
The user needs to resolve the listed issues and retry the connection.

Configuration overview

Endpoint Control requires that all hosts using the firewall policy have the FortiClient Endpoint Security application installed. Make sure that all hosts affected by this policy are able to install this application. Currently, FortiClient Endpoint Security is available for Microsoft Windows (2000 and later) only.

To set up Endpoint Control, you need to

- Enable Central Management by the FortiGuard Analysis & Management Service if you will use FortiGuard Services to update the FortiClient application or antivirus signatures. You do not need to enter account information. See "Centralized Management" in the System Administration chapter of this Handbook.
- Configure the minimum required version of FortiClient and the location from which non-compliant endpoints can download the FortiClient installer. See "Configuring FortiClient required version and download location" on page 1091.
- Create an endpoint control profile or use a predefined profile. See "About predefined profiles" on page 1094.
- If needed, modify the profile's predefined FortiClient application detection rules. You can select the action to take on endpoints that do not have FortiClient Endpoint Security and you can set conditions and actions regarding FortiClient features.
- Configure application detection rules for other applications that are required, allowed, or not allowed on endpoints. See "About application detection and control" on page 1093.
- Enable Endpoint Security in firewall policies, selecting the appropriate Endpoint Control profile.

You cannot enable Endpoint in firewall policies if *Redirect HTTP Challenge to a Secure Channel (HTTPS)* is enabled in *User* > *User* > *Authentication*.

- Optionally, modify the inactivity timeout for endpoints. The default is 5 minutes. After that time period, the FortiGate unit rechecks the endpoint for Endpoint compliance. To change the timeout, adjust the `compliance-timeout` value in the `config endpoint-control settings` CLI command.
- Optionally, modify the *Endpoint NAC Download Portal* and the *Endpoint NAC Recommendation Portal* replacement messages.

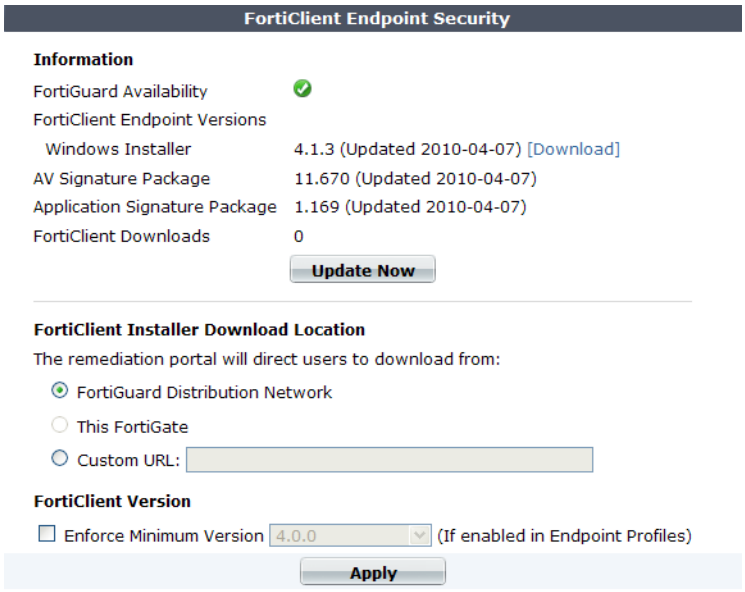
Configuring FortiClient required version and download location

The Endpoint Control feature can set a minimum FortiClient version that endpoints are required to run. To make this policy easy for users, you can configure a download source for the FortiClient installer.

Configuring FortiClient requirement and download location - web-based manager

1 Go to *UTM Profiles* > *Endpoint Control* > *Client Installers.*

Figure 92: Configuring FortiClient version requirements and installer source



2 Do one of the following:

- Select *FortiGuard Distribution Network*. FortiGuard must be configured on the FortiGate unit.
- Select *This FortiGate*. Users can download a FortiClient installer file from this FortiGate unit. This option is available only on FortiGate models that support upload of FortiClient installer files.
- Select *Custom URL*. Enter the URL from which users can download the FortiClient installer.

Select *This FortiGate* or *Custom URL* if you want to provide a customized FortiClient application. This is required if a FortiManager unit will centrally manage FortiClient applications. For information about customizing the FortiClient application, see the *FortiClient Administration Guide*.

3 Optionally, select *Enforce Minimum Version* and select the minimum acceptable version number or *Latest Available* for the FortiClient Endpoint Security application.

The list contains the FortiClient versions available from the selected *FortiClient Installer Download Location*.

Fortinet recommends that administrators wait for a reasonable period of time after deploying a FortiClient version update before updating the minimum version required to the most recent version. This gives users some time to install the update.

Configuring FortiClient requirement and download location - CLI

In this example, users are required to have FortiClient version 4.1.3 or later. FortiGuard provides the FortiClient installer.

```
config endpoint-control settings
  set enforce minimum-version enable
  set version-check minimum
  set version 4.1.3
  set download-location fortiguard
end
```

About application detection and control

In firewall policies you can select an endpoint control profile. The application detection list within the endpoint control profile allows or denies endpoint access to the network based on the applications that are installed or running on the endpoint.

The application detection list contains rules specific to individual applications, application vendors, and application categories. A rule tests for a particular condition of the application on the endpoint, which can be any of the following:

- *Installed* — application is installed and may or may not be currently running
- *Not Installed* — application is not installed
- *Running* — application is installed and currently running
- *Not Running* — application is not currently running or is not installed

The rule determines the action to take when the specified application matches the condition. The possible actions are:

- *Allow* — Allow the endpoint to connect.
- *Block* — Block the endpoint.
- *Warn* — Warn the endpoint, but then allow the user to connect.
- *Monitor* — Allow the endpoint to connect and include this endpoint's information in statistics and logs on the Endpoint Monitor page.

FortiClient application rules

There are three application rules for FortiClient that are present in every endpoint control profile: FortiClient, FortiClient AV, and FortiClient Firewall. You can edit, but not delete, these entries.

- **FortiClient — Select** the Block, Warn, or Monitor action to apply if the FortiClient application is not installed or not running on the endpoint.
- **FortiClient AV — Select** whether to allow or block endpoints that are not running the antivirus feature of the FortiClient application. Optionally, you can also apply this rule to endpoints with an outdated FortiClient antivirus database.
- **FortiClient Firewall — Select** whether to allow or block endpoints that are not running the firewall feature of the FortiClient application.

Other application rules

Application detection rules (entries) are based on application signatures provided by FortiGuard Services. You create your application detection list entries by selecting applications from FortiGuard-supplied lists of categories, vendors, and application names. To view application information from FortiGuard services, go to *UTM Profiles* > *Endpoint Control* > *Application Database*.

An application detection rule checks applications against the database from the top down until it finds a match. Specific entries, such as those that list one particular application, should precede more general entries, such as those that match all applications of a particular category.

The All application rule

At the bottom of every application detection list is the All rule. This specifies the action to apply to an endpoint with an application installed that does not match a rule higher in the list. The default action is Monitor. If you select Block, endpoints can have only a specific set of applications installed and are denied access if any other applications are installed.

About predefined profiles

Each VDOM has the following default endpoint profiles:

Enforce_FortiClient_AV — blocks endpoints without FortiClient Endpoint Security or not running FortiClient antivirus protection. Endpoints with other applications installed are monitored.

P2P_application_detection — blocks endpoints running peer-to-peer file sharing. Users whose endpoint does not have FortiClient Endpoint Security installed receive a warning.

Recommend_FortiClient — monitors endpoints and presents a warning to users whose endpoint does not have FortiClient Endpoint Security installed.

You can modify or delete these endpoint profiles.

Creating an endpoint control profile

An endpoint profile defines requirements for FortiClient Endpoint Security and other applications on endpoints. The profile is selected in firewall policies and applies to all users of the firewall policy.

To create an endpoint control profile - web-based manager

1 Go to *UTM Profiles* > *Endpoint Control* > *Profile* and select *Create New*.

2 Enter a *Name* and optionally *Comments* for the profile, then select *OK*.

The profile opens, showing the application detection list. There are default entries for FortiClient Endpoint Security with default settings.

3 Configure FortiClient-related entries as needed.

4 Create additional application detection entries as needed.

5 Select OK.

To create an endpoint control profile - CLI

```
config endpoint-control profile
  edit profile1
end
```

Setting endpoint FortiClient requirements

Every endpoint control profile requires that FortiClient Endpoint Security must be installed on all endpoints. You can choose whether non-compliant endpoints are blocked, warned, or simply monitored. By default they are blocked.

You can choose whether to require the use of FortiClient antivirus, firewall, or web filtering features. By default, endpoints are not required to use these features.

You can also choose whether to require each endpoint's FortiClient application to be licensed. This is not required by default.

To set the action for endpoints not running FortiClient - web-based manager

1 Go to *UTM Profiles* > *Endpoint Control* > *Profile* and open the profile for editing.

2 Edit the *FortiClient* application detection entry and select the required action: *Block*, *Warn*, or *Monitor*.

For information about these actions, see "About application detection and control" on page 1093.

To set the action for endpoints not running FortiClient - CLI

In this example, endpoints that do not have FortiClient Endpoint Security installed will be blocked. The other options for `recommendation-disclaimer` are `enable` to warn the endpoint and `skip` to simply monitor the endpoint.

```
config endpoint-control profile
  edit profile1
    set recommendation-disclaimer disable
  end
```

To require endpoints to use FortiClient antivirus protection - web-based manager

1 Go to *UTM Profiles* > *Endpoint Control* > *Profile* and open the profile for editing.
2 Edit the *FortiClient AV* application detection entry.
3 In *Condition*, select *Not Running* to enforce use the antivirus feature, To also require use of an up-to-date AV database, select *Not Running or Up-to-date*.
4 In *Action*, select *Block*.
5 Select *OK*.

To require endpoints to use FortiClient antivirus protection - CLI

In this example, endpoint control is configured to require that FortiClient AV is enabled and its database is up-to-date.

```
config endpoint-control profile
  edit profile1
    set feature-enforcement enable
    set require-av enable
    set require-av-uptodate enable
  end
```

To require endpoints to use FortiClient firewall protection - web-based manager

1 Go to *UTM Profiles* > *Endpoint Control* > *Profile* and open the profile for editing.
2 Edit the *FortiClient Firewall* application detection entry.
3 In *Action*, select *Block*.
4 Select *OK*.

To require endpoints to use FortiClient firewall protection - CLI

```
config endpoint-control profile
  edit profile1
    set feature-enforcement enable
    set require-firewall enable
  end
```

To require endpoints to use FortiClient web filtering

This is a CLI-only configuration. In the following example, profile1 is configured to require endpoints to use web filtering.

```
config endpoint-control profile
```

```
edit profile1
  set feature-enforcement enable
  set require-webfilter enable
end
```

To require endpoints to use a licensed FortiClient application

This is a CLI-only configuration. In the following example, profile1 is configured to require endpoints to use a licensed copy of FortiClient Endpoint Security.

```
config endpoint-control profile
  edit profile1
    set feature-enforcement enable
    set require-license enable
  end
```

Optionally, you can set `require-license` to `warn` to warn rather than block users of unlicensed FortiClient software.

Setting the default action for applications

To set the default action for applications - web-based manager

1. Go to *UTM Profiles* > *Endpoint Control* > *Profile* and open the profile for editing.
2. Select the last application detection list entry, *All*, and edit it. Select the *Action* to take for any applications ***not*** included in this application detection list:
   - **Block —** Endpoints must have only the applications you specify and are denied access if any other applications are installed.
   - **Warn** — Endpoints are warned, but not blocked, if they have any applications other than those included in this application detection list.
   - **Allow** or **Monitor** — Endpoints can have any application installed, and are denied access only if they have an application for which you created a specific Block rule.
3. Select *OK*.

To set the default action for applications - CLI

```
config endpoint-control app-detect rule-list
  edit profile1.list
    set other-application-action allow
  end
```

Adding application detection entries

You need to add an application detection entry for any application that requires a different action than the predefined All entry.

To create an application detection entry - web-based manager

1. With the endpoint control profile open, select *Create New*.
2. Select the application *Category*.
3. In *Application*, do one of the following:
   - Select *All*.
   - Select *Specify* and then select the application.

4 Select the *Action* and *Condition*, depending on the type of rule you are creating:

Application detection rule	Action	Condition
Application is allowed	Allow	N/A
Application must be installed and running	Block or Warn	Not Running
Application must be installed	Block or Warn	Not Installed
Application must not be running	Block or Warn	Running
Application must not be installed	Block or Warn	Installed
Monitor endpoint with this application running	Monitor	Running
Monitor endpoint with this application installed	Monitor	Installed

The Warn option permits users to connect after viewing a warning.

5 Select *OK*.

6 To create additional application detection entries, repeat steps 1 through 5.

To create an application detection list - CLI

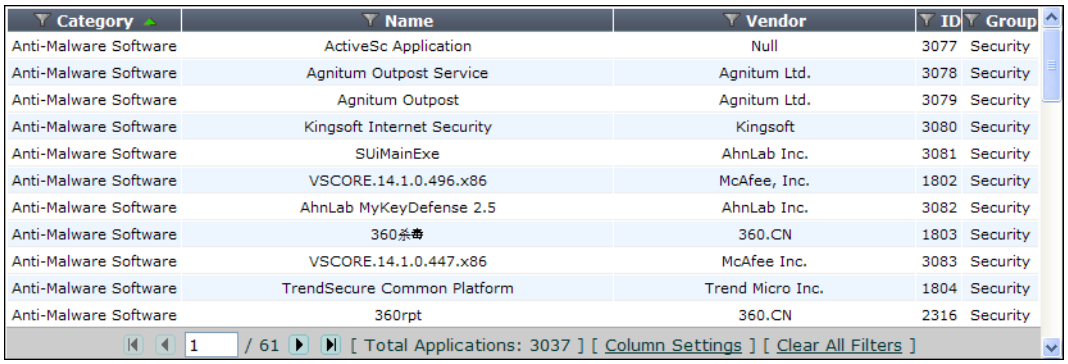
This example creates an application sensor that denies access to endpoints with peer-to-peer file sharing applications installed. All other applications are allowed.

```
config endpoint-control app-detect rule-list
  edit "applist1"
    config entries
      edit 1
        set application 0
        set category 15
        set vendor 0
        set status installed
        set action deny
      end
    set other-application-action allow
  end
config endpoint-control profile
  edit profile1
    set application-detection enable
    set application-detection-rule-list profile1.list
  end
```

Viewing the application database

You can view the application list provided by FortiGuard Services. Go to *UTM Profiles* > *Endpoint Control* > *Application Database*.

Figure 93: Endpoint Control Predefined application list



Category	Name	Vendor	ID	Group
Anti-Malware Software	ActiveSc Application	Null	3077	Security
Anti-Malware Software	Agnitum Outpost Service	Agnitum Ltd.	3078	Security
Anti-Malware Software	Agnitum Outpost	Agnitum Ltd.	3079	Security
Anti-Malware Software	Kingsoft Internet Security	Kingsoft	3080	Security
Anti-Malware Software	SUiMainExe	AhnLab Inc.	3081	Security
Anti-Malware Software	VSCORE.14.1.0.496.x86	McAfee, Inc.	1802	Security

Anti-Malware Software	360rpt	360.CN	2316	Security

1 / 61 [Total Applications: 3037] [Column Settings] [Clear All Filters]

The list contains the following information. You can select the name of any column to sort the data by that field. You can also create filters on each column.

Application Database page Lists all the applications that are provided by FortiGuard Services	
Column Settings	Select the columns to display in the list. You can also determine the order in which they appear.
Filter Settings	Set and clear column display filters.
Category	The type of application. Example: Document Viewers
Name	The name of the application.
Vendor	The vendor that the application is associated with. For example, the Adobe Reader is associated with the vendor, Adobe Systems Incorporated.
ID	Unique application ID.
Group	Another categorization of the applications. Groups are not used in application sensor rules.
Page controls	Shows the current page number in the list. Select the left and right arrows to display the first, previous, next or last page of known endpoints.
[Total Signatures: <number>]	The total number of application signatures currently in the database.

Enabling Endpoint Control in firewall policies

Endpoint Control is applied to any traffic where the controlling firewall policy has Endpoint Security enabled. The selected Endpoint Control profile determines the conditions that govern network access.

You can also enable Endpoint Security in combination with identity-based firewall policies. Users must authenticate and their computers must meet the requirements of the Endpoint Control profile.

To enable Endpoint Control - web-based manager

1 Go to *Policy* > *Policy* > *Policy* and edit the firewall policy where you want to enable Endpoint Control.

2 Select Enable Endpoint Security and select the Endpoint Control profile.

Figure 94: Enabling Endpoint Security in a firewall policy

3 Select *OK*.

To configure the firewall policy - CLI

In this example, the LAN connects to Port 2 and the Internet is connected to Port 1. An Endpoint Control profile is applied.

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr LANusers
    set dstaddr all
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
    set endpoint-check enable
    set endpoint-profile "our_profile"
  end
```

Monitoring endpoints

You can view statistical information about the endpoints that were subject to endpoint control. Data is gathered every 15 minutes and the display statistics are for the past 24 hours.

Endpoint status

Endpoint Status displays a pie chart showing the proportions of the endpoint population that:

- do not have FortiClient Endpoint Security installed
- have FortiClient Endpoint Security installed, but do not completely comply with the endpoint profile
- are fully compliant with the endpoint security profile.

To view this display, go to *UTM Profiles* > *Monitor* > *Endpoint Monitor* and in *Report by* select *Status*.

You can click on the chart for a detailed list of endpoints.

Figure 95: Endpoint Monitor detailed endpoints list

Endpoint Application Usage

Endpoint Application Usage displays a bar chart of the top ten applications by traffic volume. The counts include all endpoints with FortiClient Endpoint Security installed that are subject to endpoint control. You can select any of the chart bars to see a list of the top ten endpoints contributing to the data volume for that application.

To view this display, go to *UTM Profiles* > *Monitor* > *Endpoint Monitor* and in *Report by* select *Application Usage*.

Endpoint Traffic

Endpoint Traffic displays a bar chart of the top ten endpoints by traffic volume. The counts include all endpoints with FortiClient Endpoint Security installed that are subject to endpoint control. You can select any of the chart bars to see a list of the top ten applications on that endpoint by traffic volume.

To view this display, go to *UTM Profiles* > *Monitor* > *Endpoint Monitor* and in *Report by* select *Traffic*.

Modifying Endpoint Security replacement pages

The FortiGate unit sends one of the following HTML pages to a non-compliant user who attempts to use a firewall policy in which Endpoint Security is enabled:

- *Endpoint NAC Block Page* — The endpoint has FortiClient Connect installed, rather than FortiClient Endpoint Security. In the profile's FortiClient application detection entry, the Block action is selected. The user should check the FortiClient Connect console to view the exact reason why the endpoint is blocked.
- *Endpoint NAC Recommendation Block Page* — This is the warning version of the *Endpoint NAC Block Page*. The user can select the *Continue to* link to access their desired destination. In the profile's FortiClient application detection entry, the *Warn* action is selected.
- *Endpoint NAC Download Portal* — The endpoint does not have FortiClient Endpoint Security installed. In the profile's FortiClient application detection entry, the *Block* action is selected. The user must install the FortiClient application to proceed. The page includes a download link for the FortiClient installer.

  If you modify this replacement message, be sure to retain the %%LINK%% tag which provides the download URL for the FortiClient installer.
- *Endpoint NAC Recommendation Portal* — This is the warning version of the *Endpoint NAC Download Portal*. In the profile's FortiClient application detection entry, the *Warn* action is selected. The user can select the *Continue to* link to access their desired destination, without installing FortiClient Endpoint Security. The page also includes a download link for the FortiClient installer.

  If you modify this replacement message, be sure to retain both the %%LINK%% tag which provides the download URL for the FortiClient installer and the %%DST_ADDR%% link that contains the URL that the user requested.
- *Endpoint NAC Feature Block Page* — The endpoint does not have all of the required FortiClient features running. In the profile, the FortiClient feature application detection entry for the missing feature - AV, Firewall, or webfilter (CLI only) - has the *Block* action selected. The message lists the non-compliances. The user must correct the FortiClient settings and try again.

- *Endpoint NAC Recommendation Feature Block Page* — This is the warning version of the *Endpoint NAC Feature Block Page*. In this case, the FortiClient feature application detection entry for the missing feature - AV, Firewall, or webfilter (CLI only) - has the *Warn* action selected. The message lists the non-compliances. The user can select the *Continue to* link to access their desired destination without correcting the non-compliances.

To modify endpoint security replacement messages - web-based manager

1. Go to *UTM Profiles* > *Endpoint Control* > *Profile* and open the profile for editing.
2. Select *Customize Endpoint Messages* and then select the *Edit* icon.

   The *Edit Message* window opens.
3. In the *Message* box, select the message that you want to modify.
4. In the *Message HTML* box, modify the message HTML code.
5. Select *OK*.
6. Select *OK* to save the changes to the profile.

Example

The Example company has the following requirements for employee computers:

- must run FortiClient Endpoint Security version 4.1.3 with firewall enabled
- must have OpenOffice installed
- cannot have any peer-to-peer file sharing applications installed
- must not have any games running
- all other applications are allowed

Configuring FortiClient download source and required version

FortiGuard Services will provide the FortiClient installer.

To configure FortiClient requirements - web-based manager

1. Go to *UTM Profiles* > *Endpoint Control* > *Client Installers*.
2. Check that *FortiGuard Availability* shows a green checkmark icon.

   If you see a red 'X' icon, check your FortiGuard configuration.
3. Under *FortiGuard Installer Download Location*, select *FortiGuard Distribution Network*.
4. Select *Enforce Minimum Version* and then select *4.1.3* from the list.
5. Select Apply.

To configure FortiClient requirements - CLI

```
config endpoint-control settings
  set download-location fortiguard
  set version-check minimum
  set version 4.1.3
  set compliance-timeout 5
end
```

Creating an endpoint control profile

The endpoint control rules for FortiClient Endpoint Security and other applications are contained within an endpoint control profile.

To create an endpoint control profile

1. Go to *UTM Profiles* > *Endpoint Control* > *Profile*.
2. Select *Create New*, enter a *Name* for the profile, and then select *OK*.

To create an endpoint control profile

In this example, profile1 is created.

```
config endpoint-control profile
  edit profile1
  end
```

Configuring FortiClient application detection entries

The FortiClient application detection entry is configured by default to block endpoints that do not have FortiClient installed and running. The FortiClient AV and FortiClient Firewall entries by default allow endpoints access even if they are not using these features. Only the FortiClient Firewall entry needs to be modified.

To configure the FortiClient Firewall application detection entry

1. Go to *UTM Profiles* > *Endpoint Control* > *Profile* and open your profile for editing.
2. Open the *FortiClient Firewall* entry for editing.
3. In *Action*, select *Block*.
4. Select *OK*.
5. Select *OK* to save the change to your profile.

To configure the FortiClient Firewall application detection entry - CLI

```
config endpoint-control profile
  edit profile1
    set feature-enforcement enable
    set require-firewall enable
  end
```

Configuring application detection entries for other applications

You need to create application detection rules for OpenOffice, P2P applications, and games.

To configure the application sensor - web-based manager

1. Go to *UTM Profiles* > *Endpoint Control* > *Profile* and open your profile for editing.
2. Select *Create New*, enter the following information, and then select *OK*:

   This creates a rule requiring the OpenOffice suite.

Category	Office
Application	Specify
Browse	Open Office
Filter by Vendor	Disabled

Action	Block
Condition	Not Installed

3 Select *Create New*, enter the following information, and then select *OK*:

This creates a rule denying users with P2P applications installed.

Category	P2P File Sharing
Application	All
Action	Block
Status	Installed

4 Select *Create New*, enter the following information, and then select *OK*:

This creates a rule denying users with games applications running.

Category	Games
Application	All
Action	Block
Status	Running

5 Select the last application detection list entry, *All*, and edit it. In *Action* select *Allow*.

6 Select *OK*.

7 Select *OK* to save the changes to your profile.

To configure the application detection list and endpoint control profile - CLI

By convention, the application detection entries In the CLI are contained in a rule list prefixed with the profile name. For example, the rule list for profile1 is profile1.list.

The three application detection entries are entered in the same order as for the web-based manager, above. To find codes, use the '?'. For example, `set vendor ?` lists the vendor codes.

