counted and calculated together. However, in most cases if both proxies are active there will be many more web proxy sessions than FTP proxy sessions.

The FortiGate unit adds two sessions to its session table for every explicit proxy session started by a web browser and every FTP session started by an FTP client. An entry is added to the session table for the session from the web browser or client to the explicit proxy. All of these sessions have the same destination port as the explicit web proxy port (usually 8080 for HTTP and 21 for FTP). An entry is also added to the session table for the session between the exiting FortiGate interface and the web or FTP server destination of the session. All of these sessions have a FortiGate interface IP address and the source address of the session and usually have a destination port of 80 for HTTP and 21 for FTP.

Proxy sessions that appear in the Top sessions dashboard widget do not include the Policy ID of the web-proxy or ftp-proxy security policy that accepted them. However, the explicit proxy sessions appear in the Top Sessions dashboard widget with a destination port that matches the explicit proxy port number (usually 8080 for the web proxy and 21 for the FTP proxy). The proxied sessions from the FortiGate unit have their source address set to the IP address of the FortiGate unit interface that the sessions use to connect to their destinations (for example, for connections to the Internet the source address would be the IP address of the FortiGate interface connected to the Internet).

FortiOS limits the number of explicit proxy users. This includes both explicit FTP proxy and explicit web proxy users. The number of users varies by FortiGate model from as low as 10 to up to 18000 for high end models. You can use the following command to display the limit on the number of explicit web proxy users for a FortiGate unit:

```
get test wad 62

Total user count:1, shared user quota:500, shared user count:1
   form_auth_keepalive=0 vd=root max=0 guarantee=0 used=1
```

This command output shows that the explicit proxy user limit (the `shared user quota`) for this FortiGate unit is 500 users.

You cannot change this limit. If your FortiGate unit is configured for multiple VDOMs this limit must be shared by all VDOMs. You can also use VDOM resource limiting to limit the number of explicit proxy users for the FortiGate unit and for each VDOM. To limit the number of explicit proxy users for the FortiGate unit from the web-based manager enable multiple VDOMs and go to *System* > *VDOM* > *Global Resources* set the number of Concurrent explicit proxy users or use the following command:

```
config global
  config system resource-limits
    set proxy 50
  end
end
```

To limit the number of explicit proxy users for a VDOM, from the web-based manager enable multiple VDOMs and go to *System* > *VDOM* > *VDOM* and edit a VDOM or use the following command to change the number of explicit web proxy users for VDOM_1:

```
config global
  config system vdom-property
    edit VDOM_1
      set proxy 25
  end
end
```

The VDOM resource limit pages on the web-based manager also display the current number of explicit web proxy users. You can also use the `get test wad 60` CLI command to view the number of explicit web proxy users. For example:

```
get test wad 60
IP based users:
        user:0x9ab8350 username:User1, vf_id:0,
ip_addr:10.31.101.10, ref_cnt:9

Session based users:
        user:0x9ac3c40, username:User2, vf_id:0, ref_cnt:3
        user:0x9ab94f0, username:User3, vf_id:0, ref_cnt:1

Total allocated user:3

Total user count:3, shared user quota:50, shared user count:3
```

Users may be displayed with this command even if they are no longer actively using the proxy. All idle sessions time out after 3600 seconds.

The command output shows three explicit proxy users. The user named User1 has authenticated with a security policy that includes IP-based authentication and the user's source IP address is 10.31.101.10. The users named User2 and User3 have authenticated with a security policy that includes session-based authentication.

You can use the following command to flush all current explicit proxy users. This means delete information about all users and force them re-authenticate.

```
get test wad 61
```

Users that authenticate with explicit web-proxy or ftp-proxy security policies do not appear in the *User* > *Monitor* > *Firewall* list and selecting *De-authenticate All Users* has no effect on explicit proxy users.

How the number of concurrent explicit proxy users is determined depends on their authentication method:

- For session-based authenticated users, each authenticated user is counted as a single user. Since multiple users can have the same user name, the proxy attempts to identify users according to their authentication membership (based upon whether they were authenticated using RADIUS, LADAP, FSAE, local database etc.). If a user of one session has the same name and membership as a user of another session, the explicit proxy assumes this is one user.
- For IP Based authentication, or no authentication, or if no web-proxy security policy has been added, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.

The explicit proxy does not limit the number of active sessions for each user. As a result the actual explicit proxy session count is usually much higher than the number of explicit web proxy users. If an excessive number of explicit web proxy sessions is compromising system performance you can limit the amount of users if the FortiGate unit is operating with multiple VDOMs.

Explicit web proxy configuration options

Use the explicit web proxy to enable explicit HTTP and HTTPS proxying on one or more FortiGate interfaces. The explicit web proxy also supports proxying FTP sessions sent from a web browser and proxy auto-config (PAC) to provide automatic proxy configurations for explicit web proxy users. From the CLI, you can also configure the explicit web proxy to support SOCKS sessions sent from a web browser. See “Explicit web proxy configuration overview” on page 2809.

To configure the explicit web proxy, go to *System* > *Network* > *Explicit Proxy* > *Explicit Web Proxy Options:*

For explicit FTP proxy options, see “Explicit FTP proxy options” on page 2844.

Explicit Web Proxy Options

Use the following options to configure the explicit web proxy.

Enable Explicit Web Proxy	Enable the explicit web proxy server for HTTP/ HTTPS, FTP and proxy auto-config PAC sessions. You must select this option for the explicit web proxy to accept and forward packets. FTP and PAC is only supported from a web browser and not a standalone client.
Listen on Interfaces	Displays the interfaces that are being monitored by the explicit web proxy. If VDOMs are enabled, only interfaces that belong to the current VDOM and have explicit web proxy enabled will be displayed. If you enable the web proxy on an interface that has VLANs on it, the explicit web proxy will not be enabled for those VLAN interfaces. You must use the CLI to enable the explicit proxy for VLAN interfaces.

HTTP Port **HTTPS Port** **FTP Port** **PAC Port**	Enter the port number that traffic from client web browsers use to connect to the explicit proxy for the specific protocol. Explicit proxy users must configure their web browser's protocols proxy settings to use this port. The default value of 0 means use the same port as the configured HTTP port.
PAC File Content	Select the *Edit* icon to change the contents in a PAC file, or import a PAC file. The maximum PAC file size is 8192 bytes. You can use any PAC file syntax that is supported by your users's browsers. The FortiGate unit does not parse the PAC file. To use PAC, users must add an automatic proxy configuration URL (or PAC URL) to their web browser proxy configuration. The default PAC file URL is: http://<interface_ip>:<PAC_port_int>/<pac_file_str> For example, if the interface with the explicit web proxy has IP address 172.20.120.122, the PAC port is the same as the default HTTP explicit proxy port (8080) and the PAC file name is proxy.pac the PAC file URL would be: http://172.20.120.122:8080/proxy.pac From the CLI you can use the following command to display the PAC file url: get web-proxy explicit
Proxy FQDN	Enter the fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server.
Max HTTP request length	Enter the maximum length of an HTTP request. Larger requests will be rejected.
Max HTTP message length	Enter the maximum length of an HTTP message. Larger messages will be rejected.
Unknown HTTP version	Select the action to take when the proxy server must handle an unknown HTTP version request or message. *Best Effort* attempts to handle the HTTP traffic as best as it can. *Reject* treats known HTTP traffic as malformed and drops it.

Realm	Enter an authentication realm to identify the explicit web proxy. The realm can be any text string of up to 63 characters. If the ream includes spaces enclose the name in quotes. When a user authenticates with the explicit proxy the HTTP authentication dialog includes the realm so you can use the realm to identify the explicitly web proxy for your users.
Default Firewall Policy Action	Configure the explicit web proxy to block (deny) or accept sessions if security policies have note been added for the explicit web proxy. To add security policies for the explicit web proxy add a security policy and set the source interface to *web-proxy*. The default setting (or *Deny)* blocks access to the explicit web proxy before adding a security policy. If you set this option to *Accept* the explicit web proxy server accepts sessions even if you haven't defined a security policy.

Web Proxy Forwarding Servers Options

Use the following options to configure web proxy forwarding servers.

Create New	Select to create a new forwarding server.
Service Name	The name of the forwarding server.
Address	The IP address of the forwarding server.
Port	The port number of the forwarding server.
Health Check	Indicates whether the health check is disabled or enabled for that forwarding server. A green checkmark indicates health check is enabled; a gray x indicates that health check is disabled.
Server Down	The action that the FortiGate unit will taken when the server is down.
Ref.	Displays the number of times the object is referenced to other objects.

Adding Web Proxy Forwarding Servers

To add a forwarding server, select *Create New* in the *Web Proxy Forwarding Servers* section of the *Explicit Proxy* page by going to *System* > *Network* > *Explicit Proxy*.

Server Name	Enter the name of the forwarding server.
Proxy Address	Enter the IP address of the forwarding server.
Proxy Address Type	Select the type of IP address of the forwarding server. A forwarding server can have an FQDN or IP address.
Port	Enter the port number.
Server Down action	Select what action the FortiGate unit will take if the forwarding server is down.
Enable Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the URL address of the health check monitoring site.

Restricting the IP address of the explicit web proxy

You can use the following command to restrict access to the explicit web proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require uses to connect to the IP address 10.31.101.100 to connect to the explicit HTTP proxy:

```
config web-proxy explicit
  set incoming-ip 10.31.101.100
end
```

Restricting the outgoing source IP address of the explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit HTTP proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config http-proxy explicit
  set outgoing-ip 172.20.120.100
end
```

The FortiGate explicit FTP proxy

You can use the FortiGate explicit FTP proxy to enable explicit FTP proxying on one or more FortiGate interfaces. The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

Explicit FTP proxies are configured for each VDOM when multiple VDOMs are enabled.

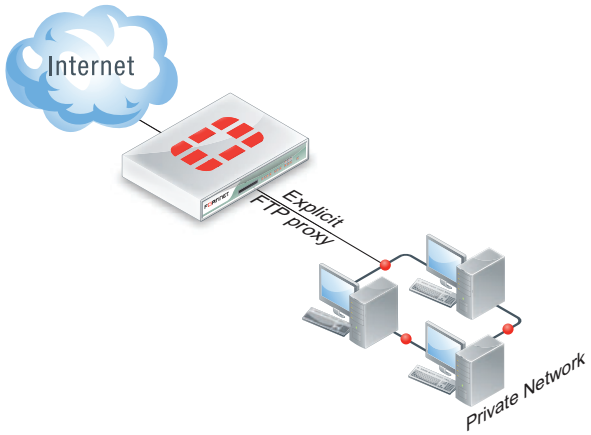
In most cases you would configure the explicit FTP proxy for users on a network by enabling the explicit FTP proxy on the FortiGate interface connected to that network. Users on the network would connect to and authenticate with the explicit FTP proxy before connecting to an FTP server. In this case the IP address of the explicit FTP proxy is the IP address of the FortiGate interface on which the explicit FTP proxy is enabled.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in Transparent mode, users would configure their browsers to use a proxy server with the FortiGate unit management IP address.

The FTP proxy receives FTP sessions to be proxied at FortiGate interfaces with the explicit FTP proxy enabled. The FTP proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit FTP proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in Transparent mode the explicit web proxy changes the source addresses to the management IP address.

Figure 341: Example explicit FTP proxy topology



To allow anyone to anonymously log into explicit FTP proxy and connect to any FTP server you can set the explicit FTP proxy default firewall proxy action to accept. When you do this, users can log into the explicit FTP proxy with any username and password.

In most cases you would want to use security policies to control explicit FTP proxy traffic and apply security features such as access control/authentication, UTM, and traffic logging. You can do this by keeping the default explicit FTP proxy firewall policy action to deny and then adding ftp-proxy security policies. In most cases you would also want users to authenticate with the explicit FTP proxy. By default an anonymous FTP login is required. Usually you would add authentication, in the form of identity based policies, to ftp-proxy security policies. Users can then authenticate with the explicit FTP proxy according to user groups added to the identity based policies. User groups added to FTP proxy identity based policies can use any authentication method supported by FortiOS including the local user database and RADIUS and other remote servers.

If you leave the default firewall policy action set to deny and add ftp-proxy security policies, all connections to the explicit FTP proxy must match an ftp-proxy security policy or else they will be dropped. Sessions that are accepted are processed according to the ftp-proxy security policy settings.

You can also change the explicit FTP proxy default firewall policy action to accept and add explicit FTP proxy security policies. If you do this, sessions that match ftp-proxy security policies are processed according to the security policy settings. Connections to the explicit FTP proxy that do not match an ftp-proxy security policy are allowed and the users can authenticate with the proxy anonymously user any username and password.

There are some limitations to the UTM features that can be applied to explicit web proxy sessions. See "UTM features and the explicit FTP proxy" on page 2837.

You cannot configure IPsec, SSL VPN, or Traffic shaping for explicit FTP proxy traffic. Security policies for the FTP proxy can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to *any*. (On the web-based manager you must set the interface to *Any*. In the CLI you must `unset` the `associated-interface`.)

This section describes:

How to use the explicit FTP proxy to connect to an FTP server

To connect to an FTP server using the explicit FTP proxy, users must run an FTP client and connect to the IP address of a FortiGate interface on which the explicit FTP proxy is enabled. This connection attempt must use the configured explicit FTP proxy port number (default 21).

The explicit FTP proxy is not compatible with using a web browser as an FTP client. To use web browsers as FTP clients configure the explicit web proxy to accept FTP sessions.

The following steps occur when a user starts an FTP client to connect to an FTP server using the explicit FTP proxy. Any RFC-compliant FTP client can be used. This example describes using a command-line FTP client. Some FTP clients may require a custom FTP proxy connection script.

1 The user enters a command on the FTP client to connect to the explicit FTP proxy.

   For example, if the IP address of the FortiGate interface on which the explicit FTP proxy is enabled is 10.31.101.100, enter:

   ```
   ftp 10.31.101.100
   ```

2 The explicit FTP proxy responds with a welcome message and requests the user's FTP proxy user name and password and a username and address of the FTP server to connect to:

   ```
   Connected to 10.31.101.100.
   220 Welcome to Fortigate FTP proxy
   Name (10.31.101.100:user):
   ```

   You can change the message by editing the FTP Proxy replacement message.

3 At the prompt the user enters their FTP proxy username and password and a username and address for the FTP server. The FTP server address can be a domain name or numeric IP address. This information is entered using the following syntax:

   ```
   <proxy-user>:<proxy-password>:<server-user>@<server-address>
   ```

   For example, if the proxy username and password are `p-name` and `p-pass` and a valid username for the FTP server is `s-name` and the server's IP address is `ftp.example.com` the syntax would be:

   ```
   p-name:p-pass:s-name@ftp.example.com
   ```

If the FTP proxy accepts anonymous logins `p-name` and `p-pass` can be any characters.

4 The FTP proxy forwards the connection request, including the user name, to the FTP server.

5 If the user name is valid for the FTP server it responds with a password request prompt.

6 The FTP proxy relays the password request to the FTP client.

7 The user enters the FTP server password and the client sends the password to the FTP proxy.

8 The FTP proxy relays the password to the FTP server.

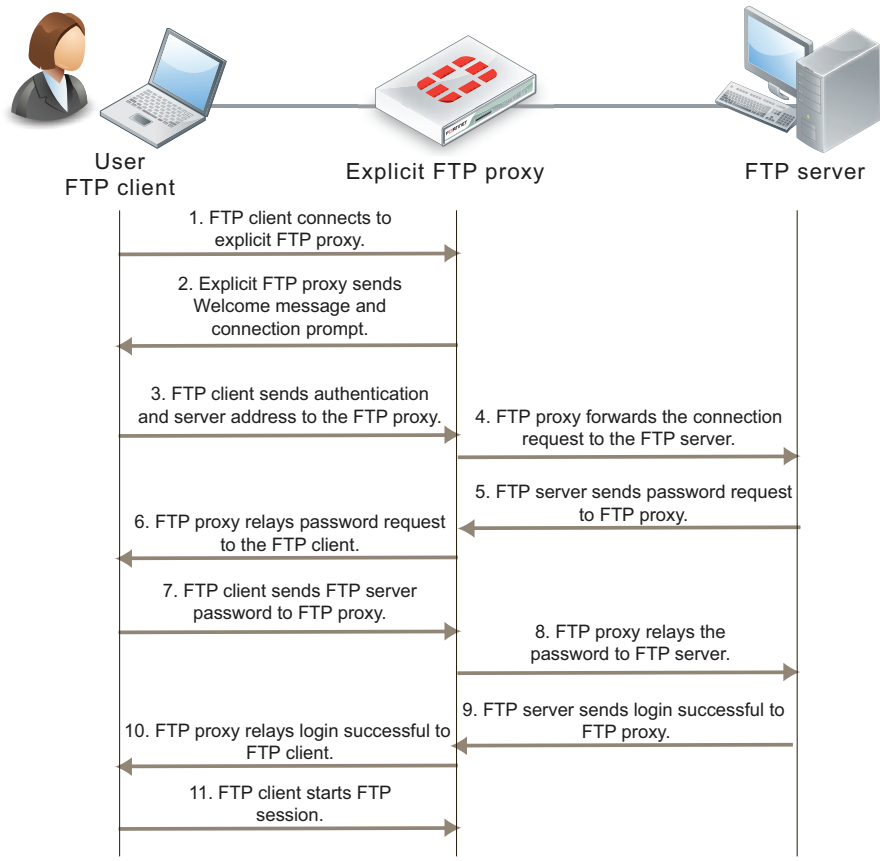
9 The FTP server sends a login successful message to the FTP proxy.

10 The FTP proxy relays the login successful message to the FTP client.

11 The FTP client starts the FTP session.

   All commands entered by the client are relayed by the proxy to the server. Replies from the server are relayed back to the FTP client.

Figure 342: Explicit FTP proxy session



From a simple command line FTP client connecting to an the previous sequence could appear as follows:

```
ftp 10.31.101.100 21
Connected to 10.31.101.100.
220 Welcome to Fortigate FTP proxy
Name (10.31.101.100:user): p-name:p-pass:s-name@ftp.example.com
331 Please specify the password.
Password: s-pass
230 Login successful.
Remote system type is UNIX
Using binary mode to transfer files.
ftp>
```

Explicit FTP proxy configuration overview

You can use the following general steps to configure the explicit FTP proxy.

To enable the explicit FTP proxy - web-based manager

1 Go to *System* > *Network* > *Explicit Proxy* > *Explicit FTP Proxy Options*. Select *Enable Explicit FTP Proxy* to turn on the explicit FTP proxy.

2 Select Apply.

The default explicit FTP proxy configuration has *Default Firewall Policy Action* set to *Deny* and requires you to add a security policy to allow access to the explicit FTP proxy. This configuration is recommended and is a best practice because you can use security policies to control access to the explicit web proxy and also apply security features such as logging, UTM, and authentication (by adding identity-based policies).

3 Go to *System* > *Network* > *Interface* and select one or more interfaces for which to enable the explicit web proxy. Edit the interface configuration and select Enable Explicit FTP Proxy.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

4 Go to *Policy* > *Policy* > *Policy* and select Create New and set the *Source Interface/Zone* to *ftp-proxy.*

You can add multiple ftp-proxy security policies.

5 Configure the security policy as required to accept the traffic that you want to be processed by the explicit web proxy.

The source address of the policy should match client source IP addresses. The firewall address selected as the source address cannot be assigned to a FortiGate interface. The Interface field of the firewall address must be blank or it must be set to *Any*.

The destination address of the policy should match the IP addresses of FTP servers that clients are connecting to. The destination address could be *all* to allow connections to any FTP server.

If *Default Firewall Policy Action* is set to Deny, traffic sent to the explicit FTP proxy that is not accepted by an ftp-proxy security policy is dropped. If *Default Firewall Policy Action* is set to Allow then all web-proxy sessions that don't match with a security policy are allowed.

For example the following security policy allows users on an internal network to access FTP servers on the Internet through the wan1 interface of a FortiGate unit.

Source Interface/Zone	ftp-proxy
Source Address	Internal_subnet
Destination Interface/Zone	wan1
Destination Address	all
Action	ACCEPT

6 You can select other security policy options as required.

For example, you can apply UTM protection to web proxy sessions and log allowed ftp proxy traffic.

7 You can also select *Enable Identity Based Policy* to apply authentication to explicit web proxy sessions.

To add identity based policies you must first add user groups to the FortiGate authentication configuration.

8 You can add multiple identity based policies to apply different authentication for different user groups and also apply different UTM and logging settings for different user groups.

To enable the explicit web proxy - CLI

1 Enter the following command to turn on the explicit FTP proxy. This command also changes the explicit FTP proxy port to 2121.

```
config ftp-proxy explicit
  set status enable
  set incoming-port 2121
end
```

The default explicit FTP proxy configuration has `sec-default-action` set to `deny` and requires you to add a security policy to allow access to the explicit FTP proxy.

1 Enter the following command to enable the explicit FTP proxy for the internal interface.

```
config system interface
  edit internal
    set explicit-ftp-proxy enable
  end
end
```

2 Use the following command to add a firewall address that matches the source address of users who connect to the explicit FTP proxy.

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
  end
```

The source address for a ftp-proxy security policy cannot be assigned to a FortiGate unit interface.

3 Use the following command to add a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the Internet.

```
config firewall policy
  edit 2
    set srcintf ftp-proxy
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set identity-based enable
    set schedule always
      config identity-based-policy
        edit 1
          set groups Internal_users
          set utm-status enable
          set profile-protocol-options default
          set av-profile Scan
          set logtraffic enable
          set schedule always
          set service ANY
```

```
        end
    end
```

The firewall address selected as the source address cannot be assigned to a FortiGate unit interface. Either the field must be blank or it must be set to *Any*.

Restricting the IP address of the explicit FTP proxy

You can use the following command to restrict access to the explicit FTP proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require uses to connect to the IP address 10.31.101.100 to connect to the explicit FTP proxy:

```
config ftp-proxy explicit
  set incoming-ip 10.31.101.100
end
```

Restricting the outgoing source IP address of the explicit FTP proxy

You can use the following command to restrict the source address of outgoing FTP proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config ftp-proxy explicit
  set outgoing-ip 172.20.120.100
end
```

UTM features and the explicit FTP proxy

You can apply protocol options, antivirus, and data leak prevention (DLP) including DLP archiving to explicit FTP proxy sessions. UTM features are applied by selecting them in a ftp proxy security policy or an identity based policy in a FTP proxy security policy. You cannot apply intrusion protection (IPS), or application control to explicit FTP proxy sessions.

To apply intrusion protection to explicit FTP proxy traffic you can add DoS policies to the FortiGate interfaces that receive and send explicit FTP proxy traffic. However, you cannot apply application control to explicit FTP proxy traffic, so you cannot filter explicit FTP proxy traffic by application and explicit FTP proxy traffic does not contribute to application control monitoring or reporting.

Explicit FTP proxy sessions and protocol options

Since the traffic accepted by the explicit FTP proxy is known to be FTP and since the ports are already known by the proxy, the explicit FTP proxy does not use the FTP port protocol options settings.

When adding UTM features to an FTP proxy security policy, you must select a protocol options profile. In most cases you can select the default protocol options profile. You could also create a custom protocol options profile.

The explicit FTP proxy supports the following protocol options:

- FTP oversized file action and threshold

The explicit FTP proxy does not support the following protocol options:

- Client comforting
- Server comforting
- Monitor content information from dashboard. URLs visited by explicit FTP proxy users are not added to dashboard usage and log and archive statistics widgets.

Explicit FTP proxy sessions and antivirus

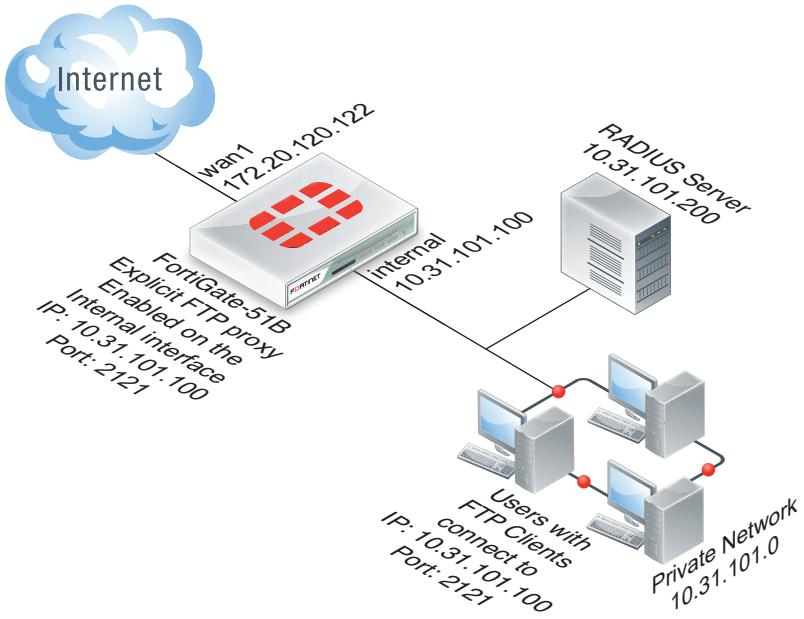
For explicit FTP proxy sessions, the FortiGate unit applies antivirus scanning to FTP file GET and PUT requests. The FortiGate unit starts virus scanning a file in an FTP session when it receives a file in the body of an FTP request.

Flow-based virus scanning is not available for explicit FTP proxy sessions. Even if the FortiGate unit is configured to use flow-based antivirus, explicit FTP proxy sessions use the regular virus database.

Example: users on an internal network connecting to FTP servers on the Internet through the explicit FTP with RADIUS authentication and virus scanning

This example describes how to configure the explicit FTP proxy for the example network shown in Figure 343. In this example, users on the internal network connect to the explicit FTP proxy through the Internal interface with IP address 10.31.101.100 of the FortiGate-51B unit. The explicit web proxy is configured to use port 2121 so to connect to an FTP server on the Internet users must first connect to the explicit FTP proxy using IP address 10.31.101.100 and port 2121.

Figure 343: Example explicit FTP proxy network topology



In this example, explicit FTP proxy users must authenticate with a RADIUS server before getting access to the proxy. To apply authentication, the security policy that accepts explicit FTP proxy traffic includes an identity based policy that applies per session authentication to explicit FTP proxy users and includes a user group with the RADIUS server in it. The identity based policy also applies UTM virus scanning and DLP.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1 Enable the explicit FTP proxy and change the FTP port to 2121.

2 Enable the explicit FTP proxy on the internal interface.

3 Add a RADIUS server and user group for the explicit FTP proxy.

4 Add a security policy for the explicit FTP proxy.

Add an identity based policy to the security policy to support authentication. Enable antivirus and DLP UTM features for the identity-based policy.

Configuring the explicit FTP proxy - web-based manager

Use the following steps to configure the explicit FTP proxy from FortiGate web-based manager.

To enable and configure the explicit FTP proxy - web-based manager

1 Go to *System* > *Network* > *Explicit Proxy* > *Explicit FTP Proxy Options* and change the following settings:

Enable Explicit FTP Proxy	Select.
Listen on Interface	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
FTP Port	2121
Default Firewall Policy Action	Deny

2 Select *Apply*.

To enable the explicit FTP proxy on the Internal interface - web-based manager

1 Go to *System* > *Network* > *Interface*.

2 Edit the internal interface.

3 Select *Enable Explicit FTP Proxy.*

4 Select *OK*.

To add a RADIUS server and user group for the explicit FTP proxy - web-based manager

1 Go to *User* > *Remote* > *RADIUS*.

2 Select Create New to add a new RADIUS server:

Name	RADIUS_1
Type	Query
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

3 Go to *User* > *User Group* > *User Group* and select *Create New*.

Name	Explict_proxy_user_group
Type	Firewall
Members	RADIUS_1

4 Select OK.

To add a security policy for the explicit FTP proxy - web-based manager

1 Go to *Firewall Objects* > *Address* > *Address* and select Create New.

2 Add a firewall address for the internal network:

Address Name	Internal_subnet
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.[1-255]
Interface	Any

3 Go to *Policy* > *Policy* > *Policy* and select Create New.

4 Configure the explicit FTP proxy security policy.

Source Interface/Zone	ftp-proxy
Source Address	Internal_subnet
Destination Interface/Zone	wan1
Destination Address	all
Action	ACCEPT

5 Select Enable Identity Based Policy, make sure *IP Based* is not selected and *Auth Method* is set to *Basic*.

6 Select Add and configure the following settings for the identity based policy:

User Group	Explicit_policy
UTM	Select
Enable Antivirus	default
Enable DLP Sensor	default
Protocol Options	default

7 Select OK.

Configuring the explicit FTP proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable and configure the explicit FTP proxy - CLI

1 Enter the following command to enable the explicit FTP proxy and set the TCP port that proxy accepts FTP connections on to 2121.

```
config ftp-proxy explicit
  set status enable
  set incoming-port 2121
  set sec-default-action deny
end
```

To enable the explicit FTP proxy on the Internal interface - CLI

1 Enter the following command to enable the explicit FTP proxy on the internal interface.

```
config system interface
```

```
  edit internal
    set explicit-ftp-proxy enable
end
```

To add a RADIUS server and user group for the explicit FTP proxy - CLI

1 Enter the following command to add a RADIUS server:

```
config user radius
  edit RADIUS_1
    set server 10.31.101.200
    set secret RADIUS_server_secret
end
```

2 Enter the following command to add a user group for the RADIUS server.

```
config user group
  edit Explicit_proxy_user_group
    set group-type firewall
    set member RADIUS_1
end
```

To add a security policy for the explicit FTP proxy - CLI

1 Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
end
```

2 Enter the following command to add the explicit FTP proxy security policy:

```
config firewall policy
  edit 0
    set srcintf web-proxy
    set dstintf wan1
    set srcaddr Internal_subnet
    set dstaddr all
    set action accept
    set schedule always
    set identity-based enable
    set ipbased disable
    set auth-method basic
      config identity-based-policy
        edit 1
          set groups Explicit_Proxy_user_group
          set schedule always
          set utm-status enable
          set av-profile default
          set dlp-sensor default
          set profile-protocol-options default
    end
end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit web proxy configuration is working as expected:

1 The user enters a command on the FTP client to connect to the explicit FTP proxy.

For example, if the IP address of the FortiGate interface on which the explicit FTP proxy is enabled is 10.31.101.100, enter:

```
ftp 10.31.101.100
```

2 The explicit FTP proxy responds with a welcome message and requests the user's FTP proxy user name and password and a username and address of the FTP server to connect to:

```
Connected to 10.31.101.100.
220 Welcome to Fortigate FTP proxy
Name (10.31.101.100:user):
```

You can change the message by editing the FTP Proxy replacement message.

3 At the prompt the user enters their FTP proxy username and password and a username and address for the FTP server. The FTP server address can be a domain name or numeric IP address. This information is entered using the following syntax:

```
<proxy-user>:<proxy-password>:<server-user>@<server-address>
```

For example, if the proxy username and password are `p-name` and `p-pass` and a valid username for the FTP server is `s-name` and the server's IP address is `ftp.example.com` the syntax would be:

```
p-name:p-pass:s-name@ftp.example.com
```

If the FTP proxy accepts anonymous logins `p-name` and `p-pass` can be any characters.

4 The FTP proxy forwards the connection request, including the user name, to the FTP server.

5 If the user name is valid for the FTP server it responds with a password request prompt.

6 The FTP proxy relays the password request to the FTP client.

7 The user enters the FTP server password and the client sends the password to the FTP proxy.

8 The FTP proxy relays the password to the FTP server.

9 The FTP server sends a login successful message to the FTP proxy.

10 The FTP proxy relays the login successful message to the FTP client.

11 The FTP client starts the FTP session.

All commands entered by the client are relayed by the proxy to the server. Replies from the server are relayed back to the FTP client.

To test the explicit web proxy configuration

1 From a system on the internal network start an FTP client and enter the following command to connect to the FTP proxy:

```
ftp 10.31.101.100
```

The explicit FTP proxy should respond with a message similar to the following:

```
Connected to 10.31.101.100.
```

```
220 Welcome to Fortigate FTP proxy
Name (10.31.101.100:user):
```

2 At the prompt enter a valid username and password for the RADIUS server followed by a user name for an FTP server on the Internet and the address of the FTP server. For example, if a valid username and password on the RADIUS server is ex_name and ex_pass and you attempt to connect to an FTP server at ftp.example.com with user name s_name, enter the following at the prompt:

```
Name
   (10.31.101.100:user):ex_name:ex_pass:s_name@ftp.example.com
```

3 You should be prompted for the password for the account on the FTP server.

4 Enter the password and you should be able to connect to the FTP server.

5 Attempt to explore the FTP server file system and download or upload files.

6 To test UTM functionality, attempt to upload or download an ECAR test file. Or upload or download a tex file containing text that would be matched by the DLP sensor.

For eicar test files, go to http://eicar.org.

7 You can use the following command to display explicit web proxy sessions.

The following output shows one explicit web proxy user with user name user_1 authenticated using IP-based authentication.

```
get test wad 60
users:
user:user_1@10.31.101.20(0x40d1b170), type:IP, vfid:0,
   ref_cnt:2, user:1(0x40f18020), user_ip:1(0x40db70f0),
   timeout:alive, id: 1

Total allocated user:1

Total user count:1, shared user quota:500, shared user count:1
   form_auth_keepalive=0

Explicit proxy authentication timeout: 300 sec, timeout
   precision: 30000 msec
```

The following output shows one explicit web proxy user with user name user2 authenticated using IP-based authentication.

```
get test wad 60
users:
user:user2@10.31.101.20(0x40d1b170), type:SESSION, vfid:0,
   ref_cnt:2, user:1(0x40f18020), user_ip:1(0x40db70f0),
   timeout:alive, id: 2

Total allocated user:1

Total user count:1, shared user quota:500, shared user count:1
   form_auth_keepalive=0

Explicit proxy authentication timeout: 300 sec, timeout precision:
30000 msec
```

Explicit FTP proxy sessions and user limits

FTP clients do not open large numbers of sessions with the explicit FTP proxy. Most sessions stay open for a short while depending on how long a user is connected to an FTP server and how large the file uploads or downloads are. So unless you have large numbers of FTP users, the explicit FTP proxy should not be adding large numbers of sessions to the session table.

Explicit FTP proxy sessions and user limits are combined with explicit web proxy session and user limits. For information about explicit proxy session and user limits, see "Explicit proxy sessions and user limits" on page 2825.

Explicit FTP proxy options

To configure the explicit FTP proxy, go to *System* > *Network* > *Explicit Proxy* > *Explicit FTP Proxy Options* and configure explicit FTP proxy options. For more information about the explicit FTP proxy, see "Explicit FTP proxy configuration overview" on page 2834.

Enable Explicit FTP Proxy	Select to enable the explicit FTP proxy.
Listen on Interface	Select *Edit* to select the interface that the FortiGate unit will use to listen on. If *None* displays, you need to go to the interface that you want to use to listen on and select *Enable FTP Proxy*.
FTP Port	Enter the port number for the FTP server.
Default Firewall Policy Action	apply the action that the default security policy will take with regards to the explicit FTP proxy activity.

FortiGate WCCP

The Web Cache Communication Protocol (WCCP) can be used to provide web caching with load balancing and fault tolerance. In a WCCP configuration, a WCCP server receives HTTP requests from user's web browsers and redirects the requests to one or more WCCP clients. The clients either return cached content or request new content from the destination web servers before caching it and returning it to the server which in turn returns the content to the original requestor. If a WCCP configuration includes multiple WCCP clients, the WCCP server load balances traffic among the clients and can detect when a client fails and failover sessions to still operating clients. WCCP is described by the Web Cache Communication Protocol internet draft.

The sessions that are cached by WCCP depend on the configuration of the WCCP clients. If the client is a FortiGate unit, you can configure the port numbers and protocol number of the sessions to be cached. For example, to cache HTTPS traffic on port 443 the WCCP client port must be set to 443 and protocol must be set to 6. If the WCCP client should also cache HTTPS traffic on port 993 the client ports option should include both port 443 and 993.

WCCP sessions are accepted by a security policy before being cached. If the security policy that accepts sessions that do not match the port and protocol settings in the WCCP clients the traffic is dropped.

WCCP is configured per-VDOM. A single VDOM can operate as a WCCP server or client (not both at the same time). FortiGate units are compatible with third-party WCCP clients and servers. If a FortiGate unit is operating as an Internet firewall for a private network, you can configure it to cache and serve some or all of the web traffic on the private network using WCCP by adding one or more WCCP clients, configuring WCCP server settings on the FortiGate unit and adding WCCP to security policies that accept HTTP session from the private network.

FortiGate units support WCCPv1 and WCCPv2. A FortiGate unit in NAT/Route or transparent mode can operate as a WCCP server. To operate as a WCCP client a FortiGate unit must be in NAT/Route mode. FortiGate units communicate between WCCP servers and clients uses UDP port 2048. This communication can be encapsulated in a GRE tunnel or just use layer 2 forwarding.

A WCCP server can also be called a WCCP router. A WCCP client can also be called a WCCP cache engine.

This section describes:

- WCCP service groups, service numbers, service IDs and well known services
- WCCP configuration overview
- Example: caching HTTP sessions on port 80 using WCCP
- Example: caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP
- WCCP packet flow
- Configuring the forward and return methods and adding authentication

WCCP service groups, service numbers, service IDs and well known services

A FortiGate unit configured as a WCCP server or client can include multiple server or client configurations. Each of these configurations is called a WCCP service group. A service group consists of one or more WCCP servers (or routers) and one or more WCCP clients working together to cache a specific type of traffic. The service group configuration includes information about the type of traffic to be cached, the addresses of the WCCP clients and servers and other information about the service.

A service group is identified with a numeric WCCP service ID (or service number) in the range 0 to 255. All of the servers and clients in the same WCCP service group must have service group configurations with the same WCCP service ID.

The value of the service ID provides some information about the type of traffic to be cached by the service group. Service IDs in the range 0 to 50 are reserved for well known services. A well known service is any service that is defined by the WCCP standard as being well known. Since the service is well known, just the service ID is required to identify the traffic to be cached.

Even though the well known service ID range is 0 to 50, at this time only one well known service has been defined. Its service ID 0, which is used for caching HTTP (web) traffic.

So to configure WCCP to cache HTTP sessions you can add a service group to the WCCP router and WCCP clients with a service ID of 0. No other information about the type of traffic to cache needs to be added to the service group.

Since service IDs 1 to 50 are reserved for well know services and since these services are not defined yet, you should not add service groups with IDs in the range 1 to 50.

FortiOS does allow you to add service groups with IDs between 1 and 50. Since these service groups have not been assigned well known services; however, they will not cache any sessions. Service groups with IDs 51 to 255 allow you to set the port numbers and protocol number of the traffic to be cached. So you can use service groups with IDs 51 to 255 to cache different kinds of traffic based on port numbers and protocol number of the traffic. Service groups 1 to 50; however, do not allow you to set port numbers or protocol numbers so cannot be used to cache any traffic.

To cache traffic other than HTTP traffic you must add service groups with IDs in the range 51 to 255. These service group configurations must include the port numbers and protocol number of the traffic to be cached. It is the port and protocol number configuration in the service group that determines what traffic will be cached by WCCP.

Example WCCP server and client configuration for caching HTTP sessions (service ID = 0)

Enter the following command to add a WCCP service group to a WCCP server that caches HTTP sessions. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service

ID of this service group is 0.

```
config system wccp
  edit 0
    set router-id 10.31.101.100
```

```
    set server-list 10.31.101.0 255.255.255.0
  end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures the client to cache HTTP sessions. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group is 0.

```
config system settings
  set wccp-cache-engine enable
end

config system wccp
  edit 0
    set cache-id 10.31.101.1
    set router-list 10.31.101.100
  end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named w.<vdom_name> is added to the FortiGate configuration (for example w.root). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

Example WCCP server and client configuration for caching HTTPS sessions

Enter the following command to add a service group to a WCCP server that caches HTTPS content on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 80.

```
config system wccp
  edit 80
    set router-id 10.31.101.100
    set server-list 10.31.101.0 255.255.255.0
    set ports 443
    set protocol 6
  end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTPS sessions on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 80 to match the service ID added to the server.

```
config system settings
  set wccp-cache-engine enable
end

config system wccp
  edit 80
    set cache-id 10.31.101.1
    set router-list 10.31.101.100
    set ports 443
    set protocol 6
  end
```

Example WCCP server and client configuration for caching HTTP and HTTPS sessions

You could do this by configuring two WCCP service groups as described in the previous examples. Or you could use the following commands to configure one service group for both types of traffic. The example also caches HTTP sessions on port 8080.

Enter the following command to add a service group to a WCCP server that caches HTTP sessions on ports 80 and 8080 and HTTPS sessions on port 443. Both of these protocols use protocol number 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 90.

```
config system wccp
  edit 90
    set router-id 10.31.101.100
    set server-list 10.31.101.0 255.255.255.0
    set ports 443 80 8080
    set protocol 6
  end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTP sessions on port 80 and 8080 and HTTPS sessions on port 443. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 90 to match the service ID added to the server.

```
config system settings
  set wccp-cache-engine enable
end

config system wccp
  edit 90
    set cache-id 10.31.101.1
    set router-list 10.31.101.100
    set ports 443 80 8080
    set protocol 6
  end
```

Other WCCP service group options

In addition to using WCCP service groups to define the types of traffic to be cached by WCCP the following options are available for servers and clients.

Server configuration options

The server configuration must include the `router-id`, which is the WCCP server IP address. This is the IP address of the interface that the server uses to communicate with WCCP clients.

The `group-address` is used for multicast WCCP configurations to specify the multicast addresses of the clients.

The `server-list` defines the IP addresses of the WCCP clients that the server can connect to. Often the server list can be the address of the subnet that contains the WCCP clients.

The `authentication` option enables or disables authentication for the WCCP service group. Authentication must be enabled on all servers and clients in a service group and members of the group must have the same `password`.

The `forward-method` option specifies the protocol used for communication between the server and clients. The default forwarding method is GRE encapsulation. If required by your network you can also select to use unencapsulated layer-2 packets instead of GRE or select any to allow both. The `return-method` allows you to specify the communication method from the client to the server. Both GRE and layer-2 are supported.

The `assignment-method` determines how the server load balances sessions to the clients if there are multiple clients. Load balancing can be done using hashing or masking.

Client configuration options

The client configuration includes the `cache-id` which is the IP address of the FortiGate interface of the client that communicates with WCCP server. The `router-list` option is the list of IP addresses of the WCCP servers in the WCCP service group.

The `ports` option lists the port numbers of the sessions to be cached by the client and the `protocol` sets the protocol number of the sessions to be cached. For TCP sessions the protocol is 6.

The `service-type` option can be auto, dynamic or standard. Usually you would not change this setting.

The client configuration also includes options to influence load balancing including the `primary-hash`, `priority`, `assignment-weight` and `assignment-bucket-format`.

WCCP configuration overview

To configure WCCP you must create a service group that includes WCCP servers and clients. WCCP servers intercept sessions to be cached (for example, sessions from users browsing the web from a private network). To intercept sessions to be cached the WCCP server must include a security policy that accepts sessions to be cached and WCCP must be enabled in this security policy.

The server must have an interface configured for WCCP communication with WCCP clients. That interface sends and receives encapsulated GRE traffic to and from WCCP clients. The server must also include a WCCP service group that includes a service ID and the addresses of the WCCP clients as well as other WCCP configuration options.

To use a FortiGate unit as a WCCP client, the FortiGate unit must be set to be a WCCP client (or cache engine). You must also configure an interface on the client for WCCP communication. The client sends and receives encapsulated GRE traffic to and from the WCCP server using this interface.

The client must also include a WCCP service group with a service ID that matches a service ID on the server. The client service group also includes the IP address of the servers in the service group and specifies the port numbers and protocol number of the sessions that will be cached on the client.

When the client receives sessions from the server on its WCCP interface, it either returns cached content over the WCCP interface or connects to the destination web servers using the appropriate interface depending on the client routing configuration. Content received from web servers is then cached by the client and returned to the WCCP server over the WCCP link. The server then returns the received content to the initial requesting user web browser.

Finally you may also need to configure routing on the server and client FortiGate units and additional security policies may have to be added to the server to accept sessions not cached by WCCP.

Example: caching HTTP sessions on port 80 using WCCP

In this example configuration (shown in Figure 344), a FortiGate unit with host name WCCP_srv is operating as an Internet firewall for a private network is also configured as a WCCP server. The port1 interface of WCCP_srv is connected to the Internet and the port2 interface is connected to the internal network.

All HTTP traffic on port 80 that is received at the port2 interface of WCCP_srv is accepted by a port2 to port1 security policy with WCCP enabled. All other traffic received at the port2 interface is allowed to connect to the Internet by adding a general port2 to port1 security policy below the HTTP on port 80 security policy.

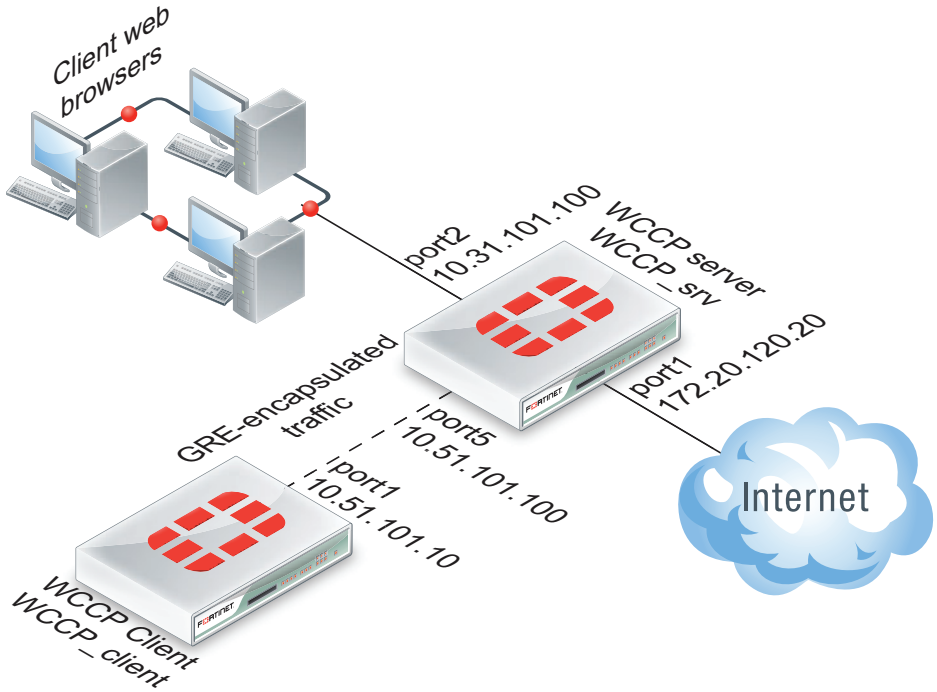
A WCCP service group is added to WCCP_srv with a service ID of 0 for caching HTTP traffic on port 80. The port5 interface of WCCP_srv is configured for WCCP communication.

A second FortiGate unit with host name WCCP_client is operating as a WCCP client. The port1 interface of WCCP_client is connected to port5 of WCCP_srv and is configured for WCCP communication.

WCCP_client is configured to cache HTTP traffic because it also has a WCCP service group with a service ID of 0.

WCCP_client connects to the Internet through WCCP_srv. To allow this, a port5 to port1 security policy is added to WCCP_srv.

Figure 344: FortiGate WCCP server and client configuration



Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1 Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and is configured for WCCP:

```
config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service HTTP
    set wccp enable
    set nat enable
end
```

2 Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```
.config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
end
```

3 Move this policy below the WCCP policy in the port2 to port1 policy list.

4 Enable WCCP on the port5 interface.

```
config system interface
  edit port5
    set wccp enable
end
```

5 Add a WCCP service group with service ID 0.

```
config system wccp
  edit 0
    set router-id 10.51.101.100
    set server-list 10.51.101.0 255.255.255.0
end
```

6 Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```
config firewall address
  edit WCCP_client_addr
    set subnet 10.51.101.10
end
```

```
config firewall policy
  edit 0
    set srtintf port5
    set dstintf port1
    set srcaddr WCCP_client_addr
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
end
```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1 Configure WCCP_client to operate as a WCCP client.