```
config endpoint-control app-detect rule-list
  edit profile1.list
    config entries
      edit 1
        set application 77
        set category 31
        set status not-installed
        set action deny
      next
      edit 2
        set category 15
        set status installed
        set action deny
      next
      edit 3
        set category 20
        set status running
        set action deny
      end
    set other-application-action allow
  end
```

```
config endpoint-control profile
  edit "our_profile"
    set application-detection enable
    set application-detection-rule-list profile1.list
  end
```

Configuring the firewall policy

The firewall policy enables access to the Internet, but requires hosts to meet the Endpoint Control requirements configured in the Endpoint Control profile that you configured earlier.

To configure the firewall policy - web-based manager

1 Go to *Policy* > *Policy* and select *Create New*.

2 Enter the following information and select *OK*:

Source Interface/Zone	Select the interface which connects to the LAN.
Source Address	Select the LAN address range.
Destination Interface/Zone	Select the interface which connects to the Internet.
Destination Address	All
Schedule	as required
Service	ANY
Action	ACCEPT
NAT	Enable NAT
Enable Endpoint Security	Select the Endpoint Control profile that you configured earlier.

To configure the firewall policy - CLI

In this example, the LAN connects to Port 2 and the Internet is connected to Port 1.

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr LANusers
    set dstaddr all
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
    set endpoint-check enable
    set endpoint-profile profile1
  end
```

Endpoint Control interface reference

The Endpoint Control menu helps you to configure profiles, application sensors and databases, including network monitoring.

Endpoint control requires that all hosts using the security policy have the FortiClient Endpoint Security application installed. Make sure that all hosts affected by this policy are able to install this application. Currently, FortiClient Endpoint Security is available for only Microsoft Windows 2000 and later.

To set up endpoint control, you need to:

- Enable Central Management if you are going to use FortiGuard Services to update the FortiClient application or antivirus signatures. You do not need to enter account information.
- Configure the minimum required version of FortiClient and the source of FortiClient installer downloads for non-compliant endpoints. See "Configuring FortiClient required version and download location" on page 1091.
- Define application detection lists to specify which applications are allowed or not allowed. Optionally, you can deny access to endpoints that have applications installed that are not on the detection list. See "FortiGuard" on page 407.
- Configure endpoint profiles which specify the FortiClient enforcement settings and the application detection list to apply.
- In firewall policies, enable Endpoint Security and select the Endpoint profile to use.
- Optionally, modify the inactivity timeout for endpoints. The default is 5 minutes. After that time period, the FortiGate unit rechecks the endpoint for Endpoint compliance. To change the timeout, adjust the `compliance-timeout` value in the `config endpoint settings` CLI command.

You can also modify the appearance of the *Endpoint Download Portal* and the *Endpoint Recommendation Portal* by making changes within their replacement messages which are Endpoint Download Portal and Endpoint Recommendation Portal.

This topic includes the following:

Profile

An endpoint control profile contains FortiClient enforcement settings and can specify an application detection list. Security policies can apply an endpoint profile to the traffic they handle.

The following are endpoint profile configuration settings in *UTM Profiles* > *Endpoint Control* > *Profile*.

Profile Settings page	
Provides settings for configuring an endpoint control profile. When you edit an existing endpoint profile, you are automatically redirected to this page.	
Name	The name that was entered in the *Name* field on the New Detection List page. To change the name, edit the text in this field and then select *OK*.
Comments	The comment that was entered in the *Comment* field on the New Detection List page. If you want to edit or add a comment, enter the text in this field and then select *OK*.

Customize Endpoint Messages	Select to allow modifying the Endpoint NAC replacement messages. Select *Edit* to modify a specific replacement message. When you select *Edit*, the Edit Message window appears where you can modify each endpoint NAC replacement message.
Create New	Creates a new application entry. When you select *Create New*, you are automatically redirected to the New Application Detection Entry page.
Edit	Modifies settings within an application entry. When you select *Edit*, you are automatically redirected to the Edit Application Detection Entry page.
Delete	Removes an entry from within the list. To remove multiple entries from within the list, on the Profile Settings page, in each of the rows of the entries you want removed, select the check box and then select *Delete*. To remove all entries in the list, on the Profile Settings page, select the check box in the check box column, and then select *Delete*.
Insert	Inserts a new application detection entry in the list. When you select *Insert*, you are automatically redirected to the New Application Detection Entry page.
Move To	Moves the entry to another position in the list. When you select *Move To*, the Move Application Detection Entry window appears. To move an entry, select the new position *Before* or *After*, which will place the current entry before or after then entry you enter in the *(Entry ID)* field. Enter the entry ID number in the field and then select *OK*.
ID	The identification number for that application detection entry. This number is used when moving an entry within the list.
Application or Category	The category and vendor. If you selected *All Applications*, then *All* will appear at the end. For example, Avaya Inc. - Games - All.
Action	The type of action that the unit will take when a match is found.
Condition	The status of the application or category, for example if the FortiClient software is not installed and not running.

New/Edit Application Detection Entry page

You can edit or create a new application detection entry from the UTM Profiles > Endpoint Control > Profile page.

Category	Select the software category for the entry. For example, Instant Messaging. This is not available for the preconfigured FortiClient application detection entries.
Application	Select whether to include all applications in the application detection entry or specify an application. You cannot specify multiple applications per application detection entry. When you select *Specify*, you can use the *Search* field to find a specific application or select one from the *Browse* list. You can also select the check box beside *Filter By Vendor* to filter the applications by vendor as well.
Tags	You can add tags to an application detection entry. If tag configuration settings are not available, they are disabled on the web-based manager. You must enable them in *System* > *Admin* > *Settings*. See "General Settings" on page 359. To add a tag, enter the tag name in the *Add tags* field and select the plus sign. To add multiple tags, enter the tags and separate each with a comma and then select the plus sign. The tags that you create are shown in the *Applied tags* row. This is not available for the preconfigured FortiClient entries.
Action	Select what to do if the application is running on the endpoint: • *Allow* – allows the endpoint to connect • *Block* – quarantines the endpoint • *Monitor* – includes this endpoint's information in statistics and logs on the Endpoint Monitor page. • *Warn* – displays a block page, but contains a button to let the user continue at his or her discretion. Information is then sent back to the client.
Condition	Select the status of the application. • *Installed* – application is installed but no currently running. • *Running* – application is currently running • *Not Installed* – application is not currently installed • *Not Running* – application is not currently running

Application Database

The Application Database page allows you to view the applications which are sorted by category. For example, iKey is found under the Encryption PKI category. This page also allows you to apply tags the applications within the list, search to find a particular application or category, as well as filter the applications within the list.

Lists the applications. On this page, you can create tags for applications, search, as well as filter and customize columns.

Tags	Adds or removes tags to the applications in the application database list. If tag configuration settings are not available, they are disabled on the web-based manager. You must enable them in *System* > *Admin* > *Settings*. See "Tag management" on page 582. When you select the down arrow beside Tags, you can add or removed tags. To add tags to an application in the list, select the application first and then select the down arrow beside *Tags* to select *Add Tags*. The Add Tags window appears. Enter the tag in the *Add tag* field and select the plus sign to add the tag *Tags* to apply. Select *OK* to permanently add the tags to the application. To remove a tag in application in the list, select the application first and then select the down arrow beside *Tags* to select *Remove Tags*. Select the tag in the *Applied tags* row; it automatically moves to the *Tags* to remove row. Repeat until all tags are listed in the *Tags to remove* row. Select *OK* to permanently remove the tags from the application. If there are tags that you want to add to an application that have been configured for another object, such as an application within *UTM Profiles* > *Application Control* > *Application List*, you can add those tags as well to the application in the application database. To apply these other object tags, select the application and then select the down arrow beside *Tags*; select *Add Tags*. In the *Add Tags* window, select each of the tags you want to add from within the *Click tag to add* row. Each tag is automatically added to the *Tags* to apply row. Select *OK* to add them to the application in the application database.
Column Settings	Customize the column view. You can select the columns to hide or display them and specify the column display order.

Filter Settings	Select to filter the information on the Application Database page. Filters appears automatically after selecting *Filter Settings*, below the column headings. **Note:** *Filter Settings* configures all filter settings. Filter icons are used to configure filter settings within that column. To apply a filter setting, select the plus sign beside *Add new filter* and then select and enter the information required. Repeat to add other filter settings. To modify settings, select *Change* beside the setting and edit the settings. To clear all filter settings, select the icon beside *Clear all filters*. To use a filter icon to filter settings within a column, select the filter icon in the column; *Filters* appears. Within *Filters*, configure the filter settings for that column. The *Filter Settings* on the Application Database page contains the option *Copy to Profile*, which allows you to copy the filter settings and apply them to an endpoint profile. To apply existing filter settings to an endpoint profile, select the down arrow beside *Filter Settings* and then select *Copy to Profile*. In the Select *Object window*, select the endpoint profile from the *Endpoint Profile*'s drop-down list. Select *OK*.
Search	Enter a search criteria into the field and then press Enter on your keyboard. Use the *Clear All* icon beside the field to clear the search results.
Category	The type of category an application is included in. For example, Anti-Mailware Software includes the Billy The Goat application. This column can display the application database list information in ascending or descending order. Select the green arrow beside Category; a green down arrow means the information is in descending order and an green up arrow means the information is in ascending order.
Name	The name of the application.
Vendor	The name of the vendor.
Tags	The tag or tags that were created for the application.
Page Controls	Use to navigate through the list.
[Total Applications:]	The maximum number of applications that are currently shown in the list on the Application Database page.

Client Installers

You can set the minimum FortiClient version that endpoints are required to run from *UTM Profiles* > *Endpoint Control* > *Client Installers*. The FortiClient Endpoint Security page also configures the download source for the FortiClient installer.

Information section	
Indicates the FortiGuard availability and current versions of antivirus and application signatures packages. This section also allows you to update your antivirus and application signature packages, as well as downloading a Windows Installer.	
FortiGuard Availability	FortiGuard Services is available if the indicator is green.
FortiClient Endpoint Versions	FortiClient software versions available from FortiGuard Services are listed. Select the *Download* link to download the installer for either a Mac computer or Windows computer.
AV Signature Package	The latest AV signature package available from FortiGuard Services.
Application Signature Package	The latest application signature package available from FortiGuard Services.
FortiClient Downloads	The number of FortiClient software downloads through this FortiGate unit.
Update Now	Retrieve the latest information from FortiGuard Services.
FortiClient Installer Download Location section	
Select one of the following options to determine the link that the FortiClient Download Portal provides to non-compliant users to download the FortiClient installer.	
FortiGuard Distribution Network	The FortiClient application is provided by the FortiGuard Distribution Network. The FortiGate unit must be able to access the FortiGuard Distribution Network. If the FortiGate unit contains a hard disk drive, the files from FortiGuard Services are cached to more efficiently serve downloads to multiple end points.
This FortiGate	Users download a FortiClient installer file from this unit. This option is available only on FortiGate models that support upload of FortiClient installer files. Upload your FortiClient installer file using the `execute restore forticlient` CLI command. For more information, refer to the *FortiGate CLI Reference*.
Custom URL	Specify a URL from which users can download the FortiClient installer. You can use this option to provide custom installer files even if your unit does not have storage space for them.

FortiClient Version section	
Enforce Minimum Version ... (If enabled in Endpoint Profiles)	From the list select either *Latest Available* or a specific FortiClient version as the minimum requirement for endpoints. The list contains the FortiClient versions available from the selected *FortiClient Installer Download Location*. Fortinet recommends that administrators deploy a FortiClient version update to their users or ask users to install the update and then wait a reasonable period of time for the updates to be installed before updating the minimum version required to the most recent version.

Select *Custom URL* if you want to provide a customized FortiClient application. This is required if a FortiManager unit will centrally manage FortiClient applications. For information about customizing the FortiClient application, see the *FortiClient Administration Guide*.

Vulnerability Scan

The Network Vulnerability Scan helps you to protect your network assets (servers and workstations) by scanning them for security weaknesses. You can scan on-demand or on a scheduled basis. Results are viewable on the FortiGate unit, but results are also sent to an attached FortiAnalyzer unit. The FortiAnalyzer unit can collect the results of vulnerability scans from multiple FortiGate units at different locations on your network, compiling a comprehensive report about network security.

This section describes how to configure a single FortiGate unit for network scanning and how to view the results of the scan.

The following topics are included in this section:

Overview

Network vulnerability scanning has three main parts:

- Select the assets to scan
- Schedule scans or initiate them manually
- View the scan results

Selecting assets to scan

An asset is a server or workstation computer on your network. You can specify assets individually, but it is easier to use the network vulnerability scan feature's asset discovery function. The discovery function searches a specified IP address range and populates the asset list. You then select the assets to include in network vulnerability scans.

Asset discovery scans the following ports:

- TCP: 21-23, 25, 53, 80, 88,110-111, 135, 139, 443, 445
- UDP: 53, 111, 135, 137, 161, 500

Discovering assets

The simplest way to build the Asset list is to perform a discovery scan on the range of IP addresses where your network assets are installed.

To discover assets - web-based manager

1 Go to *UTM Profiles* > *Vulnerability Scan* > *Asset Definition* and select *Create New*.

2 Enter a *Name* for this scan.

3 In *Type*, select *Range* and then enter the IP address *Range* to scan.

4 Select *OK*.

This creates an entry in the Asset list.

5 Select the asset list entry that you just created and then select *Discover Assets*.

Above the table header, on the top right, the status of the current scan is shown. Depending on the number of computers to be discovered, the scan can take several minutes, until the web-based manager reports “Scan completed.” The number of assets discovered is listed to the left of the *Discover Assets* button.

6 Select *Assets Found* and then select *Import*.

The discovered assets are added to the *Asset* list. By default, all are enabled for scanning.

7 Unless you want to discover assets on every scan, clear the Enable check box for this Asset discovery only asset.

You might want to add authentication credentials to some of your assets. To edit an entry in the Asset list, select its check box (at the left side of the list) and then select *Edit*. For more information about individual asset settings, see “Adding assets manually”, below.

To discover assets - CLI

This example discovers assets in the range 10.11.101.10 to 10.11.101.200.

1 First configure the asset range to scan:

```
config netscan assets
  edit 0
    set name "office_discovery"
    set addr-type range
    set start-ip 10.11.101.10
    set end-ip 10.11.101.200
    set mode discovery
    set status enable
  end
```

2 Execute the discovery scan:

```
execute netscan start discover
```

3 Check the status of the discovery scan:

```
execute netscan status
```

Repeat periodically until status is “scan complete”.

4 Optionally, view a list of the discovered assets:

```
execute netscan list
```

5 Add the discovered assets to the asset list:

```
execute netscan import
```

Adding assets manually

There is no need to perform a discovery scan if you know the IP address of the computer that you want to scan, or you know that you want to scan all of the computers in a particular IP address range.

If you create an asset with an IP address range, any authentication credentials you enter will apply to all devices in the range. If this is not appropriate, you need to create individual entries for each computer instead.

To add an asset - web-based manager

1 Go to *UTM Profiles* > *Vulnerability Scan* > *Asset Definition* and select *Create New*.

2 Enter the following information and select *OK*:

Name	Enter a name for this asset.
Type	Select *Host* to configure a single IP address. Select *Range* to configure a range of IP addresses to scan.
IP Address	Enter the IP address of the asset. (*Type* is *Host*.)
Range	Enter the start and end of the IP address range. (*Type* is *Range*.)
Scan Type	Select *Vulnerability Scan*.
Windows Authentication	Select to use authentication on a Windows operating system. Enter the username and password in the fields provided. For more information, see “Requirements for authenticated scanning” on page 1116.
Unix Authentication	Select to use authentication on a Unix operating system. Enter the username and password in the fields provided. For more information, see “Requirements for authenticated scanning” on page 1116.

To add an asset - CLI

This example adds a single computer to the Asset list:

```
config netscan assets
  edit 0
    set name "server1"
    set addr-type ip
    set start-ip 10.11.101.20
    set mode scan
    set auth-windows enable
    set win-username admin
    set win-password zxcvbnm
    set status enable
  end
```

This example adds an address range to the Asset list. Authentication is not used:

```
config netscan assets
  edit 0
    set name "fileservers"
    set addr-type range
    set start-ip 10.11.101.160
    set end-ip 10.11.101.170
    set mode scan
    set status enable
  end
```

Requirements for authenticated scanning

The effectiveness of an authenticated scan is determined by the level of access the FortiGate unit obtains to the host operating system. Rather than use the system administrator's account, it might be more convenient to set up a separate account for the exclusive use of the vulnerability scanner with a password that does not change.

Microsoft Windows hosts - domain scanning

The user account provided for authentication must

- have administrator rights
- be a Security type of account
- have global scope
- belong to the Domain Administrators group
- meet the Group Policy requirements listed below:

Group Policy - Security Options

In the Group Policy Management Editor, go to Computer Configuration > Windows Settings > Security Settings > Local Policies > Security Options.

Setting	Value
Network access: Sharing and security model for local accounts	Classic
Accounts: Guest account status	Disabled
Network access: Let Everyone permissions apply to anonymous users	Disabled

Group Policy - System Services

In the Group Policy Management Editor, go to Computer Configuration > Windows Settings > Security Settings > System Services.

Setting	Value
Remote registry	Automatic
Server	Automatic
Windows Firewall	Automatic

Group Policy - Administrative Templates

In the Group Policy Management Editor, go to Computer Configuration > Administrative Templates > Network > Network Connections > Windows Firewall > Domain Profile.

Setting	Value
Windows Firewall: Protect all network connections	Disabled

or

Setting	Value
Windows Firewall: Protect all network connections	Enabled
Windows Firewall: Allow remote administration exception	Enabled
Allow unsolicited messages from[1]	*
Windows Firewall: Allow file and printer sharing exception	Enabled

Allow unsolicited messages from[1]	*
Windows Firewall: Allow ICMP exceptions	Enabled
Allow unsolicited messages from[1]	*

[1]Windows prompts you for a range of IP addresses. Enter either "*" or the IP address of the Fortinet appliance that is performing the vulnerability scan.

Microsoft Windows hosts - local (non-domain) scanning

The user account provided for authentication must

- be a local account
- belong to the Administrators group

The host must also meet the following requirements:

- Server service must be enabled. (Windows 2000, 2003, XP)
- Remote Registry Service must be enabled.
- File Sharing must be enabled.
- Public folder sharing must be disabled. (Windows 7)
- Simple File Sharing (SFS) must be disabled. (Windows XP)

Windows firewall settings

- Enable the *Remote Administration Exception* in Windows Firewall. (Windows 2003, Windows XP)
- Allow *File and Print sharing* and *Remote Administration* traffic to pass through the firewall. Specify the IP address or subnet of the Fortinet appliance that is performing the vulnerability scan. (Windows Vista, 2008)
- For each of the active *Inbound Rules* in the *File and Printer Sharing* group, set the *Remote IP address* under *Scope* to either *Any IP address* or to the IP address or subnet of the Fortinet appliance that is performing the vulnerability scan. (Windows 7)

Unix hosts

The user account provided for authentication must be able at a minimum to execute these commands:

- The account must be able to execute "uname" in order to detect the platform for packages.
- If the target is running Red Hat, the account must be able to read /etc/redhat-release and execute "rpm".
- If the target is running Debian, the account must be able to read /etc/debian-version and execute "dpkg".

Configuring scans

You can configure regular network scans on a daily, weekly, or monthly basis. There are three scan modes. Full scan checks every TCP and UDP port and takes the most time. Standard scan checks the ports used by most known applications. Quick scan checks only the most commonly used ports. For a detailed list of the TCP and UDP ports examined by each scan mode, see Table 71 on page 1119. Also, the `get netscan settings` CLI command lists the TCP and UDP ports scanned in the current scan mode. See the `tcp-ports` and `udp-ports` fields.

You can also initiate the configured scan manually.

Table 71: Ports scanned in each scan mode

Standard Scan	***TCP:*** 1-3, 5, 7, 9, 11, 13, 15, 17-25, 27, 29, 31, 33, 35, 37-39, 41-223, 242-246, 256-265, 280-282, 309, 311, 318, 322-325, 344-351, 363, 369-581, 587, 592-593, 598, 600, 606-620, 624, 627, 631, 633-637, 666-674, 700, 704-705, 707, 709-711, 729-731, 740-742, 744, 747-754, 758-765, 767, 769-777, 780-783, 786, 799-801, 860, 873, 886-888, 900-901, 911, 950, 954-955, 990-993, 995-1001, 1008, 1010-1011, 1015, 1023-1100, 1109-1112, 1114, 1123, 1155, 1167, 1170, 1207, 1212, 1214, 1220-1222, 1234-1236, 1241, 1243, 1245, 1248, 1269, 1313-1314, 1337, 1344-1625, 1636-1774, 1776-1815, 1818-1824, 1901-1909, 1911-1920, 1944-1951, 1973, 1981, 1985-2028, 2030, 2032-2036, 2038, 2040-2049, 2053, 2065, 2067, 2080, 2097, 2100, 2102-2107, 2109, 2111, 2115, 2120, 2140, 2160-2161, 2201-2202, 2213, 2221-2223, 2232-2239, 2241, 2260, 2279-2288, 2297, 2301, 2307, 2334, 2339, 2345, 2381, 2389, 2391, 2393-2394, 2399, 2401, 2433, 2447, 2500-2501, 2532, 2544, 2564-2565, 2583, 2592, 2600-2605, 2626-2627, 2638-2639, 2690, 2700, 2716, 2766, 2784-2789, 2801, 2908-2912, 2953-2954, 2998, 3000-3002, 3006-3007, 3010-3011, 3020, 3047-3049, 3080, 3127-3128, 3141-3145, 3180-3181, 3205, 3232, 3260, 3264, 3267-3269, 3279, 3306, 3322-3325, 3333, 3340, 3351-3352, 3355, 3372, 3389, 3421, 3454-3457, 3689-3690, 3700, 3791, 3900, 3984-3986, 4000-4002, 4008-4009, 4080, 4092, 4100, 4103, 4105, 4107, 4132-4134, 4144, 4242, 4321, 4333, 4343, 4443-4454, 4500-4501, 4567, 4590, 4626, 4651, 4660-4663, 4672, 4899, 4903, 4950, 5000-5005, 5009-5011, 5020-5021, 5031, 5050, 5053, 5080, 5100-5101, 5145, 5150, 5190-5193, 5222, 5236, 5300-5305, 5321, 5400-5402, 5432, 5510, 5520-5521, 5530, 5540, 5550, 5554-5558, 5569, 5599-5601, 5631-5632, 5634, 5678-5679, 5713-5717, 5729, 5742, 5745, 5755, 5757, 5766-5767, 5800-5802, 5900-5902, 5977-5979, 5997-6053, 6080, 6103, 6110-6112, 6123, 6129, 6141-6149, 6253, 6346, 6387, 6389, 6400, 6455-6456, 6499-6500, 6515, 6558, 6588, 6660-6670, 6672-6673, 6699, 6767, 6771, 6776, 6831, 6883, 6912, 6939, 6969-6970, 7000-7021, 7070, 7080, 7099-7100, 7121, 7161, 7174, 7200-7201, 7300-7301, 7306-7308, 7395, 7426-7431, 7491, 7511, 7777-7778, 7781, 7789, 7895, 7938, 7999-8020, 8023, 8032, 8039, 8080-8082, 8090, 8100, 8181, 8192, 8200, 8383, 8403, 8443, 8450, 8484, 8732, 8765, 8886-8894, 8910, 9000-9001, 9005, 9043, 9080, 9090, 9098-9100, 9400, 9443, 9535, 9872-9876, 9878, 9889, 9989-10000, 10005, 10007, 10080-10082, 10101, 10520, 10607, 10666, 11000, 11004, 11223, 12076, 12223, 12345-12346, 12361-12362, 12456, 12468-12469, 12631, 12701, 12753, 13000, 13333, 14237-14238, 15858, 16384, 16660, 16959, 16969, 17007, 17300, 18000, 18181-18186, 18190-18192, 18194, 18209-18210, 18231-18232, 18264, 19541, 20000-20001, 20011, 20034, 20200, 20203, 20331, 21544, 21554, 21845-21849, 22222, 22273, 22289, 22305, 22321, 22555, 22800, 22951, 23456, 23476-23477, 25000-25009, 25252, 25793, 25867, 26000, 26208, 26274, 27000-27009, 27374, 27665, 29369, 29891, 30029, 30100-30102, 30129, 30303, 30999, 31336-31337, 31339, 31554, 31666, 31785, 31787-31788, 32000, 32768-32790, 33333, 33567-33568, 33911, 34324, 37651, 40412, 40421-40423, 42424, 44337, 47557, 47806, 47808, 49400, 50505, 50766, 51102, 51107, 51112, 53001, 54321, 57341, 60008, 61439, 61466, 65000, 65301, 65512 ***UDP:*** 7, 9, 13, 17, 19, 21, 37, 53, 67-69, 98, 111, 121, 123, 135, 137-138, 161, 177, 371, 389, 407, 445, 456, 464, 500, 512, 514, 517-518, 520, 555, 635, 666, 858, 1001, 1010-1011, 1015, 1024-1049, 1051-1055, 1170, 1243, 1245, 1434, 1492, 1600, 1604, 1645, 1701, 1807, 1812, 1900, 1978, 1981, 1999, 2001-2002, 2023, 2049, 2115, 2140, 2801, 3024, 3129, 3150, 3283, 3527, 3700, 3801, 4000, 4092, 4156, 4569, 4590, 4781, 5000-5001, 5036, 5060, 5321, 5400-5402, 5503, 5569, 5632, 5742, 6073, 6502, 6670, 6771, 6912, 6969, 7000, 7300-7301, 7306-7308, 7778, 7789, 7938, 9872-9875, 9989, 10067, 10167, 11000, 11223, 12223, 12345-12346, 12361-12362, 15253, 15345, 16969, 20001, 20034, 21544, 22222, 23456, 26274, 27444, 30029, 31335, 31337-31339, 31666, 31785, 31789, 31791-31792, 32771, 33333, 34324, 40412, 40421-40423, 40426, 47262, 50505, 50766, 51100-51101, 51109, 53001, 61466, 65000

Full Scan	All TCP and UDP ports (1-65535)
Quick Scan	***TCP:*** 11, 13, 15, 17, 19-23, 25, 37, 42, 53, 66, 69-70, 79-81, 88, 98, 109-111, 113, 118-119, 123, 135, 139, 143, 220, 256-259, 264, 371, 389, 411, 443, 445, 464-465, 512-515, 523-524, 540, 548, 554, 563, 580, 593, 636, 749-751, 873, 900-901, 990, 992-993, 995, 1080, 1114, 1214, 1234, 1352, 1433, 1494, 1508, 1521, 1720, 1723, 1755, 1801, 2000-2001, 2003, 2049, 2301, 2401, 2447, 2690, 2766, 3128, 3268-3269, 3306, 3372, 3389, 4100, 4443-4444, 4661-4662, 5000, 5432, 5555-5556, 5631-5632, 5634, 5800-5802, 5900-5901, 6000, 6112, 6346, 6387, 6666-6667, 6699, 7007, 7100, 7161, 7777-7778, 8000-8001, 8010, 8080-8081, 8100, 8888, 8910, 9100, 10000, 12345-12346, 20034, 21554, 32000, 32768-32790 ***UDP:*** 7, 13, 17, 19, 37, 53, 67-69, 111, 123, 135, 137, 161, 177, 407, 464, 500, 517-518, 520, 1434, 1645, 1701, 1812, 2049, 3527, 4569, 4665, 5036, 5060, 5632, 6502, 7778, 15345

To configure scanning - web-based manager

1 Go to *UTM Profiles* > *Vulnerability Scan* > *Scan*.

2 Enter the following information and select *Apply*.

Scan Mode	**Quick** — check only the most commonly used ports **Standard** — check the ports used by most known applications **Full** — check all TCP and UDP ports For a detailed list of the TCP and UDP ports examined by each scan mode, see Table 71 on page 1119.
Schedule	**Manually** – perform scan on request only **Schedule** – use the following fields to configure a schedule
Recurrence	Select *Daily*, *Weekly*, or *Monthly*. If you select Weekly, the Day of Week drop-down list appears. If you select Monthly, the Day of Month drop-down list appears.
Time	Select the time of day to start the scan, in the format HH:MM.
Day of Week	For a weekly scan, select the day of the week.
Day of Month	For a monthly scan, select the day of the month.

To configure scanning - CLI

To configure, for example, a standard scan to be performed every Sunday at 2:00am, you would enter:

```
config netscan settings
  set scan-mode standard
  set schedule enable
  set time 02:00
  set recurrence weekly
  set day-of-week sunday
end
```

To perform a vulnerability scan manually - web-based manager

1 Go to *UTM Profiles* > *Vulnerability Scan* > *Asset*.

2 Select the Enable check box for each asset you want to scan.

3 Select *Start Scan*.

Above the table header, on the top right, the status of the current scan is shown. Depending on the number of computers to be discovered, the scan can take several minutes, until the web-based manager reports “Scan completed.”

To perform a vulnerability scan manually - CLI

You must have some assets configured with `mode` set to `scan`.

1 Execute the discovery scan:

```
execute netscan start scan
```

2 Check the status of the discovery scan:

```
execute netscan status
```

Repeat periodically until status is “scan complete”.

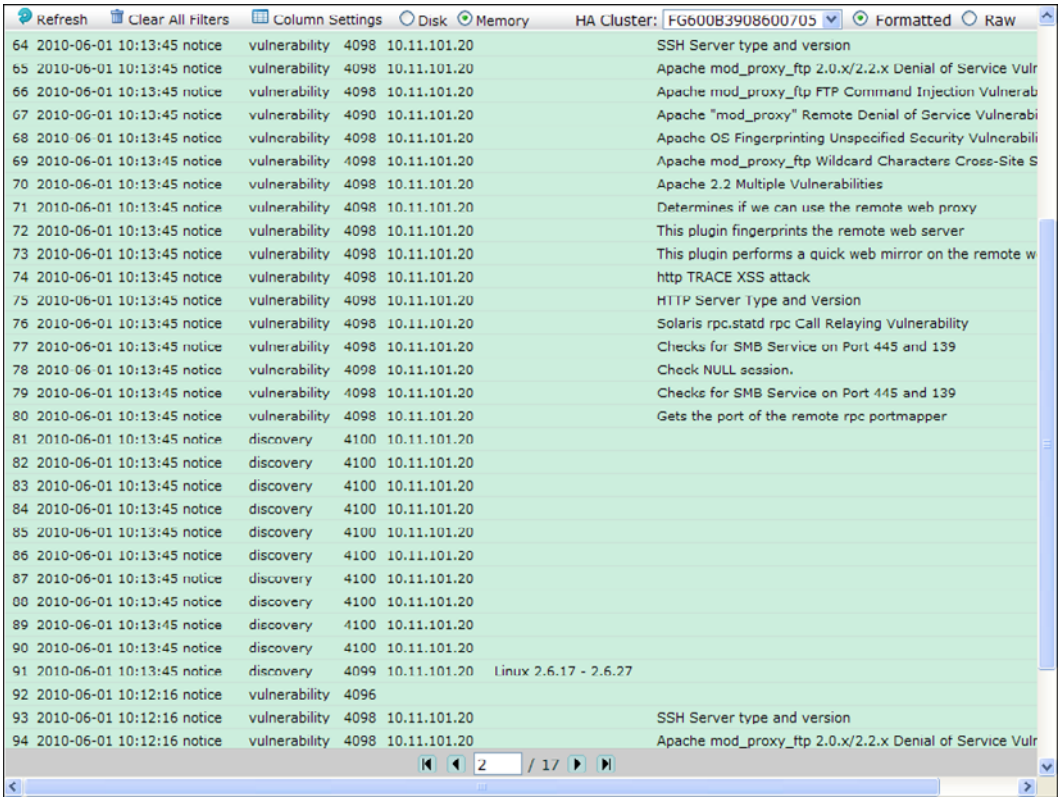
Viewing scan results

The results of network scanning are available as summary graphs and log entries.

Viewing scan logs

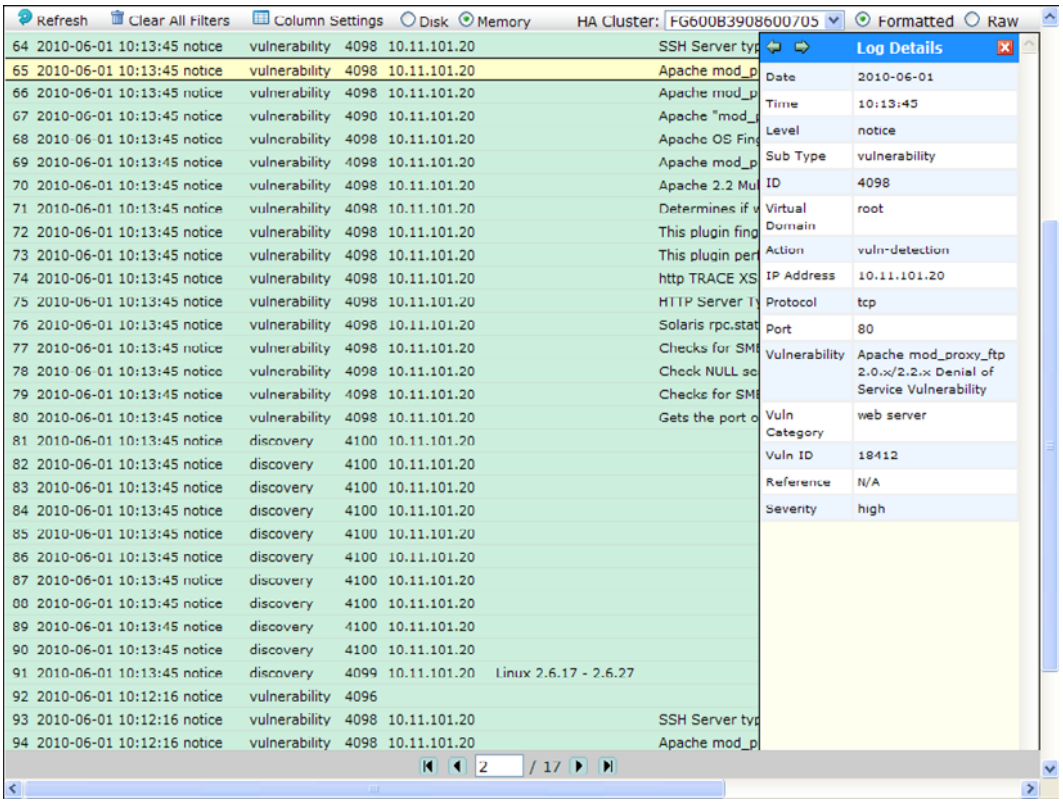
To view network scan logs, go to *Log&Report* > *Log & Archive Access* > *Vulnerability Scan Log*.

Figure 96: Network scan logs



Select any log entry to view log details.

Figure 97: Network scan log details



Viewing Executive Summary graphs

To view summary graphs, go to *Log&Report* > *Report Access* > *Executive Summary*. You might need to add the following widgets to the page to view the summaries you require.

Table 72: Executive summary widgets for network scan

Chart	Widget name
Vulnerabilities by Category	vulner-by-category-last24h
Vulnerabilities by Severity	vulner-by-severity-last24h
Top Vulnerable Operating Systems Detected	top-vulner-os-last24h
Top Vulnerable Services Detected	top-vulner-service-last24h
Top Vulnerable TCP Services Detected	top-vulner-tcp-service-last24h
Top Vulnerable UDP Services Detected	top-vulner-udp-service-last24h

Creating reports

You can use the FortiGate unit's Log&Report features to generate reports on the results of network vulnerability scanning.

To create a report of scanning results

1 Go to *Log&Report* > *Report Config* > *Layout* and select *Create New*.

2 Enter a *Name* for the report.

3 Optionally select a *Report Theme*.

4 Enter a *Title* to appear on the report.

5 Choose each *Option* and *Output Format* that you require.

6 If you want to have the report generated on a regular basis, create a *Schedule*.

7 Select the *Report Components*.

The components are listed in order below the Report Components heading. For a network vulnerability scan report, you will need to select Chart components from the Vulnerability category. The following vulnerability charts are available:

Table 73: Executive summary widgets for network scan

Chart	Component name
Vulnerabilities by Category	vulner-by-category-last24h
Vulnerabilities by Severity	vulner-by-severity-last24h
Top Vulnerable Operating Systems Detected	top-vulner-os-last24h
Top Vulnerable Services Detected	top-vulner-service-last24h
Top Vulnerable TCP Services Detected	top-vulner-tcp-service-last24h
Top Vulnerable UDP Services Detected	top-vulner-udp-service-last24h

8 Optionally select other components, such as headings and text.

9 Select OK.

The report will be generated at the scheduled time.

To generate a report manually

1 Go to *Log&Report* > *Report Config* > *Layout*.

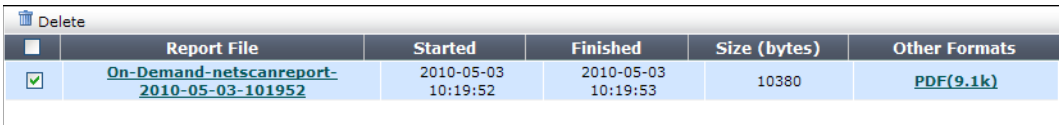
2 Select the required report.

3 Select *Run*.

Viewing reports

Go to *Log&Report* > *Report Access* > *Disk* to view generated reports.

Figure 98: List of reports



If HTML output was enabled, you can select the Report File name to view the report in a separate browser window.

If PDF output was enabled, you can select the link in the Other Formats column to view the report.

Vulnerability Scan interface reference

The *Vulnerability Scan* menu enables you to configure scanning of your network, a feature similar to the vulnerability scan features on FortiAnalyzer or FortiScan units.

This topic includes the following:

Asset Definition

In the Asset Definition menu, you can configure multiple asset lists that are used for scanning purposes. On the Asset Definition page, you can use an asset list to discover assets, start a scan or view the discovered assets.

The following are asset definition configuration settings in *UTM Profiles* > *Vulnerability Scan* > *Asset Definition*.

Asset Definition page Lists each individual asset that you created. On this page, you can edit, delete or create a new asset.	
Create New	Creates a new asset. When you select *Create New*, you are automatically redirected to the Asset Settings page.
Edit	Modifies an asset. When you select *Edit*, you are automatically redirected to the Asset Settings page.
Delete	Removes an asset from the list on the page.
View	Displays discovered hosts that were found during the scanning process. When you select *View*, the Discovered Hosts window appears. Select *Return* to go back to the Asset Definition page.
Discover Assets	Scans to discover assets. When you select *Discover Assets*, the options *Pause* and *Stop* appear. Select *Pause* to pause the scanning process or select *Stop* to stop the scanning process altogether.
Start Scan	Starts the scanning process. When you start scanning, the *Pause* and *Stop* options appear. Select *Pause* to pause the scanning process or select *Stop* to stop the scanning process altogether.
Name	The name of the asset.
IP Address/Range	If *Host* was chosen as the type for the asset, then the IP address of the host displays. If *Range* was chosen as the type for the asset, the IP address range appears.
Scheduled Vulnerability Scan	Indicates that there is a scheduled scan.
# Assets Discovered	Indicates how many assets were discovered during the scanning process.
Scan Activity	Indicates the activity of the scan.
Asset Settings page Provides settings for configuring an asset.	
Name	Enter a name for the asset that you are creating.
Type	Select *Host* to configure the host's IP address. Select *Range* to configure the IP address range.

IP Address (Range)	Enter the IP address of the host, or the IP address range. This depends on what type you selected in *Type*. If you select *Range* in *Type*, then the name *Range* appears and there are two IP address fields for you to enter the IP address range in.
Enable Scheduled Vulnerability Scanning	Select to schedule a scan.
Windows Authentication	Select to use authentication on a Windows operating system. Enter the username and password in the fields provided. The fields appear after selecting *Windows Authentication*.
Unix Authentication	Select to use authentication on a Unix operating system. Enter the username and password in the fields provided. The fields appear after selecting *Unix Authentication*.

Scan Schedule

From the Scan Schedule page, you can view the status of a vulnerability scan, and adjust the times and type of future scans.

The following are configuration settings for scheduling scans in *UTM Profiles* > *Vulnerability Scan* > *Scan Schedule.*

Status section	
Indicates the status of the previous scan, as well as when the next scan will occur. You can also start a scan using *Start Scan*.	
Scan Status	Indicates if a scan is currently running. If you select *Start Scan*, a scan will immediately begin. A progress bar appears, along with *Pause* and *Stop*, and the start time, estimated rating and completion time period. Select *Pause* to pause the scan or *Stop* to stop the scan altogether.
Last Scan Start Time	Indicates the last previous scan's start time. The format is <month> <day>, <year> - <hour>:<minute> <AM/PM>. For example, October 12, 2010 - 04:30 PM. The time is in 24-hour format.
Last Scan End Time	Indicates the last previous scan's end time. The format is <month> <day>, <year> - <hour>:<minute> <AM/PM>. For example, October 12, 2010 - 06:30 PM. The time is in 24-hour format.
Last Scan Duration	Indicates how long the scan lasted, in seconds.
Next Scheduled Scan	Indicates when the next scheduled scan will begin.

Schedule section Configure the time and day (or date if you choose to schedule a scan on a monthly basis) as well as enable to suspend a scan between a specified time period.	
Recurrence	Select when the schedule should occur, such as on a daily basis or monthly basis. If you select *Weekly*, you must select the day of the week that the scan will occur on, as well as the hour and minutes. If you select *Monthly*, you must select the day within the current month as well as the hour and minutes. For example, in the current month of October, *Recurrence* is set to *Monthly*, with *Day of Month* being 20 and *Hour* being 12, and *Minutes* being 00.
Suspend Scan between	Select to suspend the unit from scanning the network during a specified time period. Specify the hours and minutes using the drop-down lists.
Vulnerability Scan Mode section Select a mode that will be used when scanning network activity.	
Quick	Examines the most commonly used ports for vulnerabilities.
Standard	Examines a large number of application ports which cover many known applications.
Full	Examines the full port range, 1-655535, looking for applications that are running on non-standard ports.
Advanced section Provides options for specifying scanning only TCP or UDP ports, as well as operating systems or services.	
Enable TCP Port Scan	Select to scan only TCP ports.
Enable Service Detection	Select to scan for the detection of services on ports.
Enable OS Detection	Select to scan for the detection of operating systems on ports.
Enable UDP Port Scan	Select to scan only UDP ports.

Vulnerability Result

The Vulnerability Scan Results page provides a graphical and tabular representation of the information the FortiGate unit gathered from scanning the network.

The Summary table lists recent scans.

The two bar graphs, *Vulnerabilities by Severity* and *Vulnerabilities by Category* show the number of vulnerabilities that were found by severity and by category.

Sniffer policy

Sniffer policies are used to configure a physical interface on the FortiGate unit as a one-arm intrusion detection system (IDS). Traffic sent to the interface is examined for matches to the configured IPS sensor and application control list. Matches are logged and then all received traffic is dropped. Sniffing only reports on attacks. It does not deny or otherwise influence traffic.

This section describes how to configure your network topology to use the FortiGate unit as a one-arm intrusion detection system. It also describes how to configure and enable a sniffer policy.

The following topics are included in this section:

Sniffer policy concepts

Using the one-arm intrusion detection system (IDS), you can configure a FortiGate unit to operate as an IDS appliance by sniffing network traffic for attacks without actually processing the packets.

To configure one-arm IDS, you enable sniffer mode on a FortiGate interface and connect the interface to a hub or to the SPAN port of a switch that is processing network traffic. Then you add DoS policies for that FortiGate interface, Each policy can include a DoS sensor, an IPS sensor, and an application control list to detect attacks and application traffic in the network traffic that the FortiGate interface receives from the hub or switch SPAN port.

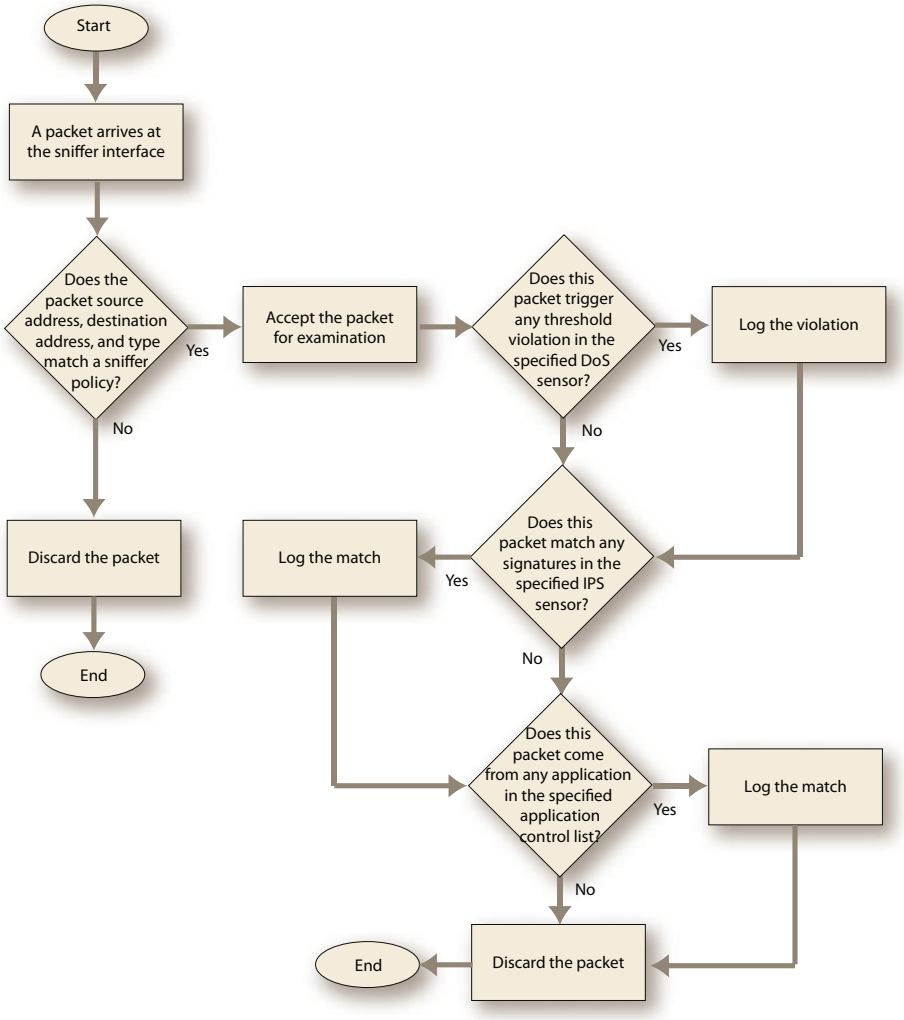
The sniffer policy list

The sniffer policy list shows all of the sniffer policies you have created. The policies are listed by sniffer interface. This is important because multiple sniffer policies can be applied to sniffer interfaces. Traffic entering a sniffer interface is checked against the sniffer policies for matching source and destination addresses and for service. This check against the policies occurs in listed order, from top to bottom. The first sniffer policy matching all three attributes then examines the traffic. Once a policy matches the attributes, checks for policy matches stop. If no sniffer policies match, the traffic is dropped without being examined.

Once a policy match is detected, the matching policy compares the traffic to the contents of the DoS sensor, IPS sensor, and application list specified in the policy. If any matches are detected, the FortiGate unit creates an entry in the log of the matching sensor/list. If the same traffic matches multiple sensors/lists, it is logged for each match. When this comparison is complete, the network traffic is dropped.

Figure 99 illustrates this process.

Figure 99: How the intrusion detection system uses sniffer policies to examine traffic



Before you begin

Traffic entering an interface in sniffer mode is examined for DoS sensor violations, IPS sensor matches, and application control matches. After these checks, all network traffic is dropped. To avoid losing data, you must direct a copy of the network traffic to the FortiGate unit interface configured to sniff packets.