```
config system settings
  set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named w.<vdom_name> is added to the FortiGate configuration (for example w.root). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2 Enable WCCP on the port1 interface.

```
config system interface
  edit port1
    set wccp enable
end
```

3 Add a WCCP service group with service ID 0.

```
config system wccp
  edit 0
    set cache-id 10.51.101.10
    set router-list 10.51.101.100
end
```

Example: caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP

This example configuration is the same as that shown in Figure 344 and described in "Example: caching HTTP sessions on port 80 using WCCP" on page 2850 except that WCCP now also cached HTTPS traffic on port 443. To cache HTTP and HTTPS traffic the WCCP service group must have a service ID in the range 51 to 255 and you must specify port 80 and 443 and protocol 6 in the service group configuration of the WCCP client.

Also the security policy on the WCCP_srv that accepts sessions from the internal network to be cached must accept HTTP and HTTPS sessions.

Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1 Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and HTTPS traffic on port 443 and is configured for WCCP:

```
config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service HTTP HTTPS
    set wccp enable
    set nat enable
end
```

2 Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```
.config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
end
```

3 Move this policy below the WCCP policy in the port2 to port1 policy list.

4 Enable WCCP on the port5 interface.

```
config system interface
  edit port5
    set wccp enable
end
```

5 Add a WCCP service group with service ID 90 (can be any number between 51 and 255).

```
config system wccp
  edit 90
    set router-id 10.51.101.100
    set server-list 10.51.101.0 255.255.255.0
end
```

6 Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```
config firewall address
  edit WCCP_client_addr
    set subnet 10.51.101.10
```

```
end

.config firewall policy
  edit 0
    set srtintf port5
    set dstintf port1
    set srcaddr WCCP_client_addr
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
end
```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1 Configure WCCP_client to operate as a WCCP client.

```
config system settings
  set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named w.<vdom_name> is added to the FortiGate configuration (for example w.root). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2 Enable WCCP on the port1 interface.

```
config system interface
  edit port1
    set wccp enable
end
```

3 Add a WCCP service group with service ID 90. This service group also specifies to cache sessions on ports 80 and 443 (for HTTP and HTTPS) and protocol number 6.

```
config system wccp
  edit 90
    set cache-id 10.51.101.10
    set router-list 10.51.101.100
    ports 80 443
    set protocol 6
end
```

WCCP packet flow

The following packet flow sequence assumes you have configured a FortiGate unit to be a WCCP server and one or more FortiGate units to be WCCP clients.

1 A user's web browser sends a request for web content.

2 The FortiGate unit configured as a WCCP server includes a security policy that intercepts the request and forwards it to a WCCP client.

   The security policy can apply UTM features to traffic accepted by the policy.

3 The WCCP client receives the WCCP session.

4 The client either returns requested content to the WCCP server if it is already cached, or connects to the destination web server, receives and caches the content and then returns it to the WCCP server.

5 The WCCP server returns the requested content to the user's web browser.

6 The WCCP router returns the request to the client web browser.

   The client we browser is not aware that all this is taking place and does not have to be configured to use a web proxy.

Configuring the forward and return methods and adding authentication

The WCCP forwarding method determines how intercepted traffic is transmitted from the WCCP router to the WCCP cache engine. There are two different forwarding methods:

- GRE forwarding (the default) encapsulates the intercepted packet in an IP GRE header with a source IP address of the WCCP router and a destination IP address of the target WCCP cache engine. The results is a tunnel that allows the WCCP router to be multiple hops away from the WCCP cache server.
- L2 forwarding rewrites the destination MAC address of the intercepted packet to match the MAC address of the target WCCP cache engine. L2 forwarding requires that the WCCP router is Layer 2 adjacent to the WCCP client.

You can use the following command on a FortiGate unit configured as a WCCP router to change the forward and return methods to L2:

```
config system wccp
  edit 1
    set forward-method L2
    set return-method L2
end
```

You can also set the forward and return methods to any in order to match the cache server configuration.

By default the WCCP communication between the router and cache servers is unencrypted. If you are concerned about attackers sniffing the information in the WCCP stream you can use the following command to enable hash-based authentication of the WCCP traffic. You must enable authentication on the router and the cache engines and all must have the same password.

```
config system wccp
  edit 1
    set authentication enable
    set password <password>
end
```

WCCP Messages

When the WCCP service is active on a web cache server it periodically sends a WCCP HERE I AM broadcast or unicast message to the FortiGate unit operating as a WCCP router. This message contains the following information:

- Web cache identity (the IP address of the web cache server).
- Service info (the service group to join).

If the information received in the previous message matches what is expected, the FortiGate unit replies with a WCCP I SEE YOU message that contains the following details:

• Router identity (the FortiGate unit's IP address.

• Sent to IP (the web cache IP addresses to which the packets are addressed)

When both ends receive these two messages the connection is established, the service group is formed and the designated web cache is elected.

Troubleshooting WCCP

Two types of debug commands are available for debugging or troubleshooting a WCCP connection between a FortiGate unit operating as a WCCP router and its WCCP cache engines.

Real time debugging

The following commands can capture live WCCP messages:

```
diag debug en
diag debug application wccpd <debug level>
```

Application debugging

The following commands display information about WCCP operations:

```
get test wccpd <integer>
diag test application wccpd <integer>
```

Where `<integer>` is a value between 1 and 5:

1 Display WCCP stats

2 Display WCCP config

3 Display WCCP cache servers

4 Display WCCP services

5 Display WCCP assignment

Enter the following command to view debugging output:

```
diag test application wccpd 3
```

Sample output from a successful WCCP connection:

```
service-0 in vdom-root: num=1, usable=1
cache server ID:
len=44, addr=172.16.78.8, weight=4135, status=0
rcv_id=6547, usable=1, fm=1, nq=0, dev=3(k3),
to=192.168.11.55
ch_no=0, num_router=1:
192.168.11.55
```

Sample output from the same command from an unsuccessful WCCP connection (because of a service group password mismatch):

```
service-0 in vdom-root: num=0, usable=0
diag debug application wccpd -1
Sample output:
wccp_on_recv()-98: vdom-root recv: num=160, dev=3(3),
172.16.78.8->192.168.11.55
wccp2_receive_pkt()-1124: len=160, type=10, ver=0200,
length=152
wccp2_receive_pkt()-1150: found component:t=0, len=20
wccp2_receive_pkt()-1150: found component:t=1, len=24
wccp2_receive_pkt()-1150: found component:t=3, len=44
wccp2_receive_pkt()-1150: found component:t=5, len=20
wccp2_receive_pkt()-1150: found component:t=8, len=24
wccp2_check_security_info()-326: MD5 check failed
```

WAN optimization, web cache, explicit proxy and WCCP get and diagnose commands

The following get and diagnose commands are available for troubleshooting WAN optimization, web cache, explicit proxy and WCCP.

- get test {wa_cs | wa_dbd | wad | wad_diskd | wccpd} <test_level>
- diagnose wad
- diagnose wacs
- diagnose wadbd
- diagnose debug application {wa_cs | wa_dbd | wad | wad_diskd | wccpd} [<debug_level>]

get test {wa_cs | wa_dbd | wad | wad_diskd | wccpd} <test_level>

Display usage information about WAN optimization and web-cache-related applications. Use `<test_level>` to display different information.

```
get test wa_cs <test_level>
get test wa_dbd <test_level>
get test wad <test_level>
get test wad_diskd <test_level>
get test wccpd <test_level>
```

Variable	Description
`wad`	Display information about WAN optimization, web caching, the explicit web proxy, and the explicit FTP proxy.
`wa_cs`	Display information about the WAN optimization web cache server.
`wa_dbd`	Display information about the WAN optimization storage server application.
`wad_diskd`	Display information about the WAN optimization disk access daemon application.
`wccpd`	Display information about the WCCP application.

Examples

Enter the following command to display WAN optimization tunnel protocol statistics. The http tunnel and tcp tunnel parts of the command output below shows that WAN optimization has been processing HTTP and TCP packets.

```
get test wad 11
wad tunnel protocol stats:
  http tunnel
```

```
    bytes_in=1751767 bytes_out=325468
  ftp tunnel
    bytes_in=0 bytes_out=0
  cifs tunnel
    bytes_in=0 bytes_out=0
  mapi tunnel
    bytes_in=0 bytes_out=0
  tcp tunnel
    bytes_in=3182253 bytes_out=200702
  maintenance tunnel
    bytes_in=11800 bytes_out=15052
```

Enter the following command to display the current WAN optimization peers. You can use this command to make sure all peers are configured correctly. The command output shows one peer with IP address 172.20.120.141, peer name Web_servers, with 10 active tunnels.

```
get test wad 26
peer name=Web_servers ip=172.20.120.141 vd=0 version=1
   tunnels(active/connecting/failover)=10/0/0
     sessions=0 n_retries=0 version_valid=true
```

Enter the following command to restart the WAN optimization web cache server.

```
get test wa_cs 99
```

Enter the following command to display all test options:

```
get test wad

WAD Test Usage
1: display total memory usage
   3: display proxy status
   4: display all stats and connections
   5: toggle AV conserve mode(for debug purpose).
   8: display all fix-sized advanced memory stats
  10: toggle cifs read-ahead
  11: display tunnel protocol stats
  12: flush tunnel protocol stats
  13: display http protocol stats
  14: flush http protocol stats
  15: display cifs protocol stats
  16: flush cifs protocol stats
  17: display ftp protocol stats
  18: flush ftp protocol stats
  19: display mapi protocol stats
  20: flush mapi protocol stats
  21: display tcp protocol stats
  22: flush tcp protocol stats
  23: display all protocols stats
  24: flush all protocols stats
  25: display all listeners
  26: display all peers
  27: display DNS stats
  28: display security profile mapping for regular firewall
   policy
  30: display Byte Cache DB state
  31: flush Byte Cache DB stats
```

```
32: display Web Cache DB state
33: flush Web Cache DB stats
35: display tunnel compressor state
36: flush tunnel compressor stats
37: discard all wad debug info that is currently pending
38: display rules
39: display video cache rules (patterns)
40: display cache state
41: flush cache stats
42: display all fix-sized advanced memory stats in details
45: display memory cache state
46: flush memory cache stats
47: display SSL stats
48: flush SSL stats
49: display SSL mem stats
50: display Web Cache stats
51: flush Web Cache stats
52: flush idle Web cache objects
53: display firewall policies
54: display WAD tunnel stats.
55: display WAD fsae state.
56yxxx: set xxx concurrent Web Cache session for object
 storage y.
57yxxx: set xxxK(32K, 64K,...) unconfirmed write/read size per
 Web Cache object for object storage y.
58yxxxx: set xxxxK maximum ouput buffer size for object
 storage y.
59yxx: set lookup lowmark(only if more to define busy status)
 to be xx for object storage y.
60: display current web proxy users
61: flush current web proxy users
62: display current web proxy user summary
63: display web cache cache sessions
65: display cache exemption patterns
66: toggle dumping URL when daemon crashes.
67: list all used fqdns.
68: list all current ftpproxy sessions.
69: display ftpproxy stats.
70: clear ftpproxy stats.
600000..699999 cmem bucket stats (699999 for usage)
70yxxx: set xxxK maximum ouput buffer size for byte storage y.
71yxxx: set number of buffered add requests to be xxx for byte
 storage y.
72yxxxx: set number of buffered query requests to be xxxx for
 byte storage y.
73yxxxxx: set number of concurrent query requests to be xxxxx
 for byte storage y.
79xxxx: set xxxxMiB maximum AV memory.(0: set to default.
80: display av memory usage
81: toggle av memory protection
800..899: mem_diag commands (800 for help & usage)
800000..899999: mem_diag commands with 1 arg (800 for help &
 usage)
```

```
80000000..89999999: mem_diag commands with 2 args (800 for
 help & usage)
90: set to test disk failure
91: unset to test disk failure
92: trigger a disk failure event
98: gracefully stopping wad proxy
99: restart proxy
```

diagnose wad

Display diagnostic information about the WAN optimization daemon (wad).

```
diagnose wad console-log {disable | enable)
diagnose wad filter {clear | dport | dst | list | negate |
   protocol | sport | src | vd}
diagnose wad history
diagnose wad session
diagnose wad stats {cache | cifs | clear | crypto | ftp | http |
   list | mapi | mem | scan | scripts | summary | tcp | tunnel}
diagnose wad tunnel {clear | list}
```

Variable	Description
`console-log`	Enable or disable displaying WAN optimization log messages on the CLI console.
`filter`	Set a filter for listing WAN optimization daemon sessions or tunnels. `clear` reset or clear the current log filter settings. `dport` enter the destination port range to filter by. `dst` enter the destination address range to filter by. `list` display the current log filter settings
`history`	Display statistics for one or more WAN optimization protocols for a specified period of time (the last 10 minutes, hour, day or 30 days).
`session`	Display diagnostics for WAN optimization sessions or clear active sessions.
`stats`	Display statistics for various parts of WAN optimization such as cache statistics, CIFS statistics, MAPI statistics, HTTP statistics, tunnel statistics etc. You can also clear WAN optimization statistics and display a summary.
`tunnel`	Display diagnostic information for one or all active WAN optimization tunnels. Clear all active tunnels. Clear all active tunnels.

Examples

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual

diagnose wacs

Display diagnostic information for the web cache database daemon (wacs).

```
diagnose wacs clear
diagnose wacs recents
diagnose wacs restart
diagnose wacs stats
```

Variable	Description
clear	Remove all entries from the web cache database.
recents	Display recent web cache database activity.
restart	Restart the web cache daemon and reset statistics.
stats	Display web cache statistics.

diagnose wadbd

Display diagnostic information for the WAN optimization database daemon (waddb).

```
diagnose wadbd {check | clear | recents | restart | stats}
```

Variable	Description
check	Check WAN optimization database integrity.
clear	Remove all entries from the WAN optimization database.
recents	Display recent WAN optimization database activity.
restart	Restart the WAN optimization daemon and reset statistics.
stats	Display WAN optimization statistics.

diagnose debug application {wa_cs | wa_dbd | wad | wad_diskd | wccpd} [<debug_level>]

View or set the debug level for displaying WAN optimization and web cache-related daemon debug messages. Include a <debug_level> to change the debug level. Leave the <debug_level> out to display the current debug level. Default debug level is 0.

```
diagnose debug application wa_cs [<debug_level>]
diagnose debug application wa_dbd [<debug_level>]
diagnose debug application wad [<debug_level>]
diagnose debug application wccpd [<debug_level>]
```

Variable	Description
wa_cs	Set the debug level for the web cache server.
wa_dbd	Set the debug level for the WAN optimization database server.
wad	Set the debug level for the WAN optimization daemon.
wccpd	Set the debug level for the WCCP daemon.

Chapter 18 Load Balancing

This FortiOS Handbook chapter contains the following sections:

Configuring load balancing describes FortiGate firewall load balancing.

Load balancing configuration examples describes includes basic and advanced load balancing configurations.

Configuring load balancing

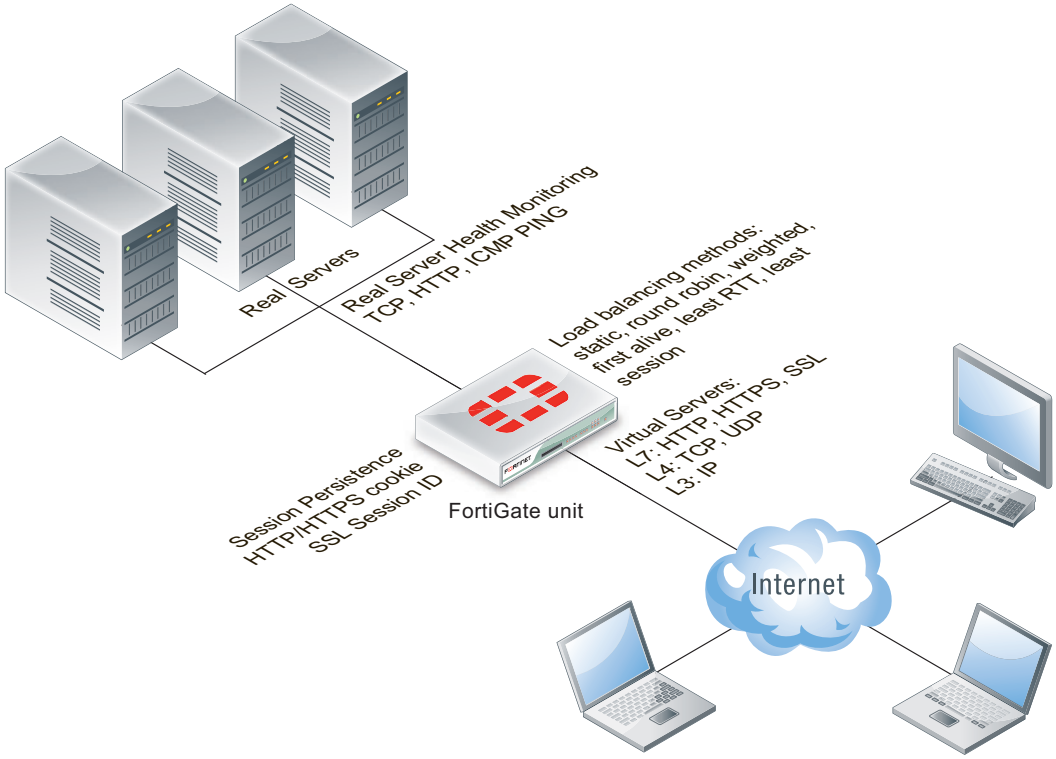
This section describes how to use the FortiGate firewall load balancing configuration to load balance traffic to multiple backend servers.

This section describes:

Load balancing overview

You can configure FortiOS load balancing to intercept incoming traffic with a virtual server and share it among one or more backend real servers. By doing so, the FortiGate unit enables multiple real servers to respond as if they were a single device or virtual server. This in turn means that more simultaneous requests can be handled.

Figure 345: Load balancing configuration



Traffic can be balanced across multiple backend real servers based on a selection of load balancing methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer can balance layer 7 HTTP, HTTPS, SSL, generic layer 4 TCP, UDP and generic layer 3 IP protocols. Session persistence is supported based on injected HTTP/HTTPS cookies or the SSL session ID.

You can bind up to 8 real servers can to one virtual server. The real server topology is transparent to end users, and the users interact with the system as if it were only a single server with the IP address and port number of the virtual server. The real servers may be interconnected by high-speed LAN or by geographically dispersed WAN. The FortiGate unit schedules requests to the real servers and makes parallel services of the virtual server to appear to involve a single IP address.

There are additional benefits to load balancing. First, because the load is distributed across multiple servers, the service being provided can be highly available. If one of the servers breaks down, the load can still be handled by the other servers. Secondly, this increases scalability. If the load increases substantially, more servers can be added behind the FortiGate unit in order to cope with the increased load.

Load balancing, UTM, authentication, and other FortiOS features

Flow-based and proxy-based UTM features such as virus scanning, IPS, DLP, application control, and web filtering can be applied to sessions that are to be load balanced. This includes SSL offloading and multiplexing. Applying these UTM features to load balancing traffic may reduce load balancing performance.

Authentication and dynamic profiles are not supported for load balancing sessions. Usually FortiGate load balancing is used to allow public access to services on servers protected by a FortiGate unit. Authentication is not generally not required for this kind of configuration.

Features such web proxying, web caching, and WAN optimization also do not work with load balanced sessions. However, most other features that can be applied by a security policy are supported.

Configuring load balancing virtual servers

A virtual server is a specialized firewall virtual IP that performs server load balancing. From the web-based manager you add load balancing virtual server by going to *Firewall Objects* > *Load Balance* > *Virtual Server*.

Name	Enter the name for the virtual server.
Color	Select *Change* beside the icon to change the color of the icon. When you select *Change*, a color palette window appears; select a color from the palette window.

Type	Select the protocol to be load balanced by the virtual server. If you select a general protocol such as *IP*, *TCP*, or *UDP* the virtual server load balances all IP, TCP, or UDP sessions. If you select specific protocols such as *HTTP*, *HTTPS*, or *SSL* you can apply additional server load balancing features such as *Persistence* and *HTTP Multiplexing*. • Select *HTTP* to load balance only HTTP sessions with destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced (usually port 80 for HTTP sessions). You can also select *HTTP Multiplex*. You can also set *Persistence* to *HTTP Cookie* to select cookie-based persistence. • Select *HTTPS* to load balance only HTTPS sessions with destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced (usually port 443 for HTTPS sessions). You can also select *HTTP Multiplex.* You can also set *Persistence* to *HTTP Cookie* to select cookie-based persistence. You can also set *Persistence* to *SSL Session ID*. • Select *IP* to load balance all sessions accepted by the security policy that contains this virtual server. • Select *SSL* to load balance only SSL sessions with destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced. • Select *TCP* to load balance only TCP sessions with destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced. • Select *UDP* to load balance only UDP sessions with destination port number that matches the *Virtual Server Port* setting. Change *Virtual Server Port* to match the destination port of the sessions to be load balanced.
Interface	Select the virtual server external interface from the list. The external interface is connected to the source network and receives the packets to be forwarded to the destination network.
Virtual Server IP	The IP address of the virtual server. This is an IP address on the external interface that you want to map to an address on the destination network.
Virtual Server Port	Enter the external port number that you want to map to a port number on the destination network. Sessions with this destination port are load balanced by this virtual server.
Load Balance Method	Select the load balancing method used by the virtual server. See “Load balancing methods” on page 2873.
Persistence	Configure persistence to make sure that a user is connected to the same server every time they make a request that is part of the same session. See “Session persistence” on page 2874. For HTTP and HTTPS sessions, see “HTTP and HTTPS persistence” on page 2886.

HTTP Multiplexing	Select to use the FortiGate unit to multiplex multiple client connections into a few connections between the FortiGate unit and the real server. See "HTTP and HTTPS multiplexing" on page 2885.
Preserve Client IP	Select to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful if you want log messages on the real servers to the client's original IP address. If this option is not selected, the header will contain the IP address of the FortiGate unit. This option appears only if *HTTP* or *HTTS* are selected for *Type*, and is available only if *HTTP Multiplexing* is selected.
SSL Offloading	Select to accelerate clients' SSL connections to the server by using the FortiGate FortiGate unit to perform SSL operations, then select which segments of the connection will receive SSL offloading. See "SSL offloading" on page 2890
Certificate	Select the certificate to use with *SSL Offloading*. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported. This option appears only if *HTTPS* or *SSL* are selected for *Type*, and is available only if *SSL Offloading* is selected.
Health Check	Select which health check monitor configuration will be used to determine a server's connectivity status. See "Health check monitoring" on page 2876.

From the CLI you configure a virtual server by added a firewall virtual IP and setting the virtual IP type to server load balance:

```
config firewall vip
  edit Vserver-HTTP-1
    set type server-load-balance
    ...
```

A virtual server includes a virtual server IP address bound to an interface. The virtual server IP address is the destination address incoming packets to be load balanced and the virtual server is bound to the interface that receives the packets to be load balanced.

For example, if you want to load balance incoming HTTP traffic from the Internet to a group of web servers on a DMZ network, the virtual server IP address is the known Internet IP address of the web servers and the virtual server binds this IP address to the FortiGate interface connected to the Internet.

When you bind the virtual server's external IP address to a FortiGate unit interface, by default, the network interface responds to ARP requests for the bound IP address. Virtual servers use proxy ARP, as defined in RFC 1027, so that the FortiGate unit can respond to ARP requests on a network for a real server that is actually installed on another network. In some cases you may not want the network interface sending ARP replies. You can use the `arp-reply` option disable sending ARP replies:

```
config firewall vip
  edit Vserver-HTTP-1
    set type server-load-balance
    set arp-reply disable
    ...
```

The load balancing virtual server configuration also includes the virtual server port. This is the TCP port on the bound interface that the virtual server listens for traffic to be load balanced on. The virtual server can listen on any port.

Load balancing methods

The load balancing method defines how sessions are load balanced to real servers. A number of load balancing methods are available as listed in Table 150.

All load balancing methods will not send traffic to real servers that are down or not responding. However, the FortiGate unit can only determine if a real server is not responding by using a health check monitor. You should always add at least one health check monitor to a virtual server or to individual real servers, or load balancing methods may attempt to distribute sessions to real servers that are not functioning.

Table 150: Load balancing methods

Method	Description
Source IP Hash	The traffic load is statically spread evenly across all real servers. However, sessions are not assigned according to how busy individual real servers are. This load balancing method provides some persistence because all sessions from the same source address always go to the same real server. However, the distribution is stateless, so if a real server is added or removed (or goes up or down) the distribution is changed and persistence could be lost.
Round Robin	Directs new requests to the next real server, and treats all real servers as equals regardless of response time or number of connections. Dead real servers or non responsive real servers are avoided.
Weighted	Real servers with a higher weight value receive a larger percentage of connections. Set the real server weight when adding a real server.
First Alive	Always directs sessions to the first alive real server. This load balancing schedule provides real server failover protection by sending all sessions to the first alive real server and if that real server fails, sending all sessions to the next alive real server. Sessions are not distributed to all real servers so all sessions are processed by the “first” real server only. First refers to the order of the real servers in the virtual server configuration. For example, if you add real servers A, B and C in that order, then all sessions always go to A as long as it is alive. If A goes down then sessions go to B and if B goes down sessions go to C. If A comes back up sessions go back to A. Real servers are ordered in the virtual server configuration in the order in which you add them, with the most recently added real server last. If you want to change the order you must delete and re-add real servers in the required order.
Least RTT	Directs sessions to the real server with the least round trip time. The round trip time is determined by a Ping health check monitor and is defaulted to 0 if no Ping health check monitors are added to the virtual server.
Least Session	Directs requests to the real server that has the least number of current connections. This method works best in environments where the real servers or other equipment you are load balancing all have similar capabilities. This load balancing method uses the FortiGate session table to track the number of sessions being processed by each real server. The FortiGate unit cannot detect the number of sessions actually being processed by a real server.

Table 150: Load balancing methods

Method	Description
HTTP Host	Load balances HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server.

Session persistence

Use persistence to make sure that a user is connected to the same real server every time they make an HTTP, HTTPS, or SSL request that is part of the same user session. For example, if you are load balancing HTTP and HTTPS sessions to a collection of eCommerce web servers, when a user is making a purchase they will be starting multiple sessions as they navigate the eCommerce site. In most cases all of the sessions started by this user during on eCommerce session should be processed by the same real server. Typically, the HTTP protocol keeps track of these related sessions using cookies. HTTP cookie persistence makes sure that all sessions that are part of the same user session are processed by the same real server

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the load balance method. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server. For more information about HTTP and HTTPS persistence, see "HTTP and HTTPS persistence" on page 2886.

Real servers

Add real servers to a load balancing virtual server to provide the information the virtual server requires to be able to send sessions to the server. A real server configuration includes the IP address of the real server and port number that the real server receives sessions on. The FortiGate unit sends sessions to the real server's IP address using the destination port number in the real server configuration.

When configuring a real server you can also specify the weight (used if the load balance method is set to weighted) and you can limit the maximum number of open connections between the FortiGate unit and the real server. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests other real servers until the connection number drops below the specified limit. Setting Maximum Connections to 0 means that the FortiGate unit does not limit the number of connections to the real server.

Real server active, standby, and disabled modes

By default the real server mode setting is active indicating that the real server is available to receive connections. If the real server is removed from the network (for example, for routine maintenance or because of a hardware or software failure) you can change the mode to standby or disabled. In disabled mode the FortiGate unit no longer sends sessions to the real server.

If a real server is in standby mode the FortiGate also does not send sessions to it unless other real servers added to the same virtual server become unavailable. For example:

- A virtual server that includes two real servers one in active mode and one in standby mode. If the real server in active mode fails, the real server in standby mode is changed to active mode and all sessions are sent to this real server.

- A virtual server includes three real servers, two in active mode and one in standby mode, if one of the real servers in active mode fails, the real server in standby mode is changed to active mode and sessions are load balanced between it and still operating real server. If both real servers in active mode fail, all sessions are sent to the real server in standby mode.

Adding real servers

To add a real server from the web-based manager go to *Firewall Objects* > *Load Balance* > *Real Server*.

Virtual Server	Select the virtual server that will send sessions to this real server.
IP Address	Enter the IP address of the real server.
Port	Enter the port number on the destination network to which the external port number is mapped.
Weight	Enter the weight value of the real server. The higher the weight value, the higher the percentage of connections the server will handle. A range of 1-255 can be used. This option is available only if the associated virtual server's load balance method is *Weighted*.
Max Connections	Enter the limit on the number of active connections directed to a real server. A range of 1-99999 can be used. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests to another server until the connection number drops below the specified limit. Setting *Maximum Connections* to *0* means that the FortiGate unit does not limit the number of connections to the real server.
HTTP Host	Enter the HTTP header for load balancing across multiple real servers. This feature is used for load balancing HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server, providing better load balancing for those specific connections.
Mode	Select a mode for the real server.

To add a real server from the CLI you configure a virtual server and add real servers to it. For example, to add three real servers to a virtual server that load balances UDP sessions on port 8190 using weighted load balancing. For each real server the port is not changed. The default real server port is 0 resulting in the traffic being sent the real server with destination port 8190. Each real sever is given a different weight. Servers with higher weights have a max-connections limit to prevent too many sessions from being sent to them.

```
config firewall vip
  edit Vserver-UDP-1
    set type server-load-balance
    set server-type udp
    set ldb-method weighted
    set extip 172.20.120.30
    set extintf wan1
    set extport 8190
    set monitor ping-mon-1
      config realservers
```

```
        edit 1
          set ip 10.31.101.30
          set weight 100
          set max-connections 10000
        next
        edit 2
          set ip 10.31.101.40
          set weight 100
          set max-connections 10000
        next
        edit 3
          set ip 10.31.101.50
          set weight 10
        end
end
```

Health check monitoring

From the FortiGate web-based manager you can go to *Firewall Objects* > *Load Balance* > *Health Check Monitor* and configure health check monitoring so that the FortiGate unit can verify that real servers are able respond to network connection attempts. If a real server responds to connection attempts the load balancer continues to send sessions to it. If a real server stops responding to connection attempts the load balancer assumes that the server is down and does not send sessions to it. The health check monitor configuration determines how the load balancer tests the real servers. You can use a single health check monitor for multiple load balancing configurations.

You can configure TCP, HTTP and Ping health check monitors. Usually you would want the health check monitor to use the same protocol for checking the health of the server as the traffic being load balanced to it. For example, for an HTTP load balancing configuration you would normally use an HTTP health check monitor.

For the TCP and HTTP health check monitors you can specify the destination port to use to connect to the real servers. If you set the port to 0, the health check monitor uses the port defined in the real server. This allows you to use the same health check monitor for multiple real servers using different ports. You can also configure the interval, timeout and retry. A health check occurs every number of seconds indicated by the interval. If a reply is not received within the timeout period the health check is repeated. If no response is received after the number of configured retires, the virtual server is considered unresponsive, and load balancing will disabling traffic to that real server. The health check monitor will continue to contact the real server and if successful, the load balancer can resume sending sessions to the recovered real server.

For HTTP health check monitors, you can add URL that the FortiGate unit connects to when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional.

The URL would not usually include an IP address or domain name. Instead it should start with a “/” and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.31.101.30, the URL “/test_page.htm” causes the FortiGate unit to send an HTTP get request to “http://10.31.101.30/test_page.htm”.

For HTTP health check monitors, you can also add a matched content phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the URL option. If the URL returns a web page, the matched content should exactly match some of the text on the web page. You can use the URL and Matched Content options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL.

For example, you can set matched content to “server test page” if the real HTTP server page defined by the URL option contains the phrase “server test page”. When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the matched content phrase.

Health Check page	
Lists each individual health check monitor that you created. On this page, you can edit, delete and create a new health check monitor.	
Create New	Creates a new health check monitor. When you select *Create New*, you are automatically redirected to the Add New Health Check Monitor page.
Edit	Modifies settings within the health check monitor configuration. When you select *Edit*, you are automatically redirected to the Edit Health Check Monitor page.
Delete	Removes a health check monitor from the list on the Health Check Monitor page. This option appears only if the health check monitor configuration is not currently being used by a virtual server configuration. To remove multiple health check monitors, on the Health Check Monitor page, in each of the rows of the monitors you want removed, select the check box and then select *Delete*. To remove all health check monitors, on the Health Check Monitor page, select the check box in the check box column, and then select *Delete*.
Name	The name of the health check monitor configuration. The names are grouped by the health check monitor types.
Details	The details of the health check monitor configuration, which vary by the type of the health check monitor, and do not include the interval, timeout, or retry, which are settings common to all types. This field is empty if the type of the health check monitor is PING.
Ref.	Displays the number of virtual servers the health check monitor has been added to. To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the list of virtual servers that the health check monitor has been added to.
Add New Health Check Monitor	
Provides settings for configuring a health check monitor.	
Name	Enter the name of the health check monitor configuration.

Type	Select the protocol used to perform the health check. • TCP • HTTP • PING
Port	Enter the port number used to perform the health check. If you set the *Port* to 0, the health check monitor uses the port defined in the real server. This way you can use a single health check monitor for different real servers. This option does not appear if the *Type* is *PING*.
Interval	Enter the number of seconds between each server health check.
URL	For HTTP health check monitors, add a URL that the FortiGate unit uses when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional. The URL would not usually include an IP address or domain name. Instead it should start with a "/" and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.10.10.1, the *URL* "/test_page.htm" causes the FortiGate unit to send an HTTP get request to "http://10.10.10.1/test_page.htm". This option appears only if *Type* is *HTTP*.
Matched Content	For HTTP health check monitors, add a phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the *URL* option. If the *URL* returns a web page, the *Matched Content* should exactly match some of the text on the web page. You can use the *URL* and *Matched Content* options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL. For example, you can set *Matched Content* to "server test page" if the real HTTP server page defined by the URL option contains the phrase "server test page". When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the *Matched Content* phrase. This option appears only if *Type* is *HTTP*.
Timeout	Enter the number of seconds which must pass after the server health check to indicate a failed health check.
Retry	Enter the number of times, if any, a failed health check will be retried before the server is determined to be inaccessible.

Virtual IP, load balance virtual server and load balance real server limitations

The following limitations apply when adding virtual IPs, Load balancing virtual servers, and load balancing real servers. Load balancing virtual servers are actually server load balancing virtual IPs. You can add server load balance virtual IPs from the CLI.

- Virtual IP *External IP Address/Range* entries or ranges cannot overlap with each other or with load balancing virtual server *Virtual Server IP* entries.
- A virtual IP *Mapped IP Address/Range* cannot be 0.0.0.0 or 255.255.255.255.
- A real server *IP* cannot be 0.0.0.0 or 255.255.255.255.
- If a static NAT virtual IP *External IP Address/Range* is 0.0.0.0, the *Mapped IP Address/Range* must be a single IP address.
- If a load balance virtual IP *External IP Address/Range* is 0.0.0.0, the *Mapped IP Address/Range* can be an address range.
- When port forwarding, the count of mapped port numbers and external port numbers must be the same. The web-based manager does this automatically but the CLI does not.
- Virtual IP and virtual server names must be different from firewall address or address group names.

Monitoring load balancing

From the web-based manager you can go to *Firewall Objects* > *Monitor* > *Load Balance Monitor* to monitor the status of configured virtual servers and real server and start or stop the real servers. You can also use the `get test ipldb` command from the CLI to display similar information.

For each real server the monitor displays health status (up or down), active sessions, round trip time and the amount of bytes of data processed. From the monitor page you can also stop sending new sessions to any real server. When you select to stop sending sessions the FortiGate unit performs of graceful stop by continuing to send data for sessions that were established or persistent before you selected stop. However, no new sessions are started.

Virtual Server	The IP addresses of the existing virtual servers.
Real Server	The IP addresses of the existing real servers.
Health Status	Displays the health status according to the health check results for each real server. A green arrow means the server is up. A red arrow means the server is down.
Monitor Events	Display each real server's up and down times.
Active Sessions	Display each real server's active sessions.
RTT (ms)	Displays the Round Trip TIme (RTT) of each real server. By default, the RTT is "<1". This value will change only when ping monitoring is enabled on a real server.
Bytes Processed	Displays the traffic processed by each real server.
Graceful Stop/Start	Select to start or stop real servers. When stopping a server, the FortiGate unit will not accept new sessions but will wait for the active sessions to finish.

Load balancing get command

The following get command is available to display testing and debug information for the FortiGate virtual server process:

```
get test vs <test-level_int>
```

Where <test-level_int> can be:

3 to display the virtual server process id.

8 to display the virtual server log configuration.

30 to display the virtual server configuration statistics.

99 to restart the virtual server process.

Load balancing diagnose commands

You can also use the following diagnose commands to view status information for load balancing virtual servers and real servers:

```
diagnose firewall vip realserver {down | flush | healthcheck |
    list | up}
diagnose firewall vip virtual-server {filter | log | real-server
    | session | stats}
```

For example, the following command lists and displays status information for all real servers:

```
diagnose firewall vip virtual-server real-server

vd root/0  vs vs/2  addr 10.31.101.30:80  status 1/1
  conn: max 0  active 0  attempts 0  success 0  drop  0  fail 0

vd root/0  vs vs/2  addr 10.31.101.20:80  status 1/1
  conn: max 0  active 0  attempts 0  success 0  drop  0  fail 0
```

Many of the diagnostic commands involve retrieving information about one or more virtual servers. To control which servers are queried you can define a filter:

```
diagnose firewall vip virtual-server filter <filter_str>
```

Where <filter_str> can be:

clear erase the current filter

dst the destination address range to filter by

dst-port the destination port range to filter by

list display the current filter

name the vip name to filter by

negate negate the specified filter parameter

src the source address range to filter by

src-port the source port range to filter by

vd index of virtual domain. -1 matches all

The default filter is empty so no filtering is done.

Logging Diagnostics

The logging diagnostics provide information about two separate features:

```
diagnose firewall vip virtual-server log {console | filter}
```

Where

`console {disable | enable}` enables or disables displaying the event log messages generated by virtual server traffic on the console to simplify debugging.

`filter` sets a filter for the virtual server debug log

The filter option controls what entries the virtual server daemon will log to the console if `diagnose debug application vs` level is non-zero. The filtering can be done on source, destination, virtual-server name, virtual domain, and so on:

```
diagnose firewall vip virtual-server log filter <filter_str>
```

where `<filter_str>` can be

`clear` erase the current filter

`dst` the destination address range to filter by

`dst-port` the destination port range to filter by

`list` display the current filter

`name` the virtual-server name to filter by

`negate` negate the specified filter parameter

`src` the source address range to filter by

`src-port` the source port range to filter by

`vd` index of virtual domain. -1 matches all

The default filter is empty so no filtering is done.

Real server diagnostics

Enter the following command to list all the real servers:

```
diag firewall vip virtual-server real-server list
```

In the following example there is only one virtual server called `slb` and it has two real-servers:

```
diag firewall vip virtual-server server
vd root/0  vs slb/2  addr 172.16.67.191:80  status 1/1
  conn: max 10  active 0  attempts 0  success 0  drop  0  fail 0
  http: available 0  total 0

vd root/0  vs slb/2  addr 172.16.67.192:80  status 1/1
  conn: max 10  active 1  attempts 4  success 4  drop  0  fail 0
  http: available 1  total 1
```

The `status` indicates the administrative and operational status of the real-server.

`max` indicates that the real-server will only allow 10 concurrent connections.

`active` is the number of current connections to the server attempts is the total number of connections attempted success is the total number of connections that were successful.

`drop` is the total number of connections that were dropped because the active count hit max.

`fail` is the total number of connections that failed to complete due to some internal problem (for example, lack of memory).

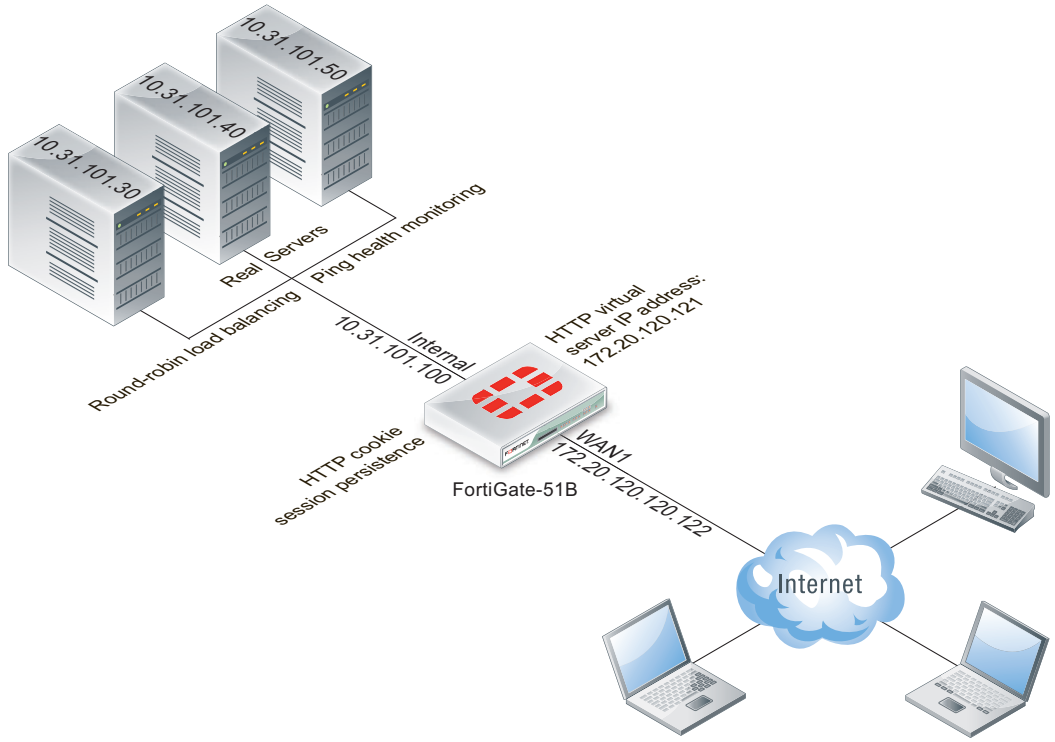
If the virtual server has HTTP multiplexing enabled then the HTTP section indicates how many established connections to the real-sever are available to service a HTTP request and also the total number of connections.

Basic load balancing configuration example

This section describes the steps required to configure the load balancing configuration shown in Figure 346. In this configuration a FortiGate-51B unit is load balancing HTTP traffic from the Internet to three HTTP servers on the Internal network. HTTP sessions are accepted at the wan1 interface with destination IP address 172.20.120.121 on TCP port 8080 and forwarded from the internal interface to the web servers. When forwarded the destination address of the sessions is translated to the IP address of one of the web servers.

The load balancing configuration also includes session persistence using HTTP cookies, round-robin load balancing, and TCP health monitoring for the real servers. Ping health monitoring consists of the FortiGate unit using ICMP ping to make sure the web servers can respond to network traffic.

Figure 346: Virtual server and real servers setup



To configure the example load balancing configuration - general configuration steps

1 Add a load balance ping health check monitor

A ping health check monitor causes the FortiGate unit to ping the real servers every 10 seconds. If one of the servers does not respond within 2 seconds, the FortiGate unit will retry the ping 3 times before assuming that the HTTP server is not responding.

2 Add a load balance virtual server.

3 Add the three load balance real servers. Include the virtual server in each real server configuration.

4 Add a security policy that includes the load balance virtual server as the destination address.

To configure the example load balancing configuration - web-based manager

1 Go to go to *Firewall Objects* > *Load Balance* > *Health Check* and add the following health check monitor.

Name	Ping-mon-1
Type	Ping
Interval	10 seconds
Timeout	2 seconds
Retry	3

2 Go to *Firewall Objects* > *Load Balance* > *Virtual Server* and add virtual server that accepts the traffic to be load balanced.

Name	Vserver-HTTP-1
Type	HTTP
Interface	wan1
Virtual Server IP	172.20.120.121
Virtual Server Port	8080
Load Balance Method	Round Robin
Persistence	HTTP Cookie
HTTP Multiplexing	Do not select
Health Check	Move Ping-mon-1 to the Selected list.

3 Go to go to *Firewall Objects* > *Load Balance* > *Real Server* and add the real servers.

Virtual Server	Vserver-HTTP-1
IP Address	10.31.101.30
Port	80
Weight	n/a
Max Connections	0
Mode	Active

Virtual Server	Vserver-HTTP-1
IP Address	10.31.101.40
Port	80
Weight	n/a
Max Connections	0
Mode	Active

Virtual Server	Vserver-HTTP-1
IP Address	10.31.101.50
Port	80

Weight	n/a
Max Connections	0
Mode	Active

4 Go to *Policy* > *Policy* > *Policy* and add a wan1 to internal security policy that includes the virtual server. This policy also applies an Antivirus profile to the load balanced sessions.

Source Interface/Zone	wan1
Source Address	all
Destination Interface/Zone	internal
Destination Address	Vserver-HTTP-1
Schedule	always
Service	ANY
Action	ACCEPT
NAT	Enable NAT
UTM	Select
Protocol Options	Select and select a protocol options profile.
Enable AntiVirus	Select and select an antivirus profile.

To configure the example load balancing configuration- CLI

1 Use the following command to add a Ping health check monitor.