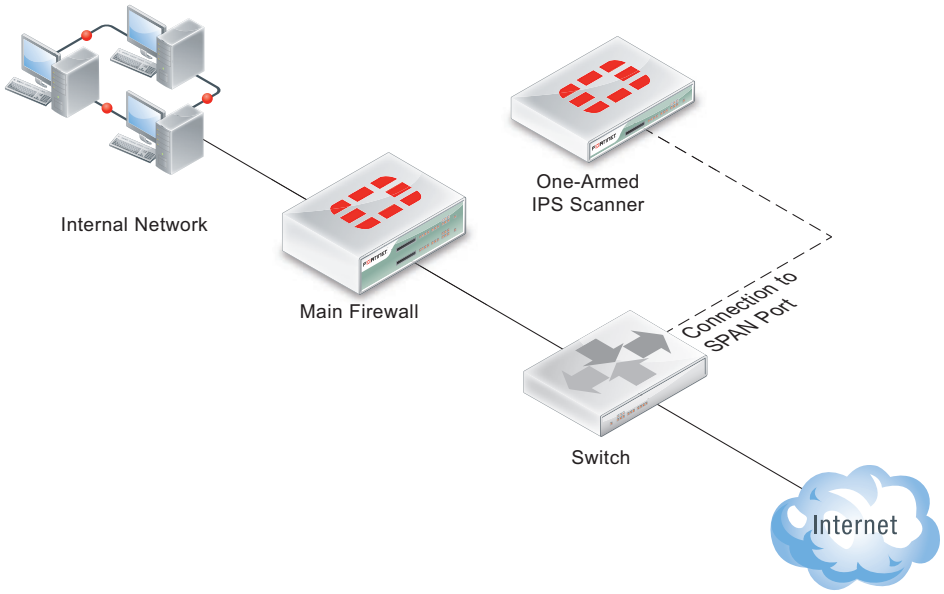
The easiest way to do this is to either use a hub or a switch with a SPAN port.

A hub is the easiest solution to implement but carries a downside. Connecting the FortiGate unit interface configured with the sniffer policy to a hub will deliver all traffic passing through the hub to the interface. However, if the network carries a heavy traffic load, the hub could slow the network because every hub interface sends out all the traffic the hub received on every interface.

A better solution is a switch with a SPAN port. Network switches receive traffic on all interfaces but they only send traffic out on the interface connected to the destination. Network slowdowns are less common when using switches instead of hubs.

Connecting the sniffer interface to a regular switch interface will not work because no traffic is addressed to the sniffer interface. A SPAN port is a special-purpose interface that mirrors all the traffic the switch receives. Traffic is handled normally on every other switch interface, but the SPAN port sends a copy of everything. If you connect your FortiGate unit sniffer interface to the switch SPAN port, all the network traffic will be examined without any being lost because of the examination.

Figure 100: A network configured for intrusion detection using a sniffer policy



Enable one-arm sniffing

Sniffer policies examine network traffic for anomalous patterns that usually indicate an attack. Since all traffic entering a sniffer interface is dropped, you need to first add a switch or hub to your network as described in "Before you begin" on page 1128. The following steps are based on the assumption that you have added the switch or hub.

General configuration steps

The interface first must be designated as the sniffer interface, then the sniffer policy can be configured to use the sniffer interface.

1 Add a switch or hub to your network as described in "Before you begin" on page 1128. This configuration will send a copy of your network traffic to the sniffer interface.

When an interface is configured as a sniffer interface, all traffic received by the interface is dropped after being examined by the sniffer policy.

2 Designate a physical interface as a sniffer interface.

3 Create a sniffer policy that specifies the sniffer interface.

4 Specify a DoS sensor, IPS sensor, application control list, or any combination of the three to define the traffic you want logged.

Designating a sniffer interface

An interface must be designated as a sniffer interface before it can be used with a sniffer policy. Once an interface is designated as a sniffer interface, if functions differently from a regular network interface in two ways:

- A sniffer mode interface accepts all traffic and drops it. If a sniffer policy is configured to use the sniffer interface, traffic matching the attributes configured in the policy will be examined before it is dropped. No traffic entering a sniffer mode interface will exit the FortiGate unit from any interface.
- A sniffer mode interface will be the only available selection in sniffer policies. The sniffer interface will not appear in firewall policies, routing tables, or anywhere else interfaces can be selected.

Designating a sniffer interface

1 Go to *System* > *Network* > *Interface*.
2 Select the interface.
3 Select the *Edit* icon.

When an interface is configured as a sniffer interface, all traffic received by the interface is dropped after being examined by the sniffer policy.

4 Select the *Enable one-arm sniffer* check box.

If the check box is not available, the interface is in use. Ensure that the interface is not selected in any firewall policies, routes, virtual IPs or other features in which a physical interface is specified.

5 Select *OK*.

Creating a sniffer policy

Sniffer interfaces accept all traffic. To examine the traffic before it is dropped, a sniffer policy is required.

To create a sniffer policy

1 Go to *Policy* > *Policy* > *Sniffer Policy* and select *Create New*.
2 For *Source Interface/Zone*, select the interface configured as the sniffer interface. If no interfaces are available for selection, no interfaces have been defined as sniffer interfaces. For more information, see “Designating a sniffer interface” on page 1130.
3 For *Source Address*, select the address or address group that defines the source addresses of the traffic the sniffer policy will examine. Network traffic from addresses not included in the selected address group is ignored by this sniffer policy.
4 For *Destination Address*, select the address or address group that defines the destination addresses of the traffic the sniffer policy will examine. Network traffic to addresses not included in the selected address group is ignored by this sniffer policy.
5 For *Service*, select the type of network traffic the sniffer policy will examine. Protocols not included in the selected service or service group are ignored by this sniffer policy.
6 To have the sniffer policy log violations specified in a DoS sensor, select the *DoS Sensor* check box and choose the sensor from the list.
7 To have the sniffer policy log signatures appearing in an IPS sensor, select the *IPS Sensor* check box and choose the sensor from the list.

8 To have the sniffer policy log traffic from applications specified in an application control list, select the *Application Black/White List* check box and choose the application control list.

9 Select *OK*.

DoS sensors, IPS sensors, and application control lists all allow you to choose actions and log traffic. When included in a sniffer sensor, these settings are ignored. Actions in these other settings do not apply, and all matches are logged regardless of the logging setting.

Sniffer example

An IDS sniffer configuration

The Example.com Corporation uses a pair of FortiGate-620B units to secure the head office network. To monitor network attacks and create complete log records of them, the network administrator has received approval to install a FortiGate-82C to record all IPS signature matches in incoming and outgoing network traffic using a sniffer policy. This example details the set-up and execution of this network configuration.

Although this example uses a separate FortiGate unit for sniffer-mode operation, the sniffer traffic can be sent to the FortiGate unit protecting the network. The switch must still be configured to create a copy of the data because the sniffer interface drops all incoming traffic. In this case, the administrator requested a FortiGate-82C for this purpose because sniffer-mode operation is resource intensive, and using a separate FortiGate unit frees the FortiGate-620B cluster from this task. The FortiGate-82C unit also has four internal hard drives, making it ideal for storing large log files.

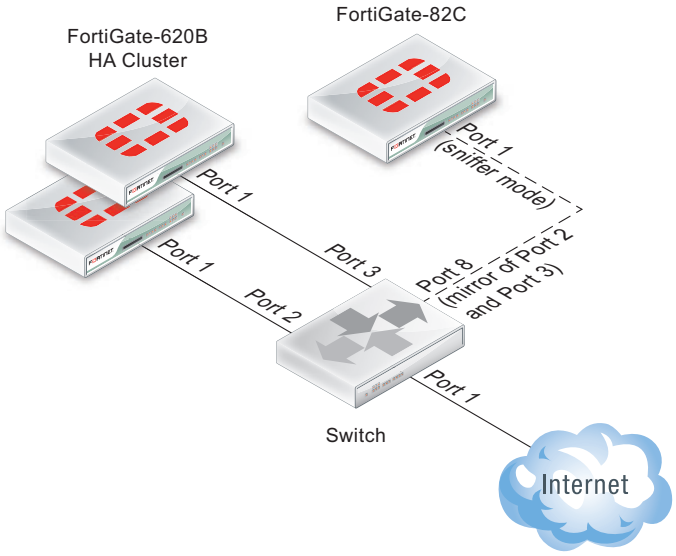
Configuring the network

Connect the Port1 interface of the FortiGate-82C to the Port8 interface of the switch.

You must configure your network to deliver a copy of the traffic to be examined to the sniffer interface because all network traffic entering a sniffer interface is dropped after examination.

Since the corporate network uses a pair of FortiGate units in an HA cluster, a switch is already in place connecting the Internet to Port1 of both FortiGate units.

Figure 101: Switch configuration



The company Internet feed is connected to Port1 of the switch. The FortiGate units are connected to Port2 and Port3 of the switch. Since they are configured as an HA cluster, they must both have access to the Internet in the event of a failure.

To allow a FortiGate unit sniffer interface to examine the network traffic, the switch must be configured to create a copy of all network traffic entering or leaving Port2 and Port3 and send it out Port8. When configured this way, the switch port sending the duplicate traffic is called a mirror port or a SPAN port.

Consult the switch documentation for instructions on how to configure a SPAN port.

The traffic between Port1 and Port2/Port3 is not modified or diverted in any way by the creation of a SPAN port. The traffic is duplicated with the copy being send out of the SPAN port.

Configuring the FortiGate sniffer interface

No sniffer interfaces are included in the default configuration of any FortiGate unit. A copy of all of the network traffic is being sent to Port1 of the FortiGate-82C so you must configure Port1 as a sniffer-mode interface.

When an interface is configured as a sniffer interface, all traffic received by the interface is dropped after being examined by the sniffer policy.

To configure the sniffer mode interface — web-based manager

1. Log in to the FortiGate-82C web-based manager.
2. Go to *System* > *Network* > *Interface*.
3. Select the Port1 interface.
4. Select *Edit*.
5. Select *Enable one-arm sniffer*.
6. Select *OK*.

To configure the sniffer mode interface — CLI

```
config system interface
  edit port1
    set ips-sniffer-mode enable
  end
```

Creating an IPS sensor

A sniffer policy allows you to select an IPS sensor, a DOS sensor, and an application control list. Any conditions these sensors and list are configured to detect and log are saved to the appropriate log.

For this example, create an IPS sensor that detects and logs the occurrence of all the predefined IPS signatures.

To create an IPS sensor — web-based manager

1. Go to *UTM Profiles* > *Intrusion Protection* > *IPS Sensor*.
2. Select *Create New*.
3. In the *Name* field, enter `IPS_sniffer`.
4. In the Comments field, enter `IPS sensor for use in the sniffer policy`.
5. In the *Filters* section, select *Create New*.
6. In the name field, enter `All signatures, logged`.
7. For the *Logging* setting under *Signatures Settings*, select *Enable all*.
8. Select *OK* to save the filter.
9. Ensure *Enable Logging* is selected in the sensor.
10. Select *OK* to save the IPS sensor.

To create an IPS sensor — CLI

```
config ips sensor
  edit IPS_sniffer
    set comment "IPS sensor for use in the sniffer policy."
    config filter
      edit "All signatures, logged"
        set log enable
    end
  end
```

Creating the sniffer policy

The sniffer policy allows us to choose

To create the sniffer policy — web-based manager

1. Go to *Policy* > *Policy* > *Sniffer Policy*.
2. Select *Create New*.
3. Select *Port1* for the *Source Interface/Zone*.
4. Enable *IPS Sensor* and select the `IPS_sniffer` sensor.
5. Select *OK* to save the sniffer policy.

To create the sniffer policy — web-based manager

```
config firewall sniff-interface-policy
```

```
edit 0
  set interface port1
  set srcaddr all
  set dstaddr all
  set service ANY
  set ips-sensor-status enable
  set ips-sensor IPS_sniffer
end
```

With this configuration, all traffic entering the sniffer port is checked for matching signatures. Matches are logged and the traffic is dropped.

To examine the network traffic for more issues, you can create a DoS sensor and select it in the sniffer policy to log traffic anomalies. You can also create an application list with the specific application you'd like to check for and select it in the sniffer policy.

Sniffer Policy interface reference

The sniffer security policy list displays sniffer security policies in their order of matching precedence for each interface, source/destination address pair, and service.

If virtual domains are enabled on the unit, sniffer security policies are configured separately for each virtual domain; you must access the VDOM before you can configure its security policies.

You can add, delete, edit, and re-order security policies in the sniffer policy list. Sniffer policy order affects policy matching. As with security policies and DoS security policies, sniffer security policies are checked against traffic in the order in which they appear in the sniffer policy list, one at a time, from top to bottom. When a matching policy is discovered, it is used and further checking for sniffer policy matches are stopped. If no match is found the packet is dropped.

Sniffer policy configuration settings

The following are sniffer policy configuration settings in *Policy* > *Policy* > *Sniffer Policy*.

Sniffer Policy page	
Lists each individual sniffer policy that you created. On this page, you can edit, delete and create a new sniffer policy. You can also move a policy or insert a new policy on the page. **Note:** All of the specified attributes must match network traffic to trigger the policy.	
Create New	Creates a new sniffer policy. Select the down arrow beside *Create New* to add a new section to the list to visually group the security policies. When you select *Create New* (or an option from the down arrow's drop-down list), you are automatically redirected to the New Policy page.
Edit	Modifies settings within the sniffer policy. When you select *Edit*, you are automatically redirected to the Edit Sniffer Policy page. You can also edit a sniffer policy by selecting the down arrow beside *Edit* and then selecting *Edit Policy*. If you want to disable or enable a sniffer policy, select the down arrow beside *Edit*, and then select either *Enable* or *Disable*.

Delete	Removes a policy from the list on the Sniffer Policy page. To remove multiple security policies from within the list, on the Sniffer Policy page, in each of the rows of the security policies you want removed, select the check box and then select *Delete*. To remove all security policies from the list, on the Sniffer Policy page, select the check box in the check box column, and then select *Delete*.
Move To	Moves the corresponding policy before or after another policy in the list. When you select *Move To*, the Move Policy window appears. To move a sniffer policy, select the new position *Before* or *After*, which will place the current policy before or after the policy you enter in the field *(Policy ID)*. Enter the policy ID number in the field and then select *OK*.
Insert	Adds a new policy above the corresponding policy (the New Policy screen appears). See "New Policy page" on page 1136.
Filter Settings	Select to filter the information on the page. *Filters* appears automatically after selecting *Filter Settings*, below the column headings. Use to configure filter settings. **Note:** *Filter Settings* configures all filter settings. Filter icons are used to configure filter settings within that column. To apply a filter setting, select the plus sign beside *Add new filter* and then select and enter the information required. Repeat to add other filter settings. To modify settings, select *Change* beside the setting and edit the settings. To clear all filter settings, select the icon beside *Clear all filters*. To use a filter icon to filter settings within a column, select the filter icon in the column; *Filters* appears. Within *Filters*, configure the settings for that column.
Column Settings	Select when you want to Include or remove columns. You can select the columns to hide or display and specify the column displaying order in the table.
Section View	Select to display security policies organized by interface.
Global View	Select to list all security policies in order according to a sequence number.
ID	A unique identifier for each policy. security policies are numbered in the order they are created.
Source	The source address or address group to which the policy applies.
Destination	The destination address or address group to which the policy applies.
Service	The service to which the policy applies.
DoS Sensor	The DoS sensor selected in this policy.

IPS Sensor	The IPS sensor selected in this policy.
Application Control List	The application sensor that is selected in this policy.
Status	When selected, the DoS policy is enabled. Clear the check box to disable the policy.
Interface	The interface used by the policy.
New Policy page Provides settings for configuring a new sniffer policy. When you select *Create New* on the Sniffer Policy page, you are automatically redirected to this page.	
Source Interface/Zone	The interface or zone to be monitored.
Source Address	Select an address, address range, or address group to limit traffic monitoring to network traffic sent from the specified address or range. Select *Multiple* to include multiple addresses or ranges. You can also select *Create New* to add a new address or address group.
Destination Address	Select an address, address range, or address group to limit traffic monitoring to network traffic sent to the specified address or range. Select *Multiple* to include multiple addresses or ranges. You can also select *Create New* to add a new address or address group.
Service	Select a firewall pre-defined service or a custom service to limit traffic monitoring to only the selected service or services. You can also select *Create New* to add a custom service.
DoS sensor	Select and specify a DoS sensor to have the unit apply the sensor to matching network traffic. You can also select *Create New* within the drop-down list to add a new DoS sensor.
Enable IPS	Select an IPS sensor from the drop-down list. You can also select *Create New* within the drop-down list to add a new IPS sensor.
Enable Application Control	Select an application sensor from the drop-down list. You can also select *Create New* within the drop-down list to add a new application sensor.
Enable Antivirus	Select an antivirus profile from the drop-down list. You can also select *Create New* within the drop-down list to add a new antivirus profile.
Enable Web Filter	Select a web filter profile from the drop-down list. You can also select *Create New* within the drop-down list to add a new web filter profile.
Enable DLP sensor	Select a DLP sensor from the drop-down list. You can also select *Create New* within the drop-down list to add a new DLP sensor.

Other UTM considerations

The following topics are included in this section:

UTM and Virtual domains (VDOMs)

If you enable virtual domains (VDOMs) on your FortiGate unit, all UTM configuration is limited to the VDOM in which you configure it.

While configuration is not shared, the various databases used by UTM features are shared. The FortiGuard antivirus and IPS databases and database updates are shared. The FortiGuard web filter and spam filter features contact the FortiGuard distribution network and access the same information when checking email for spam and web site categories and classification.

Conserve mode

FortiGate units perform all UTM processing in physical RAM. Since each model has a limited amount of memory, conserve mode is activated when the remaining free memory is nearly exhausted or the AV proxy has reached the maximum number of sessions it can service. While conserve mode is active, the AV proxy does not accept new sessions.

The AV proxy

Most content inspection the FortiGate unit performs requires that the files, email messages, URLs, and web pages be buffered and examined as a whole. The AV proxy performs this function, and because it may be buffering many files at the same time, it uses a significant amount of memory. Conserve mode is designed to prevent all the component features of the FortiGate unit from trying to use more memory than it has. Because the AV proxy uses so much memory, conserve mode effectively disables it in most circumstances. As a result, the content inspection features that use the AV proxy are also disabled in conserve mode.

All of the UTM features use the AV proxy with the exception of IPS, application control, DoS as well as flow-based antivirus, DLP, and web filter scanning. These features continue to operate normally when the FortiGate unit enters conserve mode.

Entering and exiting conserve mode

A FortiGate unit will enter conserve mode because it is nearly out of physical memory, or because the AV proxy has reached the maximum number of sessions it can service. The memory threshold that triggers conserve mode varies by model, but it is about 20% free memory. When memory use rises to the point where less than 20% of the physical memory is free, the FortiGate unit enters conserve mode.

The FortiGate unit will leave conserve mode only when the available physical memory exceeds about 30%. When exiting conserve mode, all new sessions configured to be scanned with features requiring the AV proxy will be scanned as normal, with the exception of a unit configured with the one-shot option.

Conserve mode effects

What happens when the FortiGate unit enters conserve mode depends on how you have `av-failopen` configured. There are four options:

off

The off setting forces the FortiGate unit to stop all traffic that is configured for content inspection by UTM features that use the AV proxy. New sessions are not allowed but current sessions continue to be processed normally unless they request more memory. Sessions requesting more memory are terminated.

For example, if a security policy is configured to use antivirus scanning, the traffic it permits is blocked while in conserve mode. A policy with IPS scanning enabled continues as normal. A policy with both IPS and antivirus scanning is blocked because antivirus scanning requires the AV proxy.

Use the off setting when security is more important than a loss of access while the problem is rectified.

pass

The pass setting allows traffic to bypass the AV proxy and continue to its destination. Since the traffic is bypassing the proxy, no UTM scanning that requires the AV proxy is performed. UTM scanning that does not require the AV proxy continues normally.

Use the pass setting when access is more important than security while the problem is rectified.

Pass is the default setting.

one-shot

The one-shot setting is similar to pass in that traffic is allowed when conserve mode is active. The difference is that a system configured for one-shot will force new sessions to bypass the AV proxy even after it leaves conserve mode. The FortiGate unit resumes use of the AV proxy only when the `av-failopen` setting is changed or the unit is restarted.

idledrop

The idledrop setting will recover memory and session space by terminating all the sessions associated with the host that has the most sessions open. The FortiGate may force this session termination a number of times, until enough memory is available to allow it to leave conserve mode.

The idledrop setting is primarily designed for situations in which malware may continue to open sessions until the AV proxy cannot accept more new sessions, triggering conserve mode. If your FortiGate unit is operating near capacity, this setting could cause the termination of valid sessions. Use this option with caution.

Configuring the av-failopen command

You can configure the av-failopen command using the CLI.

```
config system global
  set av-failopen {off | pass | one-shot | idledrop}
end
```

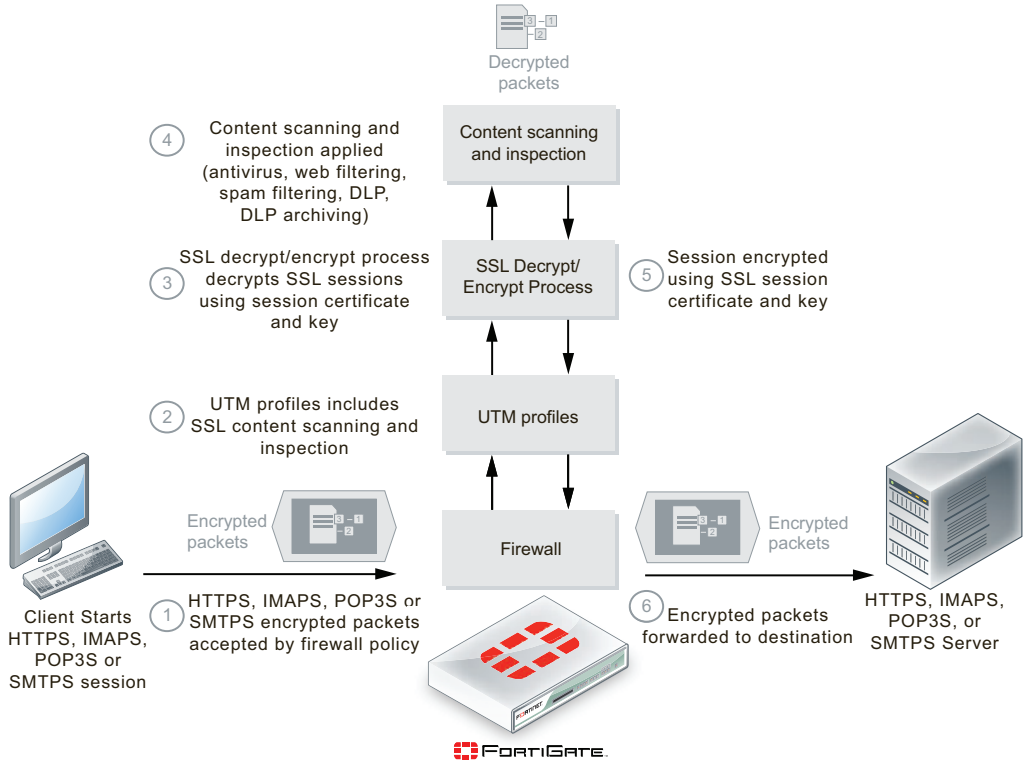
The default setting is pass.

SSL content scanning and inspection

If your FortiGate model supports SSL content scanning and inspection, you can apply antivirus scanning, web filtering, FortiGuard Web Filtering, and email filtering to encrypted traffic. You can also apply DLP and DLP archiving to HTTPS, IMAPS, POP3S, and SMTPS traffic. To perform SSL content scanning and inspection, the FortiGate unit does the following:

- intercepts and decrypts HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions between clients and servers (FortiGate SSL acceleration speeds up decryption)
- applies content inspection to decrypted content, including:
  - HTTPS, IMAPS, POP3S, and SMTPS Antivirus, DLP, and DLP archiving
  - HTTPS web filtering and FortiGuard web filtering
  - IMAPS, POP3S, and SMTPS email filtering
- encrypts the sessions and forwards them to their destinations.

Figure 102: FortiGate SSL content scanning and inspection packet flow



Setting up certificates to avoid client warnings

To use SSL content scanning and inspection, you need to set up and use a certificate that supports it. FortiGate SSL content scanning and inspection intercepts the SSL keys that are passed between clients and servers during SSL session handshakes and then substitutes spoofed keys. Two encrypted SSL sessions are set up, one between the client and the FortiGate unit, and a second one between the FortiGate unit and the server. Inside the FortiGate unit the packets are decrypted.