```
config firewall ldb-monitor
  edit ping-mon-l
    set type ping
    set interval 10
    set timeout 2
    set retry 3
  end
```

2 Use the following command to add the virtual server that accepts HTTP sessions on port 8080 at the wan1 interface and load balances the traffic to three real servers.

```
config firewall vip
  edit Vserver-HTTP-1
    set type server-load-balance
    set server-type http
    set ldb-method round-robin
    set extip 172.20.120.30
    set extintf wan1
    set extport 8080
    set persistence http-cookie
    set monitor tcp-mon-1
      config realservers
        edit 1
          set ip 10.31.101.30
          set port 80
        next
```

```
        edit 2
          set ip 10.31.101.40
          set port 80
        end
    end
```

3 Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
  edit 0
    set srcintf wan1
    set srcaddr all
    set dstintf internal
    set dstaddr Vserver-HTTP-1
    set action accept
    set schedule always
    set service ANY
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set av-profile scan
  end
```

HTTP and HTTPS load balancing, multiplexing, and persistence

In a firewall load balancing virtual server configuration, you can select HTTP to load balance only HTTP sessions. The virtual server will load balance HTTP sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches the configured virtual server port. The default virtual server port for HTTP load balancing is 80, but you can change this to any port number. Similarly for HTTPS load balancing, set the virtual server type to HTTPS and then select the interface, virtual server IP, and virtual server port that matches the HTTPS traffic to be load balanced. Usually HTTPS traffic uses port 443.

You can also configure load balancing to offload SSL processing for HTTPS and SSL traffic. See “SSL offloading” on page 2890 for more information.

HTTP and HTTPS multiplexing

For both HTTP and HTTPS load balancing you can multiplex HTTP requests and responses over a single TCP connection. HTTP multiplexing is a performance saving feature of HTTP/1.1 compliant web servers that provides the ability to pipeline many unrelated HTTP or HTTPS requests on the same connection. This allows a single HTTPD process on the server to interleave and serve multiple requests. The result is fewer idle sessions on the web server so server resources are used more efficiently. HTTP multiplexing can take multiple separate inbound sessions and multiplex them over the same internal session. This may reduce the load on the backend server and increase the overall performance.

HTTP multiplexing may improve performance in some cases. For example, if users web browsers are only compatible with HTTP 1.0. HTTP multiplexing can also improve performance between a web server and the FortiGate unit if the FortiGate unit is performing SSL acceleration. However, in most cases HTTP multiplexing should only be used if enabling it leads to a measurable improvement in performance.

To enable HTTP multiplexing from the web-based manager, select multiplex HTTP requests/responses over a single TCP connection. To enable HTTP multiplexing from the CLI enable the `http-multiplex` option.

Preserving the client IP address

Select preserve client IP from the web-based manager or enable the `http-ip-header` option from the CLI to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful in an HTTP multiplexing configuration if you want log messages on the real servers to the client's original IP address. If this option is not selected, the header will contain the IP address of the FortiGate unit.

HTTP and HTTPS persistence

Configure load balancing persistence for HTTP or HTTPS to make sure that a user is connected to the same server every time they make a request that is part of the same session. HTTP cookie persistence uses injected cookies to enable persistence.

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the *Load Balance Method*. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server.

The following example shows how to enable cookie persistence and set the cookie domain to .example.org.

```
config firewall vip
  edit HTTP_Load_Balance
    set type server-load-balance
    set server-type http
    set extport 8080
    set extintf port2
    set extip 192.168.20.20
    set persistence http-cookie
    set http-cookie-domain .example.org
      config realservers
        edit 1
          set ip 10.10.10.1
        next
        edit 2
          set ip 10.10.10.2
        next
        edit 3
          set ip 10.10.10.3
        end
  end
```

How HTTP cookie persistence options work

The following options are available for the `config firewall vip` command when `type` is set to `server-load-balance`, `server-type` is set to `http` or `https` and `persistence` is set to `http-cookie`:

```
http-cookie-domain
http-cookie-path
http-cookie-generation
http-cookie-age
http-cookie-share
```

`https-cookie-share` (appears when `server-type` is set to `https`)

When HTTP cookie persistence is enabled the `FortiGate` unit inserts a header of the following form into each HTTP response unless the corresponding HTTP request already contains a `FGTServer` cookie:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;
   Version=1; Max-Age=3600
```

The value of the `FGTServer` cookie encodes the server that traffic should be directed to. The value is encoded so as to not leak information about the internal network.

Use `http-cookie-domain` to restrict the domain that the cookie should apply to. For example, to restrict the cookie to `.server.com`, enter:

```
set http-cookie-domain .server.com
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;
   Version=1; Domain=.server.com; Max-Age=3600
```

Use `http-cookie-path` to limit the cookies to a particular path. For example, to limit cookies to the path `/sales`, enter:

```
set http-cookie-path /sales
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;
   Version=1; Domain=.server.com; Path=/sales; Max-Age=3600
```

Use `http-cookie-age` to change how long the browser caches the cookie. You can enter an age in minutes or set the age to 0 to make the browser keep the cookie indefinitely:

```
set http-cookie-age 0
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;
   Version=1; Domain=.server.com; Path=/sales
```

Use `http-cookie-generation` to invalidate all cookies that have already been generated. The exact value of the generation is not important, only that it is different from any generation that has already been used for cookies in this domain. The simplest approach is to increment the generation by one each time invalidation is required. Since the default is 0, enter the following to invalidate all existing cookies:

```
set http-cookie-generation 1
```

Use `http-cookie-share {disable | same-ip}` to control the sharing of cookies across virtual servers in the same virtual domain. The default setting `same-ip` means that any `FGTServer` cookie generated by one virtual server can be used by another virtual server in the same virtual domain. For example, if you have an application that starts on HTTP and then changes to HTTPS and you want to make sure that the same server is used for the HTTP and HTTPS traffic then you can create two virtual servers, one for port 80 (for HTTP) and one for port 443 (for HTTPS). As long as you add the same real servers to both of these virtual servers (and as long as both virtual servers have the same number of real servers with the same IP addresses), then cookies generated by accessing the HTTP server are reused when the application changes to the HTTPS server.

If for any reason you do not want this sharing to occur then select `disable` to make sure that a cookie generated for a virtual server cannot be used by other virtual servers.

Use `https-cookie-secure` to enable or disable using secure cookies. Secure cookies are disabled by default because secure cookies can interfere with cookie sharing across HTTP and HTTPS virtual servers. If enabled, then the `Secure` tag is added to the cookie inserted by the FortiGate unit:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158;
   Version=1; Max-Age=3600; Secure
```

HTTP host-based load balancing

When configuring HTTP or HTTPS load balancing you can select HTTP host load balancing to load balances HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server. HTTP 1.1 includes the concept of a virtual server which allows a HTTP or HTTPS server with a single external IP address to serve requests for multiple DNS domains by using the mandatory `Host:` header in a HTTP request to indicate which DNS domain the request is destined for.

FortiOS can load-balance HTTP and HTTPS connections among multiple real servers using the `Host:` header to guide the connection to the correct real server. The host load balancing method allows a real server to specify a `http-host` attribute which is the domain name of the traffic for that real server. Each real server can only specify a single domain name. The same domain name can appear in more than one real server but only the first one that is up will be used, any others are purely for redundancy. If the Host: header contains a domain that does not match any http-host entry then the connection will be dropped. A real server with no http-host can be matched by any Host: domain.

For example, consider a FortiGate unit that is load-balancing traffic to three real servers. Traffic for www.example1.com should go to 192.168.2.1, traffic for www.example2.com should go to 192.168.2.2 and traffic to any other domain should go to 192.168.2.3. To enable this configuration you would add a virtual server and set the load balance method to HTTP host. Then you would add three real servers and set the HTTP host of the real server with IP address 192.168.2.1 to www.example1.com, the HTTP host of the real server with IP address 192.168.2.2 to www.example2.com and you would not specify an HTTP host for the third real server.

The configuration of a virtual IP to achieve this result would be:

```
config firewall vip
  edit "http-host-ldb"
    set type server-load-balance
    set extip 172.16.67.195
    set extintf "lan"
    set server-type http
    set ldb-method http-host
    set extport 80
      config realservers
        edit 1
          set http-host "www.example1.com"
          set ip 192.168.2.1
          set port 80
        next
        edit 2
          set http-host "www.example2.com"
          set ip 192.168.2.2
          set port 80
        next
        edit 3
```

```
        set ip 192.168.2.3
        set port 80
      next
    end
end
```

Host load balancing and HTTP cookie persistence

In an HTTP host-based load balancing configuration with HTTP cookie persistence enabled you can optionally configure cookie persistence to use the domain set in the host header as the cookie domain. You can do this by enabling the `http-cookie-domain-from-host` option, for example:

```
config firewall vip
  edit "http-host-ldb"
    set type server-load-balance
    set extip 172.16.67.195
    set extintf "lan"
    set server-type http
    set ldb-method http-host
    set extport 80
    set persistence http-cookie
    set http-cookie-domain-from-host enable
      config realservers
        edit 1
          set http-host "www.example1.com"
          set ip 192.168.2.1
          set port 80
        next
        edit 2
          set http-host "www.example2.com"
          set ip 192.168.2.2
          set port 80
        next
        edit 3
          set ip 192.168.2.3
          set port 80
        next
      end
end
```

SSL/TLS load balancing

In a firewall load balancing virtual server configuration, you can select SSL to load balance only SSL and TLS sessions. The virtual server will load balance SSL and TLS sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches the configured virtual server port. Change this port to match the destination port of the sessions to be load balanced.

For SSL load balancing you can also set persistence to SSL session ID. Persistence is achieved by the FortiGate unit sending all sessions with the same SSL session ID to the same real server. When you configure persistence, the FortiGate unit load balances a new session to a real server according to the *Load Balance Method*. If the session has an SSL session ID, the FortiGate unit sends all subsequent sessions with the same SSL session ID to the same real server.

SSL offloading

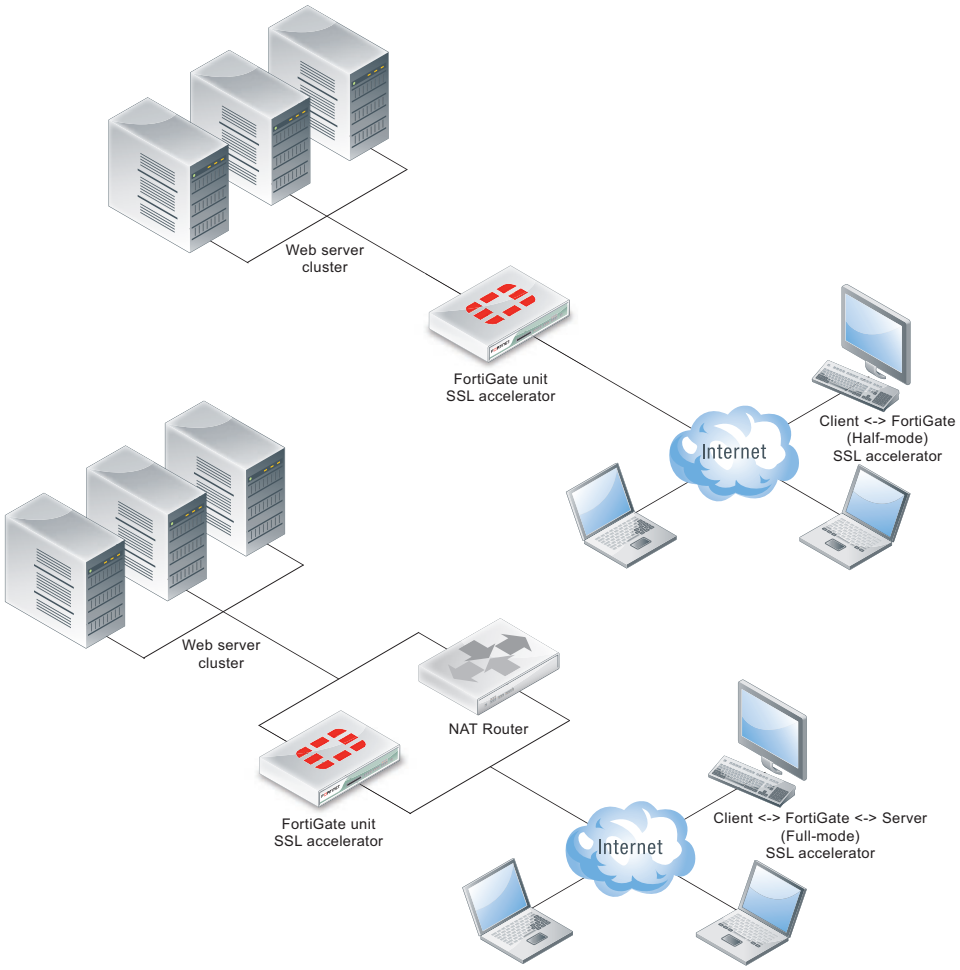
Use SSL offloading to accelerate clients' SSL or HTTPS connections to real servers by using the FortiGate unit to perform SSL operations (offloading them from the real servers using the FortiGate unit's SSL acceleration hardware). FortiGate units can offload SSL 3.0 and TLS 1.0. SSL offloading is available on FortiGate units that support SSL acceleration.

To configure SSL offloading from the web-based manager go to *Firewall Objects* > *Load Balance* > *Virtual Server*. Add a virtual server and set the type to HTTPS or SSL and select the SSL offloading type (Client <-> FortiGate or Client <-> FortiGate <->Server).

Select Client <-> FortiGate to apply hardware accelerated SSL processing only to the part of the connection between the client and the FortiGate unit. This mode is called half mode SSL offloading. The segment between the FortiGate unit and the server will use clear text communications. This results in best performance, but cannot be used in failover configurations where the failover path does not have an SSL accelerator.

Select Client <-> FortiGate <->Server to apply hardware accelerated SSL processing to both parts of the connection: the segment between client and the FortiGate unit, and the segment between the FortiGate unit and the server. This mode is called full mode SSL offloading. The segment between the FortiGate unit and the server will use encrypted communications, but the handshakes will be abbreviated. This results in performance which is less than the other option, but still improved over communications without SSL acceleration, and can be used in failover configurations where the failover path does not have an SSL accelerator. If the server is already configured to use SSL, this also enables SSL acceleration without requiring changes to the server's configuration.

Figure 347: SSL Offloading modes



Configuring SSL offloading also requires selecting a certificate to use for the SSL offloading sessions. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

The following CLI command shows an example half mode HTTPS SSL offloading configuration. In the example the `ssl-mode` option sets the SSL offload mode to `half` (which is the default mode).

```
config firewall vip
  edit Vserver-ssl-offload
    set type server-load-balance
    set server-type https
    set ldb-method round-robin
    set extip 172.20.120.30
    set extintf wan1
    set extport 443
    set persistence ssl-session-id
    set ssl-mode half
    set ssl-certificate my-cert
    set monitor tcp-mon-1
      config realservers
        edit 1
          set ip 10.31.101.30
```

```
        set port 443
      next
      edit 2
        set ip 10.31.101.40
        set port 443
      end
end
```

Additional SSL load balancing options

The following SSL load balancing and SSL offloading options are only available from the CLI:

```
ssl-client-session-state-max <sessionstates_int>
```

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the client and the FortiGate unit.

```
ssl-client-session-state-timeout <timeout_int>
```

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the client and the FortiGate unit.

```
ssl-client-session-state-type {both | client | disable | time}
```

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the client and the FortiGate unit.

- `both`: Select to expire SSL session states when either `ssl-client-session-state-max` or `ssl-client-session-state-timeout` is exceeded, regardless of which occurs first.
- `count`: Select to expire SSL session states when `ssl-client-session-state-max` is exceeded.
- `disable`: Select to keep no SSL session states.
- `time`: Select to expire SSL session states when `ssl-client-session-state-timeout` is exceeded.

```
ssl-dh-bits <bits_int>
```

Enter the number of bits of the prime number used in the Diffie-Hellman exchange for RSA encryption of the SSL connection. Larger prime numbers are associated with greater cryptographic strength.

```
ssl-http-location-conversion {enable | disable}
```

Select to replace `http` with `https` in the reply's `Location` HTTP header field. For example, in the reply, `Location: http://example.com/` would be converted to `Location: https://example.com/`

```
ssl-http-match-host {enable | disable}
```

Select to apply `Location` conversion to the reply's HTTP header only if the host name portion of `Location` matches the request's `Host` field, or, if the `Host` field does not exist, the host name portion of the request's URI. If disabled, conversion occurs regardless of whether the host names in the request and the reply match.

For example, if host matching is enabled, and a request contains `Host: example.com` and the reply contains `Location: http://example.cc/`, the `Location` field does not match the host of the original request and the reply's `Location` field remains unchanged. If the reply contains `Location: http://example.com/`, however, then the FortiGate unit detects the matching host name and converts the reply field to `Location: https://example.com/`.

This option appears only if `ssl-http-location-conversion` is `enable`.

```
ssl-max-version {ssl-3.0 | tls-1.0}
```

Enter the maximum version of SSL/TLS to accept in negotiation.

```
ssl-min-version {ssl-3.0 | tls-1.0}
```

Enter the minimum version of SSL/TLS to accept in negotiation.

```
ssl-send-empty-frags {enable | disable}
```

Select to precede the record with empty fragments to thwart attacks on CBC IV. You might disable this option if SSL acceleration will be used with an old or buggy SSL implementation which cannot properly handle empty fragments.

```
ssl-server-session-state-max <sessionstates_int>
```

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the server and the FortiGate unit.

```
ssl-server-session-state-timeout <timeout_int>
```

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if `ssl-mode` is `full`.

```
ssl-server-session-state-type {both | count | disable | time}
```

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if `ssl-mode` is `full`.

- `both`: Select to expire SSL session states when either `ssl-server-session-state-max` or `ssl-server-session-state-timeout` is exceeded, regardless of which occurs first.
- `count`: Select to expire SSL session states when `ssl-server-session-state-max` is exceeded.
- `disable`: Select to keep no SSL session states.
- `time`: Select to expire SSL session states when `ssl-server-session-state-timeout` is exceeded.

SSL offloading support or Internet Explorer 6

In some cases the Internet Explorer 6 web browser may be able to access real servers. To resolve this issue, disable the `ssl-send-empty-frags` option:

```
config firewall vip
  edit vip_name
    set ssl-send-empty-frags disable
  end
```

You can disable this option if SSL acceleration will be used with an old or buggy SSL implementation that cannot properly handle empty fragments.

Disabling SSL/TLS re-negotiation

The vulnerability CVE-2009-3555 affects all SSL/TLS servers that support re-negotiation. FortiOS when configured for SSL/TLS offloading is operating as a SSL/TLS server. The IETF is working on a TLS protocol change that will fix the problem identified by CVE-2009-3555 while still supporting re-negotiation. Until that protocol change is available, you can use the `ssl-client-renegotiation` option to disable support for SSL/TLS re-negotiation. The default value of this option is `allow`, which allows an SSL client to renegotiate. You can change the setting to `deny` to abort any attempts by an SSL client to renegotiate. If you select `deny` as soon as a `ClientHello` message indicating a re-negotiation is received from the client FortiOS terminates the TCP connection.

Since SSL offloading does not support requesting client certificates the only circumstance in which a re-negotiation is required is when more than 2^32 bytes of data are exchanged over a single handshake. If you are sure that this volume of traffic will not occur then you can disable re-negotiation and avoid any possibility of the attack described in CVE-2009-3555.

The re-negotiation behavior can be tested using OpenSSL. The OpenSSL s_client application has the feature that the user can request that it do renegotiation by typing “R”. For example, the following shows a successful re-negotiation against a FortiGate unit configured with a VIP for 192.168.2.100:443:

```
$ openssl s_client -connect 192.168.2.100:443
  CONNECTED(00000003)
  depth=1
/C=US/ST=California/L=Sunnyvale/O=Fortinet/OU=Certificate

failure:s3_pkt.c:530:
```

Use the following command to check the SSL stats to see that the `renegotiations blocked` counter is now 1:

```
 firewall vip virtual-server stats ssl
  ssl
    client
      connections total 0 active 0 max 0
```

```
      handshakes total 4 active 0 max 0 completed 4 abbreviated 0
      session states total 4 active 4 max 4
      cipher-suite failures 0
      embryonics total 0 active 0 max 0 terminated 0
      renegotiations blocked 1
    server
      connections total 0 active 0 max 0
      handshakes total 3 active 0 max 0 completed 2 abbreviated 1
      session states total 1 active 1 max 1
      cipher-suite failures 0
    internal error 0
    bad handshake length 0
    bad change cipher spec length 0
    pubkey too big 0
    persistence
      find 0  found 0  clash 0  addr 0 error 0
```

If the virtual server debug log is examined (diag debug appl vs -1) then at the point the re-negotiation is blocked there is a log:

```
vs ssl 12 handshake recv ClientHello
  vs ssl 12 handshake recv 1

  vs sock 12 free
```

IP, TCP, and UDP load balancing

You can load balance all IP, TCP or UDP sessions accepted by the security policy that includes a load balancing virtual server with the type set to IP, TCP, or UDP. Traffic with destination IP and port that matches the virtual server IP and port is load balanced. For these protocol-level load balancing virtual servers you can select a load balance method and add real servers and health checking. However, you can't configure persistence, HTTP multiplexing and SSL offloading.

Load balancing configuration examples

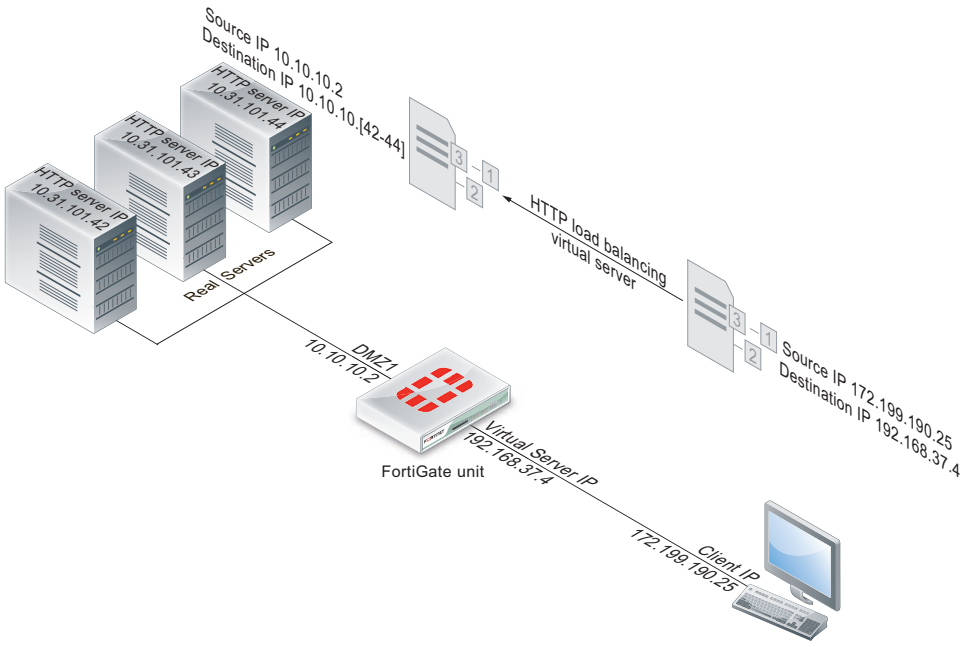
This chapter includes the following examples:

Example: HTTP load balancing to three real web servers

In this example, the virtual web server IP address 192.168.37.4 on the Internet, is mapped to three real web servers connected to the FortiGate unit dmz1 interface. The real servers have IP addresses 10.10.123.42, 10.10.123.43, and 10.10.123.44. The virtual server uses the *First Alive* load balancing method. The configuration also includes an HTTP health check monitor that includes a URL used by the FortiGate unit for get requests to monitor the health of the real servers.

Connections to the virtual web server at IP address 192.168.37.4 from the Internet are translated and load balanced to the real servers by the FortiGate unit. First alive load balancing directs all sessions to the first real server. The computers on the Internet are unaware of this translation and load balancing and see a single virtual server at IP address 192.168.37.4 rather than the three real servers behind the FortiGate unit.

Figure 348: Virtual server configuration example



Web-based manager configuration

Use the following procedures to configure this load balancing setup from the web-based manager.

To add an HTTP health check monitor

In this example, the HTTP health check monitor includes the *URL* “/index.html” and the *Matched Phrase* “Fortinet products”.

1 Go to *Firewall Objects* > *Load Balance* > *Health Check*.

2 Select *Create New*.

3 Add an HTTP health check monitor that sends get requests to http://<real_server_IP_address>/index.html and searches the returned web page for the phrase “Fortinet products”.

Name	HTTP_health_chk_1
Type	HTTP
Port	80
URL	/index.html
Matched Content	Fortinet products
Interval	10 seconds
Timeout	2 seconds
Retry	3

4 Select *OK*.

To add the HTTP virtual server

1 Go to *Firewall Objects* > *Load Balance* > *Virtual Server*.

2 Select *Create New*.

3 Add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

Name	Load_Bal_VS1
Type	HTTP
Interface	wan1
Virtual Server IP	192.168.37.4 The public IP address of the web server. The virtual server IP address is usually a static IP address obtained from your ISP for your web server. This address must be a unique IP address that is not used by another host and cannot be the same as the IP address of the external interface the virtual IP will be using. However, the external IP address must be routed to the selected interface. The virtual IP address and the external IP address can be on different subnets. When you add the virtual IP, the external interface responds to ARP requests for the external IP address.
Virtual Server Port	80
Load Balance Method	First Alive
Persistence	HTTP cookie
HTTP Multiplexing	Select. The FortiGate unit multiplexes multiple client into a few connections between the FortiGate unit and each real HTTP server. This can improve performance by reducing server overhead associated with establishing multiple connections.
Preserve Client IP	Select The FortiGate unit preserves the IP address of the client in the `X-Forwarded-For` HTTP header.
Health Check	Move the HTTP_health_chk_1 health check monitor to the *Selected* list.

4 Select *OK*.

To add the real servers and associate them with the virtual server

1 Go to *Firewall Objects* > *Load Balance* > *Real Server*.

2 Select *Create New*.

3 Configure three real servers that include the virtual server Load_Bal_VS1. Each real server must include the IP address of a real server on the internal network.

Configuration for the first real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.42
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0 Setting *Maximum Connections* to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses *First Alive* load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the *Maximum Connections* is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the second real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.43
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0 Setting *Maximum Connections* to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses *First Alive* load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the *Maximum Connections* is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the third real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.44
Port	80

Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0 Setting *Maximum Connections* to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses *First Alive* load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the *Maximum Connections* is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

To add the virtual server to a security policy

Add a wan1 to dmz1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*.

3 Configure the security policy:

Source Interface/Zone	wan1
Source Address	all (or a more specific address)
Destination Interface/Zone	dmz1
Destination Address	Load_Bal_VS1
Schedule	always
Service	HTTP
Action	ACCEPT
Log Allowed Traffic	Select to log virtual server traffic
NAT	Enable NAT

4 Select other security policy options as required.

5 Select *OK*.

CLI configuration

Use the following procedure to configure this load balancing setup from the CLI.

To configure HTTP load balancing

1 Use the following command to add an HTTP health check monitor that sends get requests to http://<real_server_IP_address>/index.html and searches the returned web page for the phrase "Fortinet products".

```
config firewall ldb-monitor
  edit HTTP_health_chk_1
    set type http
    set port 80
```

```
    set http-get /index.html
    set http-match "Fortinet products"
    set interval 10
    set timeout 2
    set retry 3
  end
```

2 Use the following command to add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

```
config firewall vip
  edit Load-Bal_VS1
    set type server-load-balance
    set server-type http
    set ldb-method first-alive
    set http-multiplex enable
    set http-ip-header enable
    set extip 192.168.37.4
    set extintf wan1
    set extport 80
    set persistence http-cookie
    set monitor HTTP_health_chk_1
      config realservers
        edit 1
          set ip 10.10.10.42
          set port 80
        next
        edit 2
          set ip 10.10.10.43
          set port 80
        next
        edit 3
          set ip 10.10.10.44
          set port 80
        end
  end
```

3 Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
  edit 0
    set srcintf wan1
    set srcaddr all
    set dstintf dmz1
    set dstaddr Load-Bal_VS1
    set action accept
    set schedule always
    set service ANY
    set nat enable
  end
```

Configure other security policy settings as required.

Example: Basic IP load balancing configuration

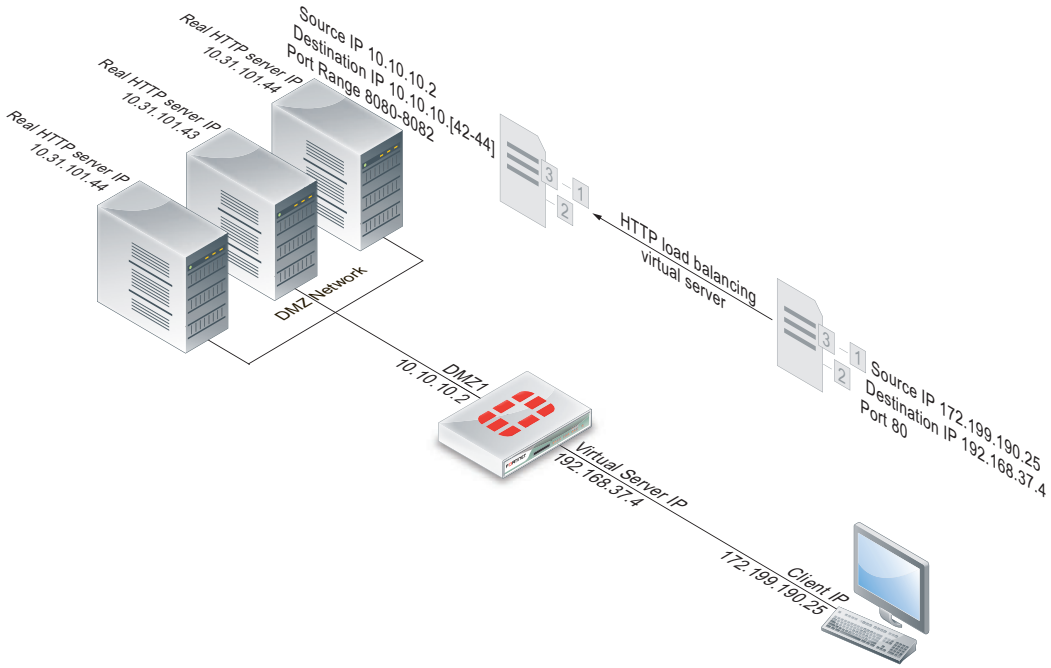
This example shows how to add a server load balancing virtual IP that load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3. The default weight is 1 and does not have to be changed for the first real server.

```
config firewall vip
  edit All_Load_Balance
    set type server-load-balance
    set server-type ip
    set extintf port2
    set extip 192.168.20.20
    set ldb-method weighted
      config realservers
        edit 1
          set ip 10.10.10.1
        next
        edit 2
          set ip 10.10.10.2
          set weight 2
        next
        edit 3
          set ip 10.10.10.3
          set weight 3
        end
  end
```

Example: Adding a server load balance port forwarding virtual IP

This example is the same as the example described in “Example: HTTP load balancing to three real web servers” on page 2899 except that each real server accepts HTTP connections on a different port number. The first real server accepts connections on port 8080, the second on port 8081, and the third on 8082.

Figure 349: Server load balance virtual IP port forwarding



To complete this configuration, all of the steps would be the same as in "Example: HTTP load balancing to three real web servers" on page 2899 except for configuring the real servers.

To add the real servers and associate them with the virtual server

Use the following steps to configure the FortiGate unit to port forward HTTP packets to the three real servers on ports 8080, 8081, and 8082.

1 Go to *Firewall Objects* > *Load Balance* > *Real Server*.

2 Select *Create New*.

3 Configure three real servers that include the virtual server Load_Bal_VS1. Each real server must include the IP address of a real server on the internal network and have a different port number.

Configuration for the first real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.42
Port	8080
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the second real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.43
Port	8081
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the third real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.44
Port	8082
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Example: Weighted load balancing configuration

This example shows how to using firewall load balancing to load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3.

This configuration does not include an health check monitor.

Web-based manager configuration

Use the following procedures to configure this load balancing setup from the web-based manager.

To add the HTTP virtual server

1 Go to *Firewall Objects* > *Load Balance* > *Virtual Server*.

2 Select *Create New*.

3 Add an IP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate port2 interface is connected to the Internet.

Name	HTTP_weghted_LB
Type	IP
Interface	port2
Virtual Server IP	192.168.20.20
Load Balance Method	Weighted

All other virtual server settings are not required or cannot be changed.

4 Select *OK*.

To add the real servers and associate them with the virtual server

1 Go to *Firewall Objects* > *Load Balance* > *Real Server*.

2 Select *Create New*.

3 Configure three real servers that include the virtual server All_Load _Balance. Because the *Load Balancing Method* is *Weighted*, each real server includes a weight. Servers with a greater weight receive a greater proportion of forwarded connections,

Configuration for the first real server.

Virtual Server	HTTP_weghted_LB
IP	10.10.10.1
Port	Cannot be configured because the virtual server is an IP server.
Weight	1
Maximum Connections	0 Setting *Maximum Connections* to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses *First Alive* load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the *Maximum Connections* is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the second real server.

Virtual Server	HTTP_weghted_LB
IP	10.10.10.2
Port	Cannot be configured because the virtual server is an IP server.
Weight	2
Maximum Connections	0 Setting *Maximum Connections* to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses *First Alive* load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the *Maximum Connections* is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the third real server.

Virtual Server	HTTP_weghted_LB
IP	10.10.10.3
Port	Cannot be configured because the virtual server is an IP server.

Weight	3
Maximum Connections	0 Setting *Maximum Connections* to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses *First Alive* load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the *Maximum Connections* is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

To add the virtual server to a security policy

Add a prot2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*.

3 Configure the security policy:

Source Interface/Zone	port2
Source Address	all (or a more specific address)
Destination Interface/Zone	port1
Destination Address	HTTP_weghted_LB
Schedule	always
Service	ANY
Action	ACCEPT
NAT	Select

4 Select other security policy options as required.

5 Select *OK*.

CLI configuration

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`. The default weight is 1 and does not have to be changed for the first real server.

Use the following command to add the virtual server and the three weighted real servers.

```
config firewall vip
  edit HTTP_weghted_LB
    set type server-load-balance
    set server-type ip
    set extintf port2
    set extip 192.168.20.20
    set ldb-method weighted
      config realservers
        edit 1
```

```
        set ip 10.10.10.1
      next
      edit 2
        set ip 10.10.10.2
        set weight 2
      next
      edit 3
        set ip 10.10.10.3
        set weight 3
      end
end
```

Example: HTTP and HTTPS persistence configuration

This example shows how to add a virtual server named *Http_Load_Balance* that load balances HTTP traffic using port 80 and a second virtual server named *Https_Load_Balance* that load balances HTTPS traffic using port 443. The Internet is connected to port2 and the virtual IP address of the virtual server is 192.168.20.20. Both server load balancing virtual IPs load balance sessions to the same three real servers with IP addresses 10.10.10.2, 10.10.10.2, and 10.10.10.3. The real servers provide HTTP and HTTPS services.

For both virtual servers, persistence is set to *HTTP Cookie* to enable HTTP cookie persistence.

To add the HTTP and HTTPS virtual servers

1 Go to *Firewall Objects* > *Load Balance* > *Virtual Server*.

2 Add the HTTP virtual server that includes HTTP Cookie persistence.

Name	HTTP_Load_Balance
Type	HTTP
Interface	port2
Virtual Server IP	192.168.20.20
Virtual Server Port	80 In this example the virtual server uses port 8080 for HTTP sessions instead of port 80.
Load Balance Method	Static
Persistence	HTTP cookie

3 Select *OK*.

4 Select *Create New*.

5 Add the HTTPs virtual server that also includes HTTP Cookie persistence.

Name	HTTPS_Load_Balance
Type	HTTPS
Interface	port2
Virtual Server IP	192.168.20.20
Virtual Server Port	443

Load Balance Method	Static
Persistence	HTTP cookie

6 Select *OK*.

To add the real servers and associate them with the virtual servers

1 Go to *Firewall Objects* > *Load Balance* > *Real Server*.

2 Select *Create New*.

3 Configure three real servers for HTTP that include the virtual server HTTP_Load_Balance.

Configuration for the first HTTP real server.

Virtual Server	HTTP_Load_Balance
IP	10.10.10.1
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the second HTTP real server.

Virtual Server	HTTP_Load_Balance
IP	10.10.10.2
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the third HTTP real server.

Virtual Server	HTTP_Load_Balance
IP	10.10.10.3
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

4 Configure three real servers for HTTPS that include the virtual server HTTPS_Load_Balance.

Configuration for the first HTTPS real server.

Virtual Server	HTTP_Load_Balance
IP	10.10.10.1
Port	443
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the second HTTPS real server.

Virtual Server	HTTP_Load_Balance
IP	10.10.10.2
Port	443
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the third HTTPS real server.

Virtual Server	HTTPS_Load_Balance
IP	10.10.10.3
Port	443
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

To add the virtual servers to security policies

Add a port2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*.

3 Configure the HTTP security policy:

Source Interface/Zone	port2
Source Address	all
Destination Interface/Zone	port1
Destination Address	HTTP_Load_Balance
Schedule	always
Service	HTTP

Action	ACCEPT
NAT	Enable NAT

4 Select other security policy options as required.

5 Select *OK*.

6 Select *Create New*.

7 Configure the HTTP security policy:

Source Interface/Zone	port2
Source Address	all
Destination Interface/Zone	port1
Destination Address	HTTPS_Load_Balance
Schedule	always
Service	HTTPS
Action	ACCEPT
NAT	Enable NAT

8 Select other security policy options as required.

9 Select *OK*.

CLI configuration: adding persistence for a specific domain

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`.

For the CLI configuration, both virtual servers include setting `http-cookie-domain` to `.example.org` because HTTP cookie persistence is just required for the `example.org` domain.

First, the configuration for the HTTP virtual IP:

```
config firewall vip
  edit HTTP_Load_Balance
    set type server-load-balance
    set server-type http
    set extport 8080
    set extintf port2
    set extip 192.168.20.20
    set persistence http-cookie
    set http-cookie-domain .example.org
      config realservers
        edit 1
          set ip 10.10.10.1
        next
        edit 2
          set ip 10.10.10.2
        next
        edit 3
          set ip 10.10.10.3
        end
  end
```

Second, the configuration for the HTTPS virtual IP. In this configuration you don't have to set `extport` to `443` because `extport` is automatically set to `443` when `server-type` is set to `https`.