While the SSL sessions are being set up, the client and server communicate in clear text to exchange SSL session keys. The session keys are based on the client and server certificates. The FortiGate SSL decrypt/encrypt process intercepts these keys and uses a built-in signing CA certificate named Fortinet_CA_SSLProxy to create keys to send to the client and the server. This signing CA certificate is used only by the SSL decrypt/encrypt process. The SSL decrypt/encrypt process then sets up encrypted SSL sessions with the client and server and uses these keys to decrypt the SSL traffic to apply content scanning and inspection.

Some client programs (for example, web browsers) can detect this key replacement and will display a security warning message. The traffic is still encrypted and secure, but the security warning indicates that a key substitution has occurred.

You can stop these security warnings by importing the signing CA certificate used by the server into the FortiGate unit SSL content scanning and inspection configuration. Then the FortiGate unit creates keys that appear to come from the server and not the FortiGate unit.

You can add one signing CA certificate for SSL content scanning and inspection. The CA certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported for SSL content scanning and encryption.

You can replace the default signing CA certificate, Fortinet_CA_SSLProxy, with another signing CA certificate. To do this, you need the signing CA certificate file, the CA certificate key file, and the CA certificate password.

All SSL content scanning and inspection uses the same signing CA certificate. If your FortiGate unit is operating with virtual domains enabled, the same signing CA certificate is used by all virtual domains.

To add a signing CA certificate for SSL content scanning and inspection

1 Obtain a copy of the signing CA certificate file, the CA certificate key file, and the password for the CA certificate.

2 Go to *System* > *Certificates* > *Local Certificates* and select *Import*.

3 Set *Type* to *Certificate*.

4 For *Certificate file,* use the *Browse* button to select the signing CA certificate file.

5 For *Key file,* use the *Browse* button to select the CA certificate key file.

6 Enter the CA certificate *Password*.

7 Select *OK*.

The CA certificate is added to the *Local Certificates* list. In this example the signing CA certificate name is Example_CA. This name comes from the certificate file and key file name. If you want the certificate to have a different name, change these file names.

8 Add the imported signing CA certificate to the SSL content scanning and inspection configuration. Use the following CLI command if the certificate name is Example_CA.

```
config firewall ssl setting
  set caname Example_CA
end
```

The Example_CA signing CA certificate will now be used by SSL content scanning and inspection for establishing encrypted SSL sessions.

SSL content scanning and inspection settings

If SSL content scanning and inspection is available on your FortiGate unit, you can configure SSL settings. The following table provides an overview of the options available and where to find further instruction:

Table 74: SSL content scanning and inspection settings

Setting	Description
Predefined firewall services	The IMAPS, POP3S and SMTPS predefined services. You can select these services in a security policy and a DoS policy.

Table 74: SSL content scanning and inspection settings (Continued)

Setting	Description
Protocol recognition	The TCP port numbers that the FortiGate unit inspects for HTTPS, IMAPS, POP3S, and SMTPS. Go to *Policy* > *Policy* > *Protocol Options*. Add or edit a protocol options profile, configure HTTPS, IMAPS, POP3S, SMTPS, and FTPS. Using *Protocol Options*, you can also configure the FortiGate unit to perform URL filtering of HTTPS or to use SSL content scanning and inspection to decrypt HTTPS so that the FortiGate unit can also apply antivirus and DLP content inspection and DLP archiving to HTTPS. Using SSL content scanning and inspection to decrypt HTTPS also allows you to apply more web filtering and FortiGuard Web Filtering options to HTTPS. To enable full SSL content scanning of web filtering, select *Enable Deep Scanning* under HTTPS in the protocol options profile.
Antivirus	Antivirus options including virus scanning and file filtering for HTTPS, IMAPS, POP3S, and SMTPS. Go to *UTM AntiVirus* > *Profile*. Add or edit a profile and configure *Virus Scan* for HTTPS, IMAPS, POP3S, and SMTPS.
Antivirus quarantine	Antivirus quarantine options to quarantine files in HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions. Go to *UTM Profiles* > *AntiVirus* > *Quarantine*. You can quarantine infected files, suspicious files, and blocked files found in HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions.
Web filtering	Web filtering options for HTTPS: • Web Content Filter • Web URL Filter • ActiveX Filter • Cookie Filter • Java Applet Filter • Web Resume Download Block • Block invalid URLs Go to *UTM Profiles* > *Web Filter* > *Profile*. Add or edit a web filter profile and configure web filtering for HTTPS.

Table 74: SSL content scanning and inspection settings (Continued)

Setting	Description
FortiGuard Web Filtering	FortiGuard Web Filtering options for HTTPS: • Enable FortiGuard Web Filtering • Enable FortiGuard Web Filtering Overrides • Provide Details for Blocked HTTP 4xx and 5xx Errors • Rate Images by URL (Blocked images will be replaced with blanks) • Allow Websites When a Rating Error Occurs • Strict Blocking • Rate URLs by Domain and IP Address • Block HTTP Redirects by Rating Go to *UTM Profiles* > *Web Filter* > *Profile*. Add or edit a profile and configure FortiGuard Web Filtering for HTTPS.
Email filtering	Email filtering options for IMAPS, POP3S, and SMTPS: • FortiGuard Email Filtering IP Address Check, URL check, E-mail Checksum Check, and Spam Submission • IP Address BWL Check • E-mail Address BWL Check • Return S-mail DNS Check • Banned Word Check • Spam Action • Tag Location • Tag Format Go to *UTM Profiles* > *Email Filter* > *Profile*. Add or edit a profile and configure email filtering for IMAPS, POP3S, and SMTPS.
Data Leak Prevention	DLP for HTTPS, IMAPS, POP3S, and SMTPS. To apply DLP, follow the steps below: • Go to *UTM Profiles* > *Data Leak Prevention* > *Sensor,* create a new DLP sensor or edit an existing one and then add any combination of the DLP advanced rules, DLP compound rules, file filters, a Regular Expressions, and file size limits to a DLP sensor. • Go to *Policy* > *Policy* > *Protocol Options*. Add or edit a profile and select *Enable Deep Scan* under HTTPS. • Go to *Policy* > *Policy* > *Policy*, edit the required policy, enable UTM, select *Enable DLP Sensor* and select the DLP sensor. • Go to *Policy* > *Policy* > *Policy*, edit the required policy, enable *Protocol Options* and select a profile that has *Enable Deep Scan* selected under HTTPS. **Note**: If no protocol options profile is selected, or if *Enable Deep Scan* is not selected within the protocol options profile, DLP rules ***cannot*** inspect HTTPS.
DLP archiving	DLP archiving for HTTPS, IMAPS, POP3S, and SMTPS. Add DLP Rules for the protocol to be archived.

Table 74: SSL content scanning and inspection settings (Continued)

Setting	Description
Monitor DLP content information on the system dashboard	DLP archive information on the Log and Archive Statistics widget on the system dashboard for HTTPS, IMAPS, POP3S, and SMTPS. Go to *Policy* > *Policy* > *Protocol Options.* Add or edit a profile. For each protocol you want monitored on the dashboard, enable *Monitor Content Information for Dashboard*. These options display meta-information on the Statistics dashboard widget.

Viewing and saving logged packets

The FortiGate unit supports packet logging for IPS and application control. The packets that trigger a signature match for IPS or application recognition for application control are saved for later viewing when packet logging is enabled.

For information on how to enable packet logging, see "Enable IPS packet logging" on page 967 and "Application control packet logging" on page 1070.

Once the FortiGate unit has logged packets, you can view or save them.

To view and save logged packets

1 Go to *Log&Report* > *Log Access* > *Attack*.

2 Depending on where the logs are configured to be stored, select the appropriate option:

Memory	Select if logs are stored in the FortiGate unit memory.
Disk	Select if the FortiGate unit has an internal hard disk and logs are stored there.
Remote	Select if logs are sent to a FortiAnalyzer unit or to the FortiGuard Analysis and Management Service.

3 Select the *Packet Log* icon of the log entry you want to view.

The *IPS Packet Log Viewer* window appears.

4 Select the packet to view the packet in binary and ASCII. Each table row represents a captured packet.

5 Select *Save* to save the packet data in a PCAP formatted file.

PCAP files can be opened and examined in network analysis software such as Wireshark.

Configuring packet logging options

You can use a number of CLI commands to further configure packet logging.

Limiting memory use

When logging to memory, you can define the maximum amount of memory used to store logged packets.

```
config ips settings
  set packet-log-memory 256
end
```

The acceptable range is from 64 to 8192 kilobytes. This command affects only logging to memory.

Limiting disk use

When logging to the FortiGate unit internal hard disk, you can define the maximum amount of space used to store logged packets.

```
config ips settings
  set ips-packet-quota 256
end
```

The acceptable range is from 0 to 4294967295 megabytes. This command affects only logging to disk.

Configuring how many packets are captured

Since the packet containing the signature is sometimes not sufficient to troubleshoot a problem, you can specify how many packets are captured before and after the packet containing the IPS signature match.

```
config ips settings
  packet-log-history
  packet-log-post-attack
end
```

The `packet-log-history` command specifies how many packets are captured before and including the one in which the IPS signature is detected. If the value is more than `1`, the packet containing the signature is saved in the packet log, as well as those preceding it, with the total number of logged packets equalling the `packet-log-history` setting. For example, if `packet-log-history` is set to `7`, the FortiGate unit will save the packet containing the IPS signature match and the six before it.

The acceptable range for `packet-log-history` is from 1 to 255. The default is 1.

Setting `packet-log-history` to a value larger than `1` can affect the performance of the FortiGate unit because network traffic must be buffered. The performance penalty depends on the model, the setting, and the traffic load.

The `packet-log-post-attack` command specifies how many packets are logged after the one in which the IPS signature is detected. For example, if `packet-log-post-attack` is set to `10`, the FortiGate unit will save the ten packets following the one containing the IPS signature match.

The acceptable range for `packet-log-post-attack` is from 0 to 255. The default is 0.

Using wildcards and Perl regular expressions

Many UTM feature list entries can include wildcards or Perl regular expressions.

For more information about using Perl regular expressions, see http://perldoc.perl.org/perlretut.html.

Regular expression vs. wildcard match pattern

A wildcard character is a special character that represents one or more other characters. The most commonly used wildcard characters are the asterisk (*), which typically represents zero or more characters in a string of characters, and the question mark (?), which typically represents any one character.

In Perl regular expressions, the '.' character refers to any single character. It is similar to the '?' character in wildcard match pattern. As a result:

- example.com not only matches example.com but also examplea.com, exampleb.com, examplec.com, and so on.

To add a question mark (?) character to a regular expression from the FortiGate CLI, enter Ctrl+V followed by ?. To add a single backslash character (\) to a regular expression from the CLI you must add precede it with another backslash character. For example, `example\\.com`.

To match a special character such as '.' and '*' use the escape character '\'. For example:

- To match example.com, the regular expression should be: example\.com

In Perl regular expressions, '*' means match 0 or more times of the character before it, not 0 or more times of any character. For example:

- exam*.com matches exammmm.com but does not match example.com

To match any character 0 or more times, use '.*' where '.' means any character and the '*' means 0 or more times. For example, the wildcard match pattern exam*.com should therefore be exam.*\.com.

Word boundary

In Perl regular expressions, the pattern does not have an implicit word boundary. For example, the regular expression "test" not only matches the word "test" but also any word that contains "test" such as "atest", "mytest", "testimony", "atestb". The notation "\b" specifies the word boundary. To match exactly the word "test", the expression should be \btest\b.

Case sensitivity

Regular expression pattern matching is case sensitive in the web and Email Filter filters. To make a word or phrase case insensitive, use the regular expression `/i`. For example, `/bad language/i` will block all instances of "bad language", regardless of case.

Perl regular expression formats

Table 75 lists and describes some example Perl regular expressions.

Table 75: Perl regular expression formats

Expression	Matches
abc	"abc" (the exact character sequence, but anywhere in the string)
^abc	"abc" at the beginning of the string
abc$	"abc" at the end of the string
a|b	Either "a" or "b"
^abc|abc$	The string "abc" at the beginning or at the end of the string
ab{2,4}c	"a" followed by two, three or four "b"s followed by a "c"
ab{2,}c	"a" followed by at least two "b"s followed by a "c"
ab*c	"a" followed by any number (zero or more) of "b"s followed by a "c"
ab+c	"a" followed by one or more b's followed by a c

Table 75: Perl regular expression formats (Continued)

ab?c	“a” followed by an optional “b” followed by a” c”; that is, either “abc” or ”ac”
a.c	“a” followed by any single character (not newline) followed by a” c “
a\.c	“a.c” exactly
[abc]	Any one of “a”, “b” and “c”
[Aa]bc	Either of “Abc” and “abc”
[abc]+	Any (nonempty) string of “a”s, “b”s and “c”s (such as “a”, “abba”, ”acbabcacaa”)
[^abc]+	Any (nonempty) string which does not contain any of “a”, “b”, and “c” (such as “defg”)
`\d\d`	Any two decimal digits, such as 42; same as \d{2}
/i	Makes the pattern case insensitive. For example, `/bad language/i` blocks any instance of `bad language` regardless of case.
`\w+`	A “word”: A nonempty sequence of alphanumeric characters and low lines (underscores), such as foo and 12bar8 and foo_1
100\s*mk	The strings “100” and “mk” optionally separated by any amount of white space (spaces, tabs, newlines)
abc\b	“abc” when followed by a word boundary (for example, in “abc!” but not in “abcd”)
perl\B	“perl” when not followed by a word boundary (for example, in “perlert” but not in “perl stuff”)
\x	Tells the regular expression parser to ignore white space that is neither preceded by a backslash character nor within a character class. Use this to break up a regular expression into (slightly) more readable parts.
/x	Used to add regular expressions within other text. If the first character in a pattern is forward slash '/', the '/' is treated as the delimiter. The pattern must contain a second '/'. The pattern between ‘/’ will be taken as a regular expressions, and anything after the second ‘/’ will be parsed as a list of regular expression options ('i', 'x', etc). An error occurs if the second '/' is missing. In regular expressions, the leading and trailing space is treated as part of the regular expression.

Examples of regular expressions

Block any word in a phrase

```
/block|any|word/
```

Block purposely misspelled words

Spammers often insert other characters between the letters of a word to fool spam blocking software.

```
/^.*v.*i.*a.*g.*r.*o.*$/i
```

```
/cr[eéèêë][\+\-\*=<>\.\,;!\?%&§@\^°\$£€\{\}()\[\]\|\\_01]dit/i
```

Block common spam phrases

The following phrases are some examples of common phrases found in spam messages.

```
/try it for free/i
/student loans/i
/you're already approved/i
/special[\+\-\*=<>\.\,;!\?%&~#$@\^°\$£€\{\}()\[\]\|\\_1]offer/i
```

Protocol Options interface reference

The Protocol Options menu allows you to configure settings for specific protocols, which are grouped together in a protocol group, and then applied to a security policy. The default groups are scan, strict, unfiltered, and web.

Protocol options configuration settings

The following are protocol option configuration settings in *Policy* > *Policy* > *Protocol Options*.

Protocol Options page	
Lists each individual protocol setting that you created. On this page, you can edit, delete or create a new group of protocol settings. **Note:** If you want to provide information about any of the protocols, select the check box beside *Monitor Content Information for Dashboard*, which is available within each protocol section.	
Create New	Creates a new protocol option. When you select *Create New*, you are automatically redirected to the Protocol Options Settings page.
Edit	Modifies settings to a protocol setting. When you select *Edit*, you are automatically redirected to the Protocol Options page.
Delete	Removes a protocol setting from the list on the Protocol Options page. To remove multiple protocol settings from within the list, on the Protocol Options page, in each of the rows of the policies you want removed, select the check box and then select *Delete*. To remove all protocol options from the list, on the Protocol Options page, select the check box in the check box column, and then select *Delete*.
Name	The name of the protocol group. This group is the group you select when applying it to a security policy.
Comments	Describes the protocol group.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM Profiles* > *Antivirus* > *Profile*), 1 appears in *Ref.*. To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when the icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
Protocol Options Settings page Provides settings for configuring options for each protocol which make up a protocol group. **Note:** There are similar settings within each protocol setting.	
Name	Enter a name for the protocol group.
Comments	Enter a description about the protocol group. This is optional.
Enable Oversized File Log	Select to allow logging of oversized files.
Enable Invalid Certificate Log	Select to allow logging of invalid certificates.
HTTP section	Configure settings for the HTTP protocol or the HTTPS protocol.
Port (i.e. 80,88, 0-auto)	This is available for every protocol except for IM.
Comfort Clients	This is available only for HTTP, FTP, and HTTPS. • **Interval (1-900 seconds)** – enter the interval time in seconds. • **Amount (1-10240 bytes)** – enter the amount in btyes.
Oversized File/Email	This is available for all protocols. • **Threshold –** enter the threshold amount for an oversized email message or file in MB.

Monitor Content Information for Dashboard	Select to view the activity of the protocol from the Dashboard menu.
Enable Chunked Bypass	Select to enable the chunked bypass setting.
FTP section	Configure settings for the file transfer protocol. *FTP* and *HTTP* contain the same settings, except the FTP section does not contain the option *Enable Chunked Bypass*.
FTPS section	Configure settings for the FTPS protocol. FTPS is an extension of the FTP protocol, adding support for both the TLS and SSL cryptographic protocols. This section contains the same settings as in the *FTP* section.
IMAP section	Configure settings for the IMAP protocol.
Allow Fragmented Messages	Allows fragmented email messages to be passed.
POP3 section	Configure settings for the POP3 protocol. This section contains the same settings as are in the IMAP section.
SMTP section	Configure settings for the SMTP section.
Append Email Signature	Select to enable the option of entering a new email signature that appears in the email message.
Email Signature Text	Enter a signature for the email message, for example, Yours sincerely. Accessible only when Append Email Signature is selected.
IM section	Configure settings for the IM protocol.
NNTP section	Configure settings for the NTTP protocol.
HTTPS section	Configure settings for the HTTPS protocol.
Allow Invalid SSL Certificate	Select to allow invalid SSL certificates.
Enable Deep Scanning	Select to allow deep scanning.
IMAPS	Configure settings for the IMAPS protocol.
POP3S	Configure settings for the POP3S protocol. This section contains the same settings as *IMAPS*.
SMTPS	Configure settings for the SMTPS protocol. This section contains the same settings as *IMAPS* and *POP3S*.

ICAP interface reference

The Internet Content Adaption Protocol (ICAP) is supported on the unit. ICAP is a light-weight response/request protocol that allows you to offload specific filtering features, such as virus scanning and content filtering, to dedicated ICAP servers.

ICAP does not appear by default in the web-based manager. You must enable it in *System* > *Admin* > *Settings* to display ICAP in the web-based manager.

In an ICAP configuration with the unit, the unit is the surrogate or “middle-man” and carries the ICAP responses from the ICAP server to the ICAP client. The ICAP client then responds back, and the unit determines the action that should be taken with these responses and requests.

An ICAP profile must be configured and then applied to a firewall policy for this feature to work. The ICAP server or servers must also be configured. The ICAP servers are applied within the ICAP profile.

This topic contains the following:

ICAP profile

The following are ICAP profile configuration settings in *UTM Profiles* > *ICAP* > *Profile*.

ICAP Profile page	
Lists each ICAP profile that you created. On this page, you can edit, delete and create a new ICAP profiles.	
Create New	Creates a new ICAP profile. When you select *Create New*, you are automatically redirected to the New ICAP Profile page.
Edit	Modifies settings within an ICAP profile. When you select *Edit*, you are automatically redirected to the Edit ICAP Profile page.
Delete	Removes the profile from within the list on the page.
Name	The name of the ICAP profile.
Request Processing	The status of the process for requests. A gray x appears if there is no request processing settings enabled and configured. A green check mark appears if request processing settings are enabled and configured.
Response Processing	The status of the process for responses. A gray x appears if there is no response processing settings enabled and configured. A green check mark appears if response processing settings are enabled and configured.
Bypass Streaming Media	The status of whether bypass streaming media is enabled or disabled. A gray x appears if bypass streaming media is disabled. A green check mark appears if bypass streaming media is enabled.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a firewall policy; on the Profile page (*UTM Profiles* > *Antivirus* > *Profile*), 1 appears in *Ref.*. To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy, and that firewall policy's settings appear within the table.
New ICAP Profile page Provides settings for configuring the ICAP profiles. **Note:** Logging is enabled in the CLI.	
Name	Enter the name of the new ICAP profile.
Enable Request Processing	Select to enable how the request from an ICAP server will be processed by the unit.
Server	Select the ICAP server from the drop-down list. An ICAP server must be configured before you can configure an ICAP profile. See "ICAP server" on page 1153.
Path	Enter the path name.
On Failure	Select either *Error* or *Bypass*. This instructs the unit on which action to take if a failure occurs.
Enable Response Processing	Select to enable how the response from an ICAP server will be processed by the unit.
Server	Select the ICAP server from the drop-down list. An ICAP server must be configured before you can configure an ICAP profile. See "ICAP server" on page 1153.
Path	Enter the path name.
On Failure	Select either *Error* or *Bypass*. This instructs the unit on which action to take if a failure occurs.
Enable Streaming Media Bypass	Select to enable streaming media bypass.

ICAP server

The following are ICAP server configuration settings in *UTM Profiles* > *ICAP* > *Server*.

ICAP Server page	
Lists each ICAP profile that you created. On this page, you can edit, delete and create a new ICAP profiles.	
Create New	Adds an ICAP server. When you select *Create New*, you are automatically redirected to the New ICAP Server page.
Edit	Modifies settings within an ICAP server configuration. When you select *Edit*, you are automatically redirected to the Edit ICAP Profile page.
Delete	Removes the profile from within the list on the page.
Name	The name of the ICAP profile.
Address	The IP address of the ICAP server.
Port	The port number used by the ICAP server.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a firewall policy; on the Profile page (*UTM Profiles* > *Antivirus* > *Profile*), 1 appears in *Ref.*. To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy, and that firewall policy's settings appear within the table.
New ICAP Server page	
Provides settings for configuring the profiles. **Note:** Logging is enabled in the CLI.	
Name	Enter the name of the new ICAP profile.
IP Type	Enter the type of IP address the ICAP server uses, either IPv4 or IPv6.

IP Address	Enter the IP address of the ICAP server.
Port	Enter the port that the ICAP server uses.

Profile Group interface reference

A profile group is a group of UTM features that include MMS profiles and replacement message groups. You can configure multiple profile groups, which are then applied to a firewall policy. This provides an easier way to apply multiple profiles and sensors to a firewall policy.

Profile Group configuration settings

The following are profile group configuration settings. If you are running FortiOS Carrier, these configuration settings are in *UTM Profiles* > *Carrier* > *Profile Group*; however, if you are running FortiOS, these configuration settings are in *UTM Profiles* > *Profile Group* > *Profile Group*.

Profile Group page	
Lists all the profile groups that you have created. On this page, you can edit, delete or create a new profile group.	
Create New	Creates a new profile group. When you select *Create New*, you are automatically redirected to the New Profile Group page.
Edit	Modifies a profile group's settings. When you select *Edit*, you are automatically redirected to the Edit Profile Group page.
Delete	Removes a profile group from the list. To remove multiple profile groups from within the list, on the Profile Group page, in each of the rows of the groups you want removed, select the check box and then select *Delete*. To remove all profile groups from the list, on the Profile Group page, select the check box in the check box column and then select *Delete*.
Name	The name of the profile group.
New Profile Group page	
Provides settings for configuring a profile group. You must configure UTM features prior to configuring a profile group because profile groups require these UTM features. If you want to include a replacement message group, that group must also be configured prior to configuring a profile group. You cannot configure a UTM feature or replacement group from the New Profile Group page.	
Name	Enter a name for the profile group.
Protocol Options	Select the check box to enable this option and then select a protocol option from the drop-down list. Protocol options are configured in *Firewall* > *Policy* > *Protocol Options*.
Enable Antivirus	Select the check box to enable this option and then select an antivirus profile from the drop-down list. Antivirus profiles are configured in *UTM Profiles* > *Antivirus* > *Profile*.