```
config firewall vip
  edit HTTPS_Load_Balance
    set type server-load-balance
    set server-type https
    set extport 443
    set extintf port2
    set extip 192.168.20.20
    set persistence http-cookie
    set http-cookie-domain .example.org
      config realservers
        edit 1
          set ip 10.10.10.1
        next
        edit 2
          set ip 10.10.10.2
        next
        edit 3
          set ip 10.10.10.3
        end
  end
```

Chapter 19 Hardware

This FortiOS Handbook chapter contains the following sections:

FortiGate installation describes installing your FortiGate unit, and how to mount the FortiGate in a rack, if applicable.

FortiGate hardware accelerated processing some FortiGate models incorporate network processors in the main unit, others support the addition of AMC (Advanced Mezzanine Card) modules. The FortiGate-5000 series supports rear transition modules (RTMs) that incorporate network processors. This chapter describes how hardware acceleration works as well as how to take full advantage of its benefits.

Configuring RAID some FortiGate models have two or more hard disks configured in a RAID array to store log messages locally on the FortiGate unit. A RAID array can provide faster disk access, redundancy in case of partial failure, or both depending on the RAID level you select.This section described how to configure RAID on FortiGate units that support it.

FortiBridge installation and operation describes a typical transparent mode FortiGate network and how to add a FortiBridge unit to provide fail open protection. In addition, detailed information about how FortiBridge units operate, a description of to add a FortiBridge unit to an HA cluster, and connecting a FortiBridge unit other FortiGate interfaces is included.

FortiGate installation

This chapter describes installing your FortiGate unit, environmental specifications, and how to mount the FortiGate unit.

This chapter contains the following topics:

Mounting the FortiGate unit

Most FortiGate units can be either rack mounted, or placed on a desk or table. Only the smallest units have no rack mounting hardware. The largest units are designed for rack mounting.

Desk or table mounting

Attach the provided rubber feet to the bottom of the FortiGate unit if they are not already attached.

Place the FortiGate unit on any flat, stable surface, ensure the unit has at least 1.5 inches (3.75 cm) of clearance on each side to ensure adequate airflow for cooling.

Rack mounting

If you are placing a 1U or 2U FortiGate unit into a rack, remove the rubber feet from the bottom of the FortiGate unit.

For rack mounting, use the mounting brackets and screws included with the FortiGate unit. The 3U 3900-series FortiGate units can be rack-mounted using either slide rails or middle-mount brackets and both procedures are covered below.

Rack mount considerations

Elevated operating ambient — If installed in a closed or multi-unit rack assembly, the operating ambient temperature of the rack environment may be greater than room ambient. Therefore, consideration should be given to installing the equipment in an environment compatible with the maximum ambient temperature (Tma) specified by the manufacturer.

Reduced air flow — Installation of the equipment in a rack should be such that the amount of air flow required for safe operation of the equipment is not compromised.

Mechanical loading — Mounting of the equipment in the rack should be such that a hazardous condition is not achieved due to uneven mechanical loading.

Circuit overloading — Consideration should be given to the connection of the equipment to the supply circuit and the effect that overloading of the circuits might have on overcurrent protection and supply wiring. Appropriate consideration of equipment nameplate ratings should be used when addressing this concern.

Reliable ground — Reliable electrical grounding of rack-mounted equipment should be maintained.

Particular attention should be given to supply connections other than direct connections to the branch circuit (e.g. use of power strips).

Depending on the size of your FortiGate unit, you may require two or more people to safely install the unit in the rack.

To install a 1U or 2U FortiGate unit into a rack

1 Attach the mounting brackets to the side to the unit so that the brackets are on the front portion of the FortiGate unit. Ensure that the screws are tight.

The following photos illustrate how the brackets should be mounted. Note that the screw configuration may vary depending on your FortiGate unit.

Figure 350: Installed 1U mounting brackets

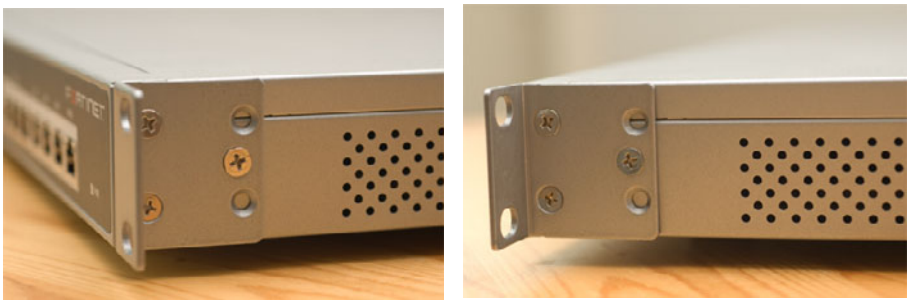


Figure 351: Installed 2U mounting brackets

2 Position the FortiGate unit in the rack to allow for sufficient air flow.

3 Line up the mounting bracket holes to the holes on the rack, ensuring the FortiGate unit is level.

4 Finger tighten the screws to attach the FortiGate unit to the rack.

5 Once you verify the spacing of the FortiGate unit and that it is level, tighten the screws with a screwdriver. Ensure that the screws are tight.

The following photos illustrate how the mounting brackets and FortiGate unit should be attached to the rack.

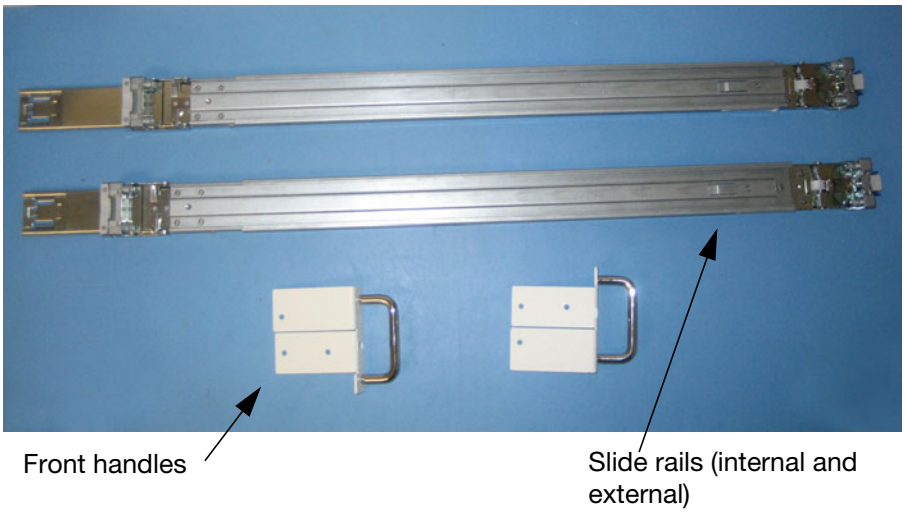
Figure 352: Mounting a 1U FortiGate unit in a rack

Figure 353: Mounting a 2U FortiGate unit in a rack

To install a 3U 3900-series FortiGate using slide rails

1 Before you start, confirm that you have the two slide rails and two front handles.

Figure 354: Slide rails and front handles.



2 Attach the internal rails to each side of the unit. The rail should snap on and slide over until you hear a click from the rear clip.

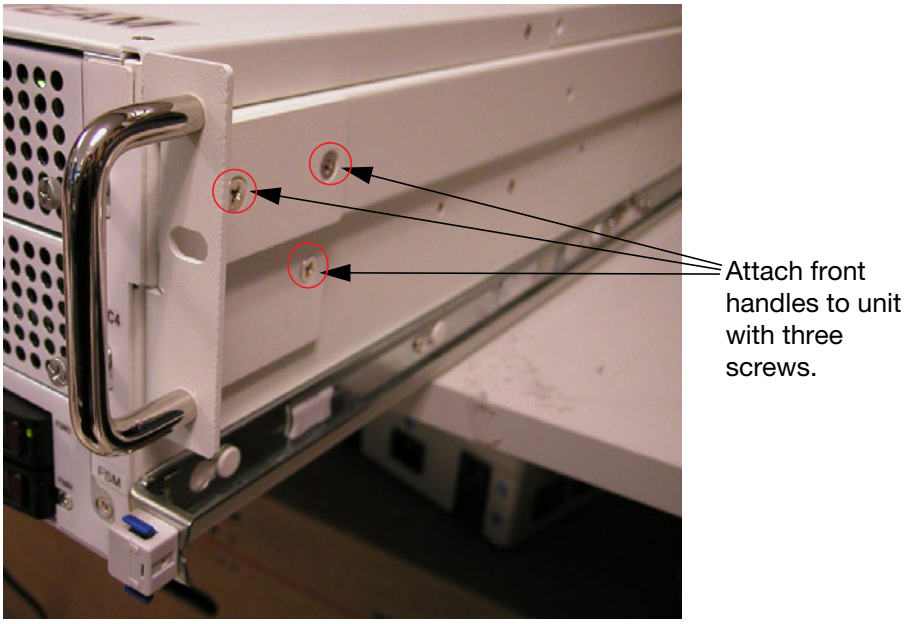
Figure 355: Locking rear clip on unit.

3 Optionally, you can add a screw to make the rail more secure.

Figure 356: Optional screw hole for additional support.

4 Attach the front handles to each side at the front of the unit with three screws. Note that the front handles are not used as rack mounts. Use only as handles to slide the unit in and out of the rack.

Figure 357: Attaching front handle to unit.



5 Orient the external rail on the rack. Ensure that the ball bearing track is forward. The front of the rail is labelled “Front” and the end of the rail is labelled “Rear”.

6 Extend the external rail to fit the rack. Use the locking mechanism on the front and back of the rail to lock into place.

Figure 358: Front locking mechanism.

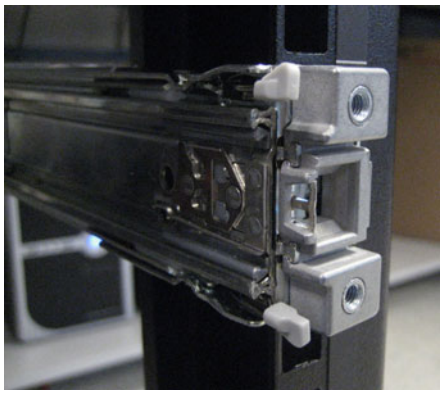


Figure 359: Rear locking mechanism.

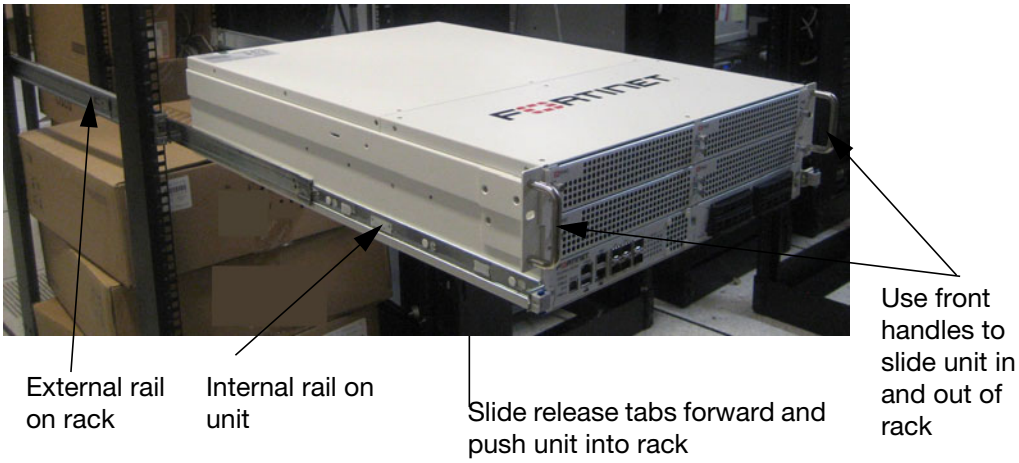
7 Use at least two people to lift the unit and insert the system approximately halfway onto the rack by sliding the external rails over the internal rails.

8 Slide the release tabs on both sides of the internal rails and push the system into the rack. Move your fingers away from the release tabs once the system is in motion.

Figure 360: FortiGate unit halfway on rack showing release tabs.

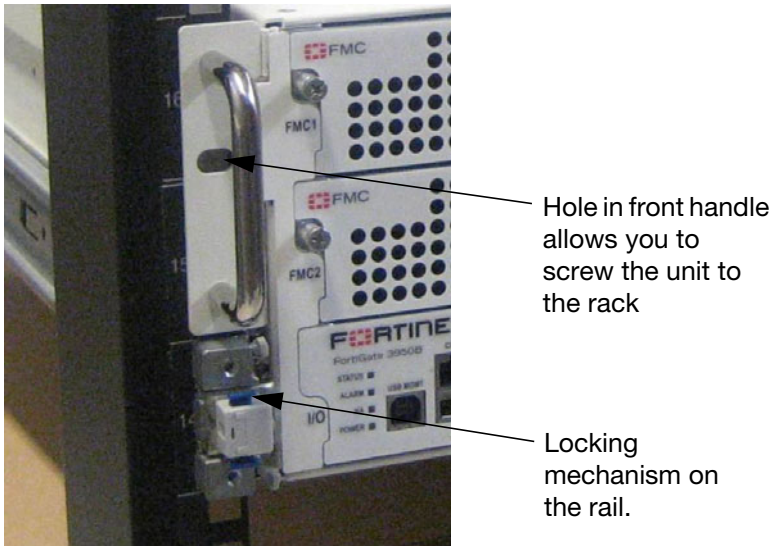


9 Lock the system into place by squeezing together the buttons at the front of the rail.

Figure 361: FortiGate unit on rack.

10 Optionally, you can add a screw through the front handles for more security.

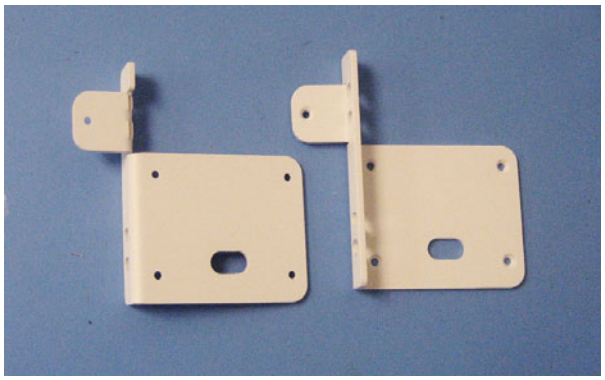
Figure 362: Location of locking mechanism on rail and screw hole in front handle.



To install a 3U 3900-series FortiGate using the middle rack mount brackets

1 Before you start, confirm that you have the two middle rack mount brackets.

Figure 363: Middle rack mount brackets.



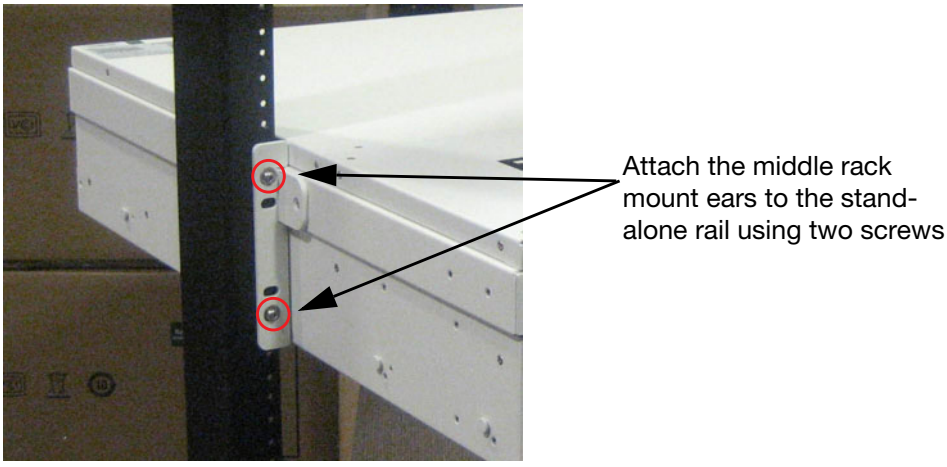
2 Attach the middle rack mount brackets to each side of the unit using five screws for each mount. Ensure the middle piece faces outwards.

Figure 364: Attaching the middle rack mount brackets to the sides of the unit.

3 Use at least two people to lift the unit and insert the system halfway onto the rack until the middle rack mount brackets meet the stand-alone rack.

4 While the two people hold the unit, use another person to attach the middle piece of the middle rack mount brackets to the stand-alone rack using two screws.

Figure 365: Attaching the middle rack mount brackets to the stand-alone rack.



5 Ensure you attach both middle rack mount brackets to both sides of stand-alone rack.

Figure 366: Fortinet unit on the stand-alone rack.

Plugging in the FortiGate unit

Most FortiGate unit do not have an on/off switch. Check the quick-start guide included with your FortiGate unit to see of your model has an on/off switch.

To power on the FortiGate unit

1 Connect the power cable to the power connection on the back of the FortiGate unit. If your model has multiple power connections, connect cables to all the connections.

2 Connect the power cable or cables to power outlets.

Each power cable should be connected to a different power source. If one power source fails, the other may still be operative.

The FortiGate unit starts and the Power and Status (if available) LEDs light up. The Status LED (if available) flashes while the FortiGate unit starts, and remains lit when the system is running.

If the FortiGate unit has two power supplies and only one is connected, an audible alarm sounds to indicate a failed power supply. Press the red alarm cancel button on the rear panel next to the power supply to stop the alarm.

Connecting to the network

Using the supplied Ethernet cable, connect one end of the cable to your router or modem, whichever is the connection to the Internet. Connect the other end to the FortiGate unit. Connect it to either the External, WAN port, or port 1 interface. Use additional cables to connect the Internal port or port 2 to your internal hub or switch.

Turning off the FortiGate unit

Always shut down the FortiGate operating system properly before turning off the power switch or unplugging the unit to avoid potential hardware problems.

To power off the FortiGate unit

1 From the web-based manager, go to *System* > *Dashboard* > *Status*.
2 In the *Unit Operation* display, select *Shutdown*, or from the CLI enter:

```
execute shutdown
```

3 Wait a moment for the shutdown operation to finish.
4 Disconnect the power cables from the power supply.

Further configuration

Further configuration is beyond the scope of this installation guide.

"Basic setup" on page 335 describes how to configure the operating mode, interface addresses, DNS server, the default gateway, and firewall policies.

Management interfaces do not support VLANs

AMC module configuration

This section explains how to configure AMC modules on the FortiGate unit. This includes auto-bypass and recovery for AMC bridge modules.

The following topics are included in this section:

Configuring AMC modules

By default, FortiGate units automatically recognize the AMC modules installed in their AMC slots or automatically recognize that an AMC slot is empty. If the module contains interfaces, FortiOS automatically adds the interfaces to the FortiGate configuration. If the module contains a hard disk, the hard disk is automatically added to the configuration. However, when the FortiGate unit is powered down and the module removed from the slot, when the FortiGate unit restarts it automatically recognizes that the slot is empty and will not retain any configuration settings for the missing module.

This default behavior is usually acceptable in most cases. However, it can be useful when a module is present in a slot to add the name of the module to the FortiGate configuration. Then, if the module fails or if you temporarily remove it from the slot, the FortiGate unit keeps the module's configuration settings so that when the module is replaced you will not have to re-configure it.

If you have added the name of a module to a slot and you are planning or removing the module and replacing it with a different type of module (for example, if you are removing a FortiGate-ASM-S08 and replacing it with a FortiGate-ASM-FX2) you should reset the slot to the default before removing the module. Then after adding the new module you should add its name to the slot.

You configure AMC slot settings from the FortiGate CLI using the `config system amc` command. For information about this command, see the *FortiGate CLI Reference*.

The following procedure shows how to add a FortiGate-ADM-FB8 to the first double-width AMC slot (dw1) and how to add the name of the module to the slot configuration.

To change the default setting for an AMC slot

1. Enter the following CLI command to verify that the slot that you will insert the FortiGate-ADM-FB8 module into is set to the default configuration.

   This command lists the AMC slots and the settings for each one. Example command output for a FortiGate-5001A with an empty double-width AMC slot:

   ```
   get system amc
   dw1       : auto
   ```

2. Power down the FortiGate unit.
3. Insert the FortiGate-ADM-FB8 module into the double-width AMC slot.

4 Power up the FortiGate unit.

As long as the slot that you have inserted the FortiGate-ADM-FB8 module into is set to `auto` the FortiGate unit should automatically find the module when it powers up.

5 Add the name of the FortiGate-ADM-FB8 module to the FortiGate configuration.

```
config system amc
  set dw1 adm-fb8
end
```

Auto-bypass and recovery for AMC bridge module

The FortiGate-ASM-CX4 and FortiGate-ASM-FX2 modules provide fail open protection for interface pairs of FortiGate units operating in Transparent mode and that have a single-width AMC slot. The FortiGate-ASM-CX4 or FortiGate-ASM-FX2 module bridges FortiGate interfaces, monitors the interfaces for traffic failures, and operate as pass-through devices if the interfaces or the entire FortiGate unit fails or for some reason cannot pass traffic between the interfaces. If a failure occurs, traffic bypasses the FortiGate unit and passes through the FortiGate-ASM-CX4 or FortiGate-ASM-FX2 module to make sure that the network can continue processing traffic after a FortiGate failure.

This section describes how to configure a FortiGate unit to use a FortiGate-ASM-CX4 or FortiGate-ASM-FX2 module to bridge FortiGate interfaces. The FortiGate unit must operate in Transparent mode and the FortiGate-ASM-CX4 and FortiGate-ASM-FX2 modules are not compatible with FortiGate HA.

The FortiGate-ASM-CX4 and FortiGate-ASM-FX2 modules include a bypass watchdog that continually verifies that traffic is flowing through the bridged FortiGate interfaces. If traffic stops flowing, for example if the FortiGate unit fails, and if the bypass watchdog detects this, the bridge module switches to bypass mode to ensure the flow of traffic on the network.

In bypass mode all traffic flows between interfaces on the FortiGate-ASM-CX4 and FortiGate-ASM-FX2 modules and not through the FortiGate unit. You can configure a recovery watchdog to verify that the bridged FortiGate interfaces cannot process traffic. If you fix the problem or the problem fixes itself, the recovery watchdog automatically detects that traffic can resume and switches the module back to normal operation by turning off bypass mode.

To configure a FortiGate unit to operate with a FortiGate-ASM-CX4 or FortiGate-ASM-FX2 module

1 Switch the FortiGate unit to operate in transparent mode.

```
config system settings
  set opmode transparent
  set manageip <management_IPv4> <netmask_ipv4>
  set gateway <gateway_ipv4>
end
```

After a short pause the FortiGate unit is operating in transparent mode.

2 Enter the following command to verify that the slot that you will insert the FortiGate-ASM-CX4 or FortiGate-ASM-FX2 module into is set to `auto`.

This command lists the AMC slots and the settings for each one. Example command output for a FortiGate-620B with an empty AMC slot:

```
get system amc
sw1      : auto
```

3 Power down the FortiGate unit.

4 Insert the FortiGate-ASM-CX4 or FortiGate-ASM-FX2 module into a single-width AMC slot.

5 Power up the FortiGate unit.

As long as the slot that you have inserted the module into is set to `auto` the FortiGate unit should automatically find the module when it powers up.

6 Add the name of the module to the FortiGate configuration and configure bypass and recovery settings.

The following command configures AMC single width slot 1 (sw1) for a FortiGate-ASM-CX4.

This command also enables the bypass watchdog and increases the bypass timeout from the default value of 10 seconds to 60 seconds. This means that if a failure occurs the bridge module will change to bypass mode 60 seconds after the bypass watchdog detects the failure.

This command also enables watchdog recovery and sets the watchdog recovery period to 30 seconds. This means that if a failure occurs, while the FortiGate-ASM-CX4 module is bridging the connection the AMC bypass watchdog monitors FortiGate processes and will revert to normal operating mode (that is disable the bridging the interfaces with the FortiGate-ASM-CX4 module) if the FortiGate unit recovers from the failure.

```
config system amc
  set sw1 asm-cx4
  set bypass-watchdog enable
  set bypass-timeout 60
  set watchdog-recovery enable
  set watchdog-recovery-period 30
end
```

Enabling or disabling bypass mode for AMC bridge modules

Use the `execute amc bypass` command to switch between normal mode and bypass mode for a FortiGate-ASM-CX4 or FortiGate-ASM-FX2 module installed in an single-width AMC slot in a FortiGate unit. Normally the FortiGate-ASM-CX4 and FortiGate-ASM-FX2 modules operate with bypass mode disabled and traffic passes through the FortiGate interfaces bridged by the FortiGate-ASM-CX4 or FortiGate-ASM-FX2 module. You can use this command manually enable bypass mode and force traffic to bypass the FortiGate interfaces and pass through the FortiGate-ASM-CX4 or FortiGate-ASM-FX2 module.

Also, if bypass mode has been enabled (using this command or because of a failure), you can also use this command to manually disable bypass mode and resume normal operation. This can be useful if the problem that caused the failure has been fixed and normal operation can resume.

To manually enable bypass mode

1 Use the following command to manually enable bypass mode:

```
execute amc bypass enable
```

2 Use the following diagnose command to view the status of the AMC modules installed in a FortiGate unit, including whether they are operating in bypass mode.

For example if you have installed a FortiGate-ASM-CX4 module in AMC slot 2 of a FortiGate-3810A and bypass mode is enabled:

```
diagnose sys amc bypass status
ASM-CX4 in slot 2:
      amc-sw2/1 <--> amc-sw2/2: mode=bypass (admin action)
      amc-sw2/3 <--> amc-sw2/4: mode=bypass (admin action)

Daemon heartbeat status: normal
Last heartbeat received: 0 second(s) ago
```

3 Log into the web-based manager and go to *System* > *Dashboard* > *Status* and view the *Unit Operation* widget to see the status of the AMC bridge module.

To manually disable bypass mode

1 Use the following command to manually disable bypass mode:

```
execute amc bypass disable
```

2 Use the following diagnose command to view the status of the AMC modules installed in a FortiGate unit, including whether they are operating in bypass mode.

For example if you have installed a FortiGate-ASM-CX4 module in AMC slot 2 of a FortiGate-3810A and bypass mode is disabled:

```
diagnose sys amc bypass status
ASM-CX4 in slot 2:
      amc-sw2/1 <--> amc-sw2/2: mode=normal
      amc-sw2/3 <--> amc-sw2/4: mode=normal

Daemon heartbeat status: normal
Last heartbeat received: 1 second(s) ago
```

3 Log into the web-based manager and go to *System* > *Dashboard* > *Status* and view the *Unit Operation* widget to see the status of the AMC bridge module.

FortiGate hardware accelerated processing

Many FortiGate models can offload some types of network traffic processing from main processing resources to specialized network processors. If your network has a significant volume of traffic that is suitable for offloading, this hardware acceleration can significantly improve your network throughput.

Some FortiGate models incorporate network processors in the main unit, others support the addition of AMC (Advanced Mezzanine Card) modules. The FortiGate-5000 series supports rear transition modules (RTMs) that incorporate network processors.

This chapter contains the following topics:

How hardware acceleration alters packet flow

Hardware acceleration generally alters packet processing flow as follows:

1. Packets initiating a session pass to the FortiGate unit's main processing resources.
2. The FortiGate unit assesses whether the session matches fast path (offload) requirements.

   To be suitable for offloading, traffic must possess only characteristics that can be processed by the fast path. For a list of requirements, see "Configuring traffic offloading" on page 2940.

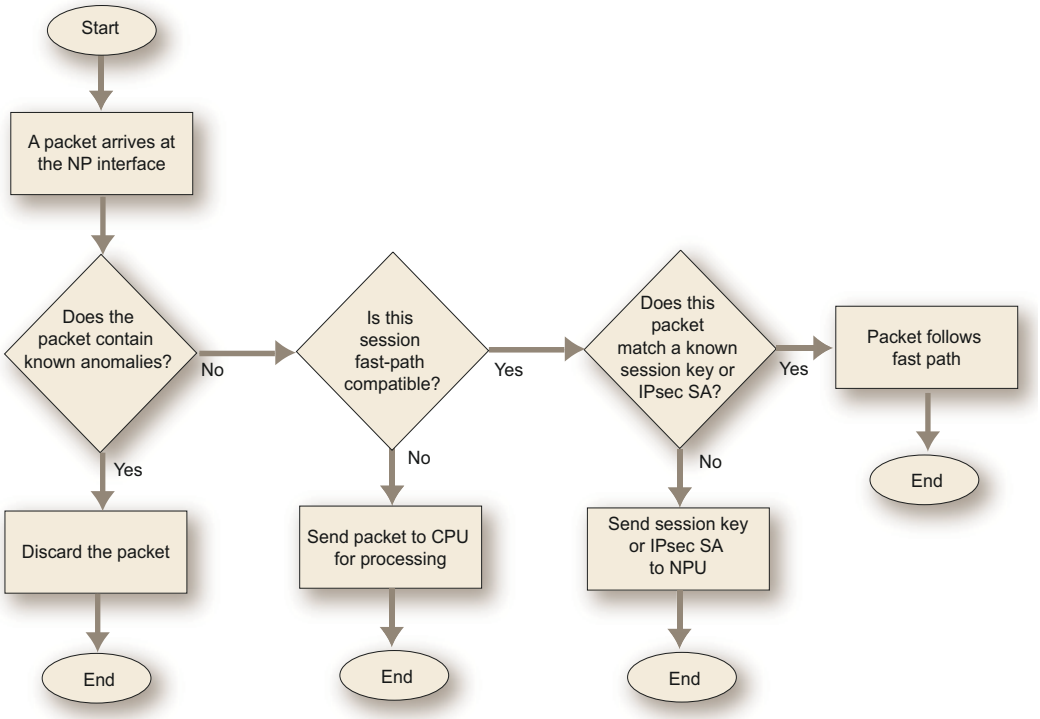
   If the traffic is categorized as fast path friendly, the FortiGate unit sends the session key or IPsec security association (SA) and configured processing action to the network processor(s).

3 Network processors continuously match packets arriving on their attached ports against the session keys and SAs they have received from the FortiGate unit's main processing resources.

- If a network processor's network interface is configured to perform hardware accelerated anomaly checks, the network processor drops or accepts packets which match the configured anomaly patterns. These checks are separate from and in advance of anomaly checks performed by IPS, which is not compatible with network processor offloading. See "Configuring pre-IPS anomaly detection" on page 2955.
- The network processor next checks for a matching session key or SA. If a matching session key or SA is found, and if the packet meets packet requirements, the network processor processes the packet according to the configured action and then sends the resulting packet. Packet processing is hardware accelerated.
- If a matching session key or SA is not found, or if the packet does not meet packet requirements, the traffic cannot be offloaded. The network processor sends the data to the FortiGate unit's main processing resources, which process the packet. Packet processing is similar to normal network interfaces (that is, packet processing is not hardware accelerated by the network processor, and requires main processing resources). Packet forwarding occurs at normal rates.

Network processors do not count offloaded packets, and offloaded packets will not be included in traffic statistics, such as FortiAnalyzer traffic reports.

Figure 367: Deciding the packet flow for accelerated interfaces



Some traffic processing can still be hardware accelerated, even though it does not meet general offloading requirements. For example, some IPsec traffic originates from the FortiGate unit itself and does not follow the offloading requirement of ingress from a network processor's network interface, but FortiGate units can still utilize network processor encryption capabilities. See "Configuring IPsec VPN offloading" on page 2949.

Packet forwarding rates vary by the percentage of offloadable processing and the type of network processing required by your configuration, but are independent of frame size. For optimal traffic types, network throughput can equal wire speed.

Offloading requirements vary slightly by the model of the network processor.

The following types of acceleration hardware are found on FortiGate units:

- network processors: NP1 (formerly known as FA2), NP2, NP4
- content processors: CP4, CP5, CP6
- accelerated interface modules: ASM-FB4, ADM-FB8, ADM-XB2, ADM-XD4, RTM-XD2
- security processor modules: ASM-CE4, ASM-XE2

Network processors overview

Many Fortinet products contain network processors. Some of these products contain NP1 network processors (also known as FortiAccel, or FA2), while others contain NP2 network processors. Some newer models contain an NP4 processor. Network processor features, and therefore offloading requirements, vary by network processor model. Differing offloading requirements are noted in "Configuring traffic offloading" on page 2940 and "Configuring IPsec VPN offloading" on page 2949.

Network processor models

FortiASIC network processors work at the interface level to support IPsec offload and unicast UDP/TCP traffic forwarding. The maximum throughput and number of network interfaces varies by processor model.

NP1: supports FW and VPN acceleration with 2Gbps capacity. It is found on FortiGate units such models 1000A-FA2, 3600A, and 3810A, and also on FortiGate-5000 series 5001FA2 and 5005FA2 blades.

NP2: supports FW and VPN acceleration with 4Gbps capacity. It is found on newer, B-series FortiGate units ranging from models 200B to 3016B, and on most AMC accelerated interface cards.

NP4: supports FW and VPN acceleration with 40 Gbps capacity. It is found on the ADM-XD4 AMC card and on the FortiGate-5000 series RTM-XD2 blade.

Table 151: Network processor models

Processor	Interfaces
NP1	2 x 1 Gb/s
NP2	1 x 10Gb/s, 4 x 1Gb/s
NP4	2 x 10Gb/s

The NP1network processor does not support frames greater than 1500 bytes. If your network uses jumbo frames, you may need to adjust the MTU (Maximum Transmission Unit) of devices connected to NP1ports.Maximum frame size for NP2 and NP4 processors is 9000 bytes.

For both NP1 and NP2 network processors, ports attached to a network processor cannot be used for firmware installation by TFTP.

Some Fortinet products contain multiple network processors. Depending on the product, network processors may or may not be directly connected to each other on the circuit board through an EEI (Enhanced Extension Interface).

- Directly connected network processors have an EEI, and can pass traffic between them without involving the FortiGate unit's main processing resources.
- Indirectly connected network processors have no EEI, and ***cannot*** pass traffic between them without involving the FortiGate unit's main processing resources.

Sessions can only be offloaded if both the source and destination port are connected to the same network processor or directly (EEI) connected network processor pair.

For information about the network processors in any specific FortiGate model, refer to the product brochure.

Determining the network processors installed on your FortiGate unit

To list the network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu <model> list
```

<model> can be `np1`, `np2` or `np4`.

The output lists the interfaces that have the specified processor. For example,

```
# get hardware npu np1 list
ID          Interface
0           port9 port10
```

This command does not detect Security processing modules.

Content processors overview

The FortiASIC Content Processor (CP) works at the system level. Its main functions are SSL VPN key generation and SSL offloading. Capabilities vary by model.

CP4

- FIPS-compliant DES/3DES/AES encryption and decryption

- SHA-1 and MD5 HMAC
- IPSEC protocol processor
- Random Number generator
- Public Key Crypto Engine
- Content processing engine
- ANSI X9.31 and PKCS#1 certificate support

CP5

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321/2104/2403/2404 and FIPS180/FIPS198
- IPsec protocol processor
- High performance IPSEC Engine
- Random Number generator compliant with ANSI X9.31
- Public Key Crypto Engine supports high performance IKE and RSA computation
- Script Processor

CP6

- Dual content processors
- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321 and FIPS180
- HMAC in accordance with RFC2104/2403/2404 and FIPS198
- IPsec protocol processor
- High performance IPsec engine
- Random Number generator compliance with ANSI X9.31
- Key exchange processor for high performance IKE and RSA computation
- Script Processor
- SSL/TLS protocol processor for SSL content scanning and SSL acceleration

CP8

- Over 10Gbps throughput IPS content processor for packet content matching with signatures
- High performance VPN bulk data engine
  - IPSEC and SSL/TLS protocol processor
  - DES/3DES/AES in accordance with FIPS46-3/FIPS81/FIPS197
  - ARC4 in compliance with RC4
  - MD5/SHA-1/SHA256 with RFC1321 and FIPS180
  - HMAC in accordance with RFC2104/2403/2404 and FIPS198

- Key Exchange Processor support high performance IKE and RSA computation
  - Public key exponentiation engine with hardware CRT support
  - Primarily checking for RSA key generation
  - Handshake accelerator with automatic key material generation
  - Random Number generator compliance with ANSI X9.31
  - Sub public key engine (PKCE) to support up to 4094 bit operation directly
- Message authentication module offers high performance cryptographic engine for calculating SHA256/SHA1/MD5 of data up to 4G bytes (used by any application like WAN opt.)
- PCI express Gen 2 four lanes interface
- Cascade Interface for chip expansion

Determining the content processor in your FortiGate unit

Use the `get hardware status` CLI command to determine which content processor your FortiGate unit contains. The output looks like this:

```
# get hardware status
Model name: Fortigate-620B
ASIC version: CP6
ASIC SRAM: 64M
CPU: Intel(R) Core(TM)2 Duo CPU     E4300  @ 1.80GHz
RAM: 2020 MB
Compact Flash: 493 MB /dev/sda
Hard disk: 76618 MB /dev/sdb
USB Flash: not available
Network Card chipset: Broadcom 570x Tigon3 Ethernet Adapter
    (rev.0x5784100)
```

The ASIC version line lists the content processor model number.

If you have a CP6 processor, you can view the status of SSL acceleration using the command `get vpn status ssl hardware-acceleration`.

Security processing modules overview

FortiGate Security Processing (SP) modules, such as the ASM-CE4 and ADM-XE2, work at both the interface and system level to increase overall system performance by accelerating some security and networking processing on the interfaces they provide. The SP frees the FortiGate unit's processor for other tasks by offloading firewall, application control, and IPS processing, including flow-based antivirus protection. You can configure the SP to favor IPS over firewall processing in hostile high-traffic environments.

The ASM-CE4 and ADM-XE2 are Advanced Mezzanine cards (AMCs) that are the first generation of SP modules. The next generation of SP modules are Fortinet Mezzanine cards (FMCs) found on newer FortiGate models, such as the 3950. FMC modules take advantage of the Integrated Switch Fabric (ISF) backplane, meaning that accelerated performance is available between any two interfaces, not just interfaces on the same FMC module.

Security processor module models

The ADM-XE2 is a dual-width AMC card with two 10 Gb/s interfaces that can be used on FortiGate-3810A and FortiGate-5001A-DW systems.

The ADM-FE8 is a dual-width AMC card with eight 1 Gb/s interfaces that can be used with the FortiGate-3810A.

The ASM-CE4 is a single-width AMC card with four 10/100/1000 Mb/s interfaces that can be used on FortiGate-3016B and FortiGate-3810A units.

Displaying information about security processing modules

You can display information about installed AMC modules using the CLI command

```
diagnose npu spm dos synproxy <sp_id>
```

Variable	Description
<sp_id>	Enter the ID of the security processing device that you want to display information for. The first device is 0, the second is 1, and so on.

Security processing modules are also called network processing units (NPUs).

Example

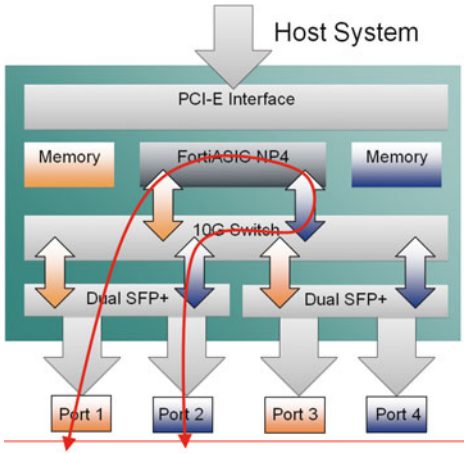
This example shows how to display details about how the module is processing sessions using the syn proxy. This is a partial output of the command:

```
Number of proxied TCP connections :                 0
Number of working proxied TCP connections :         0
Number of retired TCP connections :                 0
Number of valid TCP connections :                   0
Number of attacks, no ACK from client :             0
Number of no SYN-ACK from server :                  0
Number of reset by server (service not supportted): 0
Number of establised session timeout :              0
Client timeout setting :                            3 Seconds
Server timeout setting :                            3 Seconds
```

Setting switch-mode mapping on the ADM-XD4

The ADM-XD4 SP has four 10 Gb/s ports, but the NP4 processor it contains has only two 10 Gb/s ports. The external ports you use are important to optimize the SP for your application.

Figure 368: ADM-XD4 mapping mode



Ports 1 and 3 share one NP4 processor and ports 2 and 4 share the other. Performance ports sharing the same NP4 processor is far better than when forcing network data to move between NP4 processors by using one port from each, for example ports 1 and 2 or ports 3 and 4.

Configuring overall security priorities

You can set the priority for security processing using the CLI:

```
config system global
  set optimize {antivirus | throughput | session}
end
```

`antivirus` - Allow all CPU cores to process traffic – typically used with proxy style services (AntiX, content filtering)

`throughput` - Prevents code synchronisation delays from impacting raw throughput.

`session` - Allows distributed session set up across all cores for high session per second environments. This option is available on newer FortiGate models such as the 1240B.

Configuring traffic offloading

Offloading traffic to a network processor requires that the FortiGate unit configuration and the traffic itself is suited to hardware acceleration. There are requirements for path the sessions and the individual packets.

Session fast path requirements

Sessions must be fast path ready. Fast path ready session characteristics are:

- Layer 2 type/length must be 0x0800 (IEEE 802.1q VLAN specification is supported); link aggregation between any network interfaces sharing the same network processor(s) may be used (IEEE 802.3ad specification is supported)
- Layer 3 protocol must be IPv4
- Layer 4 protocol must be UDP, TCP or ICMP
- Layer 3 / Layer 4 header or content modification must not require a session helper (for example, SNAT, DNAT, and TTL reduction are supported, but application layer content modification is not supported)

- FortiGate unit firewall policy must not require antivirus or IPS inspection
- origin must not be local host (the FortiGate unit)
- ingress and egress network interfaces are both attached to the same network processor(s)

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See "Configuring pre-IPS anomaly detection" on page 2955.

For session offloading to NP1 network processors, the session must not use an aggregated link or require QoS, including rate limits and bandwidth guarantees. Traffic shaping and link aggregation are not supported.

If a session is not fast path ready, the FortiGate unit will not send the session key to the network processor(s). Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key to the network processor(s). Session key lookup then succeeds for subsequent packets from the known session.

Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for network processors' network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

If packet requirements are not met, an individual packet will use FortiGate unit main processing resources, regardless of whether other packets in the session are offloaded to the specialized network processor(s).

In some cases, due to these requirements, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing.

For example, FTP uses two connections: a control connection and a data connection. The control connection requires a session helper, and cannot be offloaded, but the data connection does not require a session helper, and can be offloaded. Within the offloadable data session, fragmented packets will not be offloaded, but other packets will be offloaded.

Some traffic types differ from general offloading requirements, but still utilize some of the network processors' encryption and other capabilities. Exceptions include IPsec traffic and active-active high availability (HA) load balanced traffic.

Fast path connections for specific FortiGate models

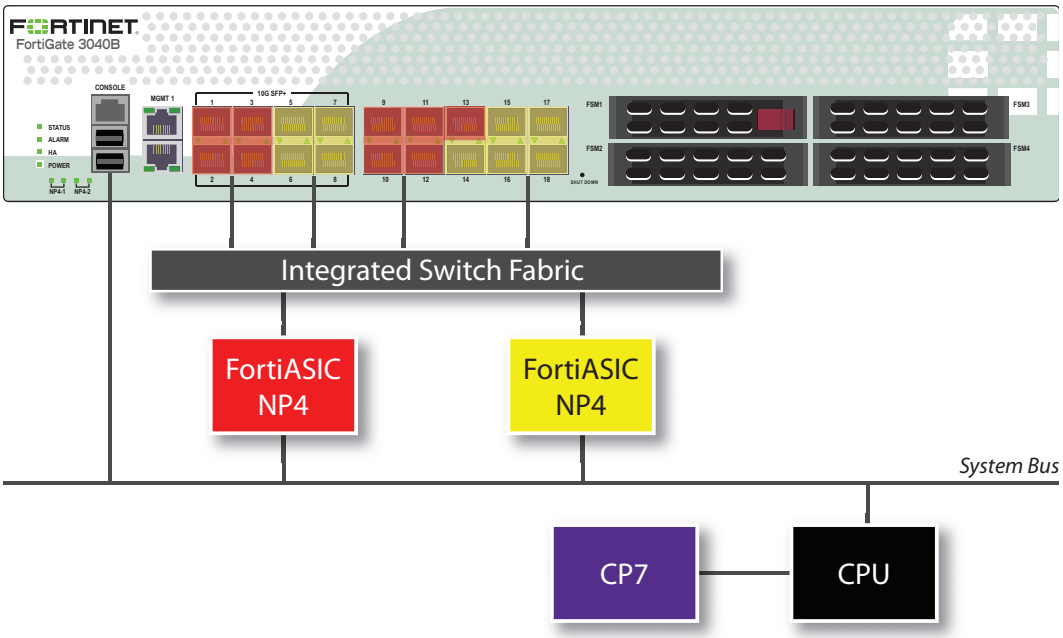
A number of FortiGate models contain multiple NP4 processors that require care when connecting network cables. For accelerated processing, traffic must enter and exit interfaces connected to the same NP4 processor.

FortiGate-3040B

The FortiGate-3040B features two NP4 processors to accelerate network traffic to wire speeds. Traffic between interfaces that use the same processor experience the highest acceleration.

- The 10 Gb interfaces, port1, port2, port3, port4, and the 1 Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10 Gb interfaces, port5, port6, port7, port8, and the 1 Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.

Figure 369: The FortiGate-3040B



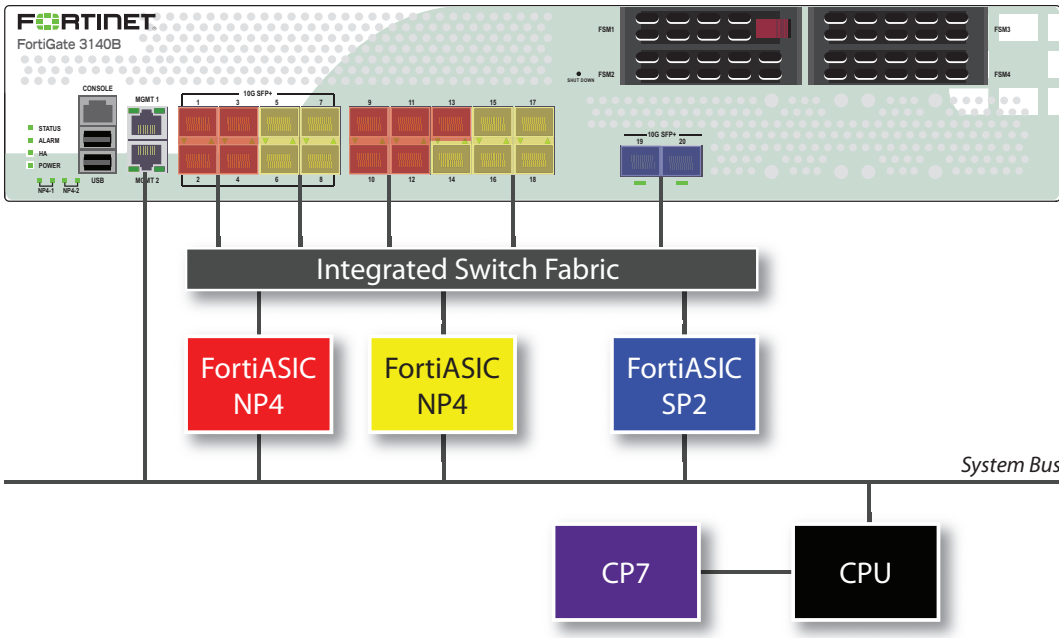
For example, for maximum NP4 acceleration of traffic received on port1, the traffic must exit the FortiGate-3040B unit on port2, port3, or port4 if the bandwidth exceeds 1 Gb. If the traffic bandwidth does not exceed 1 Gb, the traffic can also exit on port9, port10, port11, port12, or port13. Also, for maximum NP4 acceleration of traffic received on port5, the traffic must exit the FortiGate-3040B unit on port6, port7, or port8 if the bandwidth exceeds 1 Gb. If the traffic bandwidth does not exceed 1 Gb, the traffic can also exit on port14, port15, port16, port17, or port18.

FortiGate-3140B

The FortiGate-3140B features two NP4 processors and one SP2 processor to accelerate network traffic to wire speeds. Traffic between interfaces that use the same processor experience the highest acceleration.

- The 10 Gb interfaces, port1, port2, port3, port4, and the 1 Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10 Gb interfaces, port5, port6, port7, port8, and the 1 Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.
- The 10 Gb interfaces, port19 and port20, share connections to the SP2 processor.

Figure 370: The FortiGate-3140B



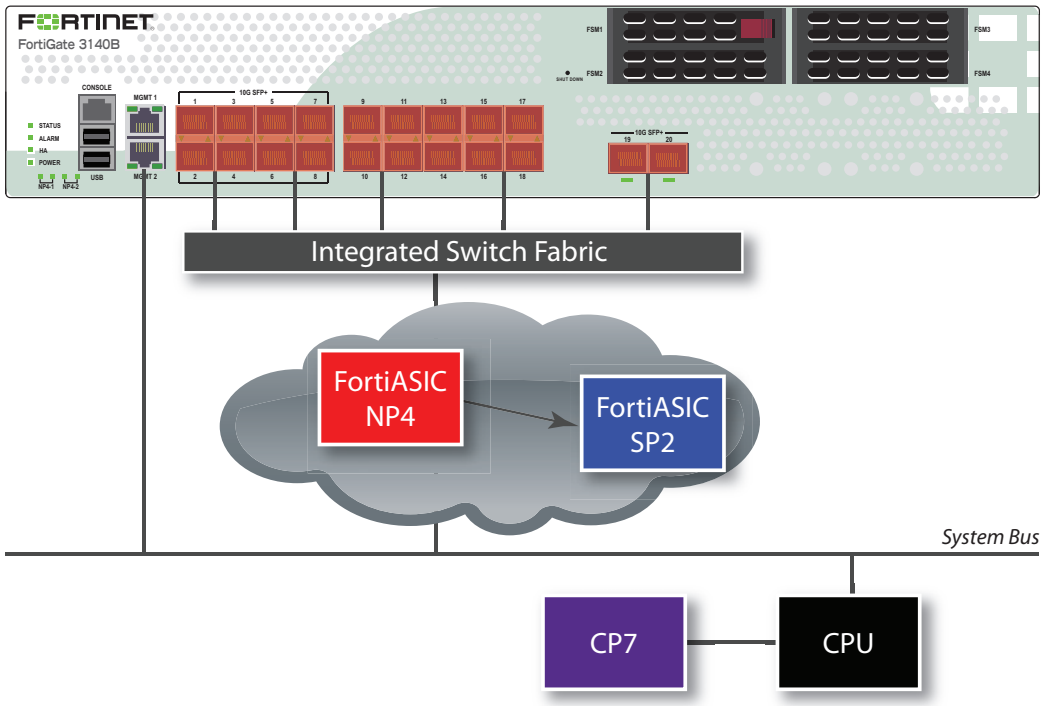
For example, for maximum NP4 acceleration of traffic received on port1, the traffic must exit the FortiGate-3140B unit on port2, port3, or port4 if the bandwidth exceeds 1 Gb. If the traffic bandwidth does not exceed 1 Gb, the traffic can also exit on port9, port10, port11, port12, or port13. For maximum NP4 acceleration of traffic received on port5, the traffic must exit the FortiGate-3140B unit on port6, port7, or port8 if the bandwidth exceeds 1 Gb. If the traffic bandwidth does not exceed 1 Gb, the traffic can also exit on port14, port15, port16, port17, or port18. Also, for maximum SP2 acceleration of traffic received on port 19, the traffic must exit the FortiGate-3140B unit on port20.

FortiGate-3140B — load balance mode

The FortiGate-3140B load balance mode allows you increased flexibility in how you use the interfaces on the FortiGate unit. When enabled, traffic between any two interfaces (excluding management and console) is accelerated. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

Figure 371: The FortiGate-3140B in load balance mode



To enable this feature, issue this CLI command.

```
config system global
  set sp-load-balance enable
end
```

The FortiGate unit will then restart.