Enable IPS	Select the check box to enable this option and then select the IPS sensor from the drop-down list. IPS sensors are configured in *UTM Profiles* > *Intrusion Protection* > *IPS Sensor*.
Enable Web Filter	Select the check box to enable this option and then select the web filter profile from the drop-down list. Web filter profiles are configured in *UTM Profiles* > *Web Filter* > *Profile*.
Enable Email Filter	Select the check box to enable this option and then select the email filter profile from the drop-down list. Email filter profiles are configured in *UTM Profiles* > *Email Filter* > *Profile*.
Enable DLP Sensor	Select the check box to enable this option and then select the DLP sensor from the drop-down list. DLP sensors are configured in *UTM Profiles* > *Data Leak Prevention* > *Sensors*.
Enable Application Control	Select the check box to enable this option and then select the application control list from the drop-down list. Application control lists are configured in *UTM Profiles* > *Application Control* > *Application Control Lists*.
Enable VoIP	Select the check box to enable this option and then select the VoIP profile from the drop-down list. VoIP profiles are configured in *UTM Profiles* > *VoIP* > *Profile*.
Enable MMS Profile	Select the check box to enable this option and then select the MMS profile from the drop-down list. MMS profiles are configured in *UTM Profiles* > *Carrier* > *MMS Profile*.
Enable Replacement Message Group	Select the check box to enable this option and then select the replacement message group from the drop-down list. Replacement message groups are configured in *System* > *Config* > *Replacement Message Group*.

Monitor interface reference

The Monitor submenus allow you to view the UTM activity occurring on your network. You must have UTM profiles and sensors applied to firewall policies, as well as logging enabled for the profiles and sensors, for the monitors to display any information regarding this activity.

This topic contains the following:

AV Monitor

The AV Monitor submenu allows you to view statistical information regarding viruses that were detected on your unit from *UTM Profiles* > *Monitor* > *AV Monitor*. The information displays in a bar chart as well as in a table below the bar chart. The table contains detailed information.

You must have antivirus logging enabled for this within the profile itself, as well as within log settings and an antivirus profile is applied to a firewall policy.

AV Monitor page	
Displays monitored information about viruses that were detected by the unit. **Tip:** To view information about a specific virus, select a bar within the chart; the virus FortiGuard definition displays.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Top Viruses (all policies) since <yyyy-mm-dd hh:mm:ss>	The top viruses detected by the unit using all firewall policies.
#	The order that the viruses are listed in the table.
Virus Name	The name of the virus.
Last Detected	The last time that the virus was detected.
Count	The number of times the virus has been detected.

Intrusion Monitor

The Intrusion Monitor submenu allows you to view statistical information regarding attacks that were detected on your unit from *UTM Profiles* > *Monitor* > *Intrusion Monitor*. The information displays in a bar chart as well as in a table below the bar chart. The table contains detailed information.

Intrusion Monitor page	
Displays monitored information about attacks that were detected by the unit. **Tip:** To view information about a specific attack, select a bar within the chart; the attack FortiGuard definition displays.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Top Attacks (all policies) since <yyyy-mm-dd hh:mm:ss>	A bar chart displaying the top attacks detected by the unit.

#	The order that the attacks are listed in the table.
Attack Name	The name of the attack.
Last Detected	The last time that the attack was detected.
Count	The number of times the attack has been detected.

Web Monitor

The Web Monitor submenu allows you to view statistical information regarding the web activity from *UTM Profiles* > *Monitor* > *Web Monitor*. The information displays in both a pie chart and a bar chart

Web Monitor page Displays monitored information about web activity detected by the unit.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Report By	Select whether to view the web filter monitored information by web filter technique or by FortiGuard web filter category. If you choose FortiGuard web filter category, you are viewing the information that was gathered from the category settings for FortiGuard web filter from the web filter profile.
Web Monitor since <yyyy-mm-dd hh:mm:ss>	
Total Requests (HTTP)	A pie chart representing the total requests detected.
Blocked Requests (HTTP)	A bar chart representing the total blocked requests detected. The information is broken down to spam, banned words, file filter, viruses, archives, FortiGuard, URL filter, and fragmented.
Total Web Requests (HTTP): <number>	The total number of web requests over HTTP that occurred.

Email Monitor

The Email Monitor submenu allows you to view statistical information regarding email filtering from *UTM Profiles* > *Monitor* > *Email Monitor*. The information displays in both a pie chart and bar chart.

Email Monitor page Displays monitored information about email filter activity detected by the unit.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Total Emails	A pie chart representing the total number of emails scanned by the unit.

Blocked Emails	A bar chart representing the total number of blocked emails, broken down by protocol. The colors indicate the type of scanning that occurred.
Total Emails: <number>	The total number of email messages detected by the unit.

Archive & Data Leak Monitor

The Archive & Data Leak Monitor submenu allows you to view statistical information regarding log archives, as well as DLP usage. This page displays the information in a bar chart in *UTM Profiles* > *Monitor* > *Archive & Data Leak Monitor*.

Archive & Data Leak Monitor page	
Displays monitored information about archive and DLP activity detected by the unit.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Report By:	Select what type of DLP information you want to view. You can view DLP usage by DLP sensor, firewall policy usage, or by protocol.
Top DLP Usage by DLP Sensor <yyyy-mm-dd hh:mm:ss>	The bar chart that displays DLP usage monitored using DLP sensor information.
Top DLP Usage by Policy <yyyy-mm-dd hh:mm:ss>	The bar chart that displays DLP usage monitored using firewall policy traffic information.
Top DLP Usage by Protocol <yyyy-mm-dd hh:mm:ss>	The bar chart that displays DLP usage monitored using protocol information.
Total Dropped Archives: <number>	The total number of dropped DLP archives.

Application Monitor

The Application Monitor submenu allows you to view statistical information regarding application usage in *UTM Profiles* > *Monitor* > *Application Monitor*.

Application Monitor page	
Displays monitored information about the application usage detected by the unit. **Tip:** To view top source IP addresses for a specific application, select a bar in the chart to view that application's source IP addresses.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.

Top Application Usage by <yyyy-mm-dd hh:mm:ss>	The bar chart that displays the top applications being used detected by the unit.
Resolve Host Name	Appears after selecting a bar for a specific application, for example SSL. Select to resolve the host name. **Tip:** Hover your mouse over the bar to view the address and total MB (or KB) used for that application.
Report By:	Appears after selecting a bar for a specific application, for example, SSL. Select to view the detailed information by destination address, or source address.
Display User Name	Appears after selecting *Source Address* from the drop-down list beside *Report By*. Select to display user names.

FortiGuard Quota

The FortiGuard Quota submenu allows you to view statistical information regarding quota usage by users in *UTM Profiles* > *Monitor* > *FortiGuard Quota*.

FortiGuard Quota page	
Lists the users and the amount of quota that they have used.	
Page Controls	Use to navigate through the list.
User Name	The user name of the user that has FortiGuard quota enabled for them.
Webfilter Profile	The web filter profile that was used for detecting users' FortiGuard quota usage.
Used Quota	The amount of used quota by a user.

Endpoint Monitor

You can view monitored endpoints in *UTM Profiles* > *Monitor* > *Endpoint Monitor*. An endpoint is added to the list when it uses a security policy that has *Endpoint Security* enabled.

Endpoint Monitor page	
Provides information about endpoints, such as endpoint traffic. Note: The pie chart displays information in percent and indicates which is non-compliant and which is compliant.	
Refresh	Updates the list, providing current endpoints that are being monitored.
Report By	Select to view endpoint information by traffic, status or application usage. When you select *Status*, a pie chart appears along with information about the total endpoints (*Total Endpoints*). When you select *Traffic* or *Application usage*, a bar chart appears; select a bar to view detailed information.

Chapter 7 User Authentication

This FortiOS Handbook chapter contains the following sections:

Introduction to authentication describes some basic elements and concepts of authentication.

Authentication and User in the web-based manager describes the web-based manager interface of FortiOS, specifically the Authentication and User top level menu items.

Authentication servers describes external authentication servers, where a FortiGate unit fits into the topology, and how to configure a FortiGate unit to work with that type of authentication server.

Dynamic profiles and end points describes how to set up dynamic profiles and carrier end points to identify users that are using RADIUS settings. Some parts are specific to FortiOS Carrier.

Users and user groups describes the different types of user accounts and user groups. Authenticated access to resources is based on user identities and user group membership. Two-factor authentication methods, including FortiToken, provide additional security.

Configuring authenticated access provides detailed procedures for setting up authenticated access in security policies and authenticated access to VPNs.

FSSO integration with Windows AD or Novell describes how to install and configure the Fortinet Single Sign On (FSSO) on Windows AD or Novell network domain controllers and the FortiGate unit. With FSSO, network users have single sign-on access to resources through the FortiGate unit. Earlier versions of FSSO were called FSAE.

Certificate-based authentication describes authentication by means of X.509 certificates.

Monitoring authenticated users describes FortiOS authenticated user monitor screens.

Examples and Troubleshooting provides a configuration example and troubleshooting in which Windows AD and other network users are provided authenticated access to the Internet.

Introduction to authentication

Identifying users and other computers—authentication—is a key part of network security. This section describes some basic elements and concepts of authentication.

The following topics are included in this section:

What is authentication?

Businesses need to authenticate people who have access to company resources. In the physical world this may be a swipe card to enter the building, or a code to enter a locked door. If a person has this swipe card or code, they have been authenticated as someone allowed in that building or room.

Authentication is the act of confirming the identity of a person or other entity. In the context of a private computer network, the identities of users or host computers must be established to ensure that only authorized parties can access the network. The FortiGate unit enables controlled network access and applies authentication to users of security policies and VPN clients.

Methods of authentication

FortiGate unit authentication is divided into three basic types: password authentication for people, certificate authentication for hosts or endpoints, and two-factor authentication for additional security beyond just passwords. An exception to this is that FortiGate units in an HA cluster and FortiManager units use password authentication.

Password authentication verifies individual user identities, but access to network resources is based on membership in user groups. For example, a security policy can be configured to permit access only to the members of one or more user groups. Any user who attempts to access the network through that policy is then authenticated through a request for their username and password.

Methods of authentication include:

Local password authentication

The simplest authentication is based on user accounts stored locally on the FortiGate unit. For each account, a username and password is stored. The account also has a disable option so that you can suspend the account without deleting it.

Local user accounts work well for a single-FortiGate installation. If your network has multiple FortiGate units that will use the same accounts, the use of an external authentication server can simplify account configuration and maintenance.

You create local user accounts in the web-based manager under *User* > *User*. This page is also used to create accounts where an external authentication server stores and verifies the password.

Server-based password authentication

Using external LDAP, RADIUS, or TACACS+ authentication servers is desirable when multiple FortiGate units need to authenticate the same users, or where the FortiGate unit is added to a network that already contains an authentication server.

When you use an external authentication server to authenticate users, the FortiGate unit sends the user's entered credentials to the external server. The password is encrypted. The server's response indicates whether the supplied credentials are valid or not.

You must configure the FortiGate unit to access the external authentication servers that you want to use. The configuration includes the parameters that authenticate the FortiGate unit to the authentication server.

You can use external authentication servers in two ways:

- Create user accounts on the FortiGate unit, but instead of storing each user's password, specify the server used to authenticate that user. As with accounts that store the password locally, you add these users to appropriate user groups.
- Add the authentication server to user groups. Any user who has an account on the server can be authenticated and have the access privileges of the FortiGate user group. Optionally, when an LDAP server is a FortiGate user group member, you can limit access to users who belong to specific groups defined on the LDAP server.

Dynamic profiles

Managed Security Service Providers (MSSPs) and carrier service providers can use the FortiOS dynamic profile configuration to dynamically assign profile groups to customer traffic. Using the dynamic profile, FortiOS can receive RADIUS Start records from service provider accounting systems when customers connect to service provider networks. In real time, FortiOS can extract identifying information and profile group names from these RADIUS Start records and match the identifying information with the customer communication session. FortiOS can then dynamically select and apply the profile group named in the RADIUS Start record to the communication session. Some parts of dynamic profiles and end points are FortiOS Carrier-only features. See "Dynamic profiles and end points" on page 1325.

Single Sign On authentication using FSSO

"Single sign on" or "Single user Sign On" means that users logged on to a computer network are authenticated for access to network resources through the FortiGate unit without having to enter their username and password again. Fortinet Single Sign On (FSSO) provides Single Sign On capability for:

- Microsoft Windows networks using either Active Directory or NTLM authentication
- Novell networks, using eDirectory

FSSO monitors user logons and sends the FortiGate unit the username, IP address, and the list of Windows AD user groups to which the user belongs. When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

For detailed information about FSSO, see "FSSO integration with Windows AD or Novell" on page 1283.

Certificate-based authentication

An RSA X.509 server certificate is a small file issued by a Certificate Authority (CA) that is installed on a computer or FortiGate unit to authenticate itself to other devices on the network. When one party on a network presents the certificate as authentication, the other party can validate that the certificate was issued by the CA. The identification is therefore as trustworthy as the Certificate Authority (CA) that issued the certificate.

To protect against compromised or misused certificates, CAs can revoke any certificate by adding it to a Certificate Revocation List (CRL). Certificate status can also be checked online using Online Certificate Status Protocol (OCSP).

RSA X.509 certificates are based on public-key cryptography, in which there are two keys: the private key and the public key. Data encrypted with the private key can be decrypted only with the public key and vice versa. As the names suggest, the private key is never revealed to anyone and the public key can be freely distributed. Encryption with the recipient's public key creates a message that only the intended recipient can read. Encryption with the sender's private key creates a message whose authenticity is proven because it can be decrypted only with the sender's public key.

Server certificates contain a signature string encrypted with the CA's private key. The CA's public key is contained in a CA root certificate. If the signature string can be decrypted with the CA's public key, the certificate is genuine.

Certificate authorities

A certificate authority can be:

- an organization, such as VeriSign Inc., that provides certificate services
- a software application, such as Microsoft Certificate Services or OpenSSH

For a company web portal or customer-facing SSL VPN, a third-party certificate service has some advantages. The CA certificates are already included in popular web browsers and customers trust the third-party. On the other hand, third-party services have a cost.

For administrators and for employee VPN users, the local CA based on a software application provides the required security at low cost. You can generate and distribute certificates as needed. If an employee leaves the organization, you can simply revoke their certificate.

Certificates for users

FortiGate unit administrators and SSL VPN users can install certificates in their web browsers to authenticate themselves. If the FortiGate unit uses a CA-issued certificate to authenticate itself to the clients, the browser will also need the appropriate CA certificate.

FortiGate IPsec VPN users can install server and CA certificates according to the instructions for their IPsec VPN client software. The FortiClient Endpoint Security application, for example, can import and store the certificates required by VPN connections.

FortiGate units are also compatible with some Public Key Infrastructure systems. For an example of this type of system, see "RSA ACE (SecurID) servers" on page 1217.

Two-factor authentication

A user can be required to provide both something they know (their username and password combination) and something they have (certificate or a random token code). Certificates are installed on the user's computer.

Two-factor authentication is available for PKI users. For more information, see "Certificate" on page 1228.

Another type of two-factor authentication is to use a randomly generated token (multi-digit number) along with the username and password combination. One method is a FortiToken — a one time passcode (OTP) generator that generates a unique code every 60 seconds. Others use email or SMS text messaging to deliver the random token code to the user or administrator.

When one of these methods is configured, the user enters this code at login after the username and password have been verified. The FortiGate unit verifies the token code after as well as the password and username. For more information, see "Two-factor authentication" on page 1228

Types of authentication

FortiOS supports two different types of authentication based on your situation and needs.

Security policy authentication, or identity-based policies, is easily applied to all users logging on to a network, or network service. For example if a group of users on your network such as the accounting department who have access to sensitive data need to access the Internet, it is a good idea to make sure the user is a valid user and not someone trying to send company secrets to the Internet. Security policy authentication can be applied to as many or as few users as needed, and it supports a number of authentication protocols to easily fit with your existing network.

VPN authentication can be for both the remote VPN device as well as the VPN users. VPNs are used to communicate with locations outside the company network as if they were part of the company network. This level of trust, once a VPN is established, is easily established with authentication to verify the remote user is in fact a valid user. In this situation without authentication, anyone malicious or otherwise could connect to the company network with potentially full access.

Firewall authentication (identity-based policies)

Security policies enable traffic to flow between networks. If you want to limit which users have access to particular resources, you create identity-based policies (IBP) that allow access only to members of specific user groups. Authentication, a request for username and password, is triggered when a user attempts to access a resource for which data must pass through an identity-based policy.

The user's authentication expires if the connection is idle for too long, 30 minutes by default but that can customized.

Identity-based policies are the mechanism for FSSO, NTLM, certificate based, and dynamic profile authentication.

FSSO

Fortinet Single Sign on (FSSO) provides seamless authentication support for Microsoft Windows Active Directory (AD) and Novell eDirectory users in a FortiGate environment.

On a Microsoft Windows or Novell network, users authenticate with the Active Directory or Novell eDirectory at logon. FSSO provides authentication information to the FortiGate unit so that users automatically get access to permitted resources. See “Introduction to FSSO” on page 1283.

NTLM

The NT LAN Manager (NTLM) protocol is used when the MS Windows Active Directory (AD) domain controller can not be contacted. NTLM is a browser-based method of authentication.

The FSSO software is installed on each AD server and the FortiGate unit is configured to communicate with each FSSO client. When a user successfully logs into their Windows PC (and is authenticated by the AD Server), the FSSO client communicates the user's name, IP address, and group login information to the FortiGate unit. The FortiGate unit sets up a temporary access policy for the user, so when they attempt access through the firewall they do not need to re-authenticate. This model works well in environments where the FSSO client can be installed on all AD servers.

In system configurations where it is not possible to install FSSO clients on all AD servers, the FortiGate unit must be able to query the AD servers to find out if a user has been properly authenticated. This is achieved using the NTLM messaging features of Active Directory and Internet Explorer.

Even when NTLM authentication is used, the user is not asked again for their username and password. Internet Explorer stores the user’s credentials and the FortiGate unit uses NTLM messaging to validate them in the Windows AD environment.

Note that if the authentication reaches the timeout period, the NTLM message exchange restarts. For more information on NTLM, see “NTLM authentication” on page 1255 and “NTLM authentication with FSSO” on page 1287, and

Certificates

Certificates can be used as part of an identity-based policy. All users being authenticated against the policy are required to have the proper certificate. See “Certificate-based authentication” on page 1165

Dynamic profile

Dynamic profile is a remote authentication method that does not require any local users to be configured, and relies on RADIUS Start records to provide the FortiGate unit with authentication information. That information identifies the user and user group, which is then matched using a security policy. See “Dynamic profiles and end points” on page 1325

FortiGuard Web Filter override authentication

Optionally, users can be allowed the privilege of overriding FortiGuard Web Filtering to view blocked web sites. Depending on the override settings, the override can apply to the user who requested it, the entire user group to which the user belongs, or all users who share the same web filter profile. As with other FortiGate features, access to FortiGuard overrides is controlled through user groups. Firewall and Directory Services user groups are eligible for the override privilege. For more information about web filtering and overrides, see the UTM chapter of this FortiOS Handbook.

VPN authentication

Authentication involves authenticating the user. In IPsec VPNs authenticating the user is optional, but authentication of the peer device is required.

This section includes:

- Authenticating IPsec VPN peers (devices)
- Authenticating IPsec VPN users
- Authenticating SSL VPN users
- Authenticating PPTP and L2TP VPN users

Authenticating IPsec VPN peers (devices)

A VPN tunnel has one end on a local trusted network, and the other end is at a remote location. The remote peer (device) must be authenticated to be able to trust the VPN tunnel. Without that authentication, it is possible for a malicious hacker to masquerade as a valid VPN tunnel device and gain access to the trusted local network.

The three ways to authenticate VPN peers are with a preshared key, RSA X.509 certificate, an a specific peer ID value.

The simplest way for IPsec VPN peers to authenticate each other is through the use of a preshared key, also called a shared secret. The preshared key is a text string used to encrypt the data exchanges that establish the VPN tunnel. The preshared key must be six or more characters. The VPN tunnel cannot be established if the two peers do not use the same key. The disadvantage of preshared key authentication is that it can be difficult to securely distribute and update the preshared keys. See “Authenticating the FortiGate unit with a pre-shared key” on page 1410.

RSA X.509 certificates are a better way for VPN peers to authenticate each other. Each peer offers a certificate signed by a Certificate Authority (CA) which the other peer can validate with the appropriate CA root certificate. For more information about certificates, see “Certificate-based authentication” on page 1263.

You can supplement either preshared key or certificate authentication by requiring the other peer to provide a specific peer ID value. The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating IPsec VPN users

An IPsec VPN can be configured to accept connections from multiple dynamically addressed peers. You would do this to enable employees to connect to the corporate network while traveling or from home. On a FortiGate unit, you create this configuration by setting the *Remote Gateway* to *Dialup User*.

It is possible to have an IPsec VPN in which remote peer devices authenticate using a common preshared key or a certificate, but there is no attempt to identify the user at the remote peer. To add user authentication, you can do one of the following:

- require a unique preshared key for each peer
- require a unique peer ID for each peer
- require a unique peer certificate for each peer
- require additional user authentication (XAuth)

The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating SSL VPN users

SSL VPN users can be

- user accounts with passwords stored on the FortiGate unit
- user accounts authenticated by an external RADIUS, LDAP or TACACS+ server
- PKI users authenticated by certificate

You need to create a user group for your SSL VPN. Simply create a firewall user group, enable SSL VPN access for the group, and select the web portal the users will access.

SSL VPN access requires an SSL VPN security policy that permits access to members of your user group.

Authenticating PPTP and L2TP VPN users

PPTP and L2TP are older VPN tunneling protocols that do not provide authentication themselves. FortiGate units restrict PPTP and L2TP access to users who belong to one specified user group. Users authenticate themselves to the FortiGate unit by username/password. You can configure PPTP and L2TP VPNs only in the CLI. Before you configure the VPN, create a firewall user group and add to it the users who are permitted to use the VPN. Users are authenticated when they attempt to connect to the VPN. For more information about configuring PPTP or L2TP VPNs, see the *FortiGate CLI Reference*.

User's view of authentication

From the user's point of view, they see a request for authentication when they try to access a protected resource, such as an FTP repository of intellectual property or simply access a website on the Internet. The way the request is presented to the user depends on the method of access to that resource.

VPN authentication usually controls remote access to a private network.

Web-based user authentication

Security policies usually control browsing access to an external network that provides connection to the Internet. In this case, the FortiGate unit requests authentication through the web browser.

The user types a username and password and then selects *Continue* or *Login*. If the credentials are incorrect, the authentication screen is redisplayed with blank fields so that the user can try again. When the user enters valid credentials, access is granted to the required resource. In some cases, if a user tries to authenticate several times without success, a message appears, such as: "Too many bad login attempts. Please try again in a few minutes." This indicates the user is locked out for a period of time. This prevents automated brute force password hacking attempts. The administrator can customize these settings if required.

After a defined period of user inactivity (the authentication timeout, defined by the FortiGate administrator), the user's access expires. The default is 5 minutes. To access the resource, the user will have to authenticate again.

VPN client-based authentication

A VPN provides remote clients with access to a private network for a variety of services that include web browsing, email, and file sharing. A client program such as FortiClient negotiates the connection to the VPN and manages the user authentication challenge from the FortiGate unit.

FortiClient can store the username and password for a VPN as part of the configuration for the VPN connection and pass them to the FortiGate unit as needed. Or, FortiClient can request the username and password from the user when the FortiGate unit requests them.

SSL VPN is a form of VPN that can be used with a standard Web browser. There are two modes of SSL VPN operation (supported in NAT/Route mode only):

- web-only mode, for remote clients equipped with a web-browser only
- tunnel mode, for remote computers that run a variety of client and server applications.

After a defined period of user inactivity on the VPN connection (the idle timeout, defined by the FortiGate administrator), the user's access expires. The default is 30 minutes. To access the resource, the user will have to authenticate again.

FortiGate administrator's view of authentication

Authentication is based on user groups. The FortiGate administrator configures authentication for security policies and VPN tunnels by specifying the user groups whose members can use the resource. Some planning is required to determine how many different user groups need to be created. Individual user accounts can belong to multiple groups, making allocation of user privileges very flexible.

A member of a user group can be:

- a user whose username and password are stored on the FortiGate unit
- a user whose name is stored on the FortiGate unit and whose password is stored on a remote or external authentication server
- a remote or external authentication server with a database that contains the username and password of each person who is permitted access

The general process of setting up authentication is as follows:

1. If remote or external authentication is needed, configure the required servers.
2. Configure local and peer (PKI) user identities. For each local user, you can choose whether the FortiGate unit or a remote authentication server verifies the password. Peer members can be included in user groups for use in security policies.
3. Create user groups.