To return to the default mode, issue this CLI command.

```
config system global
  set sp-load-balance disable
end
```

FortiGate-3950B and FortiGate-3951B

The FortiGate-3950B features one NP4 processor to accelerate network traffic to wire speeds.

- The 1 Gb SPF interfaces, port1, port2, port3, port4, and the 10 Gb SPF+ interfaces, port5, port6, share connections to one NP4 processor.

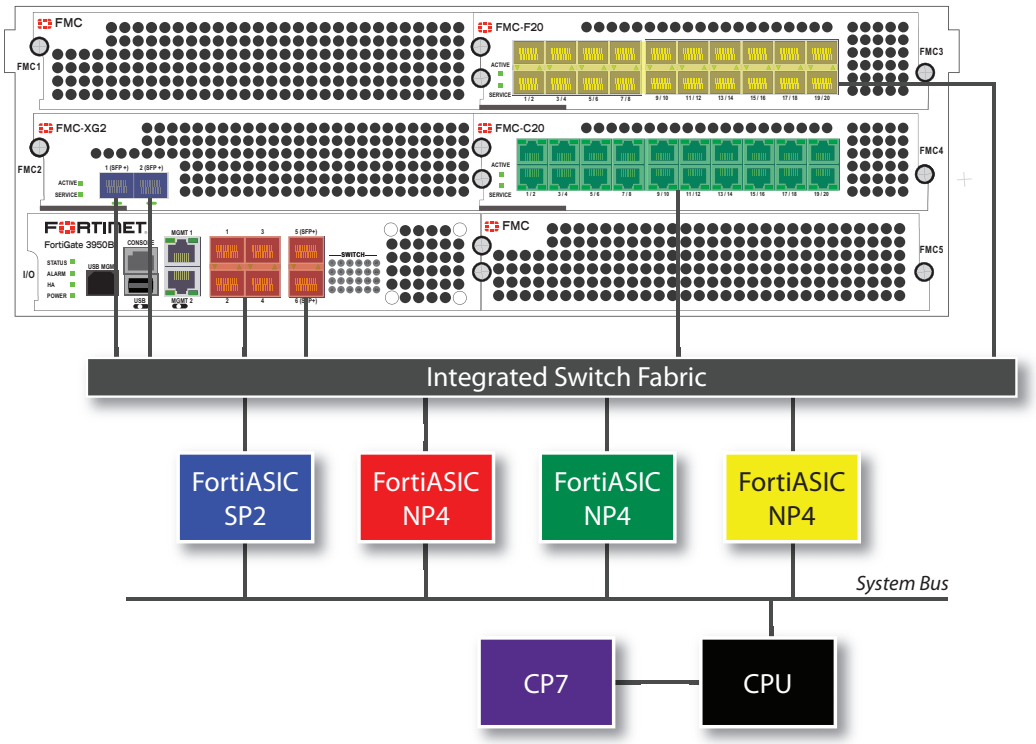
The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

You can add additional FMC interface modules. If they support network traffic acceleration, it is only between interfaces on the module. Figure 372 shows a FortiGate-3950B with three modules installed: an FMC-XG2, an FMC-F20, and an FMC-C20.

- The FMC-XG2 has one NP4 processor and one SP2 processor. The 10 Gb SPF+ interfaces, port1 and port2, share connections to both processors.

- The FMC-F20 has one NP4 processor and the twenty 1 Gb SPF interfaces, port1 through port20, share connections to the NP4 processor.
- The FMC-C20 has one NP4 processor and the twenty 10/100/1000 interfaces, port1 through port20, share connections to the NP4 processor.

Figure 372: The FortiGate-3950B with an FMC-XG2, an FMC-F20, and an FMC-C20



The processor in the FortiGate-3950B and on each FMC module can accelerate only the network traffic entering and leaving its own interfaces. For example, for maximum NP4 acceleration of traffic that exceeds 1 Gb bandwidth must enter and leave the FortiGate-3950B on its own port5 and port6, or the FMC-XG2 port1 and port2. If the traffic bandwidth does not exceed 1 Gb, the traffic can enter and exit using port1 through port4, or port1 through port20 on either the FMC-F20 or the FMC-C20.

Also, for maximum SP2 acceleration of traffic received on port1 of the FMC-XG2, the traffic must exit port2 of the FMC-XG2.

Traffic can enter an interface on one module and leaving an interface on another module, but it will not take advantage of any network or security acceleration.

FortiGate-3950B and FortiGate-3951B — load balance mode

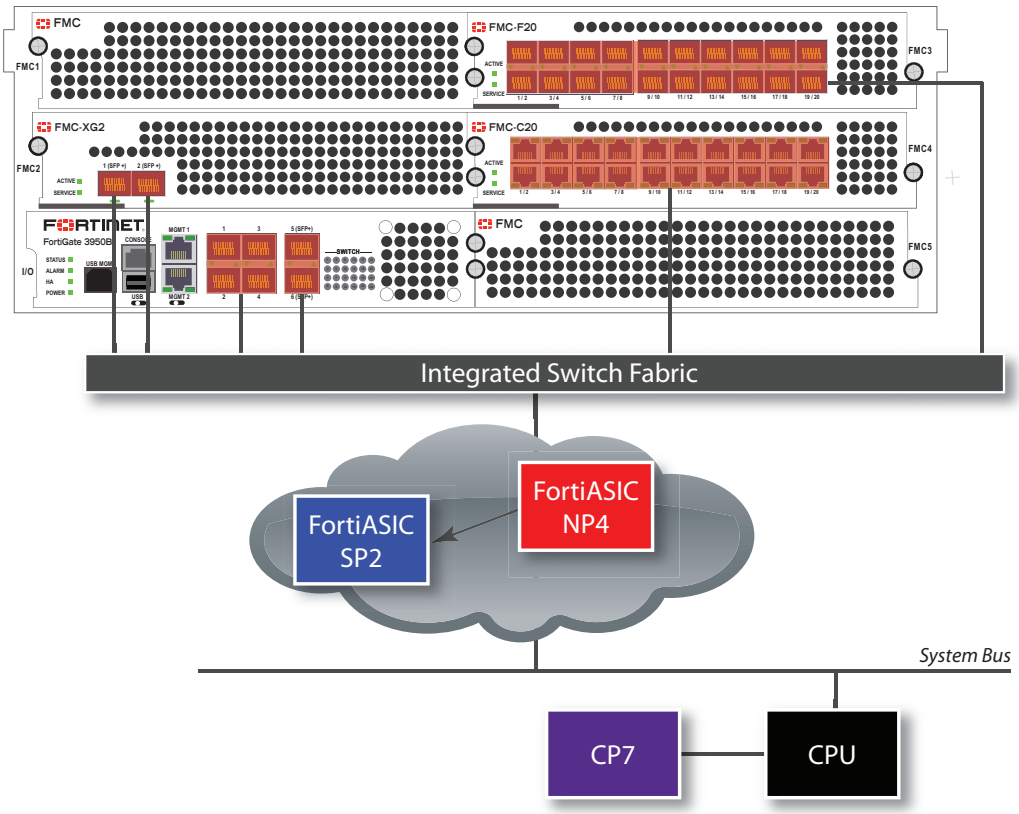
Adding one or more FMC-XG2 modules to your FortiGate-3950B allows you to enable load balance mode. This feature allows you increased flexibility in how you use the interfaces on the FortiGate unit.

The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

When enabled, traffic between any two interfaces (excluding management and console) is accelerated whether they are the six interfaces on the FortiGate-3950B itself, or on any installed FMC modules. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

Figure 373: The FortiGate-3950B in load balance mode



To enable this feature, issue this CLI command.

```
config system global
  set sp-load-balance enable
end
```

The FortiGate unit will then restart.

To return to the default mode, issue this CLI command.

```
config system global
  set sp-load-balance disable
end
```

Session offloading in HA active-active configuration

Fortinet's specialized network processors can improve network performance in active-active (load balancing) high availability (HA) configurations, even though traffic deviates from general offloading patterns, involving more than one network processor, each in a separate FortiGate unit. No additional offloading requirements apply.

Once the primary FortiGate unit's main processing resources send a session key to its network processor(s), network processor(s) on the primary unit can redirect any subsequent session traffic to other cluster members, reducing traffic redirection load on the primary unit's main processing resources.

As subordinate units receive redirected traffic, each network processor in the cluster assesses and processes session offloading independently from the primary unit. Session key states of each network processor are not part of synchronization traffic between HA members.

Configuring traffic shaping offloading

Accelerated Traffic shaping is supported with some limitations on NP2 and NP4 interfaces. Security processor modules do not perform any traffic shaping. Any traffic on which traffic shaping is enabled is handled by the FortiGate unit's main processing resources.

For traffic shaping and QoS through accelerated NP2 and NP4 ports,

- Accelerated ports support policy-based traffic policing. However, fast path traffic and traffic handled by the FortiGate CPU (slow path) are controlled separately, which means the policy setting on fast path does not consider the traffic on the slow path.
- The port based traffic policing as defined by the inbandwidth and outbandwidth CLI commands is not supported on the NP2 processor or the NP4 processor.
- NP2 and NP4 ports support DSCP configurations.
- Per-IP traffic shaping is not supported with NP2 interfaces due to hardware limitations.
- QoS in general is not supported by NP2 and NP4.

You can also use the traffic shaping features of the FortiGate unit's main processing resources by disabling the acceleration features of the NP2 and NP4 ports. See "Disabling offloading" on page 2948.

Network processing unit (`npu`) settings configure offloading for traffic shaping. Configured behavior applies to all network processors contained by the FortiGate unit itself or any installed AMC modules.

```
config system npu
  set traffic-shaping-mode {bidirection | unidirection}
```

```
end
```

Variables	Description	Default
`traffic-shaping-mode {bidirection | unidirection}`	Select the offloaded traffic shaping bandwidth calculation method. • `unidirection`: The bandwidth limit applies per direction. For example, a unidirectional limit of 10 KBps would result in an overall limit of 20 KBps — 10 KBps per direction. • `bidirection`: The bandwidth limit applies to both directions overall. For example, a bidirectional limit of 10 KBps would result in an overall limit of 10 KBps — 5 KBps per direction. This option applies only if the FortiGate unit itself or any installed AMC modules contain a network processor that supports offloading of traffic shaping.	Varies by model.

Example

You could configure the traffic shaping limit to be applied as a bidirectional total limit during hardware accelerated sessions.

```
config system npu
  set traffic-shaping-mode bidirection
end

config system interface
  edit <interface_name>
    set outbandwidth <real outbandwidth>
  end
```

Checking that traffic is offloaded

You can determine whether traffic is offloaded by using the CLI command:

```
diagnose sys session list
```

The output provides detailed information about each session. Look for the “state=” line. If “npu npr” appears on that line, the session was offloaded to a network processor.

You can also you the diagnose command:

```
diagnose sniffer packet <interface_name>
```

Disabling offloading

If you want to completely disable offloading for test purposes or other reasons, you can do so by security policy.

```
config firewall policy
  edit <policy_id_int>
    set auto-asic-offload disable
  end
```

Multicast offloading / acceleration

Only security processor modules such as the CE4, CE8, or XE2 can offload multicast traffic from the FortiGate unit's CPU-based resources. To make use of this capability, the multicast traffic must enter and exit the FortiGate unit on network interfaces on the same SPM card. Also, the session fast path requirements must be met. These are the same requirements that apply to unicast traffic. See "Session fast path requirements" on page 2940.

Like any other traffic between interfaces, multicast traffic requires a firewall policy, in this case a multicast firewall policy. These policies, for example, permit multicast traffic between the first port and each of the other ports on an ASM-CE4 card:

```
config firewall multicast-policy
  edit 1
    set srcintf amc-sw1/1
    set dstintf amc-sw11/2
    set action accept
  next
  edit 2
    set srcintf amc-sw1/1
    set dstintf amc-sw11/3
    set action accept
  next
  edit 3
    set srcintf amc-sw1/1
    set dstintf amc-sw11/4
    set action accept
  end
```

Note that simple forwarding of multicast packets is not accelerated. Also, if the FortiGate unit or VDOM is in Transparent mode, multicast is not accelerated.

Use `diagnose ip multicast npu-session list` to verify the NPU session is established

Configuring IPsec VPN offloading

Fortinet's specialized network processors contain features to improve IPsec tunnel performance. For example, network processors can encrypt and decrypt packets, reducing cryptographic load on the FortiGate unit's main processing resources.

IPsec offloading requirements

Requirements for hardware accelerated IPsec encryption or decryption are a modification of general offloading requirements. Differing characteristics are:

- origin can be local host (the FortiGate unit)
- in Phase I configuration, Local Gateway IP must be specified as an IP address of a network interface for a port attached to a network processor
- SA must have been received by the network processor

- in Phase II configuration:
  - encryption algorithm must be DES, 3DES, AES-128, AES-192, AES-256, or null
  - authentication must be MD5, SHA1, or null
  - if encryption is null, authentication must not also be null
  - if replay detection is enabled, `enc-offload-antireplay` must also be `enable` in the CLI

If replay detection is enabled in the Phase II configuration, you can enable or disable IPsec encryption and decryption offloading from the CLI. Performance varies by those CLI options and the percentage of packets requiring encryption or decryption. For details, see "Configuring VPN encryption/decryption offloading" on page 2950.

For session offloading to NP1 network processors, in Phase II configuration, the encryption algorithm must be 3DES and authentication must be MD5. Other encryption and authentication algorithms are not supported.

To apply hardware accelerated encryption and decryption, the FortiGate unit's main processing resources must first perform Phase I negotiations to establish the security association (SA). The SA includes cryptographic processing instructions required by the network processor, such as which encryption algorithms must be applied to the tunnel. After ISAKMP negotiations, the FortiGate unit's main processing resources send the SA to the network processor, enabling the network processor to apply the negotiated hardware accelerated encryption or decryption to tunnel traffic.

Possible accelerated cryptographic paths are:

- IPsec decryption offload
  - Ingress ESP packet > Offloaded decryption > Decrypted packet egress (fast path)
  - Ingress ESP packet > Offloaded decryption > Decrypted packet to FortiGate unit's main processing resources
- IPsec encryption offload
  - Ingress packet > Offloaded encryption > Encrypted (ESP) packet egress (fast path)
  - Packet from FortiGate unit's main processing resources > Offloaded encryption > Encrypted (ESP) packet egress

Configuring HMAC check offloading

Hash-based Message Authentication Code (HMAC) checks can be offloaded to network processors. To enable HMAC check offloading, enter

```
configure system global
  set ipsec-hmac-offload (enable|disable)
end
```

Configuring VPN encryption/decryption offloading

Network processing unit (`npu`) settings configure offloading behavior for IPsec VPN. Configured behavior applies to all network processors contained by the FortiGate unit itself or any installed AMC modules.

```
config system npu
  set enc-offload-antireplay {enable | disable}
  set dec-offload-antireplay {enable | disable}
  set offload-ipsec-host {enable | disable}
```

```
end
```

Variables	Description	Default
`enc-offload-antireplay {enable | disable}`	Enable or disable offloading of IPsec encryption. This option is used only when replay detection is enabled in Phase II configuration. If replay detection is disabled, encryption is always offloaded.	`disable`
`dec-offload-antireplay {enable | disable}`	Enable or disable offloading of IPsec decryption. This option is used only when replay detection is enabled in Phase II configuration. If replay detection is disabled, decryption is always offloaded.	`enable`
`offload-ipsec-host {enable | disable}`	Enable or disable offloading of IPsec encryption of traffic from local host (FortiGate unit). **Note:** For this option to take effect, the FortiGate unit must have previously sent the security association (SA) to the network processor. For details on SA offloading, see "Configuring IPsec VPN offloading" on page 2949.	`disable`

Example

You could configure the offloading of encryption and decryption for an IPsec SA that was sent to the network processor.

```
config system npu
  set enc-offload-antireplay enable
  set dec-offload-antireplay enable
  set offload-ipsec-host enable
end
```

Examples of ASM-FB4 accelerated VPNs

This section contains example IPsec configurations whose IPsec encryption and decryption processing is hardware accelerated by FortiGate-ASM-FB4 modules. Figure 374 illustrates the example network topology. Table 152 lists the example network interfaces and IP addresses.

Hardware accelerated IPsec does not require both tunnel endpoints to have the same network processor model. However, if hardware is not symmetrical, the packet forwarding rate is limited by the slower side.

Figure 374: Example network topology for offloaded IPsec processing

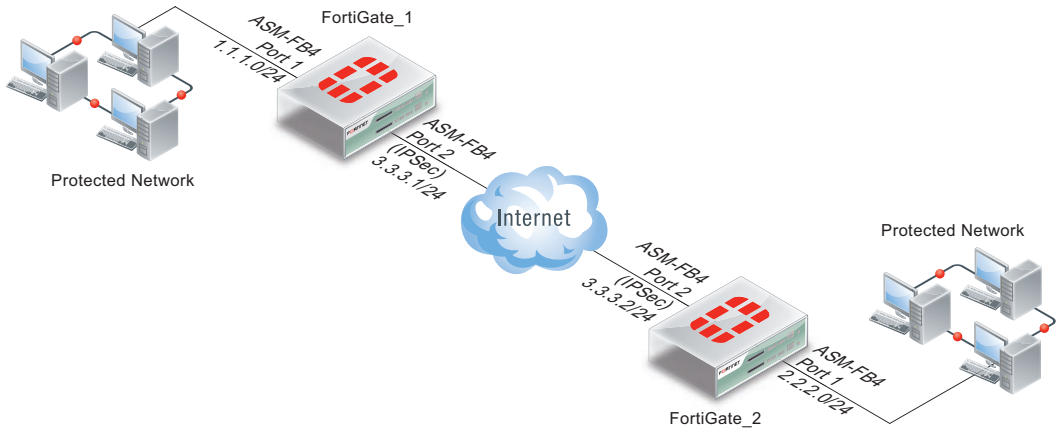


Table 152: Example ports and IP addresses for offloaded IPsec processing

	FortiGate_1		FortiGate_2	
	Port	**IP**	**Port**	**IP**
IPsec tunnel	FortiGate-ASM-FB4 port 2	3.3.3.1/24	FortiGate-ASM-FB4 port 2	3.3.3.2/24
Protected network	FortiGate-ASM-FB4 port 1	1.1.1.0/24	FortiGate-ASM-FB4 port 1	2.2.2.0/24

Tunnel mode IPsec VPN example

The following steps create a hardware accelerated tunnel mode IPsec tunnel between two FortiGate units, each containing a FortiGate-ASM-FB4 module.

To configure hardware accelerated tunnel mode IPsec

1 On FortiGate_1, go to *VPN* > *IPsec*.

2 Configure Phase I.

For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.

Select Advanced. In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2's FortiGate-ASM-FB4 module port 2.

3 Configure Phase II.

If you enable the check box "Enable replay detection," set `enc-offload-antireplay` to `enable` in the CLI. For details on encryption and decryption offloading options available in the CLI, see "Configuring VPN encryption/decryption offloading" on page 2950.

4 Go to *Firewall* > *Policy*.

5 Configure one policy to apply the Phase 1 IPsec tunnel you configured in step 2 to traffic between FortiGate-ASM-FB4 module ports 1 and 2.

6 Go to *Router* > *Static*.

7 Configure a static route to route traffic destined for FortiGate_2's protected network to VPN IP address of FortiGate_2's VPN gateway, 3.3.3.2, through the FortiGate-ASM-FB4 module's port 2 (device).

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "AMC-SW1/2"
    set dst 2.2.2.0 255.255.255.0
    set gateway 3.3.3.2
  end
```

8 On FortiGate_2, go to *VPN* > *IPsec*.

9 Configure Phase I.

For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.

Select Advanced. In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1's FortiGate-ASM-FB4 module port 2.

10 Configure Phase II.

If you enable the check box "Enable replay detection," set `enc-offload-antireplay` to `enable` in the CLI. For details on encryption and decryption offloading options available in the CLI, see "Configuring VPN encryption/decryption offloading" on page 2950

11 Go to *Firewall* > *Policy*.

12 Configure one policy to apply the Phase 1 IPsec tunnel you configured in step 9 to traffic between FortiGate-ASM-FB4 module ports 1 and 2.

13 Go to *Router* > *Static*.

14 Configure a static route to route traffic destined for FortiGate_1's protected network to VPN IP address of FortiGate_1's VPN gateway, 3.3.3.1, through the FortiGate-ASM-FB4 module's port 2 (device).

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "AMC-SW1/2"
    set dst 1.1.1.0 255.255.255.0
    set gateway 3.3.3.1
  end
```

15 Activate the IPsec tunnel by sending traffic between the two protected networks.

To verify tunnel activation, go to *VPN* > *IPSEC* > *Monitor*.

Interface mode IPsec VPN example

The following steps create a hardware accelerated interface mode IPsec tunnel between two FortiGate units, each containing a FortiGate-ASM-FB4 module.

To configure hardware accelerated interface mode IPsec

1 On FortiGate_1, go to *VPN* > *IPsec*.

2 Configure Phase I.

For interface mode IPsec and for hardware acceleration, the following settings are required.

- Select Advanced.
- Enable the check box “Enable IPsec Interface Mode.”
- In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2’s FortiGate-ASM-FB4 module port 2.

3 Configure Phase II.

If you enable the check box “Enable replay detection,” set `enc-offload-antireplay` to `enable` in the CLI. For details on encryption and decryption offloading options available in the CLI, see “Configuring VPN encryption/decryption offloading” on page 2950

4 Go to *Firewall* > *Policy*.

5 Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 2 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.

6 Go to *Router* > *Static*.

7 Configure a static route to route traffic destined for FortiGate_2’s protected network to the Phase 1 IPsec device, `FGT_1_IPsec`.

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "FGT_1_IPsec"
    set dst 2.2.2.0 255.255.255.0
  end
```

8 On FortiGate_2, go to *VPN* > *IPsec*.

9 Configure Phase I.

For interface mode IPsec and for hardware acceleration, the following settings are required.

- Enable the check box “Enable IPsec Interface Mode.”
- In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1’s FortiGate-ASM-FB4 module port 2.

10 Configure Phase II.

If you enable the check box “Enable replay detection,” set `enc-offload-antireplay` to `enable` in the CLI. For details on encryption and decryption offloading options available in the CLI, see “Configuring VPN encryption/decryption offloading” on page 2950

11 Go to *Firewall* > *Policy*.

12 Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 9 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.

13 Go to *Router* > *Static*.

14 Configure a static route to route traffic destined for FortiGate_1's protected network to the Phase 1 IPsec device, `FGT_2_IPsec`.

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "FGT_2_IPsec"
    set dst 1.1.1.0 255.255.255.0
    next
  end
```

15 Activate the IPsec tunnel by sending traffic between the two protected networks.

To verify tunnel activation, go to *VPN* > *IPSEC* > *Monitor*.

Configuring IPS offloading

Security modules offload IPS. Requirements are:

- Source port is on CE4
- Destination port is on the same CE4
- UTM configuration must enable only IPS, not AV or content archive.
- Packet protocol is ICMP, UDP or TCP.

IPS offloading functions with policy-based IPS and interface-based IPS, as well as sniffer-mode.

Configuring pre-IPS anomaly detection

Network interfaces associated with a port attached to a network processor can be configured to use hardware acceleration to drop or allow certain anomaly types, separately from and in advance of any anomaly checks specified by Intrusion Prevention (IPS). Configured behavior applies separately to each of these network interfaces.

```
config system interface
  edit <name_str>
    set fp-anomaly
        {drop_icmpland | pass_icmpland}
        {drop_ipland | pass_ipland}
        {drop_iplsrr | pass_iplsrr}
        {drop_iprr | pass_iprr}
        {drop_ipsecurity | pass_ipsecurity}
        {drop_ipssrr | pass_ipssrr}
        {drop_ipstream | pass_ipstream}
        {drop_iptimestamp | pass_iptimestamp}
        {drop_ipunknown_option | pass_ipunknown_option}
        {drop_unknown_prot | pass_ipunknown_prot}
        {drop_tcpland | pass_tcpland}
        {drop_udpland | pass_udpland}
        {drop_winnuke | pass_winnuke}
  end
```

where:

icmpland	ICMP land
ipland	IP land
iplsrr	IP with loose source record route
iprr	IP with record route option
ipsecurity	IP with security option
ipssrr	IP with strict source record route option
ipstream	IP with stream option
iptimestamp	IP with timestamp option
ipunknown_option	IP with unknown option
ipunknown_prot	IP with unknown protocol
tcpland	TCP land
udpland	UDP land
winnuke	TCP WinNuke

Example

You might configure a FortiGate-ASM-FB4 module to drop packets with TCP WinNuke or unknown IP protocol anomalies, but to pass packets with an IP time stamp, using hardware acceleration provided by the network processor.

```
config system interface
  edit AMC-SW1/1
    set fp-anomaly drop_winnuke drop_ipunknown_prot
       pass_iptimestamp
  end
```

Configuring policy-based IPS on SP modules

In the firewall policy, enable UTM, then enable IPS and select the desired IPS profile.

Configuring interface-based IPS on SP modules

1. Define the IPS sensor. This step is the same with current policy-based IPS. For system predefined sensor, this step can be ignored.
2. Define on which interface IPS should be enabled and what sensor you want to use to scan traffic. Both physical interface and VLAN interface are valid interface choices.

The followed is an example to enable IPS sensor “all_default” on physical port AMC-SW1/2.

```
config ips interface
  edit AMC-SW1/2
    set ips-sensor all_default
  end
```

This command will enable IPS on all traffic ingress and egress through AMC-SW1/2.

Do not enable policy-based IPS when either the source or destination port has interface IPS enabled. Doing so provides no additional security and results in reduced performance.

Examples

Hardware accelerated IPsec processing, involving either partial or full offloading, can be achieved in either tunnel or interface mode IPsec configurations.

To achieve offloading for both encryption and decryption:

- In Phase I configuration's Advanced section, Local Gateway IP must be specified as an IP address of a network interface associated with a port attached to a network processor. (In other words, if Phase 1's Local Gateway IP is Main Interface IP, or is specified as an IP address that is not associated with a network interface associated with a port attached to a network processor, IPsec network processing is not offloaded.)
- In Phase II configuration's P2 Proposal section, if the checkbox "Enable replay detection" is enabled, `enc-offload-antireplay` and `dec-offload-antireplay` must be set to `enable` in the CLI.
- `offload-ipsec-host` must be set to `enable` in the CLI.

This section contains example IPsec configurations whose IPsec encryption and decryption processing is hardware accelerated by FortiGate-ASM-FB4 modules. Figure 374 illustrates the example network topology. Table 152 lists the example network interfaces and IP addresses.

Hardware accelerated IPsec does not require both tunnel endpoints to have the same network processor model. However, if hardware is not symmetrical, the packet forwarding rate is limited by the slower side.

Figure 375: Example network topology for offloaded IPsec processing

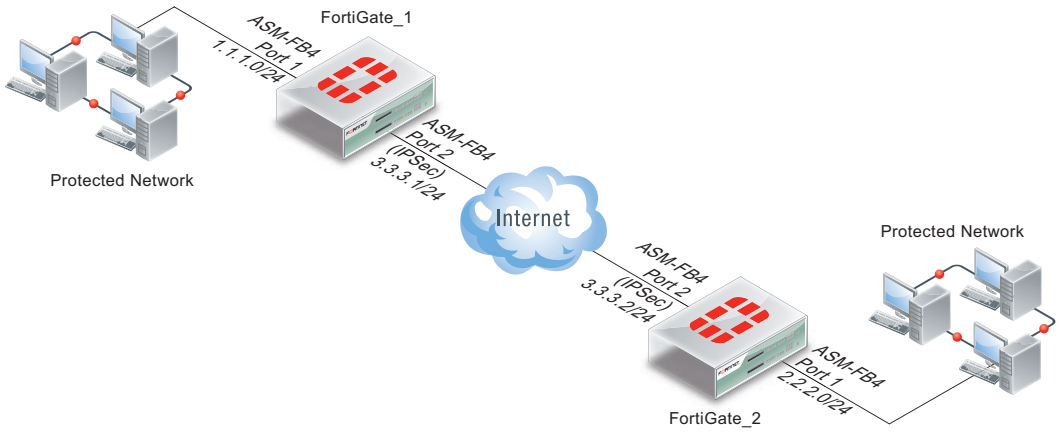

Table 153: Example ports and IP addresses for offloaded IPsec processing

	FortiGate_1		FortiGate_2	
	Port	**IP**	**Port**	**IP**
IPsec tunnel	FortiGate-ASM-FB4 port 2	3.3.3.1/24	FortiGate-ASM-FB4 port 2	3.3.3.2/24

Table 153: Example ports and IP addresses for offloaded IPsec processing

Protected network	FortiGate-ASM-FB4 port 1	1.1.1.0/24	FortiGate-ASM-FB4 port 1	2.2.2.0/24

This section includes the following topics:

- Tunnel mode IPsec VPN example
- Configuring traffic offloading

Accelerated tunnel mode IPsec

The following steps create a hardware accelerated tunnel mode IPsec tunnel between two FortiGate units, each containing a FortiGate-ASM-FB4 module.

To configure hardware accelerated tunnel mode IPsec

1 On FortiGate_1, go to *VPN* > *IPsec*.

2 Configure Phase I.

For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.

Select Advanced. In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2's FortiGate-ASM-FB4 module port 2.

3 Configure Phase II.

If you enable the checkbox "Enable replay detection," set `enc-offload-antireplay` to `enable` in the CLI. For details on encryption and decryption offloading options available in the CLI, see "Configuring VPN encryption/decryption offloading" on page 2950

4 Go to *Firewall* > *Policy*.

5 Configure one policy to apply the Phase 1 IPsec tunnel you configured in step 2 to traffic between FortiGate-ASM-FB4 module ports 1 and 2.

6 Go to *Router* > *Static*.

7 Configure a static route to route traffic destined for FortiGate_2's protected network to VPN IP address of FortiGate_2's VPN gateway, 3.3.3.2, through the FortiGate-ASM-FB4 module's port 2 (device).

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "AMC-SW1/2"
    set dst 2.2.2.0 255.255.255.0
    set gateway 3.3.3.2
  end
```

8 On FortiGate_2, go to *VPN* > *IPsec*.

9 Configure Phase I.

For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.

Select Advanced. In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1's FortiGate-ASM-FB4 module port 2.

10 Configure Phase II.

If you enable the checkbox “Enable replay detection,” set `enc-offload-antireplay` to `enable` in the CLI. For details on encryption and decryption offloading options available in the CLI, see “Configuring VPN encryption/decryption offloading” on page 2950

11 Go to *Firewall* > *Policy*.

12 Configure one policy to apply the Phase 1 IPsec tunnel you configured in step 9 to traffic between FortiGate-ASM-FB4 module ports 1 and 2.

13 Go to *Router* > *Static*.

14 Configure a static route to route traffic destined for FortiGate_1’s protected network to VPN IP address of FortiGate_1’s VPN gateway, 3.3.3.1, through the FortiGate-ASM-FB4 module’s port 2 (device).

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "AMC-SW1/2"
    set dst 1.1.1.0 255.255.255.0
    set gateway 3.3.3.1
  end
```

15 Activate the IPsec tunnel by sending traffic between the two protected networks.

To verify tunnel activation, go to *VPN* > *IPSEC* > *Monitor*.

Accelerated interface mode IPsec

The following steps create a hardware accelerated interface mode IPsec tunnel between two FortiGate units, each containing a FortiGate-ASM-FB4 module.

To configure hardware accelerated interface mode IPsec

1 On FortiGate_1, go to *VPN* > *IPsec*.

2 Configure Phase I.

For interface mode IPsec and for hardware acceleration, the following settings are required.

- Select Advanced.
- Enable the checkbox “Enable IPsec Interface Mode.”
- In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2’s FortiGate-ASM-FB4 module port 2.

3 Configure Phase II.

If you enable the checkbox “Enable replay detection,” set `enc-offload-antireplay` to `enable` in the CLI. For details on encryption and decryption offloading options available in the CLI, see “Configuring VPN encryption/decryption offloading” on page 2950

4 Go to *Firewall* > *Policy*.

5 Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 2 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.

6 Go to *Router* > *Static*.

7 Configure a static route to route traffic destined for FortiGate_2's protected network to the Phase 1 IPsec device, `FGT_1_IPsec`.

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "FGT_1_IPsec"
    set dst 2.2.2.0 255.255.255.0
  end
```

8 On FortiGate_2, go to *VPN* > *IPsec*.

9 Configure Phase I.

For interface mode IPsec and for hardware acceleration, the following settings are required.

- Enable the checkbox "Enable IPsec Interface Mode."
- In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1's FortiGate-ASM-FB4 module port 2.

10 Configure Phase II.

If you enable the checkbox "Enable replay detection," set `enc-offload-antireplay` to `enable` in the CLI. For details on encryption and decryption offloading options available in the CLI, see "Configuring VPN encryption/decryption offloading" on page 2950

11 Go to *Firewall* > *Policy*.

12 Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 9 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.

13 Go to *Router* > *Static*.

14 Configure a static route to route traffic destined for FortiGate_1's protected network to the Phase 1 IPsec device, `FGT_2_IPsec`.

You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "FGT_2_IPsec"
    set dst 1.1.1.0 255.255.255.0
    next
  end
```

15 Activate the IPsec tunnel by sending traffic between the two protected networks.

To verify tunnel activation, go to *VPN* > *IPSEC* > *Monitor*.

Configuring RAID

This section describes how to configure RAID on a FortiGate unit with multiple disk support. RAID arrays can provide faster disk access, redundancy in case of partial failure, or both depending on the RAID level you select.

The following topics are included in this section:

RAID levels

Some FortiGate models have two or more hard disks configured in a RAID array to store log messages locally on the FortiGate unit. A RAID array can provide faster disk access, redundancy in case of partial failure, or both depending on the RAID level you select.

When changing the RAID level, the available levels depend on the number of working disks that are actually present in the unit. For example, RAID-5 is not available on units with fewer than three disks. When a disk fails, becomes corrupt, or is removed you must rebuild the RAID array. For more information, see "Rebuilding a RAID array" on page 2964.

If the FortiGate unit has only one disk installed, the RAID monitor widget will not be displayed as it is not possible to configure a RAID array with only one disk.

Available RAID levels include:

- RAID-0
- RAID-1
- RAID-5

RAID-0

A RAID-0 array is also referred to as striping. The FortiGate unit writes information evenly across all hard disks. The total space available is that of all the disks in the RAID array. There is no redundancy available. If any single drive fails, the data on the array is lost and cannot be recovered. Because of this lack of redundancy, a RAID-0 array will never report a degraded condition. This RAID level is beneficial because it provides better performance, since the FortiGate unit can distribute disk writing across multiple disks.

For example if your FortiGate unit has three disks each with a 1 terabyte (TB) capacity, your RAID-0 array will have a 3TB capacity.

RAID-1

A RAID-1 array is also referred to as mirroring. The FortiGate unit writes information to one hard disk, and writes a copy (a mirror image) of all information to all other hard disks. The total disk space available is that of only one hard disk, as the others are solely used for mirroring. This provides redundant data storage. Should any of the hard disks fail, there one or more backup hard disks available. For example, if one disk fails, the unit can still access three other hard disks and continue functioning.

RAID-5

A RAID-5 array employs striping with a parity check. Similar to RAID-0, the FortiGate unit writes information evenly across all drives but additional parity blocks are written on the same stripes. The parity block is staggered for each stripe. RAID-5 requires three or more hard disks. The total disk space is the total number of disks in the array, minus the capacity of one disk for parity storage. For example, with four hard disks, the total capacity available is the capacity of three hard disks. RAID-5 performance is typically better with reading than with writing, although performance is degraded when one disk has failed. With RAID-5, one disk can fail without the loss of data. If a drive fails, it can be replaced and the FortiGate unit will restore the data on the new disk by using reference information from the parity volume.

Configuring a RAID array

Do not remove a disk while the RAID array is synchronizing — you may lose stored information. This will also degrade the array, requiring a rebuild.
A RAID array provides no redundancy in a degraded state. Any disk failure while the RAID is in a degraded state will cause data loss.

When switching RAID levels, you may see the message “RAID status is OK and RAID is doing background synchronization.” Synchronization of the disks in the array will take considerable time — it will take longer for larger arrays and for disks with more storage capacity.

To configure a RAID array

1 Go to *System* > *Dashboard* > *Status* where the RAID Monitor widget is located, and then select *Configure* in the widget title bar area.

Changing the RAID level will erase any stored log information on the array, and reboot the FortiGate unit. The unit will remain offline while it reconfigures the RAID array. When it reboots, the array will need to synchronize before being fully operational.

2 Confirm that the FortiGate unit recognizes the installed hard disks. Each slot in which you have installed a hard disk displays a green check mark for *Member* and OK for *Status*. The Capacity figure for each hard disk simply lists its size.

The available space on the array will depend on the size of the member drives, but it may not be equal to the total size of the member drives. Further, the hard disks in a RAID array need to have the same capacity. If you use disks with differing capacities, the member hard disks will be treated as if they all have the capacity of the smallest drive in the array. The RAID level determines how the size of the RAID array relates to the size of the member hard disks. For example, an array of three 1TB hard disks will result in 3TB of usable space with RAID-0, 2TB of usable space with RAID-5, and 1TB of space with RAID-1.

3 Select the RAID level.

RAID-0 (Striping)	Better performance than a single disk, but no redundancy. If either disk fails, all data is lost.
RAID-1 (mirroring)	Performance comparable to a single disk, and data is protected by redundancy. One disk can fail with no data loss.
RAID-5 (striping with parity)	Performance is mixed with disk writes slower than a single disk and disk reads faster. Data is protected by redundancy. One disk can fail with no data loss.

For more information on RAID levels, see "RAID levels" on page 2961.

4 Select *Apply*.

The FortiGate unit reboots and reconfigures the RAID array. You may log in again when it is complete.

Checking the status of a RAID array

Once a RAID array is configured, it requires no regular maintenance. Attention is required only when a member hard drive fails. The RAID widget reports the RAID array condition and disk space utilization.

To check the status of a RAID array

1 Go to *System* > *Dashboard* > *Status* where the RAID Monitor widget is located.

2 The widget shows three pieces of status information about the RAID array.

Array Status	Displays the RAID level and status of the RAID array. The hard disks installed in the FortiGate unit are also displayed, with indicators to show which are part of the RAID array and the status of each disk. The status can be: **OK** — standard status, everything is normal **OK (Background-Synchronizing) (%)** — synchronizing the disks after changing RAID level, Synchronizing progress bar shows percent complete **Degraded** — One or more of the disks in the array has failed, been removed, or is not working properly. A warning is displayed about the lack of redundancy in this state. Also, a degraded array is slower than a healthy array. Select *Rebuild RAID* to fix the array after replacing the defective or missing disk. **Degraded (Background-Rebuilding) (%)** — The same as degraded, but the RAID array is being rebuilt in the background. The array continues to be in a fragile state until the rebuilding is completed.

Disk Space Usage	Shows a bar graph of the used space as well as text listing the used space, free space, and total disk space available in the array.
Synchronize Status	Shows that the array is synchronized or reports the synchronization progress, as well as any information about the current synchronization status.

Rebuilding a RAID array

A RAID array has multiple disks with writing to the disks being spread out so that if one disk in the array fails, the array can still provide all the stored information. Some forms of RAID do not provide redundancy, however most do.

When a disk fails, or the RAID array becomes degraded

The Alert Message Console widget, located in *System* > *Dashboard* > *Status*, displays any messages about events or activities that need urgent attention, such as a failed hard disk. This widget provides detailed messages that contain the date and time of the event or activity, as well as an explanation about what happened.

Why rebuild a RAID array?

When the RAID array has redundancy and one disk in the array fails, becomes corrupted, or is removed the array becomes degraded. In a degraded state the array can still function, but there are some changes. The two main changes are that there is no longer redundancy and accessing the array takes longer than before.

There is no redundancy because with one disk removed from the array, the information that was stored on that disk can be retrieved using the other disks in the array. However, removing another disk from the array would remove information that has no backup or parity data. This second disk's removal would result in data loss and the array will fail. This delicate state of the RAID array is displayed in the warning message on the dashboard RAID monitor when the status is degraded in the form of a warning.

The array takes longer to access data because instead of the data being retrieved in the format and order it is expected, the array has to jump around to find it and at times recreate the missing data from the parity information. This all takes longer than just the usual straight read operation and will continue until the RAID array has been rebuilt.

The reasons you rebuild a RAID array include:

- a disk has failed
- the array has become corrupted
- a disk has been removed

How to rebuild the RAID array

When the RAID array is in its normal OK state, there is no option to rebuild the array because there is no need for it. You only need to rebuild the array when it is in a degraded state and in danger of loosing data.

Before you rebuild the RAID array, you should have a replacement disk for the one that failed if that is the cause of the degraded array. You cannot rebuild an array that is missing a disk. A replacement disk should be the same storage capacity as the disk it is replacing.

Also before rebuilding the array, you should backup the data if possible. As soon as the RAID array becomes degraded you should backup the array if possible to prevent data loss.

To rebuild the RAID array

1. Go to *System* > *Dashboard* > *Status*, and then in the RAID Monitor widget, select *[Configure]*.
2. Verify the status of the RAID array is degraded, and the Rebuild button is not greyed out.
3. Remove the failed disk from the FortiGate unit.
   - Ensure you have the correct disk.
   - Press the green button to unlock the disk.
   - Gently push the lever to the left as far as it will go to disconnect the disk.
   - Remove the disk from the FortiGate unit by pulling on the lever.
4. Insert the new disk into the FortiGate unit that is replacing the failed disk.
   - Insert the disk carefully into the FortiGate unit.
   - Push the front panel of the disk to make the connection—the lever will start to move to the right. Ensure that both sides of the disk are in line with the other disks.
   - When in place push the bar fully to the right, until the green button clicks.
5. Refresh your display to ensure the new disk is installed properly. If it is not recognized, repeat steps 3 and 4 with the new disk to ensure it is properly installed.
6. On the configure screen, select *Rebuild RAID*.

   Rebuilding the RAID array will normally take several hours. You can follow its progress on the RAID Monitor display on the dashboard.
7. When the rebuild is complete, the status of the RAID array will change to OK.

FortiBridge installation and operation

This chapter describes a typical transparent mode FortiGate network and how to add a FortiBridge unit to this network to provide fail open protection. This chapter also contains detailed information about how FortiBridge units operate and concludes with descriptions of adding a FortiBridge unit to an HA cluster and connecting a FortiBridge unit other FortiGate interfaces.

This chapter contains the following sections:

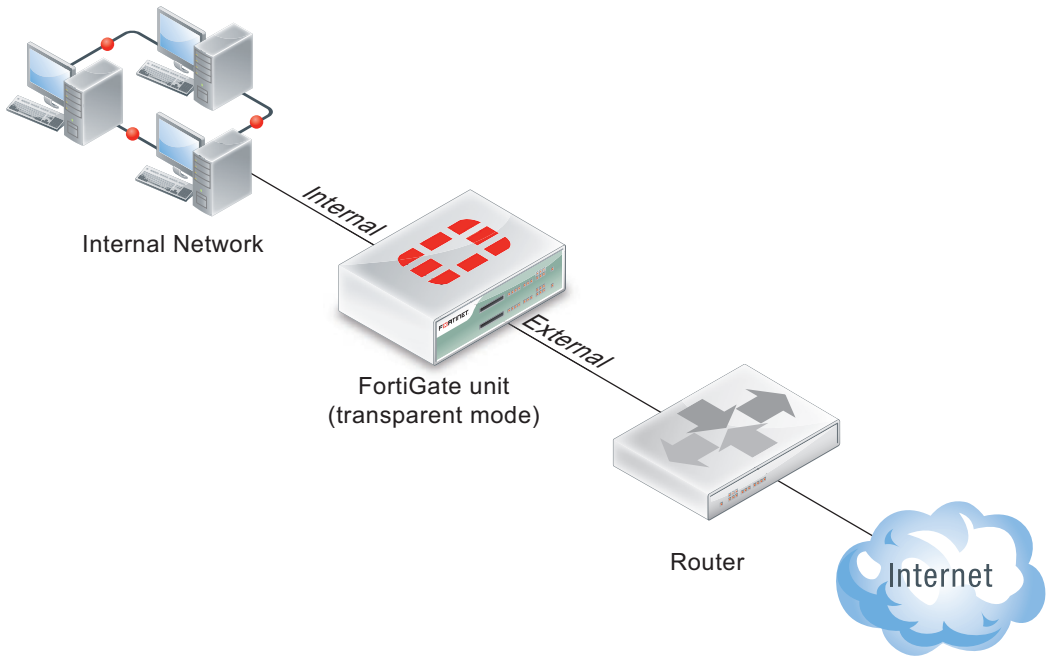
Example FortiBridge application

A typical application of a FortiGate unit operating in transparent mode is to insert the FortiGate unit into an internal network, between the network and the router that connects the network to the Internet. In this configuration, the FortiGate unit can provide security services for all traffic passing between the internal network and the internet. These security services can include:

- applying firewall policies and IPS attack prevention to all traffic,
- applying virus scanning to HTTP, FTP, POP3, SMTP, and IMAP traffic,
- applying web filtering to HTTP traffic,
- applying Spam filtering to POP3, SMTP, and IMAP traffic.

The internal network is connected to the FortiGate unit internal interface. The router is connected to the FortiGate unit external interface. The FortiGate unit can be added to the network without changing the configuration of the network (except to add the FortiGate management IP address).

Figure 376: Example transparent mode network



To allow users on the internal network to connect to resources on the Internet, add Internal -> External firewall policies to the FortiGate unit. Add protection profiles to the firewall policies to apply security services such as virus scanning, web filtering, spam filtering and IPS to the traffic that passes through the FortiGate unit.

The FortiGate unit acts as an extra layer of protection for your internal network. While it is operating, the FortiGate unit protects the internal network from threats originating on the Internet. All users on the internal network connect through the FortiGate unit to the Internet. This also means that if a failure or other interruption caused the FortiGate unit to stop functioning, users on the internal network would not be able to connect to the Internet.