   Add local/peer user members to each user group as appropriate. You can also add an authentication server to a user group. In this case, all users in the server's database can authenticate. You can only configure peer user groups through the CLI.
4. Configure security policies and VPN tunnels that require authenticated access.

For authentication troubleshooting, see the specific chapter for the topic or for general issues see "Troubleshooting" on page 1377.

Authentication and User in the web-based manager

This section provides an introduction to the web-based manager User menu.

The following topics are included in this section:

- User
- User groups
- Remote
- FortiToken
- Fortinet Single Sign On Agent (FSSO)
- PKI
- Monitor

The word “unit” refers to the FortiGate unit. The words “FortiGate unit” are used when talking about different Fortinet products in one sentence. For example, “The Central Management menu provides the option of remotely managing your FortiGate unit by a FortiManager unit.”

User

The User menu allows you to configure authentication settings and user accounts. The User menu also allows you to configure user groups, remote servers, as well as monitor users.

A user is a user account that consists of a user name, password and in some cases, other information that can be configured on the unit or on an external authentication server. Users can access resources that require authentication only if they are members of an allowed user group. For more information about user groups, see “User groups” on page 1176.

This topic contains the following:

- Local user accounts
- IM users
- Authentication settings

Local user accounts

A local user is a user configured on a unit. The user can be authenticated with a password stored on the unit (the user name and password must match a user account stored on the unit) or with a password stored on an authentication server. The user name must match a user account stored on the unit and the user name and password must match a user account stored on the authentication server associated with the user.

When configuring a user account, you can enable two-factor authentication. This feature allows you to add what is referred to as a FortiToken, which is a serial number used in log in credentials, and this FortiToken can be emailed to the user or sent to their mobile phone. Two-factor authentication is a security measure that provides an additional log in credential, in this case a FortiToken, that the user must enter so that they can log in. You must have the FortiToken device to use the FortiToken feature on your unit.

Local user accounts configuration settings

Local users are configured in *User* > *User* > *User*. Use the following table when configuring local user accounts.

User page	
Lists each individual local user's list that you created. On this page, you can edit, delete or create a new local users list. **Note:** If you want to have users always authenticate whenever their time expires, use the `hard-timeout` value in the `auth-type` command. This is available only in the CLI.	
Create New	Creates a new local user account. When you select *Create New*, you are automatically redirected to New User page.
Delete	Removes a user from the list. Removing the user name removes the authentication configured for the user. The *Delete* icon is not available if the user belongs to a user group. To remove multiple local user accounts from within the list, on the User page, in each of the rows of user accounts you want removed, select the check box and then select *Delete*. To remove all local user accounts from the list, on the User page, select the check box in the check box column and then select *Delete*.
Edit	Modifies a user's account settings. When you select *Edit*, you are automatically redirected to the Edit User page.
User Name	The local user name.
Type	The authentication type to use for this user. The authentication types are Local (user and password stored on FortiGate unit), LDAP, RADIUS, and TACACS+ (user and password matches a user account stored on the authentication server).
Two-factor Authentication	Indicates the status of whether two-factor authentication is configured for the user. A gray x displays if there is no two-factor authentication enabled for the user. A green check mark displays if two-factor authentication is enabled for the user.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New User page Provides settings for configuring whether to allow or block a local user from authenticating.	
User Name	A name that identifies the user.
Disable	Select to prevent this user from authenticating.
Password	Select to authenticate this user using a password stored on the unit and then enter the password. Best practices dictate that the password be at least six characters long.
Match users on LDAP servers	Select to authenticate this user using a password stored on an LDAP server. Select the LDAP server from the list. You can select only an LDAP server that has been added to the FortiGate LDAP configuration. For more information, see "LDAP" on page 1184.
Match users on RADIUS server	Select to authenticate this user using a password stored on a RADIUS server. Select the RADIUS server from the list. You can select only a RADIUS server that has been added to the FortiGate RADIUS configuration. For more information, see "RADIUS" on page 1182.
Match users on TACACS+ server	Select to authenticate this user using a password stored on a TACACS server. Select the TACACS+ server from the list. You can select only a TACACS server that has been added to the FortiGate TACACS configuration. For more information, see "TACACS+" on page 1187.

Enable Two-factor Authentication	Select to enable the two-factor authentication feature. When you enable this feature, *FortiToken*, *Email to* and *SMS* appear below. You can enable two-factor authentication for FortiGate administrators as well as users. For more information about enabling two-factor authentication for FortiGate administrators, see "Associating FortiTokens with accounts" on page 1233.
Deliver Token Code by	When you enable two-factor authentication, you can send the FortiToken number to an email address or to a mobile phone.
FortiToken	Select the serial number of the FortiToken that will be used by the user for generating the token password code. See "FortiToken configuration settings" on page 1189.
Email to	Enter the email address of the recipient that will be receiving the token password code.
SMS	Enter the phone number of the mobile phone that will receive the token password code. You must first enter the SMS in the CLI before you can select one from the drop-down list.

IM users

Instant Messenger (IM) protocols are gaining in popularity as an essential way to communicate between two or more individuals in real time. Some companies even rely on IM protocols for critical business applications such as Customer/Technical Support.

The most common IM protocols in use today include AOL Instant Messenger, Yahoo Instant Messenger, MSN messenger, and ICQ. FortiGate units allow you to set up IM users that either allow or block the use of applications, to determine which applications are allowed.

IM users configuration settings

IM users are configured in the CLI first, and then appear in *User* > *User* > *IM*. IM users must be configured using the `config imp2p` command in the CLI.

The following are IM user configuration settings in *User* > *User* > *IM*.

IM page	
Lists each individual IM user. On this page, you can edit, delete or create a new IM user. You can also filter the information by protocol or policy.	
Create New	Creates an IM user. When you select *Create New*, you are automatically redirected to the Edit User page.
Edit	Modifies an IM user's settings. When you select *Edit*, you are automatically redirected to the Edit User page.
Delete	Removes an IM user from the list on the page. To remove multiple IM users from within the list, on the IM page, in each of the rows of users you want removed, select the check box and then select *Delete*. To remove all IM users from the list, on the IM page, select the check box in the check box column and then select *Delete*.

Protocol:	Filter the information on the page using a specific protocol. For example, only ICQ users appear when the protocol selected is ICQ. You can use both Protocol and Policy to filter the information on the page. For example, only ICQ users that are blocked appear when protocol is set to ICQ and policy is set to Block
Policy:	Filter the information on the page using a specific policy. For example, only policies that are blocked appear when the policy selected is Block. You can use both Protocol and Policy to filter the information on the page. For example, only ICQ users that are blocked appear when protocol is set to ICQ and policy is set to Block
Protocol	The type of instant messaging protocol. For example, ICQ is for all ICQ instant messaging software.
Username	The name of the user.
Policy	The type of action that will be taken when the protocol is detected.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
Edit User page Provides settings for configuring an IM user.	
Protocol	Select an instant messaging protocol from the drop-down list.
Username	Enter the user name for accessing the IM user.
Policy	Select the type of action that will be taken when the protocol is detected, for example, the protocol AIM will be blocked.

Authentication settings

The Authentication submenu provides settings for configuring authentication timeout, protocol support, and authentication certificates.

When user authentication is enabled within a security policy, the authentication challenge is normally issued for any of the four protocols (depending on the connection protocol):

- HTTP (can also be set to redirect to HTTPS)
- HTTPS
- FTP
- Telnet.

The selections made in the *Protocol Support* list of the Authentication Settings screen control which protocols support the authentication challenge. Users must connect with a supported protocol first so they can subsequently connect with other protocols. If HTTPS is selected as a method of protocol support, it allows the user to authenticate with a customized Local certificate.

When you enable user authentication within a security policy, the security policy user will be challenged to authenticate. For user ID and password authentication, users must provide their user names and passwords. For certificate authentication (HTTPS or HTTP redirected to HTTPS only), you can install customized certificates on the unit and the users can also have customized certificates installed on their browsers. Otherwise, users will see a warning message and have to accept a default FortiGate certificate.

Authentication settings are configured in *User* > *User* > *Authentication*. Use the following table when configuring authentication settings.

Authentication Settings Provides settings for defining how users authenticate a session. For example, the authentication timeout is configured for 10 minutes so a user's session, if idle for 10 minutes, will log them out of the session automatically.	
Authentication Timeout	Enter a length of time in minutes, from 1 to 480. Authentication timeout controls how long an authenticated firewall connection can be idle before the user must authenticate again. The default value is 30
Protocol Support	Select the protocols to challenge during firewall user authentication.
Certificate	If using HTTPS protocol support, select the local certificate to use for authentication. Available only if HTTPS protocol support is selected.
Apply	Select to apply the selections for user authentication settings.

When you use certificate authentication, if you do not specify any certificate when you create the security policy, the global settings will be used. If you specify a certificate, the per-policy setting will overwrite the global setting.

User groups

A user group is a list of user identities. An identity can be:

- a local user account (user name and password) stored on the FortiGate unit
- a local user account with a password stored on a RADIUS, LDAP, or TACACS+ server

- a RADIUS, LDAP, or TACACS+ server (all identities on the server can authenticate)
- a user or user group defined on a Directory Service server.

Each user group belongs to one of three types: Firewall, Directory Service or SSL VPN.

In most cases, the unit authenticates users by requesting each user name and password. The unit checks local user accounts first. If the unit does not find a match, it checks the RADIUS, LDAP, or TACACS+ servers that belong to the user group. Authentication succeeds when the unit finds a matching user name and password.

This topic contains the following:

User Group

For each resource that requires authentication, you specify which user groups are permitted access. You need to determine the number and membership of user groups appropriate to your authentication needs.

Users that are associated with multiple groups have access to all services within all the user groups that they are associated with. This is only available in the CLI. The command used is `auth-multi-group`, which is enabled by default. This feature checks all groups a user belongs to for firewall authentication.

User Group configuration settings

The following are user group configuration settings in *User* > *User Group* > *User Group*.

User Group page	
Lists each individual user group list according to their type of group. On this page, you can edit, delete or create a new user group list.	
Create New	Creates a new user group. When you select *Create New*, you are automatically redirected to New User Group page.
Delete	Removes a user group from the list on the User Group page. You cannot delete a user group that is included in a security policy, a dialup user phase 1 configuration, or a PPTP or L2TP configuration. To remove multiple user groups, expand the section (either *Firewall* or *Directory Service*, and in each of the rows of user groups you want removed, select the check box and then select *Delete*. To remove all user groups, on the User Group page, select the check box in the check box column and then select *Delete*.
Edit	Modifies membership and options of a group. When you select *Edit*, you are automatically redirected to the Edit User Group page.

Group Name	The name of the user group. User group names are listed by type of user group: Firewall, Directory Service and SSL VPN. For more information, see "Fortinet Single Sign-On (FSSO) user groups" on page 1180, and "SSL VPN user groups" on page 1180.
Members	The Local users, RADIUS servers, LDAP servers, TACACS+ servers, Directory Service users/user groups or PKI users found in the user group.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

New User Group page

Provides settings for configuring a list of users and/or groups.

Note: The *Remote authentication servers* section does not appear unless there is a RADIUS, LDAP, or TACAS+ server configured.

Name	Enter the name of the user group.
Type	Select the user group type. See "Firewall user groups" on page 1179, "SSL VPN user groups" on page 1180 and "Fortinet Single Sign-On (FSSO) user groups" on page 1180.
Firewall	Select this group in any security policy that requires Firewall authentication.
Fortinet Single Sign-On (FSSO)	Select this group in any security policy that requires FSSO authentication.

	SSL VPN	Select this group in any security policy with *Action* set to *SSL VPN*. See "SSL VPN access" on page 1236. This option is not available in Transparent mode.
	Allow SSL-VPN Access	Select the type of SSL VPN access from the drop-down list.
Available Users		The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, Directory Service users/user groups, or PKI users that can be added to the user group. To add a member to *Available Users* list, select the name and then select the -> arrow. To remove a member from the *Members* list, select the member and then select the <- arrow. * *Available Members* displays only if the user group type is *Directory Service*.
Members		The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, Directory Service users/user groups, or PKI users that belong to the user group. To remove a member, select the name and then select the <- arrow.
Remote authentication servers The following appear only if a RADIUS, LDAP or TACACS+ server has been configured and if *Type* is *Firewall*.		
Add		Select to add a new remote authentication server. When you select add the following appear: • remote server drop-down list • *Any* and *Specify and its field* • Delete icon
Remote Server		Select a remote server from the drop-down list.
Group Name		Select to specify the group name or to have any group name. If you select Specify, you must enter the name in the field provided. If you want to specify more than one, use a comma to separate each name.
Delete		Select to remove the remote server from within the list.

Firewall user groups

A firewall user group provides access to a security policy that requires authentication and lists the user group as one of the allowed groups. The unit requests the group member's user name and password when the user attempts to access the resource that the policy protects. The reason for the name firewall user group is when creating a new user group you have the option to select Firewall or FSSO as the group type.

You can also authenticate a user by certificate if you have selected this method.

A firewall user group can also provide access to an IPSec VPN for dialup users. In this case, the IPSec VPN phase 1 configuration uses the Accept peer ID in dialup group peer option. The user's VPN client is configured with the user name as peer ID and the password as pre-shared key. The user can connect successfully to the IPSec VPN only if the user name is a member of the allowed user group and the password matches the one stored on the unit.

A user group cannot be a dialup group if any member is authenticated using a RADIUS or LDAP server.

You can also use a firewall user group to provide override privileges for FortiGuard web filtering.

Fortinet Single Sign-On (FSSO) user groups

On a network, you can configure the unit to allow access to members of FSSO user groups who have been authenticated on the network. The Fortinet Single Sign On Agent must be installed on the network domain controllers.

An FSSO user group provides access to a security policy that requires FSSO type authentication and lists the user group as one of the allowed groups. The members of the user group are FSSO users or groups that you select from a list that the unit receives from the FSSO servers that you have configured. For more information, see "Fortinet Single Sign On Agent (FSSO)" on page 1191.

An FSSO user group cannot have SSL VPN access.

You cannot use FSSO user groups directly in FortiGate security policies. You must add FSSO groups to FortiGate user groups. An FSSO group belong to only one FortiGate user group according to best practices. If you assign it to multiple FortiGate user groups, the unit recognizes only the last user group assignment.

You can also use an FSSO user group to provide override privileges for FortiGuard web filtering.

SSL VPN user groups

An SSL VPN user group provides access to a security policy that requires SSL VPN type authentication and lists the user group as one of the allowed groups. Local user accounts, LDAP, and RADIUS servers can be members of an SSL VPN user group. The unit requests the user's user name and password when the user accesses the SSL VPN web portal. The user group settings include options for SSL VPN features.

An SSL VPN user group can also provide access to an IPSec VPN for dialup users. In this case, the IPSec VPN phase 1 configuration uses the Accept peer ID in dialup group peer option. You configure the user's VPN client with the user name as peer ID and the password as pre-shared key. The user can connect successfully to the IPSec VPN only if the user name is a member of the allowed user group and the password matches the one stored on the unit.

A user group cannot be an IPSec dialup group if any member is authenticated using a RADIUS or LDAP server.

For information on configuring user groups, see "User groups" on page 1176. For SSL VPN information, see "SSL VPN access" on page 1236.

By default, the web-based manager displays Firewall options. You cannot add local users to a group that is used to authenticate administrators.

Dynamically assigning VPN client IP addresses from a user group

SSL VPN tunnel mode, dialup IPSec VPN, and PPTP VPN sessions can assign IP addresses to remote users by getting the IP address to assign to the user from the Framed-IP-Address field in the RADIUS record received when the RADIUS server confirms that the user has authenticated successfully. For more information about RADIUS fields, see RFC 2865 and RFC 2866.

For the unit to dynamically assign an IP address, the VPN users must be configured for RADIUS authentication and you must include the IP address to assign to the user in the Framed-IP-Address RADIUS field on your RADIUS server. You configure each type of VPN differently. In each case you are associating the configuration that assigns IP addresses to users with a user group.

Assigning IP addresses from a RADIUS record replaces dynamically assigning IP addresses from an address range. You cannot include an IP address range and assigning IP addresses from a RADIUS record in the same configuration.

Remote

Remote authentication is generally used to ensure that employees working offsite can remotely access their corporate network with appropriate security measures in place. In general terms, authentication is the process of attempting to verify the (digital) identity of the sender of a communication such as a login request. The sender may be someone using a computer, the computer itself, or a computer program. Since best practices dictate a computer system be used only by those who are authorized to do so, there must be a measure in place to detect and exclude any unauthorized access.

On a unit, you can control access to network resources by defining lists of authorized users, called user groups. To use a particular resource, such as a network or VPN tunnel, the user must:

- belong to one of the user groups that is allowed access
- correctly enter a user name and password to prove his or her identity, if asked to do so.

This topic contains the following:

- Administrators
- RADIUS
- LDAP
- TACACS+

Administrators

A local administrator account, admin, is configured by default on all FortiOS units. If you have remote servers configured, you can create remote administrator accounts as well.

These are accounts with local administrator privileges that use remote authentication. One version of this are wildcard administrator accounts. See "Example — wildcard admin accounts - CLI" on page 1211.

Configuring a remote administrator account is the same as a local administrator account with the following differences:

- You must have a remote authentication server and user group with an associated authentication server configured before creating the administrator account.
- Even though the administrator account with be authenticated remotely, when creating the account using the web-based manager you must enter a password or the account will not be created. You are not prompted for the password if the account is created in the CLI. This password acts as a backup password in case the remote server does not responde during authentication. The exception to this is when wildcard admin is selected — for wildcard administrators, the password field is skipped over.

RADIUS

Remote Authentication and Dial-in User Service (RADIUS) servers provide authentication, authorization, and accounting functions. FortiGate units use the authentication function of the RADIUS server. You must configure the server before you configure the FortiGate users or user groups that will need it to use the RADIUS server for authentication.

If you have configured RADIUS support and a user is required to authenticate using a RADIUS server, the unit sends the user's credentials to the RADIUS server for authentication. If the RADIUS server can authenticate the user, the user is successfully authenticated with the unit. If the RADIUS server cannot authenticate the user, the unit refuses the connection. You can override the default authentication scheme by selecting a specific authentication protocol or changing the default port for RADIUS traffic.

The default port for RADIUS traffic is 1812. If your RADIUS server is using port 1645, use the CLI command, `config system global`, to change the default RADIUS port.

If you want to configure settings for UTF-8 encoding, you must enable this in the CLI using the `config vpn ssl setting` command.

RADIUS configuration settings

The following are RADIUS server configuration settings in *User* > *Remote* > *RADIUS*.

RADIUS page	
Lists each individual RADIUS server that you created. On this page, you can edit, delete or create a new RADIUS server.	
Create New	Creates a new RADIUS server. The maximum number is 10. When you select *Create New*, you are automatically redirected to the New RADIUS Server page.
Delete	Removes a RADIUS server from the list on the RADIUS page. **Note:** You cannot delete a RADIUS server that has been added to a user group. To remove multiple RADIUS servers from within the list, on the RADIUS page, in each of the rows of servers you want removed, select the check box and then select *Delete*. To remove all RADIUS servers from the list, on the RADIUS page, select the check box in the check box column and then select *Delete*.
Edit	Modifies settings within a RADIUS server configuration. When you select *Edit*, you are automatically redirected to the Edit RADIUS Server page.
Name	Name that identifies the RADIUS server on the unit.
Type	The type of server, either query or dynamic start.
Server Name/IP	Domain name or IP address of the RADIUS server.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New RADIUS Server page	
Provides settings for configuring a RADIUS server.	
Name	Enter the name that is used to identify the RADIUS server on the unit.

Type	Select either *Query* or *Dynamic Start*.
Primary Server Name/IP	Enter the domain name or IP address of the primary RADIUS server.
Primary Server Secret	Enter the RADIUS server secret key for the primary RADIUS server. The primary server secret key length can be up to a maximum of 16 characters. **Note:** Best practices dictate that the server secret key should be the maximum length for security reasons.
Secondary Server Name/IP	Enter the domain name or IP address of the secondary RADIUS server, if you have one.
Secondary Server Secret	Enter the RADIUS server secret key for the secondary RADIUS server. The secondary server secret key can be up to a maximum length of 16 characters.
Authentication Scheme	Select *Use Default Authentication Scheme* to authenticate with the default method. The default authentication scheme uses PAP, MS-CHAP-V2, and CHAP, in that order. Select *Specify Authentication Protocol* to override the default authentication method, and choose the protocol from the list: MS-CHAP-V2, MS-CHAP, CHAP, or PAP, depending on what your RADIUS server needs.
NAS IP/Called Station ID	Optionally enter the NAS IP address (RADIUS Attribute 31 outlined in RFC 2548). In this configuration, the FortiGate unit is the Network Access Server (NAS) and this is how the RADIUS server registers all valid servers that use its records. If you do not enter an IP address, the IP address that the FortiGate interface uses to communicate with the RADIUS server will be applied.
Include in every User Group	Select the check box beside *Enable* to have the RADIUS server automatically included in all user groups.

LDAP

Lightweight Directory Access Protocol (LDAP) is an Internet protocol used to maintain authentication data that may include departments, people, groups of people, passwords, email addresses, and printers. An LDAP consists of a data-representation scheme, a set of defined operations, and a request/response network.

If you have configured LDAP support and require a user to authenticate using an LDAP server, the unit contacts the LDAP server for authentication. To authenticate with the unit, the user enters a user name and password. The unit sends this user name and password to the LDAP server. If the LDAP server can authenticate the user, the unit successfully authenticates the user. If the LDAP server cannot authenticate the user, the unit refuses the connection.

FortiGate LDAP supports password renewal, and these settings are configured in the CLI. There are settings for a warning that the password is going to expire, and threshold of the expiry as well.

LDAP configuration settings

The following are LDAP server configuration settings in *User* > *Remote* > *LDAP*. You can use both IPv6 and IPv 4 addresses when configuring LDAP servers.

LDAP page Lists each individual LDAP server that you created. On this page, you can edit, delete or create a new LDAP server.	
Create New	Creates a new LDAP server. The maximum number is 10. When you select *Create New*, you are automatically redirected to the New LDAP Server page.
Delete	Removes the LDAP server configuration from the list on the LDAP page. To remove multiple LDAP servers from within the list, on the LDAP page, in each of the rows of servers you want removed, select the check box and then select *Delete*. To remove all LDAP servers from the list, on the LDAP page, select the check box in the check box column and then select *Delete*.
Edit	Modifies settings from within an LDAP server configuration. When you select *Edit*, you are automatically redirected to the Edit LDAP Server page.
Name	The name that identifies the LDAP server on the unit.
Server Name/IP	The domain name or IP address of the LDAP server.
Port	The TCP port used to communicate with the LDAP server.
Common Name Identifier	The common name identifier for the LDAP server. Most LDAP servers use cn. However, some servers use other common name identifiers such as uid.
Distinguished Name	The distinguished name used to look up entries on the LDAP servers use. The distinguished name reflects the hierarchy of LDAP database object classes above the common name identifier.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New LDAP Server page Provides settings for configuring an LDAP server.	
Name	Enter the name that identifies the LDAP server on the FortiGate unit.
Server Name/IP	Enter the domain name or IP address of the LDAP server.
Server Port	Enter the TCP port used to communicate with the LDAP server. By default, LDAP uses port 389. If you use a secure LDAP server, the default port changes when you select *Secure Connection*.
Common Name Identifier	Enter the common name identifier for the LDAP server. The maximum number of characters is 20.
Distinguished Name	Enter the base distinguished name for the server using the correct X.500 or LDAP format. The unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.
Query icon	View the LDAP server Distinguished Name Query tree for the LDAP server that you are configuring so that you can cross-reference to the Distinguished Name. The *Query* icon is located beside the *Distinguished Name* field. For more information, see "Using Query" on page 1187.
Bind Type	Select the type of binding for LDAP authentication.