You can install a FortiBridge unit to maintain internet connectivity for the internal network if the FortiGate unit stops functioning. The FortiBridge unit provides fail open protection for your network by bypassing the FortiGate unit if a failure occurs.

Connecting the FortiBridge unit

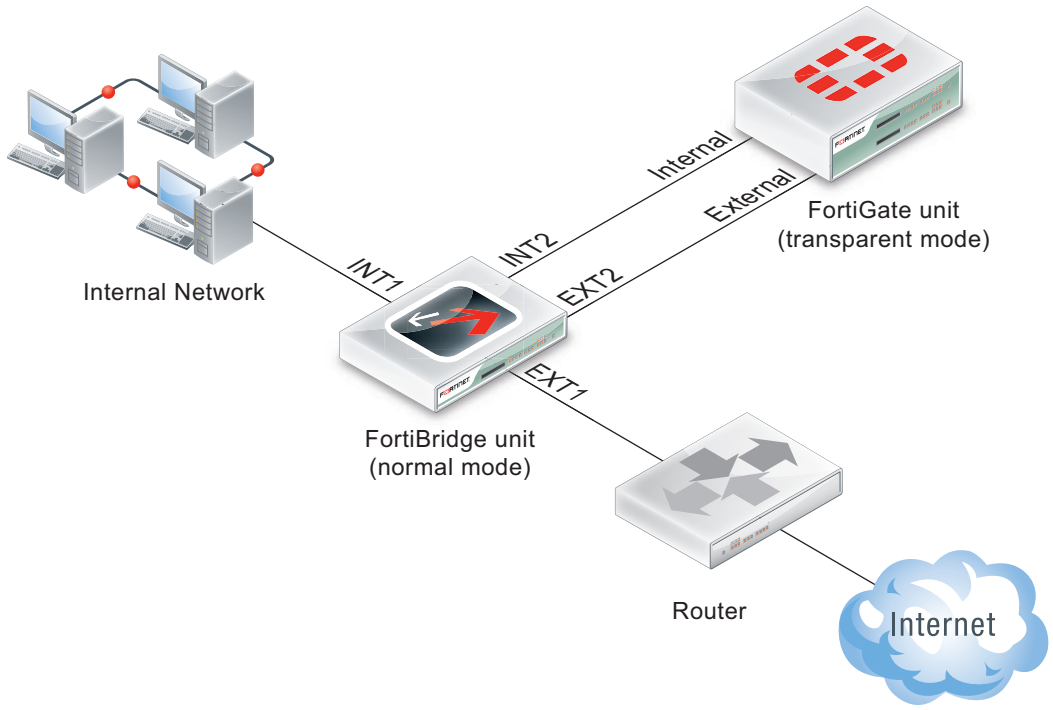
Operating in normal mode, the FortiBridge unit functions like a layer-2 bridge, passing all traffic to the FortiGate unit. The FortiGate unit processes the traffic, which passes through the FortiBridge unit again and then to its final destination.

In most cases, you do not have to make changes to the FortiGate unit configuration or to the network to add a FortiBridge unit. The only network requirement for FortiBridge is the availability of a single management IP address for the FortiBridge unit. The FortiBridge management IP address is required in addition to the FortiGate management IP address.

The connection procedure is different depending on whether the FortiBridge unit uses copper gigabit ethernet network connections or fiber gigabit ethernet network connections. This section includes the following connection procedures:

- Connecting the FortiBridge-2002 (copper gigabit ethernet)
- Connecting the FortiBridge-2002F (fiber gigabit ethernet)

Figure 377: FortiBridge unit providing fail open protection



Connecting the FortiBridge-2002 (copper gigabit ethernet)

The FortiBridge-2002 unit contains 4 auto-sensing 10/100/1000 Ethernet interfaces that connect to the internal and external networks and to the FortiGate interfaces that were connected to these networks. Use the following steps to connect a FortiBridge-2002 unit to the network as shown in Figure 377.

Normally, you would use straight-through ethernet cables to connect the FortiBridge-2002 unit to the FortiGate unit and to your networks. However, for some connections you may need a crossover ethernet cable (for example, for compatibility with network devices that do not support Auto MDI/MDIX).

1. Connect the FortiBridge-2002 INT2 interface to the FortiGate internal interface.
2. Connect the FortiGate external interface to the FortiBridge-2002 EXT2 interface.
3. Connect the internal network to the FortiBridge-2002 INT1 interface.
4. Connect the FortiBridge-2002 EXT1 interface to the router.

Connecting the FortiBridge-2002F (fiber gigabit ethernet)

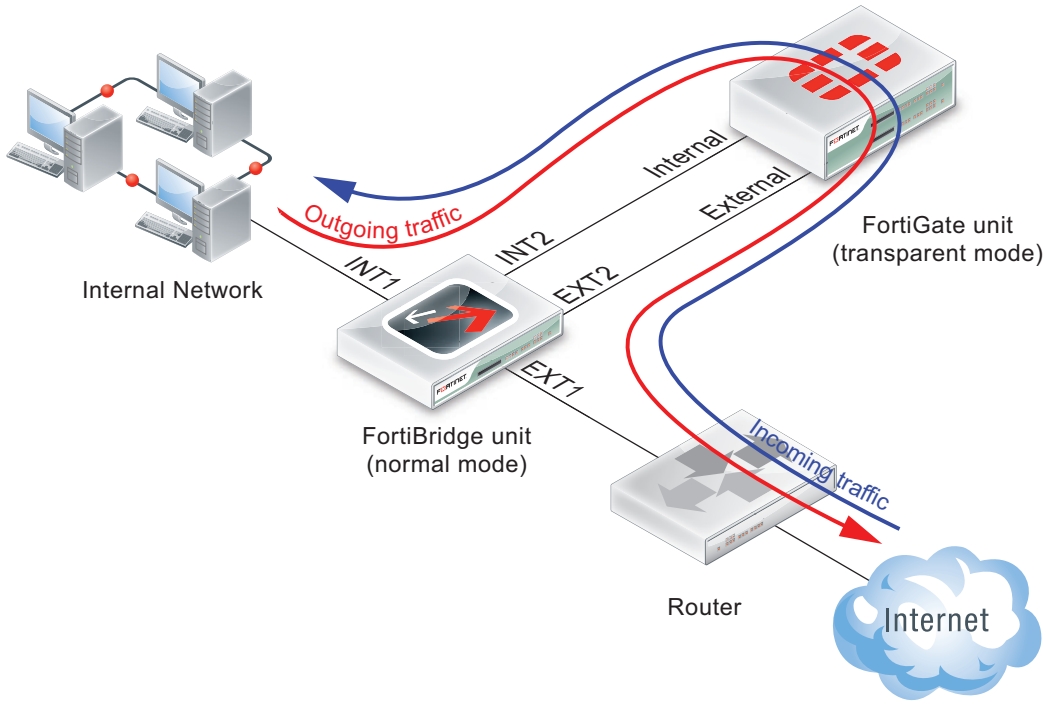
The FortiBridge-2002F unit contains 4 multimode fiber optic gigabit interfaces that connect to the internal and external networks and to the FortiGate interfaces that were connected to these networks. Use the following steps to connect a FortiBridge-2002F unit to the network as shown in Figure 377.

1. Connect the FortiBridge-2002F INT2 interface to the FortiGate internal interface.
2. Connect the FortiGate external interface to the FortiBridge-2002F EXT2 interface.
3. Connect the internal network to the FortiBridge-2002F INT1 interface.
4. Connect the FortiBridge-2002F EXT1 interface to the router.

Normal mode operation

If the FortiGate unit is processing traffic normally, the FortiBridge unit operates in Normal mode. Traffic from the internal network enters the FortiBridge INT1 interface then exits the INT2 interface to the FortiGate unit. The traffic from the FortiBridge INT2 interface enters the FortiGate internal interface. Firewall policies and protection profiles are applied to the traffic by the FortiGate unit. Accepted traffic exits the FortiGate External interface and enters the FortiBridge EXT2 interface. The traffic then exits the FortiBridge EXT1 interface and goes to the external network. Traffic from the external network follows this sequence in the opposite direction.

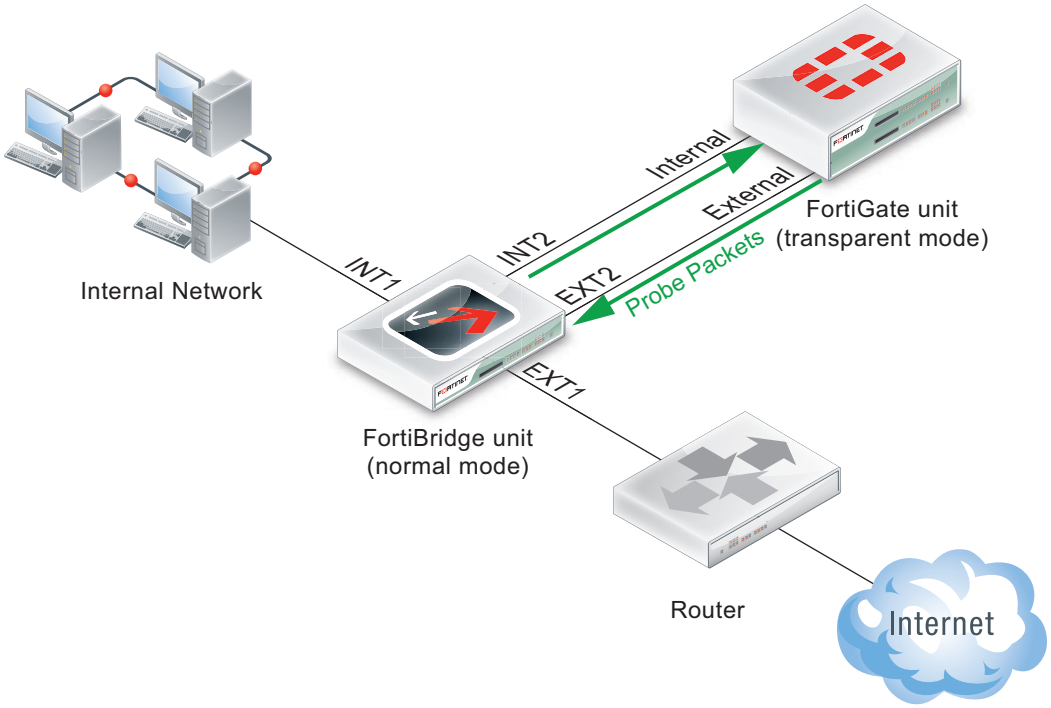
Figure 378: Normal mode traffic flow



How the FortiBridge unit monitors the FortiGate unit

To monitor the FortiGate unit for failure, you must enable probes on the FortiBridge unit. When you enable a probe, the FortiBridge unit sends packets from the FortiBridge INT2 interface, through the FortiGate unit to the FortiBridge EXT2 interface. If the EXT2 interface receives the probe packets, the FortiGate unit is operating normally. If the EXT2 interface does not receive probe packets the FortiBridge unit assumes that the FortiGate unit has failed.

Figure 379: FortiBridge unit operating in normal mode sending probe packets



You can enable ICMP (ping), HTTP, FTP, POP3, SMTP, and IMAP probes to test connectivity through the FortiGate unit for each of these protocols. The FortiBridge unit simultaneously tests connectivity through the FortiGate unit for each probe that is enabled.

The first probe that registers a failure causes the FortiBridge unit to stop sending all probe packets. The FortiBridge unit responds to the failure according to the action on failure that you configure. The action on failure can include fail open, send alert email, send a syslog message, and send an SNMP trap. You can enable any combination of these actions on failure. Fail open switches the FortiBridge unit to bypass mode. Other actions on failure alert system administrators that the FortiBridge has determined that a failure occurred.

Probes and FortiGate firewall policies

Probe packets are accepted and passed through the FortiGate unit by firewall policies added to the FortiGate unit. When enabling probes, you must make sure that the firewall policies added to the FortiGate unit can accept probe packets. For example, if your FortiGate unit does not accept FTP packets, you should not enable the FTP probe. Table 154 describes FortiGate firewall policy requirements for each FortiBridge probe.

Table 154: FortiBridge probes and FortiGate firewall policy requirements

Probe	Description	FortiGate Firewall policy	
		Direction	Service
Ping	ICMP packets are sent from the INT2 interface to the EXT2 interface. The EXT2 interface responds to the ping.	Internal -> External	ICMP or ANY

Table 154: FortiBridge probes and FortiGate firewall policy requirements

Probe	Description	FortiGate Firewall policy	
		Direction	Service
HTTP	HTTP requests are sent from an HTTP client at the INT2 interface to a web server at the EXT2 interface. The web server sends a response from the EXT2 interface to the INT2 interface.	Internal –> External	HTTP or ANY
SMTP	SMTP packets are sent from an SMTP server at the INT2 interface to an SMTP server at the EXT2 interface. The SMTP server sends a response from the EXT2 interface to the INT2 interface.	Internal –> External	SMTP or ANY
POP3	POP3 packets are sent from a POP3 client at the INT2 interface to a POP3 server at the EXT2 interface. The POP3 server sends a response from the EXT2 interface to the INT2 interface.	Internal –> External	POP3 or ANY
IMAP	IMAP packets are sent from an IMAP client at the INT2 interface to an IMAP server at the EXT2 interface. The IMAP server sends a response from the EXT2 interface to the INT2 interface.	Internal –> External	IMAP or ANY
FTP	FTP requests are sent from an FTP client at the INT2 interface to an FTP server at the EXT2 interface. The FTP server sends a response from the EXT2 interface to the INT2 interface.	Internal –> External	FTP or ANY
mm1	MM1 packets are sent from the INT2 interface to the EXT2 interface, through the FortiGate unit. When the packet is received, an MM1 response is sent back from the EXT2 interface to the INT2 interface.	Internal –> External	custom or ANY
mm3	MM3 packets are sent from the INT2 interface to the EXT2 interface, through the FortiGate unit. When the packet is received, an MM3 response is sent back from the EXT2 interface to the INT2 interface.	Internal –> External	custom or ANY
mm4	MM4 packets are sent from the INT2 interface to the EXT2 interface, through the FortiGate unit. When the packet is received, an MM4 response is sent back from the EXT2 interface to the INT2 interface.	Internal –> External	custom or ANY

Table 154: FortiBridge probes and FortiGate firewall policy requirements

Probe	Description	FortiGate Firewall policy	
		Direction	Service
mm7	MM7 packets are sent from the INT2 interface to the EXT2 interface, through the FortiGate unit. When the packet is received, an MM7 response is sent back from the EXT2 interface to the INT2 interface.	Internal –> External	custom or ANY

*No predefined service selections are offered for the MMS protocols. To allow the probes for these protocols, you can select the ANY service or create custom services for TCP packets with the destination ports listed in *Probe* > *Settings*.

Enabling probes to detect FortiGate hardware failure

A FortiGate unit can stop processing network traffic because of a hardware failure such as the failure of a hardware component, a loss of power, or a loss of connectivity if a network cable is unplugged.

If a hardware failure occurs, the FortiGate unit stops processing all traffic. You can enable any FortiBridge probe for the FortiBridge unit to detect a FortiGate hardware failure.

Enabling probes to detect FortiGate software failure

A FortiGate unit can also stop processing network traffic because of a software failure. For example, a firmware issue could cause a specific software process to crash. Also, network traffic could increase to a point where the FortiGate unit cannot process all traffic. As a result, the FortiGate unit could stop processing some or all traffic without a hardware failure occurring.

To detect a FortiGate software failure, you can enable probes for FortiGate services that you want to provide fail open protection for. For example, if SMTP email services are a high priority for your network, you should enable the SMTP probe. If the SMTP probe detects a failure of SMTP traffic through the FortiGate unit, the FortiBridge unit switches to bypass mode to maintain SMTP traffic flow.

If you do not consider FTP traffic a high priority, you can leave the FTP probe disabled. In this configuration, if only FTP traffic fails, the FortiBridge does not switch to bypass mode.

Probe interval and probe threshold

For each probe, you set a probe interval and a probe threshold. The probe interval defines how often to test the connection. The probe threshold defines how many consecutive failed probes can occur before the FortiBridge considers the connection to have failed.

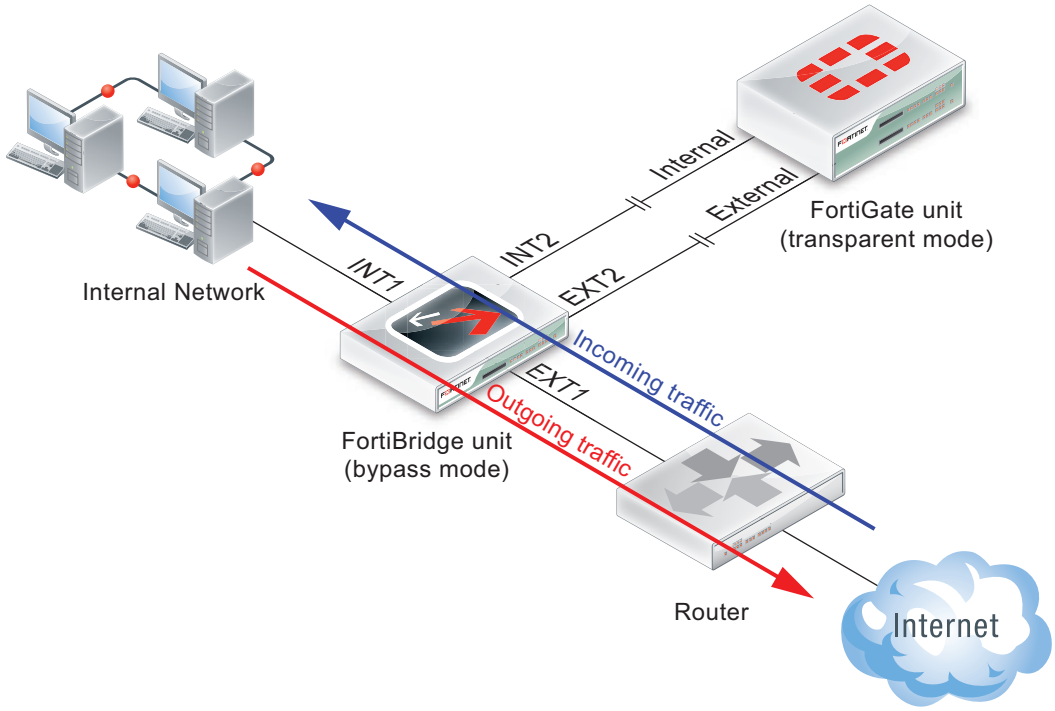
Bypass mode operation

When the FortiBridge unit operates in bypass mode, the FortiBridge INT1 and EXT1 interfaces are directly connected. All traffic between the internal and external network segments flows, whether or not the FortiGate unit is operating normally.

Because the INT1 and EXT1 interfaces are directly connected, you cannot use Telnet or SSH to connect to the FortiBridge CLI. Instead you must use a console connection.

The FortiBridge unit remains in bypass mode even if the FortiGate unit recovers. To restore the FortiGate unit, you must manually switch the FortiBridge unit back to normal mode. You can switch the FortiBridge unit to normal mode by pressing the mode switch on the FortiBridge front panel or by using a console connection to the CLI and entering the command `execute switch-mode`. You can also use the mode switch and the `execute switch-mode` command to manually switch the FortiBridge unit from normal mode to bypass mode.

Figure 380: FortiBridge unit operating in bypass mode



When the FortiBridge unit is operating in bypass mode you can still connect to the FortiBridge CLI and manage the FortiBridge unit (for example to switch the FortiBridge unit to normal mode). When the FortiBridge unit operates in bypass mode, you cannot connect to the FortiGate interfaces that are connected to the FortiBridge unit.

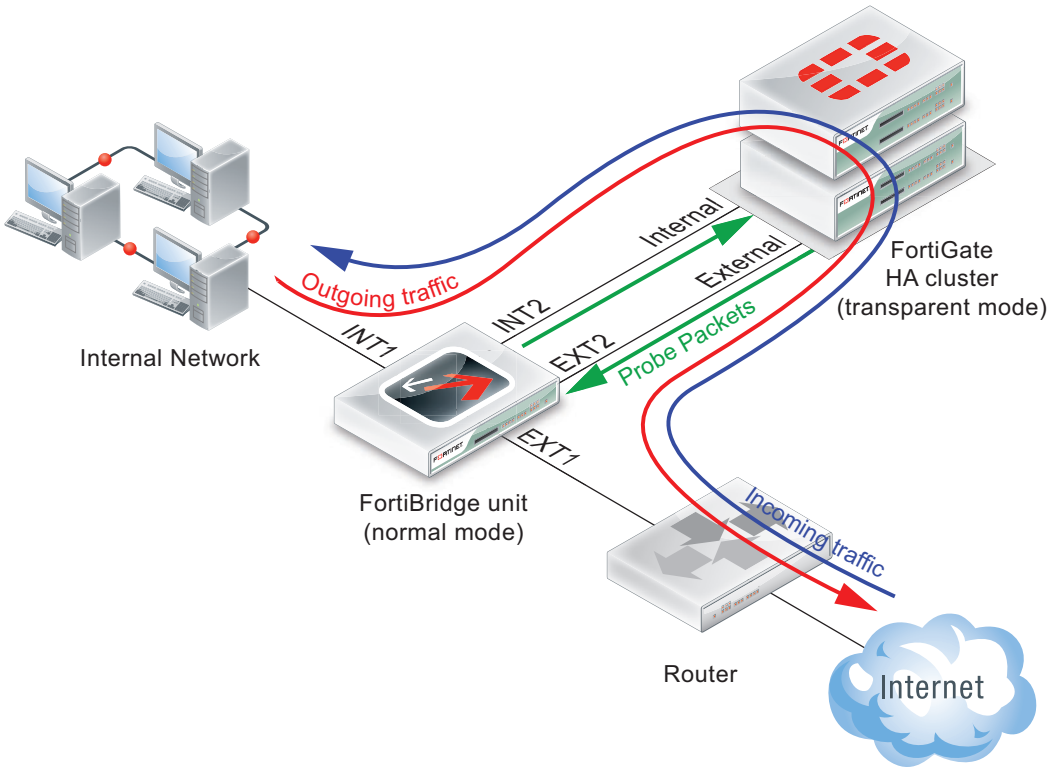
FortiBridge power failure

If a power failure occurs and the FortiBridge unit loses power, zero power fail-open technology causes FortiBridge unit to fail open. The FortiBridge unit bypasses the FortiGate unit and all traffic passes between the FortiBridge INT1 and EXT1 interfaces. If power is restored to the FortiBridge unit, it starts up in bypass mode and then switches to normal mode when its start up sequence is complete, reconnecting the FortiGate unit to the network.

Example FortiGate HA cluster FortiBridge application

A FortiBridge unit can provide fail open protection for a FortiGate HA cluster operating in transparent mode in much the same way as for a standalone FortiGate unit. To provide fail open protection for an HA cluster, connect the FortiBridge unit to the switches that connect the internal and external interfaces of the cluster. Use the following steps to connect a FortiBridge unit to the HA cluster, as shown in Figure 381:

Figure 381: FortiBridge unit providing fail open protection for a FortiGate HA cluster



The network configuration and FortiBridge configuration are the same for a cluster and for a standalone FortiGate unit. In normal mode, packets pass through the FortiBridge unit and through the FortiGate HA cluster and back through the FortiBridge unit. For the cluster to process this traffic, you must add Internal -> External firewall policies to the cluster configuration. If a failure occurs and the cluster no longer processes traffic, the FortiBridge unit switches to bypass mode, bypassing the cluster.

The connection procedure is different depending on whether the FortiBridge unit uses copper gigabit ethernet network connections or fiber gigabit ethernet network connections. This section includes the following connection procedures:

- Connecting the FortiBridge-2002 (copper gigabit ethernet)
- Connecting the FortiBridge-2002F (fiber gigabit ethernet)

Connecting the FortiBridge-2002 (copper gigabit ethernet)

The FortiBridge-2002 unit contains 4 auto-sensing 10/100/1000 Ethernet interfaces that connect to the internal and external networks and to the cluster interfaces that were connected to these networks. Use the following steps to connect a FortiBridge-2002 unit to the network as shown in Figure 381.

Normally, you would use straight-through ethernet cables to connect the FortiBridge-2002 unit to the FortiGate unit and to your networks. However, for some connections you may need a crossover ethernet cable (for example, for compatibility with network devices that do not support Auto MDI/MDIX).

1. Connect the FortiBridge-2002 INT2 interface to the switch connected to the HA cluster internal interface.
2. Connect the switch connected to the HA cluster external interface to the FortiBridge-2002 EXT2 interface.
3. Connect the internal network to the FortiBridge-2002 INT1 interface.
4. Connect the FortiBridge-2002 EXT1 interface to the router.

Connecting the FortiBridge-2002F (fiber gigabit ethernet)

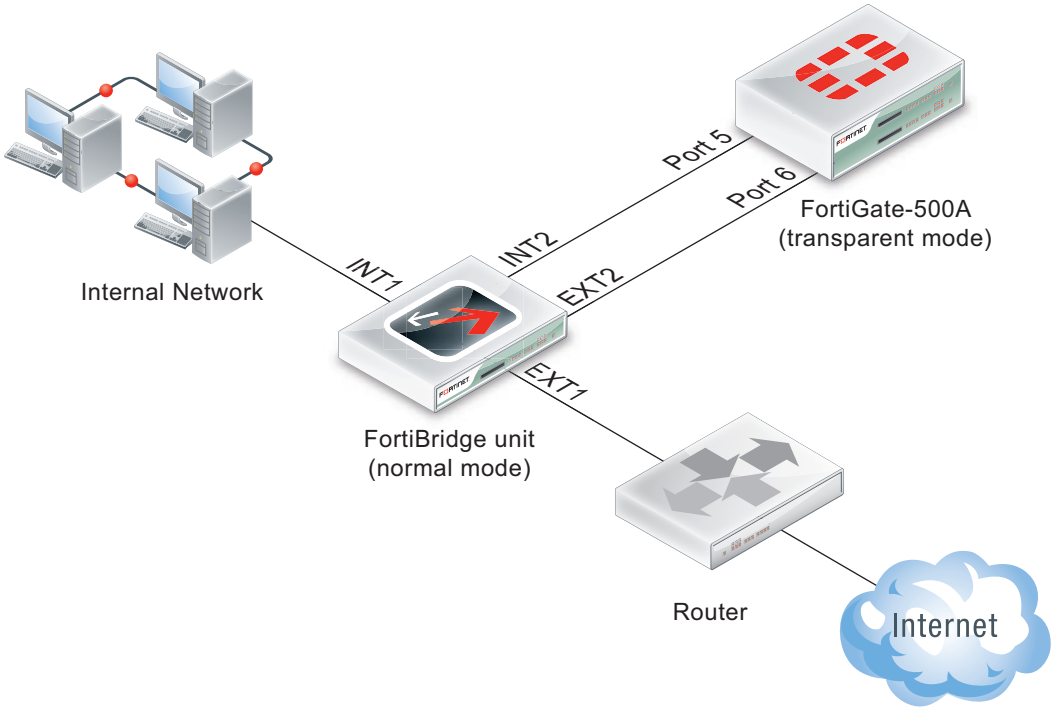
The FortiBridge-2002F unit contains 4 multimode fiber optic gigabit interfaces that connect to the internal and external networks and to the FortiGate cluster interfaces that were connected to these networks. Use the following steps to connect a FortiBridge-2002F unit to the network as shown in Figure 377.

1. Connect the FortiBridge-2002F INT2 interface to the switch connected to the HA cluster internal interface.
2. Connect the switch connected to the HA cluster external interface to the FortiBridge-2002F EXT2 interface.
3. Connect the internal network to the FortiBridge-2002F INT1 interface.
4. Connect the FortiBridge-2002F EXT1 interface to the router.

Example configuration with other FortiGate interfaces

All of the examples in this chapter describe using the FortiBridge unit to provide fail open protection for traffic passing between the FortiGate unit internal and external interfaces. You can actually use a FortiBridge unit to provide fail open protection for any two FortiGate unit interfaces. No limitation is implied by naming the FortiBridge interfaces INT and EXT. These names are used to simplify installation procedures. Figure 382 shows a FortiBridge unit providing fail open protection for network traffic between ports 5 and 6 of a FortiGate-500A unit.

Figure 382: FortiBridge unit providing fail open protection for a single FortiGate unit



To connect a FortiBridge unit to the network shown in Figure 382:

1. Connect the FortiBridge INT2 interface to the FortiGate-500A port 5 interface.
2. Connect the FortiGate-500A port 6 interface to the FortiBridge EXT2 interface.
3. Connect the internal network to the FortiBridge INT1 interface.
4. Connect the FortiBridge EXT1 interface to the router.

You must add port 5 -> port 6 firewall policies to the FortiGate-500A unit configuration.

Completing the basic FortiBridge configuration

Now that you have connected the FortiBridge unit to your network and connected to the FortiBridge CLI, use the following procedures to complete the basic configuration of the FortiBridge unit.

Not all of the following procedures are required to complete the basic FortiBridge unit configuration. Choose the procedures that apply to your installation.

- Adding an administrator password
- Changing the management IP address
- Changing DNS server IP addresses
- Changing the default gateway and adding static routes
- Allowing management access to the EXT1 interface
- Changing the system time and date
- Adding administrator accounts

When you complete the procedures in this chapter, the FortiBridge unit will be operating and connected to your network and to your FortiGate unit. See "Example network configuration" on page 2987 to configure the FortiBridge unit to monitor the status of the FortiGate unit and to fail open if the FortiBridge unit detects that the FortiGate unit has failed.

Adding an administrator password

Add an administrator password to the default admin administrator account to prevent unauthorized users from connecting to and managing the FortiBridge unit.

To add an administrator password — Web-based manager

1. Go to *System* > *Status*.
2. In the Administrators section of the dashboard, select the *Edit* icon of the admin user.
3. Select the *Change Password* link.
4. Enter the new password.
5. Enter the new password again in the second field.
6. Select *OK*.

To add an administrator password — CLI

```
config system admin
  edit admin
    set password <password_str>
end
```

Changing the management IP address

Change the FortiBridge unit management IP address so that you can connect to the FortiBridge CLI from your network (instead of being required to use a direct console connection). The management IP should be a valid IP address for your network.

To change the management IP address — Web-based manager

1 Go to *System* > *Status*.
2 Select the *Change* link in the Management Port section of the dashboard.
3 Enter the new management IP address and netmask in the IP/Netmask field.
4 Select *OK*.

To change the management IP address — CLI

```
config system manageip
  set ip <management_ipv4mask>
end
```

Changing DNS server IP addresses

Change the FortiBridge DNS server IP addresses to the IP addresses of your DNS servers. The correct DNS server configuration is required for alert email.

To change DNS server IP addresses — Web-based manager

1 Go to *System* > *Status*.
2 Select the *Change* link in the Management Port section of the dashboard.
3 Enter the primary DNS IP address in the *Primary DNS Server* field.
4 Enter the secondary DNS IP address in the *Secondary DNS Server* field.
5 Select *OK*.

To change DNS server IP addresses — CLI

```
config system dns
  set primary <primary_ipv4>
  set secondary <secondary_ipv4>
end
```

Changing the default gateway and adding static routes

Add static routes if you need to route packets from the FortiBridge unit through a router to another network. For example, if alert email sends email messages from the internal network to an email server on the Internet, you should add a route to the Internet.

The web-based manager allows you to enter only the default gateway. If you require additional static routes, use the CLI to enter them.

To change the default gateway — Web-based manager

1 Go to *System* > *Status*.
2 Select the *Change* link in the Management Port section of the dashboard.
3 Enter the default gateway IP address in the *Default Gateway* field.

To change the default gateway — CLI

```
config system route
  edit <sequence_int>
  set gateway <gateway_ipv4>
end
```

To add additional static routes — CLI

```
config system route
```

```
  edit <sequence_int>
    set gateway <gateway_ipv4>
    set dst <destination_ipv4mask>
end
```

Allowing management access to the EXT1 interface

By default no management access is configured for the EXT1 interface. Use the following procedure to add management access to this interface if required.

Configuring the EXT1 interface to allow management access is possible only using the CLI.

To allow management access to the EXT1 interface — CLI

```
config system interface external
  set allowaccess ssh
end
```

Changing the system time and date

Use the following procedure to change the system time and date.

To change the system time and date — Web-based manager

1. Go to *System* > *Status*.
2. Select the *Change* link beside *System Time* in the System Information section of the dashboard.
3. Enter the time, date, and timezone as required.
4. Select *OK*.

To change the system time and date — CLI

```
execute time <hh:mm:ss>
execute date <mm/dd/yyyy>
config system global
  set timezone <timezone_int>
end
```

Enter the number corresponding to your time zone. Type `?` to list time zones and their numbers.

For example, to set the time zone to Central time (time zone number 8), enter:

```
config system global
  set timezone 8
end
```

For information about configuring other global settings, see “system global” in the *FortiBridge CLI Reference* .

Adding administrator accounts

The factory default FortiBridge configuration includes the admin administrator account. Use this procedure to add more administrator accounts.

To add administrator accounts — Web-based manager

1. Go to *System* > *Status*.
2. In the Administrators section of the dashboard, select *Create New*.

3 Enter the administrator account name.
4 Enter the administrator account password.
5 Enter the password again in the second field.
6 Select *OK*.

To add administrator accounts — CLI

```
config system admin
  edit <admin_name_str>
    set password <password_str>
    set accprofile prof_admin
end
```

For more information about configuring administrators see “system admin” in the *FortiBridge CLI Reference*.

Resetting to the factory default configuration

Use the following procedure to reset the FortiBridge unit to the factory default configuration. You might want to reset the FortiBridge to the factory default condition if the FortiBridge unit is not functioning as expected and you would like to re-start the configuration process. Resetting to the factory default configuration resets all configuration changes that you have made, including the management IP address.

To reset to factory default configuration from the FortiBridge front panel

1 Use a pen or other pointed object to press the Factory reset button.

After a few seconds the FortiBridge unit restarts; reset to the factory default configuration. You can now re-configure the FortiBridge unit.

To reset to factory defaults — CLI

```
execute factoryreset
```

A few seconds after confirming your command, the FortiBridge unit restarts, reset to the factory default configuration. You can now re-configure the FortiBridge unit.

Installing FortiBridge unit firmware

Before beginning any of the procedures in this section, you must have the FortiBridge firmware image file that you are going to install on the FortiBridge unit. During these procedures you are required to enter the name of the firmware image file.

Changing firmware versions

You can use these procedure to upgrade to a newer version of the FortiBridge firmware, re-install the current version, or revert to an older version of the firmware.

The CLI-based procedure requires that you have a TFTP server you can connect to from the FortiBridge unit.

Changing firmware versions — Web-based manager

1 Go to *System* > *Status*.
2 In the System Information section, the Firmware Version displays the currently installed firmware version.

3 Select *Update* to install another version of the firmware.
4 Select *Browse* to choose the firmware file on your computer.
5 Select *OK* to install the firmware file.
6 If you are installing an older version of the firmware, you must confirm your selection before the installation can proceed.
7 The FortiBridge installs the firmware and restarts. This process takes a few minutes.
8 To confirm that the firmware you selected is installed, log into the web-based manager, go to *System* > *Status*, and confirm that the firmware version is correct.

Changing firmware versions — CLI

1 Make sure that the TFTP server is running.
2 Copy the new firmware image file to the root directory of your TFTP server.
3 Log into the CLI as an administrator with `sysshutdowngrp` access.

   Normally this would be the admin administrator. But you can use access profiles to control administrative access. See “system accprofile” in the *FortiBridge CLI Reference* for more information.
4 Make sure the FortiBridge unit can connect to the TFTP server.

   You can use the following command to ping the computer running the TFTP server. For example, if the TFTP server IP address is 192.168.1.168:

   ```
   execute ping 192.168.1.168
   ```
5 Enter the following command to copy the firmware image from the TFTP server to the FortiBridge unit:

   ```
   execute restore image <name_str> <tftp_ip>
   ```

   Where `<name_str>` is the name of the firmware image file on the TFTP server and `<tftp_ip>` is the IP address of the TFTP server. For example, if the firmware image file name is `FBG_2002-v30-build010-FORTINET.out` and the IP address of the TFTP server is `192.168.1.23`, enter:

   ```
   execute restore image FBG_2002-v30-build010-FORTINET.out
     192.168.1.168
   ```
6 If you are downgrading to an older firmware version, a message is displayed:

   ```
   Get image from tftp server OK.
   This operation will downgrade the current firmware version!
   Do you want to continue? (y/n)
   ```

   If you are certain that you want to downgrade to the older firmware version, press `Y`.
7 The FortiBridge installs the firmware and restarts. This process takes a few minutes.
8 Reconnect to the CLI.
9 To confirm that the new firmware image has been loaded, enter:

   ```
   get system status
   ```

Installing firmware from a system reboot

This procedure installs a specified firmware image and resets the FortiBridge unit to default settings. You can use this procedure to upgrade to a new firmware version, revert to an older firmware version, or to re-install the current firmware.

To use this procedure you:

- access the CLI by connecting to the FortiBridge console port,

- install a TFTP server that you can connect to from the FortiBridge EXT2 interface. The TFTP server should be on the same network as the EXT2 interface. The FortiBridge unit cannot access the TFTP server if its behind a router.

During this procedure you will be asked to enter a local IP address for the FortiBridge unit. This is a temporary address used for downloading the firmware image.

This procedure reverts your FortiBridge unit to its factory default configuration. Before running this procedure you can backup the FortiBridge unit configuration using the command `execute backup config`.

To install firmware from a system reboot

1 Connect to the CLI using the FortiBridge console port.

2 Make sure the TFTP server is running.

3 Copy the new firmware image file to the root directory of the TFTP server.

4 Make sure the EXT2 interface of the FortiBridge unit can connect to the TFTP server.

5 Enter the following command to restart the FortiBridge unit:

```
execute reboot
```

As the FortiBridge unit starts, a series of system startup messages are displayed. When the following messages appears:

```
Hit any key to stop autoboot:
```

6 Immediately press any key to interrupt the system startup.

You only have 3 seconds to press any key. If you do not press any key soon enough, the FortiBridge unit reboots and you must log in and repeat the `execute reboot` command.

When you successfully interrupt the startup process, the => prompt appears:

7 Type `upgrade` and press Enter to get the new firmware image from the TFTP server.

The following message appears:

```
Enter TFTP server address [192.168.1.168]:
```

8 Type the address of the TFTP server and press Enter.

The following message appears:

```
Enter local address [192.168.1.188]:
```

9 Type an IP address that the FortiBridge unit can use to connect to the TFTP server press Enter.

The local IP address is a temporary address used to download the firmware image. The local IP address should be on the same subnet as the TFTP server IP address.

The following message appears:

```
Enter firmware image file [image.out]:
```

10 Type the firmware image file name and press Enter.

The TFTP server uploads the firmware image file to the FortiBridge unit and the FortiBridge unit installs the new firmware image, resets the configuration to factory defaults, and restarts. This process takes a few minutes.

11 Reconnect to the CLI.

12 To confirm that the firmware image has been loaded, enter:

```
get system status
```

Example network configuration

This chapter describes how to configure a FortiBridge unit to provide fail open protection for a FortiGate unit operating in transparent mode. This chapter also describes some commonly required FortiBridge operating procedures such as recovering from a fail open event, manually switching between FortiBridge operating modes and backing up and restoring the FortiBridge configuration.

The procedures in this chapter assume that you have connected the FortiBridge unit to your network and completed its basic configuration as described in "Completing the basic FortiBridge configuration" on page 2979.

The information in this chapter can be applied to any standalone FortiGate transparent mode network configuration. These procedures can also be applied to a FortiBridge unit providing fail open protection for a FortiGate HA cluster operating in transparent mode.

The descriptions and procedures in this section assume that the FortiGate unit is installed between an internal network and the router that connects the internal network to the Internet as show in Figure 383. The FortiGate unit can provide the following security services for all traffic passing between the internal network and the internet:

- Internal –> External firewall policies for HTTP, FTP, POP3, SMTP, and IMAP connections from Internal network to the Internet.
- Virus scanning of HTTP, FTP, POP3, SMTP, and IMAP traffic,
- Web filtering of HTTP traffic,
- Spam filtering of POP3, SMTP, and IMAP traffic.

In addition to the above security services, a FortiCarrier unit can process MM1, MM3, MM4, and MM7 traffic.

Figure 383: Example FortiBridge application

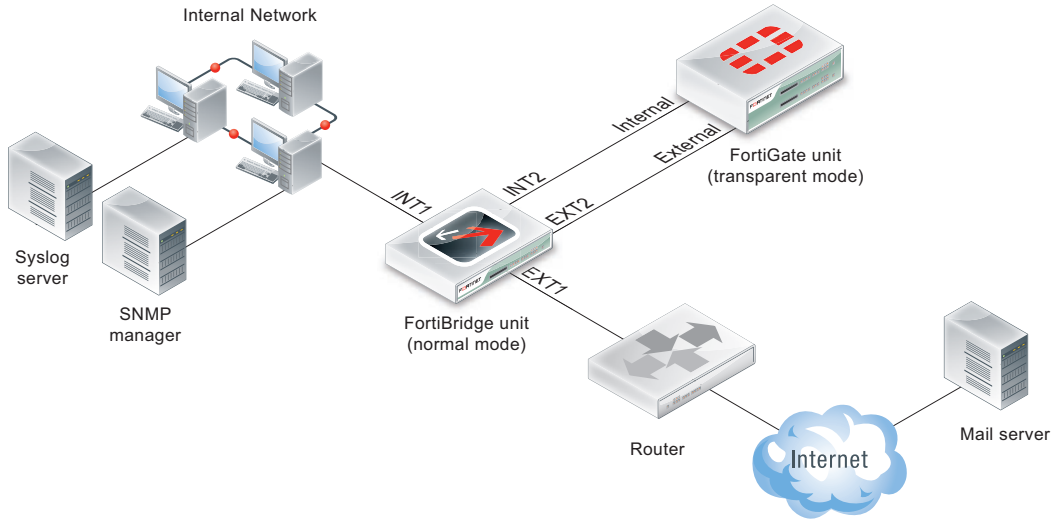


Table 155 lists the internal network configuration.

Table 155: Internal network configuration

FortiGate management IP address	172.20.120.10/24
Internal network subnet IP address	172.20.120.0/24

Table 155: Internal network configuration (Continued)

Router internal IP address	172.20.120.1/24
Internal network default route	172.20.120.1
Primary DNS server	172.20.120.2
Secondary DNS server	172.20.120.3
Syslog Server IP address	172.20.120.11
SNMP Manager IP address	172.20.120.12
Mail Server Name	mail.myorg.com

Table 156 lists the basic FortiBridge unit configuration settings.

Table 156: Basic FortiBridge unit configurations settings

Administrator password	passWORD
Management IP address	172.20.120.20/24
Default route	172.20.120.1
Primary DNS server	172.20.120.2
Secondary DNS server	172.20.120.3

Configuring FortiBridge probes

To monitor a FortiGate unit for failure, you configure the FortiBridge unit to send probe packets through the FortiGate unit. Using probe packets, the FortiBridge unit can confirm that the FortiGate unit can process ICMP (ping), HTTP, FTP, POP3, SMTP, IMAP, MM1, MM3, MM4, and MM7 traffic. Until you configure probes, the FortiBridge unit cannot detect if the FortiGate unit has failed.

This section describes:

- Probe settings
- Enabling probes
- Verifying that probes are functioning
- Tuning the failure threshold and probe interval

Probe settings

Configure probe settings to control the response when a FortiBridge probe detects that the FortiGate unit has failed. Probe settings consist of:

Table 157: Probe settings

Probe Setting	Description	Default
Action on failure	Set the FortiBridge unit response when a probe detects that the FortiGate unit has failed. The FortiBridge unit can, • Send alertmail • Fail open • Send an SNMP trap • Send a message to a syslog server You can add up to four actions on failure. All of the configured actions on failure occur when the FortiBridge unit detects a failure.	fail open
Dynamic IP pattern	Configure the INT2 and EXT2 interfaces with dynamic probe IP addresses. The dynamic probe IP addresses should not conflict with IP addresses on the network that the FortiGate unit is connected to. These IP addresses are not visible from the outside network, but they should not conflict with IP addresses in packets passing through the FortiBridge unit. You cannot change the dynamic IP pattern if any probes are enabled.	(none)
FortiGate unit serial number	The serial number of the FortiGate unit that the FortiBridge unit is connected to. The serial number appears in FortiBridge alert mail, and syslog messages to identify the FortiGate unit.	(none)

To configure probe settings

This procedure shows how to configure the following probe settings:

- The FortiBridge unit responds to a FortiGate unit failure by failing open and by sending an alert email, a syslog message, and an SNMP trap
- The dynamic IP pattern is 2.2.2.*
- The FortiGate unit serial number is FGT8002803923050

The FortiBridge unit does not have to fail open if the FortiGate unit fails. The FortiBridge unit can be configured just to send alerts if the FortiGate unit fails.

Configure probe settings — Web-based manager

1 Go to *Probe* > *Settings*.

2 Enter the IP pattern in the *Probe IP Address Pattern* field.

3 Select *Apply*.

4 Go to *Probe* > *Notifications*.

5 Select the notification types you require.

6 Select *Apply*.

You cannot set the failopen or failcutoff action, nor the FortiGate serial number using the web-based manager.

Configure probe settings — CLI

```
config probe setting
  set action_on_failure alertmail failopen snmp syslog
  set dynamic_ip_pattern 2.2.2.*
  set fgt_serial FGT8002803923050
end
```

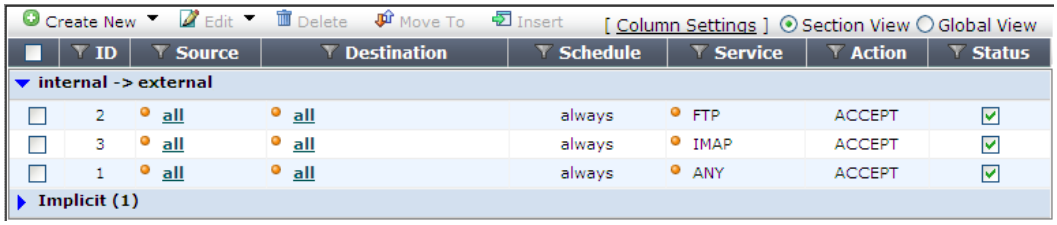
Enabling probes

Enable probes to control the protocols that the FortiBridge unit uses to confirm that the FortiGate unit is functioning normally. You can configure probes for ping (ICMP), HTTP, FTP, POP3, SMTP, IMAP, MM1, MM3, MM4, and MM7 protocols. For all probes you can configure the probe interval (the time between consecutive probe packets) and the probe threshold (the number of probe packets lost before the FortiBridge unit registers a failure). For HTTP, FTP, POP3, SMTP, and IMAP probes you can also change the probe port. You would change the probe port for a protocol if the FortiGate unit uses a non-standard port for that protocol.

The FortiBridge unit simultaneously tests connectivity through the FortiGate unit for each probe that you have enabled. The first probe that registers a failure causes all probes to stop and the configured action on failure to occur.

Before you configure probes, the FortiGate unit must be configured to pass the probe traffic. A single Internal->External firewall policy that allows all traffic also allows all probe packets. You can also configure individual policies for each protocol. For example, you could add the firewall policies shown in Figure 384 to the FortiGate unit.

Figure 384: Sample firewall policies



Policy 1 processes any network traffic. Policy 2 processes all FTP traffic. Policy 2 is above Policy 1 in the policy list, so FTP traffic is matched by policy 2. In the same way, Policy 3 processes all IMAP traffic.

FTP and IMAP probes would be processed by policies 2 and 3 respectively. All other probes would be processed by policy 1. This would include pings, SMTP traffic and so on.

To enable and configure FortiBridge probes — Web-based manager

The following steps show examples for configuring ping, HTTP, FTP, POP3, SMTP, and IMAP probes. For a complete description of FortiBridge probes see “probe probe_list {ping | http | ftp | pop3 | smtp | imap | mm1 | mm3 | mm4 | mm7}” in the *FortiBridge CLI Reference* .

1 Go to *Probe* > *Settings*.

2 For the ping protocol, select *Enable*.

This enables ping probes with the default settings.

3 For the FTP protocol, select *Enable*, enter `5` for the *Interval*, and enter `8` for the *Failure-Threshold*.

These settings have the FortiBridge unit send an FTP probe every 5 seconds and fail open if 8 consecutive FTP probe packets are not received.

4 For the IMAP protocol, select *Enable*.

This enables IMAP probes with the default settings.

5 For the SMTP protocol, select *Enable* and enter 26 for the *Port Number*.

This enables SMTP probes on port 26.

To enable and configure FortiBridge probes — CLI

1 Enable the ping probe using the default ping probe parameters. Enter:

```
config probe probe_list ping
  set status enable
end
```

2 Display ping probe settings, enter:

```
get probe probe_list ping
  name                : ping
  failure_threshold   : 3
  probe_interval      : 1
  status              : enable
```

3 Enable the FTP probe. Increase the failure threshold to 5 and the probe interval to 8.

```
config probe probe_list ftp
  set status enable
  set failure_threshold 8
  set probe_interval 5
end
```

The FortiBridge unit sends an FTP probe every 5 seconds and fails open if 8 consecutive FTP probe packets are not received.

4 Display FTP probe settings. Enter:

```
get probe probe_list ftp
  name                : ftp
  failure_threshold   : 8
  probe_interval      : 5
  status              : enable
  test_port           : 21
```

5 Enable the IMAP probe. Enter:

```
config probe probe_list IMAP
  set status enable
end
```

6 Enable the SMTP probe and change the port used by the probe from 25 to 26. Enter:

```
config probe probe_list SMTP
  set status enable
  set test_port 26
end
```

Verifying that probes are functioning

You verify that the probes are functioning by viewing the sessions being processed by the FortiGate unit.

To verify that probes are functioning

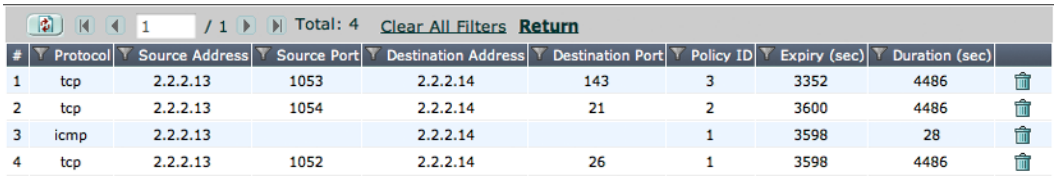
1 Go to *System* > *Dashboard* > *Status*.

2 In the Top Sessions widget, select *Details* at the bottom of the widget.

The current sessions list appears. Optionally select *Detach* to detach and expand the browser window to see the entire list.

3 View the sessions on the *Session* list.

Figure 385: FortiGate Session list showing FortiBridge probes



This session list shows the following:

- The FortiBridge dynamic probe IP addresses are 2.2.2.213 and 2.2.2.214.
- IMAP probe packets (port 143) are processed by firewall policy 3.
- FTP probe packets (port 21) are processed by firewall policy 2.
- ping probe packets are processed by firewall policy 1.
- SMTP packets using port 26 are processed by firewall policy 1.

Tuning the failure threshold and probe interval

If you find the FortiBridge unit failing open when the FortiGate unit has not failed or if the FortiGate unit fails and there is an unacceptably long delay before the FortiBridge unit fails open, you should adjust the failure threshold and probe interval.

Failing open when the FortiGate unit has not failed indicates that you should increase the time the FortiBridge unit waits to fail open. During startup, if the FortiBridge unit begins sending probe packets before the FortiGate unit has completed its start up sequence the FortiBridge unit may detect a failure and switch to bypass mode. Also, if the FortiGate unit is processing high traffic volumes, a fail open could occur if the FortiGate unit delays FortiBridge probe packets. You can increase the fail open delay by increasing the failure threshold and probe interval.

An unacceptable delay before failing open means network traffic can be interrupted for the time period between when the FortiGate unit fails and the FortiBridge unit fails open. You can minimize the delay by reducing the failure threshold and probe interval.

Configuring FortiBridge alerts

Configure FortiBridge alerts so that the `alertemail`, `syslog`, and `snmp` actions on failure cause the FortiBridge unit to notify system administrators that the FortiGate unit has failed. Until you configure alert email, syslog, and SNMP alerts, the FortiBridge cannot notify system administrators of a FortiGate failure.

You can configure the following FortiBridge alerts:

- FortiBridge alert email

- FortiBridge syslog
- FortiBridge SNMP

FortiBridge alert email

If you set the probe action on failure to `alertmail`, you can configure alert email so that the FortiBridge unit sends an email message to up to three email addresses if the FortiBridge unit detects a failure. The alert email informs the recipient that a FortiGate unit has failed, includes the protocol for which the failure was detected, and includes the serial number of the FortiGate unit that failed.

Only the first probe to detect a failure triggers the actions on failure. So, even if multiple probes are configured, when a failure is detected, the FortiBridge unit sends one alert email.

Figure 386: Sample FortiBridge alert email message

```
FortiBridge detect FortiGate failure

Time: Tue Feb  1 19:58:46 2010
failed protocol: http
failed FortiGate serial number: FGT8002803923050
```

To configure alert email — Web-based manager

Configuring FortiBridge alert email is similar to configuring FortiGate alert email.

1. Go to *Probe* > *Notifications*.
2. Enable *Email*.
3. Enter your email server name in the *SMTP Server* field.
4. Enter the email addresses to which the alert email messages are sent in the *Email to* fields. Three fields are provided for up to three addresses.
5. If your email server requires authentication to send messages, select *Authentication* and enter your SMTP user name and password.
6. Select *Apply*.

To configure alert email — CLI

```
config alertemail setting
    set server mail.myorg.com
    set username user@company.com
    set password PassWORD
    set mailto1 user@company.com
    set mailto1 user2@company.co.uk
    set mailto1 user3@company.com
  end
```

FortiBridge syslog

If you set the probe action on failure to `syslog`, you can configure the FortiBridge unit to send a syslog message to one syslog server if the FortiBridge unit detects a failure. The message informs the recipient that a FortiGate unit has failed, includes the protocol for which the failure was detected, and includes the serial number of the FortiGate unit that failed.

Only the first probe to detect a failure triggers the actions on failure. So, even if multiple probes are configured, when a failure is detected, the FortiBridge unit sends one message.

Figure 387: Sample FortiBridge syslog messages

```
02-01-2010 18:22:50 Local7.Alert 172.20.120.13 date=2010-02-01
time=15:28:22 device_id= log_id=0100020001 type=event
subtype=system pri=alert msg="FortiBridge detect FortiGate
failure: [failed time: Tue Feb  1 15:28:22 2010][failed protocol:
http] [failed FortiGate serial number: FGT8002803923050]"

02-01-2010 8:21:27 Local7.Alert 172.20.120.13 date=2010-02-01
time=15:26:59 device_id= log_id=0100020001 type=event
subtype=system pri=alert msg="FortiBridge detect FortiGate
failure: [failed time: Tue Feb  1 15:26:59 2010][failed protocol:
ftp] [failed FortiGate serial number: FGT8002803923050]"

02-01-2010 18:17:17 Local7.Alert 172.20.120.13 date=2010-02-01
time=15:22:49 device_id= log_id=0100020001 type=event
subtype=system pri=alert msg="FortiBridge detect FortiGate
failure: [failed time: Tue Feb  1 15:22:49 2010][failed protocol:
ping] [failed FortiGate serial number: FGT8002803923050]"

02-01-2010 8:13:43 Local7.Alert 172.20.120.13 date=2010-02-01
time=15:19:15 device_id= log_id=0100020001 type=event
subtype=system pri=alert msg="FortiBridge detect FortiGate
failure: [failed time: Tue Feb  1 15:19:15 2010][failed protocol:
smtp] [failed FortiGate serial number: FGT8002803923050]"
```

To configure FortiBridge syslog — Web-based manager

In most cases you should only need to configure the IP address of the syslog server to receive FortiBridge syslog messages. See “log syslogd setting” in the *FortiBridge CLI Reference* for more FortiBridge syslog options.

1. Go to *Probe* > *Notifications*.
2. Enable *Syslog*.
3. In the IP address field, enter the syslog server address
4. If required, configure the port, facility, and format.
5. Select *Apply*.

To configure FortiBridge syslog — CLI

```
config log syslogd setting
  set server 172.20.120.11
end
```

FortiBridge SNMP

If you set the probe action on failure to `snmp`, you can configure FortiBridge SNMP settings so that the FortiBridge unit sends SNMP v1 and v2c compliant traps to SNMP v1 and v2c compliant SNMP managers if the FortiBridge unit detects a failure. The traps inform the recipient that a FortiGate unit has failed and include the protocol for which the failure was detected.

Only the first probe to detect a failure triggers the actions on failure. So, even if multiple probes are configured, when a failure is detected, the FortiBridge unit sends one v1 SNMP trap and one v2c SNMP trap.

Configure FortiBridge SNMP by adding and configuring an SNMP community. An SNMP community is a grouping of equipment for network administration purposes. You can add up to three SNMP communities. Each community can have a different configuration for SNMP traps. You can add the IP addresses of up to 8 SNMP managers to each community.

To add and enable an SNMP community — Web-based manager

1 Go to *Probe* > *Notifications*.
2 Enable *SNMP*.
3 In the *Community Name* field, enter an SNMP community name.
4 Enter the address of an SNMP manager in the *IP Address* field.
   You may enter up to eight SNMP manager addresses.
5 Select *Apply*.

To add and enable an SNMP community — CLI

```
config system snmp community
  edit 1
    set name snmp_1
  end
```

The new SNMP community, named snmp1, is enabled by default. SNMP v1 and v2 traps are also enable by default. You can disable traps and change ports. See "system snmp community" in the *FortiBridge CLI Reference* for more information.

Add the IP addresses of two SNMP managers that can receive traps.

```
config system snmp community
  edit 1
    config hosts
      edit 1
        set ip 172.20.120.12
      next
      edit 2
        set ip 192.168.20.102
    end
  end
```

Recovering from a FortiGate failure

After a FortiBridge probe detects a FortiGate failure, the FortiBridge unit stops sending probes. To restart probes you can restart the FortiBridge unit, connect to the FortiBridge CLI and enter the `execute switch-mode` command, or press the mode button on the FortiBridge unit front panel.

Normally, an action on failure causes the FortiBridge unit to fail open. When the FortiBridge unit fails open, it begins operating in Bypass mode. In bypass mode the INT1 and EXT1 interfaces are directly connected and you cannot use Telnet or SSH to connect to the FortiBridge CLI. Use the following procedure to recover from bypass mode after a FortiGate failure and resume normal operation.

To resume normal operation from bypass mode

When the FortiBridge unit is operating in bypass mode, you need to do the following to resume normal operation:

1 Review FortiBridge alerts and check the status of your FortiGate unit and network components to determine the source of the failure.

A network component or the FortiGate unit could have experienced a general hardware failure or a specific software failure.

2 Make the required changes to fix the problem.

Depending on the cause, this could mean re-connecting and restarting the FortiGate unit, or diagnosing a problem with the FortiGate unit or other network component.

If all network and FortiGate unit hardware and software is functioning normally, you may have to adjust FortiBridge probe settings. See "Tuning the failure threshold and probe interval" on page 2992.

3 Manually switch the FortiBridge unit from bypass to normal mode.

Connect to the FortiBridge CLI using the console connection and enter the command:

```
execute switch-mode
```

Or press the Mode button on the FortiBridge unit front panel.

Or restart the FortiBridge unit by cycling the power or from the console using he `execute reboot` command. The FortiBridge unit always restarts in normal mode.

Manually switching between FortiBridge operating modes

You can manually switch between FortiBridge operating modes from the FortiBridge CLI or by pressing the Mode button on the FortiBridge front panel. To switch operating modes from the CLI enter:

```
execute switch-mode
```

Backing up and restoring the FortiBridge configuration

Use the following procedures to backup and restore your FortiBridge configuration. For both of these procedures, you must have a TFTP server that you can connect to from any FortiBridge unit interface. The FortiBridge unit must be operating in normal mode.

To back up the FortiBridge configuration — Web-based manager

1 Go to *System* > *Status*.

2 In the System Configuration section, select the Configuration *Backup* link.

3 You browser prompts you for the file name and location of the configuration file.

Using the web-based manager, the configuration backup file is saved to the computer you are using.

To back up the FortiBridge configuration — CLI

1 Make sure that the TFTP server is running.

2 Log into the FortiBridge CLI.

3 Backup the system configuration to a text file on the TFTP server. Enter:

```
execute backup config <filename_str> <tftp-server_ipv4>
```

The config file is copied to the TFTP server and saved with the specified file name.

To restore the FortiBridge configuration — Web-based manager

1. Go to *System* > *Status*.
2. In the System Configuration section, select the Configuration *Restore* link.
3. Select Browse and find the configuration backup file you want to restore.
4. Select OK to begin the restore procedure.
5. The FortiBridge unit reboots after loading the configuration file. While the FortiBridge unit is rebooting, all network traffic passes directly from INT1 and EXT1 bypassing the FortiGate unit.

To restore the FortiBridge configuration — CLI

1. Make sure that the TFTP server is running.
2. Log into the FortiBridge CLI.
3. Restore the system configuration from a text file on the TFTP server. Enter:

```
execute restore config <filename_str> <tftp-server_ipv4>
```

The config file is copied from the TFTP server to the FortiBridge unit. The FortiBridge unit reboots after loading the new configuration. While the FortiBridge unit is rebooting, all network traffic passes directly from INT1 and EXT1 bypassing the FortiGate unit.

Chapter 20 Certifications and Compliances

This FortiOS Handbook chapter contains the following sections:

FIPS-CC operation of FortiGate units describes how to install and use special FortiOS firmware builds certified to either Federal Information Processing Standards (FIPS) or Common Criteria (CC) requirements.

Configuring FortiGate units for PCI DSS compliance explains the Payment Card Industry Data Security Standard (PCI DSS). It provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements.

FIPS-CC operation of FortiGate units

Fortinet produces special FortiOS firmware builds that are compliant with U.S. Federal Information Processing Standards (FIPS), Common Criteria (CC) security requirements, or both. These are enhanced security options for some FortiGate Unified Threat Management System models.

This section describes how to install these special builds on a FortiGate Unified Threat Management System and how to operate the unit in the FIPS-CC compliant mode. It provides information about features that differ from the standard firmware for your FortiGate unit. Installation of FIPS-CC certified firmware is required only if the unit was not ordered with this firmware pre-installed.

At the publication date of this document, the latest FIPS certified systems use firmware based on FortiOS version 4.0 and the latest Common Criteria certified systems use firmware based on FortiOS version 3.0 MR4.

This document is intended to be used by a system administrator.

This chapter contains the following sections:

Introduction to FIPS-CC

Security level summary

Fortinet performs Common Criteria certifications on specific FortiOS versions in combination with specific FortiGate models. Fortinet performs FIPS 140-2 certifications on specific FortiOS versions in combination with specific FortiGate models (FIPS 140-2 Level 2 certification) and on FortiOS independent of the FortiGate hardware (FIPS 140-2 Level 1 certification). Information on Common Criteria certification is found in the relevant Security Target. Information on FIPS 140-2 certification is found in the relevant Security Policy. These documents are available on the Fortinet Support web site from the same directory where you download the firmware.

Documentation

The documentation for FortiGate units operated in FIPS-CC mode consists of this FortiOS Handbook chapter and the standard FortiGate unit documentation set for the version of FortiOS that the FIPS-CC build is based on. This documentation is available from the Fortinet Technical Documentation web site at http://docs.forticare.com.

Overview of Common Criteria compliant operation

Common Criteria compliant operation requires both that you use the FortiGate Unified Threat Management System in its FIPS-CC mode and that you follow secure procedures for installation and operation of the FortiGate unit. You must ensure that:

- The FortiGate unit is installed in a secure physical location.
- Physical access to the FortiGate unit is restricted to authorized operators.
- Strong password policies are enabled by default.
- Administration of the FortiGate unit is permitted using only certified administrative methods. These are:
  - console connection
  - web-based manager via HTTPS
  - command line interface (CLI) access via SSH
- The FortiGate unit can be used in either of its two operation modes: NAT/Route or Transparent. NAT/Route mode applies security features between two or more different networks (for example, between a private network and the Internet). Transparent mode applies security features at any point in a network. The current operation mode is displayed on the web-based manager Status page and in the output of the `get system status` CLI command. Also, on -equipped units, Transparent mode is indicated by “FIPS-CC-TP” and NAT/Route by “FIPS-CC-NAT” on the display.

Use of non-FIPS-CC compliant features

FIPS-CC mode does not prevent you from using non-FIPS-CC compliant features that are not permanently disabled.If you use these features, however, you are not operating the FortiGate unit in strict FIPS-CC compliance according to the Security Target or Security Policy.

Effects of FIPS-CC compliant mode

The following list describes, not necessarily in order, the effects of enabling FIPS-CC mode with respect to the normal mode of operation.

Interfaces

- Immediately after switching to FIPS-CC mode, all network interfaces are down and have no IP address assigned. Configure interfaces as needed.
- By default, admin access (except for ping access) is disabled and must be enabled on a per-interface basis.
- Network interfaces cannot be configured for HTTP or Telnet administrative access.
- NPU support is disabled by default, but can be re enabled.
- Some FortiGate models have grouped interfaces that by default operate as a switch with a single IP address. Optionally, these interfaces can be configured as individual interfaces, each with its own IP address. FIPS-CC supports both configurations.

Administration

- Administrative access via HTTPS or SSH requires strong cryptography: AES or 3DES encryption with SHA1 digest. DES encryption and MD5 digest are not available.
- By default, after three failed attempts to log on to an administrator account, the account is locked out for one hour. You can change the number of attempts permitted and the length of the lockout. See “Administrator account lockout settings” on page 3010.
- Optionally, you can limit administrator access to scheduled times. See “Scheduled administrator access” on page 3011.
- On a CLI session, when an administrator logs out or the session times out, the FortiGate unit sends 300 carriage return characters to clear the screen. Note: if your terminal buffer is large, not all information from the session is cleared.
- The USB auto install options are disabled.
- The control panel keys cannot be used to modify the FortiGate unit configuration.
- The FortiGate unit front panel displays “FIPS-CC-” followed by the operation mode, “NAT” or “TP”. You might have to press an panel key to deactivate the screen saver and view this display.
- The `get system status` CLI command display includes “FIPS-CC mode: enable”.
- By default, all administrators must accept a disclaimer statement at logon. This disclaimer can be disabled or modified. See “Disclaimer access banner” on page 3010.
- When configuring passwords or keys, the FortiGate unit requires you to enter the password or key a second time as confirmation.
- Configuration backups use 3DES encryption with a HMAC-SHA1 checksum and a user-defined password. FIPS-CC mode backup files are not valid in non-FIPS-CC mode and vice-versa.
- The FortiGate unit performs self-tests at startup, when cryptographic keys are generated, and on a recurring basis. If any of these tests fail, the unit goes into FIPS Error mode and shuts down. The self-tests cannot be disabled, except by leaving FIPS-CC mode. Also, the administrator can run self-tests at any time. See “Running self-tests manually” on page 3008.
- TFTP communication is insecure and is disabled by default. In non-FIPS-CC operation TFTP can be used to back up or restore the configuration remotely. In FIPS-CC mode, you should use a USB drive for this purpose. TFTP can be re-enabled using the `tftp` keyword in the `config system global` CLI command, but this is not FIPS-CC compliant operation.
- Remote access clients must meet security requirements. See “Remote access requirements” on page 3009.
- There is an alarm capability. See “Alarms” on page 3018.
- USB auto-install options are disabled.
- The fnsysctl command, which provides some access to the underlying operating system, is not available.
- Virus attack reporting to FortiGuard Distribution Service (FDS) is disabled.

HA

- In HA mode, HA heartbeat data is exchanged using AES encryption and SHA1 authentication. The key is automatically generated, but can overridden by setting the `key` field to a new 16-byte hexadecimal value, like this:

```
config system ha
  set key fdoa0803e0157d4e
end
```

  FortiOS will require the key value to be entered again to confirm it.

Routing

- Immediately after switching to FIPS-CC mode, no DNS addresses are configured.
- Immediately after switching to FIPS-CC mode, no default route is configured.

Logging

- Logging is enabled by default for:
  - new security policies
  - interfaces where administrative access is enabled
  - attempts to gain administration access on network interfaces where administrative access is not enabled
  - failed connection attempts to the FortiGate unit using TCP/IP ports other than 22 (ssh), 23 (telnet), 80 (HTTP), and 443 (HTTPS).
  - all configuration changes
  - configuration failures
  - remote IP lockout due to reaching maximum number of failed login attempts
  - log viewing
  - interface going up or down
  - other traffic: dropped ICMP packets, dropped invalid IP packets, session start and session deletion
- Logging is enabled for all event types at debug severity level.
- Memory logging is enabled on units that do not contain a hard disk. Logging includes traffic logging and all event types.
- Traffic logging to memory is available only in FIPS-CC mode.
- Reaching 95% of the log storage capacity results in the FortiGate unit entering an error mode that shuts down all of the interfaces until the administrator intervenes.

Firewall

- Immediately after switching to FIPS-CC mode, all security policies are removed.
- Newly-created security policies have Log allowed traffic enabled by default.
- Newly-created security policies are disabled and must be explicitly enabled.
- Blocking of spoofed TCP RST packets is enabled by default.

VPN

- The DES and MD5 algorithms are not available.
- Diffie-Hellman groups 14 through 18 are available to VPN configurations and group 15 is the default. DH groups 15 through 18 use 3072 to 8192-bit keys. You should use these groups for FIPS-CC complaint VPNs between FortiGate units. Current versions of the FortiClient Host Security application support only DH groups 1, 2 and 5.
- ANSI X9.31 RSA signature is an optional authentication method for IPSec VPNs. This method is supported by default on FortiGate units in FIPS-CC mode.
- By default, 2048-bit RSA certificates are configured, but 1024-bit certificates can be configured.

Initial configuration of the FortiGate unit

This section describes how to configure your FortiGate unit in the FIPS-CC mode of operation. Proceed as follows:

- Install the unit following the procedures in the documentation.
- Register your FortiGate unit with Fortinet.
- If you are upgrading an existing FortiGate unit to FIPS-CC firmware, download the appropriate firmware from Fortinet and install it on your unit.
- Verify the firmware version of your FortiGate unit.
- Enable FIPS-CC mode.

Installing the unit

Both the *Quick Start Guide* and the Getting Started section of the *Installation Guide* for your FortiGate unit provide instructions on the physical installation and initial configuration of your unit. When you have completed these procedures you will be able to access both the web-based manager and Command Line Interface (CLI).

Configuration of units with AMC/FMC modules

To use AMC/FMC modules, you must insert and configure them before enabling FIPS-CC mode. Modules inserted during FIPS-CC mode operation cause intermittent failures of integrity self-tests.

For more information about using AMC/FMC modules, refer to the documentation provided with your FortiGate unit.

Downloading and installing FIPS-CC compliant firmware

Unless you purchased a FortiGate unit with FIPS-CC firmware pre-installed, you need to download and install the appropriate firmware for your FortiGate unit. The Support web site provides FIPS-certified and CC-certified versions of FortiOS firmware for specific FortiGate models. Refer to the relevant CC Security Target or FIPS Security Policy document to determine which specific build you need.

To download the firmware

1 With your web browser, go to https://support.fortinet.com/ and log in using the name and password you received when you registered with Fortinet Support.

2 Navigate to the download page for the appropriate version of FortiGate firmware and select the FIPS-CC-Certified folder. Download the FIPS-CC compliant firmware build you need. Save the file on the management computer or on your network where it is accessible from the FortiGate unit.

Installing the FIPS-CC firmware

You can install the FIPS-CC compliant firmware as an upgrade from the standard firmware.

To install the FIPS-CC firmware

1 Using the management computer, connect to the unit's web-based manager. See the the *Quick Start Guide* or the *Installation Guide* for information.

2 Type `admin` in the name field. If you have assigned a password, type it in the *Password* field. Select *Login*.

3 Go to *Dashboard* > *Status*.

4 Under *System Information* > *Firmware* version, select *Update*.

5 Type the path and filename of the firmware image file, or select *Browse* and locate the file.

6 Select *OK*.

The unit uploads the firmware image file, upgrades to the new firmware version, restarts, and displays the Login page. This process takes a few minutes.

Verifying the firmware version of the unit

Execute the following command from the command line:

```
get system status
```

The version line of the status display shows the FortiGate model number, firmware version, build number and date. For example:

```
Version: Fortigate-500A 4.00,build6204,100928
```

Verify in the relevant security target or security policy document that your firmware version, build number and date are appropriate.

A note about non FIPS-CC functionality

Even when operated in non-FIPS-CC mode, the FIPS-CC firmware functionality differs in some ways from the standard FortiGate firmware on which it is based.

Access Profiles

Log & Report access is split into Log & Report Configuration and Log & Report Data. In the web-based manager, the Log & Report access control item expands to show these two access controls. In the CLI, you can independently control administrator access to logging configuration and data as follows:

```
config system accprofile
  edit <profile_name>
    set loggrp custom
    config loggrp-permission
      set config {none | read | read-write}
      set data-access {none | read | read-write}
    end
  end
```

Memory log size

Maximum memory log size is configurable from the CLI:

```
config log memory global-setting
  set max-lines <value>
end
```

Log full limit thresholds are configurable from CLI

```
config log memory global-setting
  set full-first-warning-threshold [1-100 default=75]
  set full-second-warning-threshold [1-100 default=90]
  set full-final-warning-threshold [1-100 default=95]
end
```

These threshold values are a percentage of the max-lines limit. When the first threshold is reached, an informational event is logged. When the second and final thresholds are reached, warning events are logged. The log message in each case is in the form, “Memory [log-type] log is [percentage]% full.” After the final threshold is reached, new log messages overwrite the oldest log message.

Enabling FIPS-CC mode

If you have verified the firmware version, you are ready to enable FIPS-CC mode. As part of enabling FIPS-CC mode, you must define the administrator password. You must use a console connection to enable FIPS-CC mode. If you try to use another type of connection, a “check permission failed” error occurs.

When you enable FIPS-CC mode, all of the existing configuration is lost.

To enable FIPS-CC mode

1 Log in to the CLI using default admin account or another account with super_admin access profile. Enter the following commands:

```
config system fips-cc
  set status enable
end
```

If the FortiGate unit is currently in multi-VDOM mode, you need to precede the above commands with the command `config global`.

2 In response to the following prompt, enter the password for the administrator:

```
Please enter administrator password:
```

3 When prompted, re-enter the administrator password.

The CLI displays the following message:

```
Warning: most configuration will be lost,
   do you want to continue? (y/n)
```

4 Enter `y`.

The FortiGate unit restarts and runs in FIPS-CC compliant mode.

Configuring interfaces

When FIPS-CC mode is initially enabled, all network interfaces are down and have no IP addresses assigned. This example shows how to configure port1 with an IP address of 192.168.0.99 and administrative access to permit use of the web-based manager.

```
config system interface
  edit port1
    set ip 192.168.0.99 255.255.255.0
    set allowaccess https
    set status up
  end
```

For detailed information about configuring network interfaces, refer to the FortiGate documentation supplied with your unit.

Re-enabling NPU support

Support for NPU accelerated interfaces is disabled by default in FIPS-CC mode. The following CLI command will re enable NPU support:

```
config system npu
  set offload-ipsec-host enable
end
```

FIPS-CC mode status indicators

There are two status indicators that show when the FortiGate unit is running in the FIPS-CC mode of operation:

Table 158: FIPS-CC mode status indicators

Location	Indication
Front panel (some models) (press a button to deactivate screen saver)	FIPS-CC-NAT (NAT/Route mode) FIPS-CC-TP (Transparent mode)
Output of `get system status` command	FIPS-CC mode: enable

Self-test settings

The default self-test period is every 1440 minutes. The following CLI command can change this to any period from 1 to 1440 minutes, inclusive.

```
config system fips-cc
  set self-test-period <minutes_int>
  end
```

Self-tests on key generation (SSL, SSH, and IPsec) are disabled by default. The following command will re-enable the tests:

```
config vpn fips-cc
  set key-generation-self-test enable
  end
```

Running self-tests manually

The administrator can run self-tests manually at any time. To run all of the tests, enter the following CLI command:

```
execute fips kat all
```

To run an individual test, enter `execute fips kat <test_name>`. To see the list of valid test names, enter `execute fips kat ?`

Administration

When you invoke FIPS-CC mode for the first time, the FortiGate unit prompts you for a password to assign to the administrator account. After the initial configuration of administrators when you enable FIPS-CC mode, you can create additional administrator accounts as needed.

User guidance

It is the administrator's responsibility to ensure users know how to use the user authentication functions of the FortiGate unit, as described in the Authentication chapter of the FortiOS Handbook.

Remote access requirements

In FIPS-CC mode, remote administration is not allowed via HTTP or Telnet, which are not secure. SSH and HTTPS access are permitted but must meet certain security requirements.

Setting minimum DH primes size

By default, in FIPS-CC mode the FortiGate unit requires values at least 3072 bits long to be used in the Diffie-Hellman key exchange when an SSL or HTTPS session begins. Using the CLI, you can set this minimum to any of the safe standard values specified in RFC 3526: 1024, 1536, 2048, 3072, 4096, 6144 or 8192 bits. For example, to use commercially available browsers, you might need to set the key size to 1024, like this:

```
config system global
  set dh-params 1024
  end
```

Enabling administrative access

In FIPS-CC mode, the network interfaces by default do not allow administrative access, preventing you from using the web-based manager. You can re-enable use of the web-based manager using CLI commands on the console. This example enables HTTPS administrative access on the port1 interface to allow use of the web-based manager and SSH clients:

```
config system interface
  edit port1
    set allowaccess https ssh
  end
```

For detailed information about accessing the web-based manager, see "Connecting to the web-based manager" in the *Installation Guide* for your unit.

SSH client requirements

To access the CLI through network interfaces in FIPS-CC mode, your SSH client must support the following:

Authentication:

- RSA X9.31 or HMAC SHA-1

Encryption:

- AES128, AES192, AES256 or 3DES

Web browser requirements

To use the web-based manager in FIPS-CC mode, your web browser application must meet the following requirements:

- Authentication algorithm: RSA X9.31, PKCS1 RSA or DSS (in descending order of preference)
- Connection security: TLS 1.0

Disclaimer access banner

By default, in FIPS-CC mode, each time you log on as an administrator, you see a warning statement that usage is monitored and that unauthorized usage can result in disciplinary or legal action. You must accept the statement to continue. If you decline the statement, you are immediately logged out. Logs record response to the disclaimer at each logon.

You can disable the disclaimer in the CLI as follows:

```
config system global
  set access-banner disable
end
```

Similarly, you can enable the disclaimer, like this:

```
config system global
  set access-banner enable
end
```

Modifying the disclaimer text

You can modify the disclaimer to meet the requirements of your organization. The disclaimer is an editable replacement message. Using the CLI, enter the disclaimer text in the buffer field. To put a carriage return in the message, use Shift-Enter. For example,

```
config system replacemsg admin admin-disclaimer-text
  set buffer "Warning! Warning! Warning!
  This system is monitored at all times.
  Unauthorized use may be prosecuted.
  "
end
```

To restore the default message, enter

```
config system replacemsg admin admin-disclaimer-text
  unset buffer
end
```

Administrator account lockout settings

By default, after three failed attempts to log on to an administrator account, the account is locked out for one hour. The lockout applies only to the IP address from which the failed attempts were made. The login name is logged. You can change the number of logon attempts permitted and the length of the lockout using the following CLI commands:

```
config system global
  set admin-lockout-threshold <tries>
  set admin-lockout-duration <seconds>
end
```

where `<tries>` is permitted number of attempts, range 1 to 10 (default 3) and `<seconds>` is the lockout duration in seconds, range 1 to 4,294,967,295 (default 60).

The Security Administrator can clear a lockout with the following CLI command:

```
execute clear system login-lockout <index>
```

Use a ? as the index to see the list of locked-out accounts.

Scheduled administrator access

For additional security, you can limit administrator access to certain times, business days for example. To do this, you need to create a firewall schedule and then assign the schedule to the administrator.

You can create a firewall schedule in the web-based manager or the CLI. For more information, refer to the documentation provided with your FortiGate unit.

To assign a schedule to an administrator, enter the following CLI commands:

```
config system admin
  edit <admin-name>
    set schedule <schedule-name>
  end
```

where `<admin-name>` is the name of the administrator account and `<schedule-name>` is the name of the firewall schedule.

Using custom administrator access keys (certificates)

You, as cryptographic administrator, can upload VPN certificates to use as custom RSA keys to authenticate administrators. To do this, you must upload the signed public certificate to the FortiGate unit. If the private key was not generated on the FortiGate unit, it also must be uploaded. Certificates must have a modulus of at least 2048 bits.

Importing the custom RSA key

In FIPS-CC mode, you cannot import certificates using TFTP. You must use a USB storage device instead. Put the files you want to upload on the device and connect the device to the FortiGate unit. Use one of the following commands to import the files:

If you have a PKCS12 format key-certificate file,

```
execute vpn certificate local import usb pkcs12 <file_name>
   <password>
```

If you have separate certificate and key files,

```
execute vpn certificate local import usb cert <cert_file_name>
   <keyfile_name> <password_for_keyfile>
```

Enabling the custom RSA key

To enable the custom RSA key you imported, use the following CLI command:

```
config system global
  set admin-server-cert <certificate-name>
end
```

This applies to both HTTPS and SSH connections.

Configuration backup

Configuration backup files created in FIPS-CC mode are not compatible with backup files created in non-FIPS-CC mode. A FIPS-CC mode configuration backup cannot be restored in non-FIPS-CC mode and vice-versa.

You can create FIPS-CC configuration backup files to use for disaster recovery. They are valid on a replacement FortiGate unit or to restore configuration after you exit and then re-enter FIPS-CC mode.

For detailed information about creating configuration backup files, refer to the documentation provided with your FortiGate unit.

Configuration backup or restoration using TFTP is not permitted in FIPS-CC mode.

Firewall

FIPS-CC mode has additional requirements for security policies and firewall authentication, compared to the standard firmware.

Security policies

When you create a security policy in FIPS-CC mode, by default the policy is not enabled. You must explicitly enable it. In the web-based manager, after creating the policy, select the checkbox at the beginning of the policy entry on the **Policy > Policy** page. In the CLI, enable a policy by setting its status to enable. You can do this when you create the policy or later:

```
config firewall policy
  edit 2
    set status enable
  end
```

Policies are identified by policy ID. In the preceding example, the ID was 2.

Firewall authentication

In FIPS-CC mode, user passwords must be 8 characters or more. FTP and Telnet mechanisms for Proxy User Authentication are not allowed, and SSL redirection must be enabled for the HTTP mechanism.

User account lockout settings

Optionally, you can lock out a user's account for a period of time after a number of unsuccessful attempts to authenticate. You can configure this in the CLI using the following commands:

```
config system global
  set auth-lockout-threshold <tries>
  set auth-lockout-duration <seconds>
end
```

where `<tries>` is permitted number of attempts, range 1 to 10 (default 3) and `<seconds>` is the lockout duration in seconds, range 1 to 4,294,967,295, or 0 to disable lockout. The default is 0.

This lockout applies to end users only. Administrator lockout is configured separately. See "Administrator account lockout settings" on page 3010.

Logging

The Common Criteria protection profile requires logging of all traffic and logging of system events, including startup and shutdown of functional components. The severity threshold for logging is set to the lowest level: debug. This ensures that the maximum amount of information is logged.

Logs are written to the FortiGate unit hard disk on all models except model 5001, which contains a flash memory drive and models 50A and 100A that log to system memory.

Traffic logging to system memory is available only in FIPS-CC mode.

The FortiGate unit generates warning log entries when the space allocated for logging is filled to 75%, then 90% and finally 95% of capacity. For information about setting the log size, see "Memory log size" on page 3007. When logs exceed 95% of capacity, the default action is to block further traffic and switch to Error mode. See "CC Error mode" on page 3022 for more information.

Logging to external devices

Logging to external devices is disabled due to the security requirements of FIPS-CC operation, except for logging to a FortiAnalyzer unit through a secure tunnel. By default, the secure tunnel uses the SHA-256 HMAC algorithm. You can also select SHA-1 using the following CLI command:

```
config log fortianalyzer setting
  set hmac-algorithm sha1
end
```

Downloading of logs to the management computer is also permitted. See "Backing up log messages" on page 3017.

Required logging settings

Table 160 and Table 161 list the logging settings required for FIPS-CC mode. The `config log memory setting` command settings apply to models 50A and 100A. The `config log disk setting` command settings apply to all other models. If you change these options from the default, the operation of your FortiGate unit is no longer compliant with the FIPS-CC Security Target.

Table 159: config log disk filter command keywords and variables

Keywords and variables	Description	Default
`admin {disable | enable}`	Enable or disable logging all administrative events, such as user logins, resets, and configuration updates in the event log. This is available only if `event` is set to `enable`.	`enable`
`allowed {disable | enable}`	Enable or disable logging all traffic that is allowed according to the firewall policy settings in the traffic log. This is available only if `traffic` is set to `enable`.	`enable`

Table 159: config log disk filter command keywords and variables (Continued)

Keywords and variables	Description	Default
`auth {disable | enable}`	Enable or disable logging all firewall-related events, such as user authentication in the event log. This is available only if `event` is set to `enable`.	`enable`
`event {disable | enable}`	Enable or disable the event log.	`enable`
`severity {alert | critical | debug | emergency | error | information | notification | warning}`	Select the logging severity level. The FortiGate unit logs all messages at and above the logging severity level you select. For example, if you select `error`, the unit logs `error`, `critical`, `alert` and `emergency` level messages. `emergency` - The system is unusable. `alert` - Immediate action is required. `critical` - Functionality is affected. `error` - An erroneous condition exists and functionality is probably affected. `warning` - Functionality might be affected. `notification` - Information about normal events. `information` - General information about system operations. `debug` - Information used for diagnosing or debugging the FotiGate unit.	`debug`
`system {disable | enable}`	Enable or disable logging of all system-related events, such as ping server failure and gateway status, in the event log. This is available only if `event` is set to `enable`.	`enable`
`traffic {disable | enable}`	Enable or disable the traffic log.	`enable`
`violation {disable | enable}`	Enable or disable logging of all traffic that violates the firewall policy settings in the traffic log. This is available only if `traffic` is set to `enable`.	`enable`

Table 160: config log disk setting command keywords and variables

Keywords and variables	Description	Default
diskfull {blocktraffic | nolog | overwrite}	Enter the action to take when the log disk is full.	blocktraffic

Table 161: config log memory setting command keywords and variables

Keywords and variables	Description	Default
diskfull {blocktraffic | nolog | overwrite}	Enter the action to take when the log memory is full.	blocktraffic
status {disable | enable}	Enter enable to enable logging to the FortiGate system memory.	enable

Excluding specific logs (selective audit)

Use the exclude-list option of the log filtering command to define log entries that will not be recorded:

```
config log disk filter
  config exclude-list
    edit <number>
      set category <category>
      config fields
        edit <field_name>
          set args <argvalue>
          set negate {enable | disable}
        end
      end
    end
  end
end
```

Table 162: log filter exclude-list command keywords and variables

Keywords and variables	Description	Default
category <category>	category is one of: attack, content, event, im, spam, traffic, virus, webfilter	No default.
edit <field_name>	Enter the name of the field on which to base exclusion. Available field_name values depend on the category setting. If you enter an invalid field name, valid field names are listed.	No default.
args <argvalue>	Enter the field value to match.	No default.

Table 162: log filter exclude-list command keywords and variables (Continued)

Keywords and variables	Description	Default
negate {enable | disable}	Enable to exclude logs where the value of the <field_name> field does not match <argvalue>. Disable to exclude logs where the value of the <field_name> field matches <argvalue>.	disable

Viewing log messages from the web-based manager

To view log messages from the web-based manager, go to *Log & Report* > *Log Access*. For detailed instructions about viewing the logs, consult the online Help system or see the Logging & Reporting chapter of the *FortiOS Handbook*.

Viewing log messages from the CLI

You can view and clear log messages from the CLI. Before viewing logs, you must set filter options to select the logs that you want to view. You can view one log category on one device at a time. Optionally, you can filter the listing to show only specified date ranges or severities of log messages. For traffic logs, you can filter log messages by source or destination IP address.

Setting filtering for log messages

Use `execute log filter` commands to select which logs to display with the `execute log display` command. Commands are cumulative. Enter `execute log filter list` to see the current settings. For more information about log filtering, see the *FortiGate CLI Reference*.

The command syntax is:

```
execute log filter <keyword> <variable>
```

Table 163: execute log filter command keywords and variables

Keywords and variables	Description	Default
category {event | ids | spam | traffic | virus | webfilter | list }	Type of log, except list, which displays the current setting.	event
device {disk | memory | list}	Device where the logs are stored, except list, which displays the current setting.	disk
field <field_name>	Filter on log field. Use ? as field_name to see a list of valid fields.	No default.
lines-per-view <number>	Set lines per view. Range: 5 to 1000	10
list	Display current filter settings.	No default.
reset	Reset filter settings.	No default.
rolled-number <number>	Select logs from rolled log files. 0 selects current log file.	0

Table 163: execute log filter command keywords and variables (Continued)

Keywords and variables	Description	Default
`sortby`	Set display order. See "Sorting log messages" on page 3017.	No default.
`start_line <integer>`	Select first line of logs to display.	`1`

Use as many `execute log filter` commands as you need to define the log messages that you want to view. For example, to select the memory event logs from 10-14 July 2006, you use the following commands:

```
execute log filter category event
execute log filter device memory
execute log filter field date 2006-07-10 2006-07-14
```

Sorting log messages

In addition to selecting logs to display, the `execute log filter` command can sort logs by field.

```
execute log filter sortby <field_name>
```

Enter the command without a field name to see a list of valid field names.

Viewing log messages

After you have selected the log messages that you want to view using the `execute log filter` command, you can display them with the following command:

```
execute log display
```

The console displays the first 10 log messages. To view more messages, run the command again. You can do this until you have seen all of the selected log messages. To restart viewing the list from the beginning, use the commands

```
execute log filter start_line 1
execute log display
```

Resetting log filters

You can restore the log filters to their default values using the command

```
execute log reset
```

Backing up log messages

You can back up log messages to your Administrative computer or other computer on the network.

Backing up log messages using the web-based manager

The FortiGate unit downloads log files to the Administrative computer using HTTPS.

1. Go to *Log & Report* > *Log Access*.
2. Select either the *Disk* or *Memory* tab as appropriate.
3. From the *Log Type* list, select the type of log you want to back up.
4. Select the download icon for the log file you want to back up.
5. Select either *Download file in the normal format* or *Download file in CSV format*, as appropriate.
6. Follow your browser's procedure for saving the downloaded file.

Viewing log file information

You can view the list of current and rolled log files on the console. The list shows the file name, size and timestamp. The CLI command is as follows:

```
execute log list <category>
```

<category> must be one of: event, ids, spam, traffic, virus or webfilter.

The output looks like this:

```
elog                 8704    Fri Jan 28 14:24:35 2005
elog.1               1536    Thu Jan 27 18:02:51 2005
elog.2              35840    Wed Jan 26 22:22:47 2005
```

At the end of the list the total number of files in the category is displayed. For example:

```
501 event log file(s) found.
```

Deleting filtered log messages

You can select log messages with the execute log filter command and then delete them with the execute log delete-filtered command. On units that provide only memory logging, be sure to specify memory as the log device.

For example, to delete all the traffic logs from memory, enter the following commands:

```
execute log filter category traffic
execute log filter device memory
execute log delete-filtered
```

For information about the execute log filter command, see "Setting filtering for log messages" on page 3016.

Deleting rolled log files

You can delete rolled log files using the execute log delete-rolled command:

execute log delete-rolled <category> <start> [<end>]

<category> must be one of: event, ids, spam, traffic, virus or webfilter. The <start> and <end> values represent the range of log files to delete. If <end> is not specified, only the log number specified by <start> is deleted.

For example, to delete all of the rolled traffic log files, enter the following command:

```
execute log delete-rolled traffic 1 9999
```

Alarms

In FIPS-CC mode, the FortiGate unit can raise alarms for the following types of events:

- failed administrator authentication
- packet replay attempts (IPS)
- bootup self-test failure
- cryptographic failure
- security policy violation (blocked sessions)

Alarms for all of these events are based on logs that report these events. For firewall events, traffic violation logs are used.

Configuring alarms

An alarm consists of one or more trigger events that occur a specified number of times in a particular time period. For example, you could configure the FortiGate unit to raise an alarm if there are three unsuccessful administrative login attempts in the same minute.

You can configure alarms only in the CLI. Each alarm is defined as an “alarm group”. There are separate alarm groups for each virtual domain (VDOM). You can select whether the alarms in each VDOM are audible. Within each alarm group, you specify:

- the threshold for each triggering event, 0 for events that will not trigger the alarm
- the period over which the number of triggering events is counted, 0 to count from startup

If you include more than one trigger event, the threshold for all the trigger events must be met to trigger the alarm. Security policy violations are configured together.

Alarm notification messages appear on the web-based manager, in SSH administrator sessions and on the console. The messages repeat until the administrator acknowledges the alarm.

Alarm CLI configuration

The `system alarm` command syntax is as follows:

```
config system alarm
  set status {enable | disable}
  set audible {enable | disable}
  config groups
    edit <group_id>
      set admin-auth-failure-threshold <integer>
      set decryption-failure-threshold <integer>
      set encryption-failure-threshold <integer>
      set log-full-warning-threshold <integer>
      set period <integer>
      set replay-attempt-threshold <integer>
      set self-test-failure-threshold <integer>
      set user-auth-failure-threshold <integer>
      config fw-policy-violations
        edit <violation_id>
          dst-port <dport_number>
          dst-ip <dst_ip>
          src-port <sport_number>
          src-ip <src_ip>
          threshold <integer>
        end
      end
    end
```

The keywords and variables are:

Table 164: system alarm keywords and variables

Keywords and variables	Description	Default
`audible {enable | disable}`	If enabled, the console beeps when the alarm notification appears.	`disable`
`status {enable | disable}`	Enable or disable all alarms.	`disable`

Table 164: system alarm keywords and variables

Keywords and variables	Description	Default
Alarm group keywords and variables		
`edit <group_id>`	`<group_id>` is the group identifier. Use 0 to automatically assign the next available number.	No default.
`admin-auth-failure-threshold <integer>`	Enter threshold for administrator authentication failures. Use 0 to disregard in this alarm group.	0
`decryption-failure-threshold <integer>`	Enter threshold for cryptographic failure in decryption. Use 0 to disregard in this alarm group.	0
`encryption-failure-threshold <integer>`	Enter threshold for cryptographic failure in encryption. Use 0 to disregard in this alarm group.	0
`log-full-warning-threshold <integer>`	Enter the threshold for log full warnings. Use 0 to disregard in this alarm group.	0
`period <integer>`	Enter the period over which triggering events are counted. Use 0 for no limit (events are counted from startup).	0
`replay-attempt-threshold <integer>`	Enter threshold for packet replay attempts. Use 0 to disregard in this alarm group.	0
`self-test-failure-threshold <integer>`	Enter threshold for failure of startup integrity tests. Use 0 to disregard in this alarm group. A self-test failure alarm is visible only after you recover from Error mode.	0
`user-auth-failure-threshold <integer>`	Enter threshold for user authentication failures. Use 0 to disregard in this alarm group.	0
`fw-policy-violations` ***keywords and variables***		
`edit <violation_id>`	`<violation_id>` is the identifier for this trigger. Use 0 to automatically assign the next available number.	No default.
`dst-port <dport_number>`	Enter the destination port number to match in the traffic violation log.	0
`dst-ip <dst_ip>`	Enter the destination IP or subnet address to match in the traffic violation log.	0
`src-port <sport_number>`	Enter the source port number to match in the traffic violation log.	0
`src-ip <src_ip>`	Enter the source IP or subnet address to match in the traffic violation log.	0

Alarm notifications

Alarm notifications appear on both the CLI console and the web-based manager. On the CLI console alarm notifications look like this:

```
****************** !!! A L A R M !!! ******************
* ID: 1                    Time: Tue Sep 5 09:39:55 2006
* Group ID: 1              VD: root
* Type: Authentication failures
* Message: Alarm is triggered
*******************************************************
```

On the web-based manager, alarm notifications appear in a separate browser window and look like this:

Figure 388: Alarm notification - web-based manager

The notification clearly shows the time, virtual domain, alarm group and type. Alarm notifications repeat until you acknowledge them. On the CLI console, the notification repeats every time you use the Enter key. In the web-based manager, you can close the alarm notification window, but the alarm will reappear in a few seconds.

Acknowledging alarms

To acknowledge an alarm in the web-based manager, you simply select OK in the alarm notification window. On the CLI console, you acknowledge alarms using one of the following commands:

To acknowledge a single alarm

```
execute ack-alarm <alarm-ID>
```

To acknowledge all alarms

```
execute ack-alarm all
```

Alarm polling

A terminal connected to the console connector can display alarm messages periodically if no one is logged in to the console. You can set how often alarm messages are reported on the console.

```
config system global
  set alarm-poll-interval <second>
end
```

You can set the polling interval to a value from 1 to 60 seconds. The default is 5 seconds.

Error modes

There are two error modes in FIPS-CC mode: FIPS Error and CC Error.

FIPS Error mode

When one or more of the self-tests fail, the FortiGate unit switches to FIPS Error mode. The FortiGate unit shuts down all interfaces including the console and blocks traffic.

To resume normal FIPS-CC mode operation, switch the unit off and then on again. If the self-tests pass after the reboot, the unit will resume normal FIPS-CC compliant operation. If a self-test continues to fail after rebooting, there is likely a serious firmware or hardware problem and the unit should be removed from the network until the problem is solved.

If the self-test failure persists across reboots, you can attempt to reload the firmware after resetting the unit to the factory default configuration. If the self-test failure persists after reloading the firmware and re-enabling the FIPS-CC mode of operation, contact Fortinet technical support.

CC Error mode

When current logs and rolled log files consume more than 95% of log capacity, the FortiGate unit switches to CC Error mode, shuts down network interfaces and blocks traffic.

The FortiGate unit indicates Error mode as follows:

- The console displays “FIPS-CC-ERR”. You might have to press a panel key to see this display.
- “CC-ERR” is prepended to the CLI prompt, `CC-ERR FortiGate-500A$`, for example.

To resume normal FIPS-CC mode operation, you first must reduce logs to less than 95% of device capacity and exit error mode.

To reduce logs

From the console, do any of the following:

- Delete selected logs. See “Deleting filtered log messages” on page 3018. Ideally, you should reduce logs to 50% or less of device capacity.
- Delete rolled log files using the command `execute log delete-rolled`.
- Delete all current log entries using the command `execute log delete-all`.

To exit error mode

From the console, enter the following CLI command:

```
execute error-mode exit
```

The FortiGate unit resumes normal FIPS-CC compliant operation unless there is still too little free space on the log device.

Disabling FIPS-CC mode

The only way that you can return the FortiGate unit to the normal mode of operation is to restore the factory default configuration. Enter the following CLI command:

```
execute factoryreset
```

Disabling FIPS-CC mode erases the current configuration, including VPN certificates and encryption keys for SSH and HTTPS.

Configuring FortiGate units for PCI DSS compliance

This chapter provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements. The following topics are included in this section:

Introduction to PCI DSS

The primary source of information for your PCI DSS compliance program is the *Payment Card Industry (PCI) Data Security Standard* itself. Version 1.2.1 of the standard was published in July 2009. The following is only a brief summary of PCI DSS.

What is PCI DSS?

The Payment Card Industry Data Security Standard (PCI DSS) sets data handling requirements for organizations that hold, process, or exchange cardholder information.

What is the Customer Data Environment

Throughout the PCI DSS requirements, there are references to the Customer Data Environment (CDE). The CDE is the computer environment wherein cardholder data is transferred, processed, or stored, and any networks or devices directly connected to that environment.

PCI DSS objectives and requirements

PCI DSS consists of 7 control objectives and 12 requirements.

Table 165: PCI DSS Control Objectives and Requirements

Control Objective	Requirement	Fortinet Solution
Build and Maintain a Secure Network	1) Install and maintain a firewall configuration to protect cardholder data	FortiGate firewall functionality. See "Security policies for the CDE network" on page 3028.
	2) Do not use vendor-supplied defaults for system passwords and other security parameters	FortiDB vulnerability assessment and auditing FortiScan OS vulnerability management FortiWeb web application password checking See "Password complexity and change requirements" on page 3034.
Protect Cardholder Data	3) Protect stored cardholder data	FortiDB vulnerability assessment and monitoring FortiWeb web application firewall See "Protecting stored cardholder data" on page 3031.
	4) Encrypt transmission of cardholder data across open, public networks	FortiGate IPsec VPN. See "Protecting communicated cardholder data" on page 3031.

Table 165: PCI DSS Control Objectives and Requirements (Continued)

Control Objective	Requirement	Fortinet Solution
Maintain a Vulnerability Management Program	5) Use and regularly update anti-virus software	FortiGate integrated AV FortiClient integrated AV FortiMobile integrated AV FortiMail integrated AV FortiGuard automated AV updates See "Protecting the CDE network from viruses" on page 3032.
	6) Develop and maintain secure systems and applications	FortiDB vulnerability assessment, auditing and monitoring FortiWeb web application security FortiScan OS vulnerability management FortiAnalyzer network vulnerability scanning See "Monitoring the network for vulnerabilities" on page 3033.
Implement Strong Access Control Measures	7) Restrict access to cardholder data by business need-to-know	FortiDB vulnerability assessment, auditing and monitoring. See "Restricting access to cardholder data" on page 3034.
	8) Assign a unique ID to each person with computer access	FortiGate integrated database or hooks to Active Directory. See "Controlling access to the CDE network" on page 3034.
	9) Restrict physical access to cardholder data	Fortinet professional services in partnership with partner solutions

Table 165: PCI DSS Control Objectives and Requirements (Continued)

Control Objective	Requirement	Fortinet Solution
Regularly Monitor and Test Networks	10) Track and monitor all access to network resources and cardholder data	FortiDB auditing and monitoring FortiAnalyzer event reporting, vulnerability scanning. See "Monitoring the network for vulnerabilities" on page 3033.
	11) Regularly test security systems and processes	FortiDB vulnerability assessment FortiScan OS vulnerability management. See "Monitoring the network for vulnerabilities" on page 3033.
Maintain an Information Security Policy	12) Maintain a policy that addresses information security	FortiManager security policy management appliance

This chapter describes how the FortiGate unit's features can help your organization to be compliant with PCI DSS. Requirements that the FortiGate cannot enforce need to be met through organization policies with some means determined for auditing compliance.

Be sure to read the section, "Wireless guidelines", below. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

Wireless guidelines

While wired networks usually connect fixed known workstations, wireless networks are more dynamic, introducing a different set of security concerns.

Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that unauthorized wireless networking has not been introduced into the CDE. Wireless networking could be introduced quite casually by adding a wireless device to a PC on the CDE network.

For all PCI DSS networks, whether they use wireless technology or not, the following requirement applies:

- Test for the presence of wireless access points by using a wireless analyzer at least quarterly or deploying a wireless IDS/IPS to identify all wireless devices in use. (11.1)

If your organization uses wireless networking outside the CDE network and the firewall prevents communication with the CDE network, the wireless network is outside the PCI DSS scope, but the firewall configuration must meet PCI DSS requirements.

If your organization uses wireless networking inside the CDE network, the wireless network is within the PCI DSS scope. For information about wireless network requirements, see "Wireless network security" on page 3029.

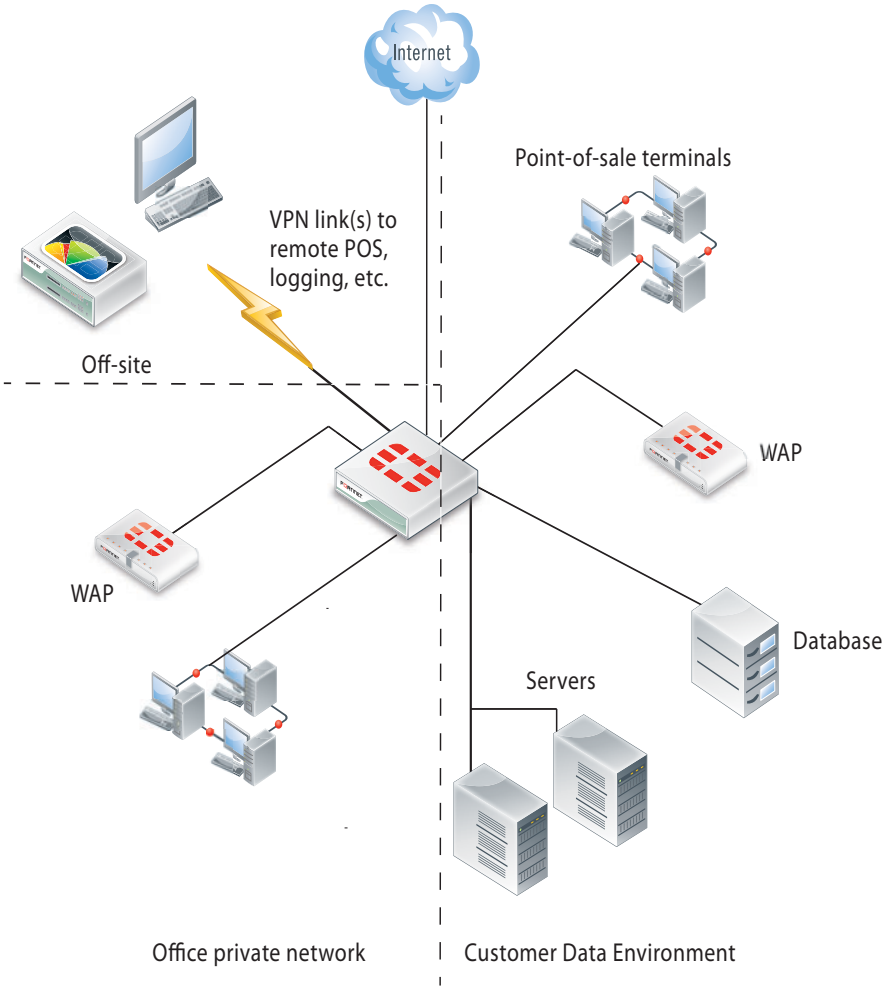
Network topology

The cardholder data environment must be protected against unauthorized access from the Internet and from other networks in your organization. FortiGate unit firewall functionality provides tight control over the traffic that can pass between the following network interfaces:

- Internet
- CDE wired LAN
- CDE wireless LAN
- Other internal networks

Figure 389 shows how the Customer Data Environment can be delineated in a typical network.

Figure 389: Enterprise network with a customer data environment



Internet

The FortiGate unit has at least one network interface connected to the Internet. If your organization uses more than one Internet service provider, there could be additional network interfaces that function as a route to the Internet.

The CDE wired LAN

The CDE network typically contains point-of-sale (POS) terminals, databases, and servers. The only security policies between the CDE network and the Internet should be for encrypted connections. For remote point-of-sale terminals or off-site databases, VPN connections are required and they should use strong encryption. For a web server that handles online purchases, only HTTPS (SSL or TLS) connections can be permitted. The security policies that enable these connections should have the narrowest possible definitions for source address, destination address and service.

PCI DSS does not require the CDE network to be isolated from the rest of your corporate LAN. But isolating the CDE network reduces the scope of required data protection measures and may reduce the scope of PCI DSS assessments that are periodically required.

The CDE wireless LAN

Wireless networking is a special issue. Even if you do not use wireless technology you must monitor to ensure that unauthorized wireless access has not been added to the CDE network. For this purpose, Figure 389 shows a FortiAP device in the CDE. The FortiAP device can provide dedicated wireless monitoring, an access point, or both.

A small retail outlet could reduce costs by using a FortiWiFi unit, a FortiGate unit with integrated wireless networking. The FortiWiFi unit would have to be located where it could provide sufficient wireless monitoring (or access point) coverage for the entire premises.

Other internal networks

Other internal networks such as your office LAN, unless they provide connection to the CDE, are not subject to PCI DSS requirements.

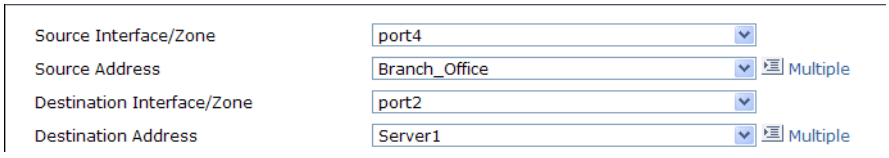
Security policies for the CDE network

The FortiGate unit's firewall functionality is ideally suited to PCI DSS requirement 1.2.1, "Restrict inbound and outbound traffic to that which is necessary for the cardholder data environment." Security policies control the source, destination, and type of traffic passing between networks.

The PCI DSS standard includes requirements to document your network topology and configuration. As part of that requirement, and to assist the auditing of your network, make use of the *Comment* field available in FortiGate security policies. Describe the purpose of each policy.

Controlling the source and destination of traffic

The source and destination are the first parameters you specify in a security policy. (Go to *Policy* > *Policy* > *Policy* and select *Create New*.)



The *Interface/Zone* settings depend on network topology. The Address settings define the IP addresses to which the policy applies. These should be as narrow as possible, so that only the appropriate hosts are included. For example, if the destination is a server with a single IP address, the named Destination Address should be defined as that single address, not the entire subnet on which the server resides.

Addresses are defined in *Firewall Objects* > *Address* > *Address*. You can also define a new address by selecting [Create New...] from either the *Source Address* or *Destination Address* drop-down lists in a security policy. Some addresses will be used in several security policies, so it is best to plan ahead and define the addresses first.

Controlling the types of traffic in the CDE

The *Service* setting in each security policy determines which types of traffic can pass based on protocol.

You can select a single protocol from the *Service* drop-down list or select *Multiple* and create a list of services to permit in this policy. If several security policies will need the same list of services, consider creating a named service group. (Go to *Firewall Objects* > *Service* > *Group*.) In the security policy, service groups are available at the bottom of the *Service* drop-down list.

The default deny policy

All traffic not specifically allowed by a security policy that you create is blocked by the Implicit policy listed at the bottom of the *Policy* > *Policy* > *Policy* page.

You cannot delete this policy and you can edit the policy only to enable or disable logging of the traffic that it handles.

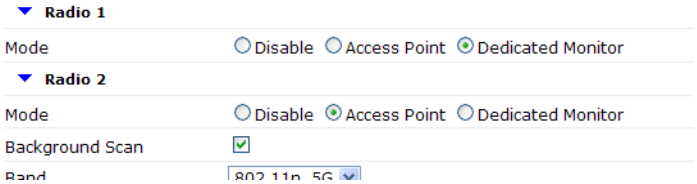
Wireless network security

Scanning for rogue access points is the minimum requirement for wireless security. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

If you use wireless networking, the wireless network is only within the PCI DSS scope if it can connect to the CDE.

Scanning for rogue access points

A FortiGate unit with a connected FortiAP unit can perform wireless scanning. Each of the FortiAP radios can act as a dedicated monitor or can perform scanning in the background while acting as a wireless access point.



To configure rogue AP scanning

1. Go to *Wifi Controller* > *Configuration* > *AP Profile*.
2. Select an existing *AP Profile* and edit it, or select *Create New*.
3. For each radio, select either Access Point or Dedicated Monitor, as required.
4. If you selected *Access Point*, enable *Background Scan*.
5. If needed, modify other settings.
6. Select *OK*.

Radio 1 operates in the 2.4GHz band and Radio 2 operates in the 5GHz band. Both bands should be monitored. The FortiAP unit(s) used for scanning must be located within the coverage area that would result if an access point were added to the CDE.

Automatic detection of rogue APs

Some FortiGate units include an “on-wire” detection technique that correlates the SSID MAC addresses of the unknown access points with MAC addresses detected on your wired networks. This helps to differentiate unrelated neighboring APs from security-compromising unauthorized APs connected to your network.

Viewing the results of rogue AP scanning

Go to *Wifi Controller* > *Monitor* > *Rogue AP* to view information about detected wireless access points.

Logging the results of rogue AP scanning

To ensure that detection of rogue access points is logged, go to *Log&Report* > *Log Config* > *Log* Setting and enable logging for *Wifi activity event*.

In the logs, the *Type* is event and the *Sub Type* is wireless.

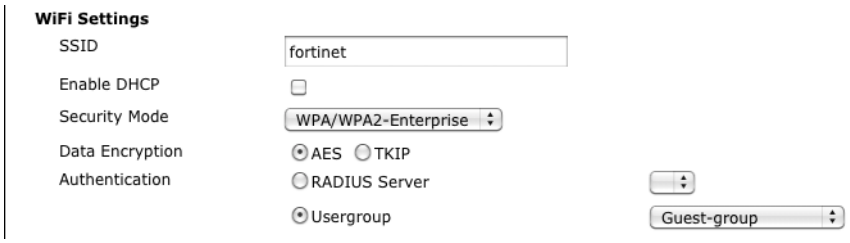
Securing a CDE network WAP

If your wireless network is within PCI DSS scope, it must meet the following requirements:

- Default settings such as SSID and passphrases must be changed.
- Use WPA security, not WEP.
- Log wireless activity.

Setting wireless security

On FortiGate units, go to *Wifi Controller* > *WiFi Network* > *SSID* to configure wireless security settings for either a new or existing virtual access point.



The default SSID for the FortiAP is “fortinet”. You must change this.

The *Security Mode* ***must*** be set to one of the WPA/WPA2 modes. Both WPA or WPA2 clients can be served. In the CLI, you can optionally select exclusively WPA or WPA2 operation.

AES is stronger *Data Encryption* than TKIP.

WPA/WPA2-Enterprise *Authentication* uses separate logon credentials for each user. Either FortiGate user group security or an external RADIUS server performs the authentication. Optionally, certificate-based security can also be applied. WPA/WPA2-Personal authentication requires a single pre-shared key that is used by all clients and is thus less secure.

For detailed information about wireless access points, see the *Deploying Wireless Networks* chapter of this Handbook.

Logging wireless network activity

To ensure that wireless network activity is logged, go to *Log&Report* > *Log Config* > *Log Setting* and enable logging for *WiFi activity event*. In the logs, the *Type* is event and the *Sub Type* is wireless.

Protecting stored cardholder data

The Fortinet FortiDB and FortiWeb products can provide security for your sensitive cardholder data.

The Fortinet Database Security (FortiDB) device provides vulnerability assessment, database activity monitoring, auditing and monitoring. For more information about this product, see the Fortinet web site, www.fortinet.com.

The Fortinet FortiWeb Web Application Firewall deployed in front of public-facing web applications protects Web applications, databases, and the information exchanged between them. In particular, it addresses the PCI DSS requirements 6.5 and 6.6 regarding web application vulnerabilities such as cross-site scripting, SQL injection, and information leakage. For more information about this product, see the Fortinet web site, www.fortinet.com.

Protecting communicated cardholder data

If cardholder data must be communicated over an untrusted network, such as the Internet, use the FortiGate unit's IPsec VPN capability to exchange the data securely. If you support customer on-line transactions, use HTTPS (SSL or TLS encryption) for security. The relevant PCI DSS requirement is:

- Use strong cryptography and security protocols such as SSL/TLS or IPsec to safeguard sensitive cardholder data during transmission over open, public networks. (4.1)

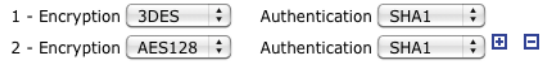
This does not prescribe particular cryptography, but it can be interpreted as a requirement to follow industry best practices.

Configuring IPsec VPN security

The security considerations for IPsec VPNs are encryption and authentication.

Encryption

Go to *VPN* > *IPsec* > *Auto Key (IKE)* to configure an IPsec VPN. In both Phase 1 and Phase 2 parts of the configuration, you select the encryption to use.



These are advanced settings, overriding defaults that are not necessarily the strongest algorithms. VPNs negotiate over standards, so you can list multiple proposed algorithms. The VPN will use the strongest encryption that both ends support.

Choose strong encryption. The available encryption algorithms in descending order of strength are AES256, AES192, AES128, 3DES, DES. DES encryption is the weakest with only a 64-bit key and does not meet the 80-bit key length minimum that PCI DSS requires. NULL means no encryption and must not be used.

The message digest (authentication) algorithms in descending order of strength are SHA256, SHA1 and MD5. MD5 is particularly weak and should be avoided. NULL means no message digest and must not be used.

Authentication

VPN peers authenticate each other before establishing a tunnel. FortiGate units support two different authentication methods: pre-shared key and RSA signature (certificate). Certificates provide the best security. PCI DSS does not prohibit pre-shared keys, but you should limit access to the keys to the personnel who are responsible for the FortiGate units or other equipment at either end of the VPN.

Configuring SSL VPN security

The SSL VPN configuration includes a choice of encryption algorithm. Go to *VPN* > *SSL* > *Config*. The *Default* selection, *RC4 (128 bits)* is acceptable, but the *High* option, *AES (128/256 bits) and 3DES* is more secure. The *Low* option, *RC4 (64 bits), DES and higher* does not meet PCI DSS requirements.

Protecting the CDE network from viruses

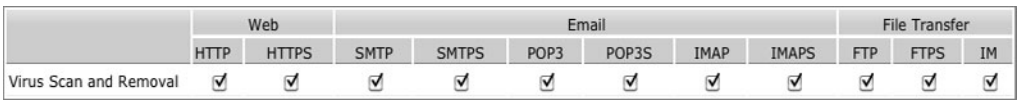
PCI DSS requires the use of regularly updated antivirus protection. The antivirus functionality of the FortiGate unit protects both the FortiGate unit and the networks it manages. Workstations on these networks can be protected using FortiClient Endpoint Security. Both FortiGate and FortiClient antivirus protection can receive updates from Fortinet's FortiGuard service. Workstations can also use third-party antivirus applications with update services.

The FortiGate unit can enforce the use of antivirus software, denying unprotected workstations access to the network.

Enabling FortiGate antivirus protection

To create the antivirus profile

1. Go to *UTM Profiles* > *Antivirus* > *Profile*.
2. Edit the *default* predefined profile or select *Create New*.



3 Ensure that all check boxes are selected.

4 Select *OK*.

To select the antivirus database

1 Go to *UTM Profiles* > *Antivirus* > *Virus Database*.

2 Select the *Extended Virus Database*.

3 Select *Enable Grayware Detection*.

4 Select *Apply*.

For detailed information about the Antivirus feature, see the *UTM* chapter of this Handbook.

Configuring antivirus updates

On the system dashboard, check the *License Information* widget. The *Support Contract* section should show Valid Contract and the contract expiry date. If your FortiGate unit is not registered, you need to visit the Fortinet Support web page (http://support.fortinet.com/) to register. Go to Product Registration and follow the instructions.

In the *FortiGuard Services* section, check the *Antivirus* field. If the service is unreachable, see the online Help for information about troubleshooting your connectivity to FortiGuard Services.

Enforcing firewall use on endpoint PCs

PCI DSS requires you to “install personal firewall software on any mobile and/or employee-owned computers with direct connectivity to the Internet (for example, laptops used by employees), which are used to access the organization’s network. (1.4)” Consider using the Endpoint Control feature of the FortiGate unit to enforce use of this software.

Monitoring the network for vulnerabilities

There are several tools that can assist you in monitoring your network for vulnerabilities and provide evidence to the PCI DSS auditor of such monitoring.

Using the FortiOS Network Vulnerability Scan feature

As part of its UTM features, FortiGate units provide a Network Vulnerability Scan. You define assets to monitor, such as servers, workstations, or point-of-sale terminals. Then, the FortiGate unit scans those devices on a regular schedule. The scan checks TCP and UDP ports against a list of known vulnerabilities provided by FortiGuard Services. Scan settings determine how many of the ports are checked. Optionally, all ports are scanned. To view scan logs, go to *Log&Report* > *Log & Archive Access* > *Vulnerability Scan Log*.

FortiGate units can be configured to send logs to FortiAnalyzer unit. In a larger network, this enables you to collect log information, including vulnerability scan information, in a central location from several FortiGate units.

For more information, see “Vulnerability Scan” on page 1113.

Monitoring with other Fortinet products

In addition to your FortiGate unit and its FortiOS firmware, there are several other Fortinet products that can assist your organization to comply with PCI DSS requirements.

FortiAnalyzer network vulnerability scan

FortiAnalyzer units provide a Network Vulnerability Scan similar to the FortiGate vulnerability scan but with more features. In particular, the FortiAnalyzer scan generates compliance reports specifically tailored to PCI DSS requirements. For more information, see the Vulnerability Management chapter of the *FortiAnalyzer Administration Guide*.

Fortinet Database Security (FortiDB)

A FortiDB appliance or FortiDB software can provide vulnerability scanning and activity monitoring for your databases. For more information, see the *FortiDB User Guide*.

FortiScan Vulnerability and Compliance Management platform

The FortiScan Vulnerability and Compliance Management (VCM) platform combines a FortiScan appliance with FortiScan agent software to monitor your network assets such as servers, workstations, or point-of-sale terminals. This system can perform vulnerability scans and apply software patches provided by the software vendors. The scan profiles include a predefined one for PCI DSS. The FortiScan appliance produces compliance reports detailing the results of the vulnerability scan.

For more information, see the *FortiScan Administration Guide*.

FortiWeb Web Application Security

If your organization engages in e-Commerce, you can use FortiWeb Application Security to protect your web servers against attack. The FortiWeb application protects against HTTP and XML-based attacks, guards against attempts to deface your web sites, and scans web servers for vulnerabilities. For more information, see the *FortiWeb Web Application Security Administration Guide*.

Restricting access to cardholder data

In addition to security policies and authentication governing access to the CDE, you can deploy the Fortinet Database Security (FortiDB) device, which provides vulnerability assessment, database activity monitoring, auditing and monitoring. For more information about this product, see the Fortinet web site, www.fortinet.com.

Controlling access to the CDE network

PCI DSS requires each user to be uniquely identified and authenticated. On the FortiGate unit, this applies to administrators and to users of SSL VPN and IPsec VPNs.

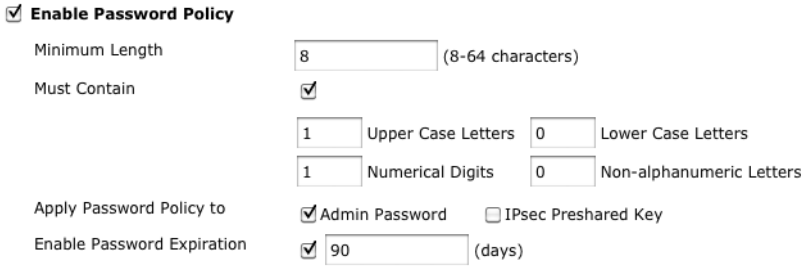
Password complexity and change requirements

By default, the FortiGate unit admin account has no password. Be sure to define a password.

PCI DSS password requirements are

- Require a minimum password length of at least seven characters. (8.5.10)
- Use passwords containing both numeric and alphabetic characters. (8.5.11)
- Change user passwords at least every 90 days. (8.5.9)

To facilitate creation of compliant administrator passwords, you can set a password policy. Go to *System* > *Admin* > *Settings*. In the *Password Policy* section, enter the following and then select OK at the bottom of the page.



Enable	Select the check box.
Minimum Length	8 or more. (Field does not accept a value less than 8.)
Must Contain	At minimum, set a required number of *Numerical Digits* and either *Upper Case Letters* or *Lower Case Letters*. Also setting a required number of *Non-alphabetic Letters* is acceptable.
Apply Password Policy to	Select *Admin Password*.
Enable Password Expiration	Set to 90 days or less. The default is 90 days.

Note that the FortiGate password policy does not apply to user passwords. Both password complexity and password expiry for users would need to addressed by making them a policy in your organization.

Password non-reuse requirement

PCI DSS requires that passwords are not re-used to satisfy the change requirement:

“Do not allow an individual to submit a new password that is the same as any of the last four passwords he or she has used.” (8.5.12)

FortiGate users don’t set their own passwords. The super_admin administrators can and so can admins with appropriate access. There is, however, no FortiGate-based mechanism to enforce non re-use of passwords.

Administrator lockout requirement

PCI DSS requires a user account lockout for administrators to guard against unauthorized access attempts:

- Limit repeated access attempts by locking out the user ID after not more than six attempts. (8.5.13),
- Set the lockout duration to a minimum of 30 minutes or until administrator enables the user ID. (8.5.14)

You can meet these requirements with the following CLI commands:

```
config system global
  set admin-lockout-threshold 6
  set admin-lockout-duration 1800
end
```

The threshold can be less than 6 and the lockout duration can be more than 1800.

Administrator timeout requirement

PCI DSS requires:

- If a session has been idle for more than 15 minutes, require the user to re-enter the password to reactivate the terminal. (8.5.15)

By default, the idle timeout is five minutes. You can go to *System* > *Admin* > *Settings* and change the *Idle Timeout* timeout to any value up to the permitted value of 15 minutes.

Administrator access security

To accommodate the requirement for unique identification of each user, the generic admin account should either be assigned to only one administrator or not used at all. You can create an administrator account for each administrator in *System* > *Admin* > *Administrators*.

If an administrator always works from the same workstation, consider using the Trusted Host feature. The administrator will be able to log in only from a trusted IP address. You can define up to three trusted IP addresses per administrator.

Administrative access must also be enabled per network interface. Go to *System* > *Network* > *Interface* to edit the interface settings. Enable administrative access only on interfaces where you would expect the administrator to connect. Allow only secure connection protocols, HTTPS for web-based access, SSH for CLI access.

Remote access security

For remote access, PCI DSS requires two-factor authentication: a password and some other authentication, such as a smart token or certificate. This applies to employees, administrators, and third parties.

SSL VPN users

For SSL VPN users, implement two-factor authentication by requiring users to have a certificate in addition to the correct password. Go to *VPN* > *SSL* > *Config*, enable *Require Client Certificate*, and then select *Apply*. For more information, see the SSL VPN chapter of this Handbook.

IPsec VPN users

If users access your network using an IPsec VPN, you can implement two-factor authentication by enabling extended authentication (XAUTH). This requires the user to enter a password in addition to the VPN authentication provided by the certificate or pre-shared key. As PCI DSS requires each user to have a unique identifier, you should already have user accounts and user groups defined.

To configure XAUTH on your VPN

1. Go to *VPN* > *IPsec* > *Auto Key (IKE)* and edit your Phase 1 configuration.
2. Select *Advanced*.
3. In *XAUTH*, select *Enable as Server*.

   Enable as Server is available only if *Remote Gateway* is *Dialup User*.
4. Set *Server Type* to *PAP*, *CHAP*, or *AUTO* as appropriate.
5. Select the *User Group* to which the VPN users belong.
6. Select *OK*.

Appendix

Document conventions

Fortinet technical documentation uses the conventions described below.

IPv4 IP addresses

To avoid publication of public IPv4 IP addresses that belong to Fortinet or any other organization, the IP addresses used in Fortinet technical documentation are fictional and follow documentation guidelines specific to Fortinet. The addresses used are from the private IP address ranges defined in RFC 1918: Address Allocation for Private Internets, available at http://ietf.org/rfc/rfc1918.txt?number-1918.

Most of the examples in this document use the following IP addressing:

IP addresses are made up of A.B.C.D:

- A - can be one of 192, 172, or 10 - the private addresses covered in RFC 1918.
- B - 168, or the branch / device / virtual device number.
  - Branch number can be 0xx, 1xx, 2xx - 0 is Head office, 1 is remote, 2 is other.
  - Device or virtual device - allows multiple FortiGate units in this address space (VDOMs).
  - Devices can be from x01 to x99.
- C - interface - FortiGate units can have up to 40 interfaces, potentially more than one on the same subnet
  - 001 - 099- physical address ports, and non -virtual interfaces
  - 100-255 - VLANs, tunnels, aggregate links, redundant links, vdom-links, etc.
- D - usage based addresses, this part is determined by what the device is doing. The following gives 16 reserved, 140 users, and 100 servers in the subnet.
  - 001 - 009 - reserved for networking hardware, like routers, gateways, etc.
  - 010 - 099 - DHCP range - users
  - 100 - 109 - FortiGate devices - typically only use 100
  - 110 - 199 - servers in general (see later for details)
  - 200 - 249 - static range - users
  - 250 - 255 - reserved (255 is broadcast, 000 not used)
  - The D segment servers can be farther broken down into:
    - 110 - 119 - Email servers
    - 120 - 129 - Web servers
    - 130 - 139 - Syslog servers
    - 140 - 149 - Authentication (RADIUS, LDAP, TACACS+, FSAE, etc)
    - 150 - 159 - VoIP / SIP servers / managers
    - 160 - 169 - FortiAnalyzers
    - 170 - 179 - FortiManagers
    - 180 - 189 - Other Fortinet products (FortiScan, FortiDB, etc.)
    - 190 - 199 - Other non-Fortinet servers (NAS, SQL, DNS, DDNS, etc.)
    - Fortinet products, non-FortiGate, are found from 160 - 189.

Example Network

Variations on network shown in Figure 390 are used for many of the examples in this document. In this example, the 172.20.120.0 network is equivalent to the Internet. The network consists of a head office and two branch offices.

Figure 390: Example network

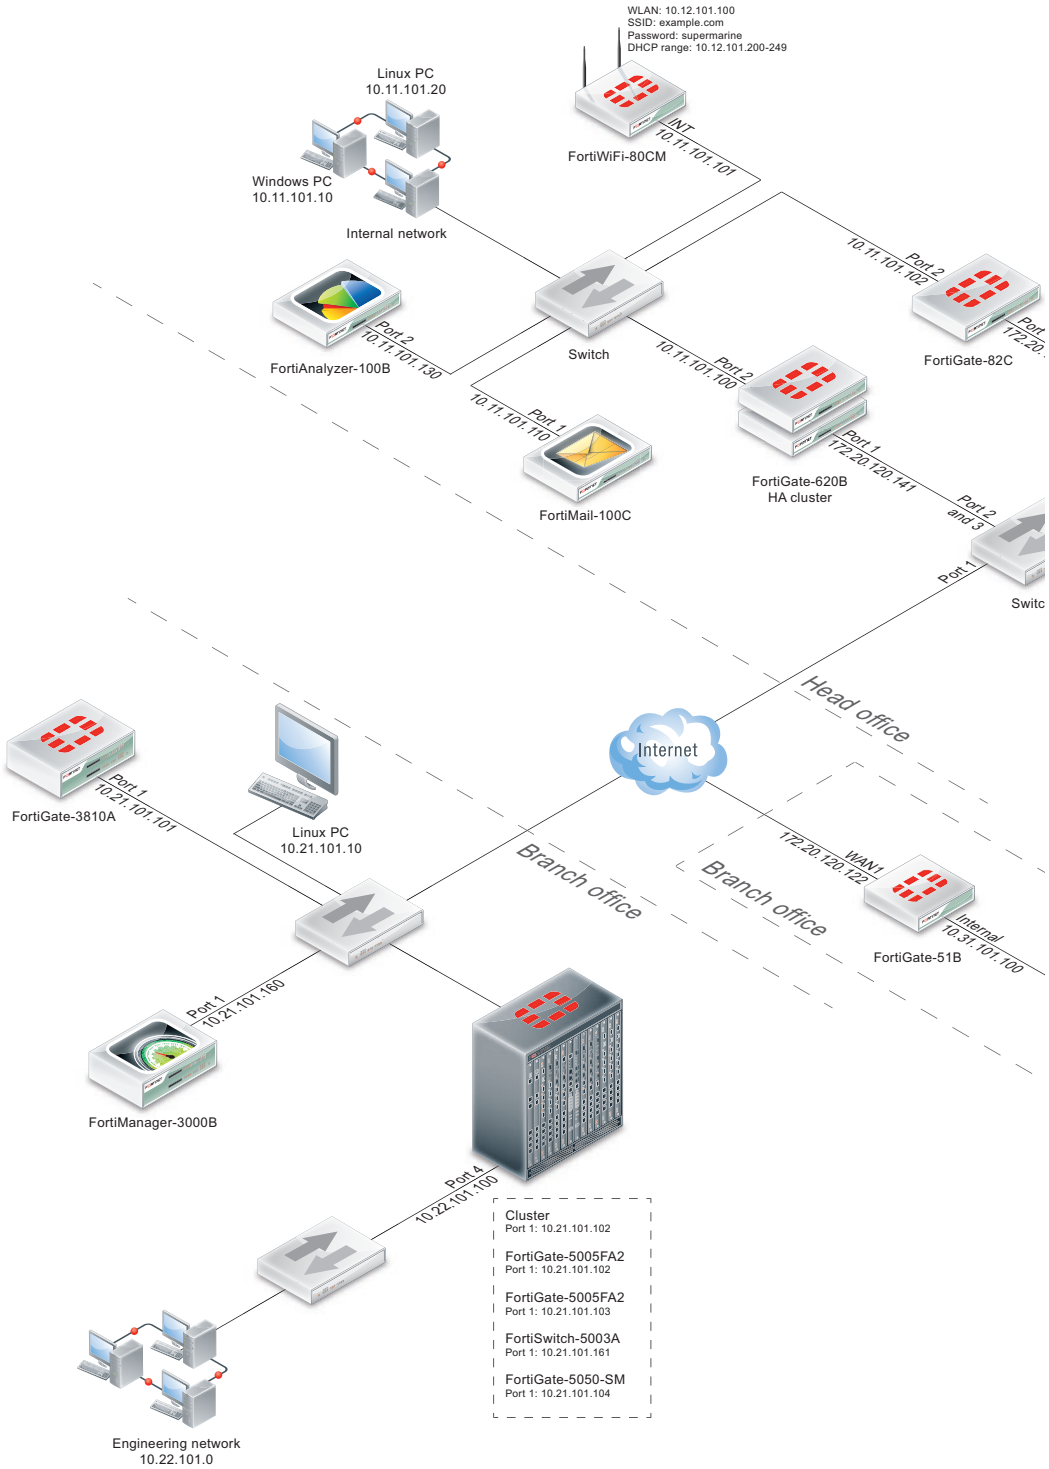


Table 166: Example IPv4 IP addresses

Location and device	Internal	Dmz	External
Head Office, one FortiGate	10.11.101.100	10.11.201.100	172.20.120.191
Head Office, second FortiGate	10.12.101.100	10.12.201.100	172.20.120.192
Branch Office, one FortiGate	10.21.101.100	10.21.201.100	172.20.120.193
Office 7, one FortiGate with 9 VDOMs	10.79.101.100	10.79.101.100	172.20.120.194
Office 3, one FortiGate, web server	n/a	10.31.201.110	n/a
Bob in accounting on the corporate user network (DHCP) at Head Office, one FortiGate	10.0.11.101.200	n/a	n/a
Router outside the FortiGate	n/a	n/a	172.20.120.195

Tips, must reads, and troubleshooting

A Tip provides shortcuts, alternative approaches, or background information about the task at hand. Ignoring a tip should have no negative consequences, but you might miss out on a trick that makes your life easier.

A Must Read item details things that should not be missed such as reminders to back up your configuration, configuration items that must be set, or information about safe handling of hardware. Ignoring a must read item may cause physical injury, component damage, data loss, irritation or frustration.

A Troubleshooting tip provides information to help you track down why your configuration is not working.

Typographical conventions

Table 167: Typographical conventions in Fortinet technical documentation

Convention	Example
Button, menu, text box, field, or check box label	From *Minimum log level*, select *Notification*.

CLI input	`config system dns`
	`  set primary <address_ipv4>`
	`end`

CLI output	`FGT-602803030703 # get system settings`
	`comments  : (null)`
	`opmode  : nat`

Table 167: Typographical conventions in Fortinet technical documentation

Emphasis	HTTP connections are ***not*** secure and can be intercepted by a third party.
File content	`<HTML><HEAD><TITLE>Firewall Authentication</TITLE></HEAD> <BODY><H4>You must authenticate to use this service.</H4>`
Hyperlink	Visit the Fortinet Technical Support web site, https://support.fortinet.com.
Keyboard entry	Type a name for the remote VPN peer or client, such as `Central_Office_1`.
Navigation	Go to *VPN* > *IPSEC* > *Auto Key (IKE)*.
Publication	For details, see the *FortiOS Handbook*.

Registering your Fortinet product

Access to Fortinet customer services, such as firmware updates, support, and FortiGuard services, requires product registration. You can register your Fortinet product at http://support.fortinet.com.

Training Services

Fortinet Training Services offers courses that orient you quickly to your new equipment, and certifications to verify your knowledge level. Fortinet training programs serve the needs of Fortinet customers and partners world-wide.

Visit Fortinet Training Services at http://campus.training.fortinet.com, or email training@fortinet.com.

Technical Documentation

Visit the Fortinet Technical Documentation web site, http://docs.fortinet.com, for the most up-to-date technical documentation.

The Fortinet Knowledge Base provides troubleshooting, how-to articles, examples, FAQs, technical notes, and more. Visit the Fortinet Knowledge Base at http://kb.fortinet.com.

Comments on Fortinet technical documentation

Send information about any errors or omissions in this or any Fortinet technical document to techdoc@fortinet.com.

Customer service and support

Fortinet is committed to your complete satisfaction. Through our regional Technical Assistance Centers and partners worldwide, Fortinet provides remedial support during the operation phase of your Fortinet product's development life cycle. Our Certified Support Partners provide first level technical assistance to Fortinet customers, while the regional TACs solve complex technical issues that our partners are unable to resolve.

Visit Customer Service and Support at http://support.fortinet.com.

Fortinet products End User License Agreement