	Regular	Connect to the LDAP server directly with user name/password, then receive accept or reject based on search of given values. When you select *Regular*, the *Use DN* and *Password* fields appear.
	Anonymous	Connect as an anonymous user on the LDAP server, then retrieve the user name/password and compare them to given values.
	Simple	Connect directly to the LDAP server with user name/password authentication.
User DN		Enter the Distinguished name of the user to be authenticated. Available if *Bind Type* is *Regular*.
Password		Enter the password of the user to be authenticated. This is available if *Bind Type* is *Regular*.
Secure Connection		Select to use a secure LDAP server connection for authentication.
Protocol		Select a secure LDAP protocol to use for authentication. Depending on your selection, the value in *Server Port* will change to the default port for the selected protocol. This is available only if *Secure Connection* is selected. • *LDAPS*: port 636 • *STARTTLS*: port 389
Certificate		Select a certificate to use for authentication from the list. The certificate list comes from CA certificates at *System* > *Certificates* > *CA Certificates*. For more information about certificates, see "Certificate-based authentication" on page 1263.

Using Query

The LDAP Distinguished Name Query list displays the LDAP Server IP address, and all the distinguished names associated with the Common Name Identifier for the LDAP server. The tree helps you to determine the appropriate entry for the DN field. You can see the distinguished name associated with the Common Name identifier, by expanding *CN identifier* and then selecting the DN from the list. The DN you select is displayed in the *Distinguished Name* field. You must select *OK* to save your selection in the *Distinguished Name* field of the LDAP Server configuration.

If you want to see the users with the LDAP Server user group for the selected Distinguished Name, expand *Distinguished Name* in the LDAP Distinguished Name Query tree.

TACACS+

Terminal Access Controller Access-Control System (TACACS+) is a remote authentication protocol that provides access control for routers, network access servers, and other networked computing devices via one or more centralized servers. TACACS+ allows a client to accept a user name and password and send a query to a TACACS+ authentication server. The server host determines whether to accept or deny the request and sends a response back that allows or denies network access to the user. The default TCP port for a TACACS+ server is 49.

TACAS+ configuration settings

The following are TACACS+ server configuration settings in *User* > *Remote* > *TACACS+*.

TACACS+ page	
Lists each individual TACACS+ server that you created. On this page, you can edit, delete or create a new TACACS+ server.	
Create New	Creates a new TACACS+ server. The maximum number of TACACS+ servers that you can create is 10. When you select *Create New*, you are automatically redirected to the New TACACS+ Server page.
Delete	Removes a TACACS+ server from the list on the TACACS+ page. To remove multiple TACACS+ servers from within the list, on the TACACS+ page, in each of the rows of servers you want removed, select the check box and then select *Delete*. To remove all TACACS+ servers from the list, on the TACACS+ page, select the check box in the check box column and then select *Delete*.
Edit	Modifies settings within a TACACS+ server configuration. When you select *Edit*, you are automatically redirected to the Edit TACASCS+ Server page.
Name	The name of the TACACS+ server.
Server	The server domain name or IP address of the TACACS+ server.
Authentication Type	The supported authentication method. TACACS+ authentication methods include: Auto, ASCII, PAP, CHAP, and MSCHAP.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New TACACS+ Server page	
Provides settings for configuring a TACACS+ server.	

Name	Enter the name of the TACACS+ server.
Server Name/IP	Enter the server domain name or IP address of the TACACS+ server.
Server Key	Enter the key to access the TACACS+ server. The server key can be a maximum of 16 characters in length.
Authentication Type	Select the authentication type to use for the TACACS+ server. Selection includes: Auto, ASCII, PAP, CHAP, and MSCHAP. Auto authenticates using PAP, MSCHAP, and CHAP (in that order).

FortiToken

In *User* > *FortiToken* > *FortiToken*, you can add token password codes that are then used by users to authenticate when logging in, for example the FortiGate unit. These token password codes are generated by the FortiToken device, which is a small device that generates a unique token password code. This can then be activated by the unit so that it can then be used for authentication purposes. This code provides additional security for you and users. This is part of the two-factor authentication feature, providing an extra login credential to prove that the user is who they claim to be.

For more information about FortiToken and two-factor authentication, see "FortiToken" on page 1230.

FortiToken configuration settings

You can apply two-factor authentication to administrators that are logging into the FortiGate unit.

The following are FortiToken configuration settings in *User* > *FortiToken* > *FortiToken*.

FortiToken page	
Lists each individual FortiToken list that is currently being used and which user the token is being used by. A FortiToken list provides up to ten FortiToken serial numbers that one user can use to authenticate when entering log in credentials. **Note:** You can import FortiToken serial numbers from a file.	
Create New	Creates a new FortiToken list. When you select *Create New*, you are automatically redirected to the Add new FortiToken page.
Edit	Modifies the settings within the FortiToken list. When you select *Edit*, you are automatically redirected to the Edit new FortiToken page.
Delete	Removes a FortiToken list from within the list on the FortiToken page. To remove multiple token serial numbers from within the list, on the FortiToken page, in each of the rows of codes you want removed, select the check box and then select *Delete*. To remove all token codes from the list, on the FortiToken page, select the check box in the check box column and then select *Delete*.

Import	Select to import FortiToken serial numbers from a file. When you select Import, the Upload window appears. From the Upload window you can select Browse to locate the file and then select OK to import the file to the unit.
Activate	Activates the FortiToken device so that you can use the device to code so that the code can then be used by a user or FortiGate administrator.
Syncronization	Select to synchronize the FortiToken with an NTP server. This allows the unit's system time to be the same as the FortiToken's system time.
Serial Number	The serial number of the FortiToken device. This serial number is found on the back of the device.
Status	The status of the FortiToken, whether it is activated or not.
Drift	The synchronization of the unit's system time and the FortiToken's time, which can "drfit" away or become unsynchronized. When you synchronize the FortiToken, it calculates the unit's and its own drift. The drift is the number of minutes that the FortiToken has drifted away from the unit's system time. The minutes is shown in integers only. If drift is zero, then the FortiToken's internal time is the same as the unit's system time. If the drift is -1, the FortiToken is lagging behind the unit by one minute. If the drift is 1, then the FortiToken is ahead of the unit by one minute.
User	The user that the FortiToken is currently being used by.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
Add new FortiToken page Provides settings for configuring multiple FortiToken serial numbers.	
Serial Number #<number>	Enter the FortiToken's serial number that you see on the back of the FortiToken. You can add up to ten FortiTokens.
Automatically Send Activate Request to FortiGuard	By default, this is enabled. When this is selected, the serial numbers that were inputted in the fields are automatically sent to FortiGuard after selecting *OK*.

Fortinet Single Sign On Agent (FSSO)

Windows Active Directory (AD) and Novell eDirectory provide central authentication services by storing information about network resources across a domain (a logical group of computers running versions of an operating system) in a central directory database. Each person who uses computers within a domain receives his or her own unique account/user name. This account can be assigned access to resources within the domain based on the role of the user. In a domain, the directory resides on computers that are configured as domain controllers. A domain controller is a server that manages all security-related features that affect the user/domain interactions, security centralization, and administrative functions.

FortiGate units use security policies to control access to resources based on user groups configured in the policies. Each FortiGate user group is associated with one or more Directory Service user groups. When a user logs in to the Windows or Novell domain, a Fortinet Single Sign On Agent (FSSO) sends the user's IP address and the names of the Directory Service user groups to which the user belongs to the FortiGate unit.

The Fortinet Single Sign On Agent has two components that you must install on your network:

- The domain controller (DC) agent must be installed on every domain controller to monitor user logins and send information about them to the collector agent.
- The Collector agent must be installed on at least one domain controller to send the information received from the DC agents to the FortiGate unit. Alternately a FortiAuthenticator server can take the place of the Collector agent in an FSSO polling mode configuration.

The unit uses this information to maintain a copy of the domain controller user group database. Because the domain controller authenticates users, the unit does not perform authentication. It recognizes group members by their IP address.

You must install the Fortinet Single Sign On Agent on the network and configure the unit to retrieve information from the Directory Service server. For more information about Fortinet Single Sign On Agent, see the **"Introduction to FSSO" on page 1283**.

Fortinet Single Sign-on Agent configuration settings

The following are configuration settings for collector agents in *User* > *FSSO* > *FSSO Agent*.

FSSO Agent page	
Lists all the collector agents' lists that you have configured. On this page, you can create, edit or delete FSSO agents. **Note:** You can create a redundant configuration on your unit if you install a collector agent on two or more domain controllers. If the current (or first) collector agent fails, the FortiGate unit switches to the next one in its list of up to five collector agents.	
Create New	Creates a new agent. When you select *Create New*, you are automatically redirected to the New page.
Edit	Modifies settings within the Collector agent list. When you select *Edit*, you are automatically redirected to the Edit page. To remove multiple agents from within the list, on the FSSO Agent page, in each of the rows of servers you want removed, select the check box and then select *Delete*. To remove all agents from the list, on the FSSO Agent page, select the check box in the check box column and then select *Delete*.
Delete	Removes an agent from the list on the page.
Add User/Group	Adds a user or group to the list on the FSSO Agent page. You must know the distinguished name for the user or group. When you select *Add User/Group*, you are automatically redirected to the Add User/Group page.
Edit User/Group	Modifies users or groups from the remote server. When you select *Edit Users/Groups*, you are automatically redirected to the Edit Users/Groups page.
Refresh	Refreshes the current information on the page.
Name	The name of the FSSO agent list.
FSSO Agent IP/Name	The IP address or name of the agent or agents.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New page Provides settings for configuring FSSO agents. You can configured up to five agents, either Collector or Novell eDirectory.	
Name	Enter a name for the FSSO agent.
FSSO Agent IP/Name	Enter the IP address or name of the Directory Service server where this collector agent is installed. The maximum number of characters is 63.
Port	Enter the TCP port used for Directory Service. This must be the same as the FortiGate listening port specified in the Fortinet Single Sign On Agent collector agent configuration.
Password	Enter the password for the collector agent. This is required only if you configured your Fortinet Single Sign On Agent collector agent to require authenticated access.
LDAP Server	Select the check box and select an LDAP server to access the Directory Service.

PKI

Public Key Infrastructure (PKI) authentication utilizes a certificate authentication library that takes a list of peers, peer groups, and/or user groups and returns authentication successful or denied notifications. Users only need a valid certificate for successful authentication—no user name or password are necessary. Firewall and SSL VPN are the only user groups that can use PKI authentication.

If you use the CLI to create a peer user, best practices dictate that you enter a value for either `subject` or `ca`. If you do not do so, and then open the user record in the web-based manager, you will be prompted to enter a subject or ca value before you can continue.

PKI configuration settings

If your unit is currently running FortiOS 4.0 MR2 or higher, you must configure a PKI user first in the CLI to enable the PKI menu in the web-based manager, then you can then configure other PKI users in *User* > *PKI* > *PKI*.

The following are PKI configuration settings in *User* > *PKI* > *PKI*.

PKI page	
Lists each individual PKI user that you have created. On this page, you can edit, delete or create a new PKI user.	
Create New	Creates a new PKI user. When you select *Create New*, you are automatically redirected to the New PKI User page.
Delete	Removes a PKI user from the list on the PKI page. The delete icon is not available if the peer user belongs to a user group. Remove it from the user group first. To remove multiple PKI users from within the list, on the PKI page, in each of the rows of users you want removed, select the check box and then select *Delete*. To remove all PKI users from the list, on the PKI page, select the check box in the check box column and then select *Delete*.
Edit	Modifies settings within the PKI user configuration. When you select *Edit*, you are automatically redirected to the Edit PKI User page.
Name	The name of the PKI user.
Subject	The text string that appears in the subject field of the certificate of the authenticating user.
CA	The CA certificate that is used to authenticate this user. **Note:** PKI certificate authentication supports the extraction of the user name from within the UPN field, which allows users to log in without having to enter their user name. This is available only in the CLI.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*UTM* > *Antivirus* > *Profile*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is available within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New PKI User page Provides settings for configuring a new PKI user.	
Name	Enter the name of the PKI user.
Subject	Enter the text string that appears in the subject field of the certificate of the authenticating user. This field is optional.
CA	Enter the CA certificate that must be used to authenticate this user. This field is optional.
Two-factor authentication section	
Require two-factor authentication	Require this PKI user to authenticate by password in addition to certificate authentication.
Password	Enter the password that this PKI user must enter.

Peer users and peer groups

You can define peer users and peer groups used for authentication in some VPN configurations and for PKI certificate authentication in security policies. Defining peer users and peer groups is configured in the CLI.

A peer user is a digital certificate holder that can use PKI authentication. Before using PKI authentication, you must define peer users to include in the user group that is incorporated into the firewall authentication policy.

When defining a peer user, you need:

- a peer user name
- the text from the subject field of the certificate of the authenticating peer user, or the CA certificate used to authenticate the peer user.

You can add or modify other configuration settings for PKI authentication.

Peer users are created in *User* > *PKI* > *PKI* for authentication; however, you must enter a value for at least one of the fields, *Subject* or *CA*. You can configure peer user groups only through the CLI.

PKI certificate authentication supports the extraction of the user name from within the UPN field, which allows users to log in without having to enter their user name. This is available only in the CLI.

Monitor

You can go to the Monitor menu to view lists of currently authenticated users, authenticated IM users, and banned users. For each authenticated user, the list includes the user name, user group, how long the user has been authenticated (*Duration*), how long until the user's session times out (*Time left*), and the method of authentication used. The list of IM users includes the source IP address, protocol, and last time the protocol was used. The Banned User list includes users configured by administrators in addition to those quarantined based on AV, IPS, or DLP rules.

This topic contains the following:

Firewall monitor list

In some environments, it is useful to determine which users are authenticated by the FortiGate unit and allow the system administrator to de-authenticate (stop current session) users. With the Firewall monitor, you can de-authenticate all currently authenticated users, or select single users to de-authenticate. To permanently stop a user from re-authenticating, change the FortiGate configuration (disable a user account) and then use the User monitor to immediately end the user's current session.

Monitored firewall users are viewed from *User* > *Monitor* > *Firewall*.

Firewall page	
Lists all authenticated firewall users that are currently authenticated by the FortiGate unit and are active. This page allows you to refresh the information on the page, as well as filter the information.	
Refresh	Refresh the Firewall user monitor list.
Filter Settings	Select to filter the information on the page. *Filters* appears automatically after selecting *Filter Settings*, below the column headings. Use to configure filter settings. **Note:** *Filter Settings* configures all filter settings. Filter icons are used to configure filter settings within that column.
	To apply a filter setting, select the plus sign beside *Add new filter* and then select and enter the information required. Repeat to add other filter settings.
	To modify settings, select *Change* beside the setting and edit the settings.
	To clear all filter settings, select the icon beside *Clear all filters*.

		To use a filter icon to filter settings within a column, select the filter icon in the column; Filters appears. Within Filters, configure the settings for that column.
		Select to filter the information on the page. *Filters* appears automatically after selecting *Filter Settings*, below the column headings. Use to configure filter settings. **Note:** *Filter Settings* configures all filter settings. Filter icons are used to configure filter settings within that column.
De-authenticate All Users		Stop authenticated sessions for all users in the Firewall user monitor list. Users must re-authenticate with the firewall to resume their communication session.
Page Controls		Use to navigate through the list.
Column Settings		Customize the table view. You can select the columns to hide or display and specify the column displaying order in the table.
User Name		The user names of all connected remote users. In the *User Name* column heading, there is a green arrow beside the name. This green arrow allows you to sort the list alphabetically. By default, the green arrow is up and when you select it, the green arrow is down. The green up arrow indicates that the list is in alphabetical order, starting with the letter A; when the green arrow is down, the list is the opposite.
User Group		The user group that the remote user is part of.
Policy ID		The policy identification number.
Duration		Length of time since the user was authenticated.
IP Address		The user's source IP address.
Traffic Volume		The amount of traffic that is going through the unit, that is generated by the user.
Method		Authentication method used for the user by the unit (authentication methods can be Fortinet Single Sign On Agent, firewall authentication, or NTLM).

IM user monitor list

User lists can be managed to allow or block certain users. Each user can be assigned a policy to allow or block activity for each IM protocol. Each IM function can be individually allowed or blocked providing the administrator the granularity to block the more bandwidth consuming features such as voice chat while still allowing text messaging. The IM user monitor list displays information about instant messaging users who are currently connected. The list can be filtered by protocol. After IM users connect through the firewall, the unit displays which users are connected. You can analyze the list and decide which users to allow or block. A policy can be configured to handle unknown users.

Active IM users are viewed from *User* > *Monitor* > *IM*.

IM users who are already logged on before changes are made to the IM user profile will not be affected until their next login. You cannot disconnect users who have already logged on by enabling logon blocking.

IM page	
Lists all active IM users that are currently active. This page allows you to view blocked users as well as users that are currently using a particular IM protocol, such as MSN.	
Protocol	Filter the list by selecting the protocol for which to display current users: AIM, ICQ, MSN, or Yahoo. All current users can also be displayed.
#	The position number of the IM user in the list.
Protocol	The protocol being used.
User Name	The name selected by the user when registering with an IM protocol. The same user name can be used for multiple IM protocols. Each user name/protocol pair appears separately in the list.
Source IP	The IP address where the user initiated the IM session from.
Last Login	The last time the current user used the protocol.
Block	Select to add the user name to the permanent black list. Each user name/protocol pair must be explicitly blocked by the administrator.

The Banned User list

The Banned User list shows all IP addresses and interfaces blocked by NAC quarantine. The list also shows all IP addresses, authenticated users, senders, and interfaces blocked by Data Leak Prevention (DLP). The system administrator can selectively release users or interfaces from quarantine or configure quarantine to expire after a selected time period.

All sessions started by users or IP addresses on the Banned User list are blocked until the user or IP address is removed from the list. All sessions to an interface on the list are blocked until the interface is removed from the list.

You can configure NAC quarantine to add users or IP addresses to the Banned User list under the following conditions:

- **Users or IP addresses that originate attacks detected by IPS** - To quarantine users or IP addresses that originate attacks, enable and configure *Quarantine Attackers* in an IPS Sensor Filter.
- **IP addresses or interfaces that send viruses detected by virus scanning** - To quarantine IP addresses that send viruses or interfaces that accept traffic containing a virus, enable *Quarantine Virus Sender* in an antivirus profile.
- **Users or IP addresses that are banned or quarantined by Data Leak Prevention** - Set various options in a DLP sensor to add users or IP addresses to the Banned User list.

For more information, see *FortiOS Handbook UTM chapter*.

Banned users are viewed from *User* > *Monitor* > *Banned User.*

Banned User page	
Lists all banned users.	
Page Controls	Use to navigate through the list.
Clear	Removes all users and IP addresses from the Banned User list.
#	The position number of the user or IP address in the list.

Ban key	The Ban key.
Application Protocol	The protocol that was used by the user or IP address added to the Banned User list.
Cause or rule	The FortiGate function that caused the user or IP address to be added to the Banned User list. *Cause or rule* can be IPS, Antivirus, or Data Leak Prevention.
Created	The date and time the user or IP address was added to the Banned User list.
Expires	The date and time the user or IP address will be automatically removed from the Banned User list. If *Expires* is *Indefinite*, you must manually remove the user or host from the list.
Delete	Removes the selected user or IP address from the Banned User list.

Authentication servers

FortiGate units support the use of external authentication servers. An authentication server can provide password checking for selected FortiGate users or it can be added as a member of a FortiGate user group.

If you are going to use authentication servers, you must configure the servers before you configure FortiGate users or user groups that require them.

MAC OS and iOS devices, including iPhones and iPads, can perform user authentication with FortiOS units using RADIUS servers, but not with LDAP or TACACS+ servers.

This section includes the following topics:

FortiAuthenticator servers

FortiAuthenticator is an Authentication, Authorization, and Accounting (AAA) server, that includes a RADIUS server, an LDAP server, and can replace the FSSO Collector Agent on a Windows AD network. Multiple FortiGate units can use a single FortiAuthenticator for FSSO, remote authentication, and FortiToken management.

For more information, see the *FortiAuthenticator Administration Guide*.

RADIUS servers

Remote Authentication and Dial-in User Service (RADIUS) is a broadly supported client-server protocol that provides centralized authentication, authorization, and accounting functions. RADIUS clients are built into gateways that allow access to networks such as Virtual Private Network servers, Network Access Servers (NAS), as well as network switches and firewalls that use authentication. FortiGate units fall into the last category.

RADIUS servers use UDP packets to communicate with the RADIUS clients on the network to authenticate users before allowing them access to the network, to authorize access to resources by appropriate users, and to account or bill for those resources that are used. RADIUS servers are currently defined by RFC 2865 (RADIUS) and RFC 2866 (Accounting), and listen on either UDP ports 1812 (authentication) and 1813 (accounting) or ports 1645 (authentication) and 1646 (accounting) requests. RADIUS servers exist for all major operating systems.

You must configure the RADIUS server to accept the FortiGate unit as a client. FortiGate units use the authentication and accounting functions of the RADIUS server.

FortiOS does not accept all characters from auto generated keys from MS Windows 2008. These keys are very long and as a result RADIUS authentication will not work. Maximum key length for MS Windows 2008 is 128 bytes. In older versions of FSAE, it was 40 bytes.

Microsoft RADIUS servers

Microsoft Windows Server 2000, 2003, and 2008 have RADIUS support built-in. Microsoft specific RADIUS features are defined in RFC 2548. The Microsoft RADIUS implementation can use Active Directory for user credentials.

For details on Microsoft RADIUS server configurations, refer to Microsoft documentation.

RADIUS user database

The RADIUS user database is commonly an SQL or LDAP database, but can also be any combination of:

- usernames and passwords defined in a configuration file
- user account names and passwords configured on the computer where the RADIUS server is installed.

If users are members of multiple RADIUS groups, then the user group authentication timeout value does not apply. See “Membership in multiple groups” on page 1239.

RADIUS authentication with a FortiGate unit

To use RADIUS authentication with a FortiGate unit

- configure one or more RADIUS servers on the FortiGate unit
- assign users to a RADIUS server

When a configured user attempts to access the network, the FortiGate unit will forward the authentication request to the RADIUS server which will match the username and password remotely. Once authenticated the RADIUS server passes the authorization granted message to the FortiGate unit which grants the user permission to access the network.

The RADIUS server uses a “shared secret” key along with MD5 hashing to encrypt information passed between RADIUS servers and clients, including the FortiGate unit. Typically only user credentials are encrypted. Additional security can be configured through IPSec tunnels.

RADIUS attribute value pairs

RADIUS packets include a set of attribute value pairs (AVP) to identify information about the user, their location and other information. The FortiGate unit sends the following RADIUS attributes.

Table 76: FortiOS supported RADIUS attributes

RADIUS Attribute	Name	Description	AVP type

Table 76: FortiOS supported RADIUS attributes

1	Acct-Session-ID	Unique number assigned to each start and stop recard to make it easy to match them, and to eliminate duplicate records.	44
2	username	Name of the user being authenticated	1
3	NAS-Identifier	Identifier or IP address of the Network Access Server (NAS) that is requesting authentication. In this case, the NAS is the FortiGate unit.	32
4	Framed-IP-Address	Address to be configured for the user.	8
5	Fortinet-VSA	See "Vendor-specific attributes" on page 1203	26
6	Acct-Input-Octets	Number of octets received from the port over the course of this service being provided. Used to charge the user for the amount of traffic they used.	42
7	Acct-Output-Octets	Number of octets sent to the port while delivering this service. Used to charge the user for the amount of traffic they used.	43

Table 77 describes the supported authentication events and the RADIUS attributes that are sent in the RADIUS accounting message.

Table 77: RADIUS attributes sent in RADIUS accounting message

	RADIUS ATTRIBUTE						
AUTHENTICATION METHOD	**1**	**2**	**3**	**4**	**5**	**6**	**7**
Web	✔	✔	✔		✔		
XAuth of IPsec (without DHCP)	✔	✔	✔		✔		
XAuth of IPsec (with DHCP)	✔	✔	✔	✔	✔		
PPTP/L2TP (in PPP)	✔	✔	✔	✔	✔	✔	✔
SSL-VPN	✔	✔	✔		✔		

Vendor-specific attributes

Vendor specific attributes (VSA) are the method RADIUS servers and client companies use to extend the basic functionality of RADIUS. Some major vendors, such as Microsoft, have published their VSAs, however many do not.

In order to support vendor-specific attributes (VSA), the RADIUS server requires a dictionary to define which VSAs to support. This dictionary is typically supplied by the client or server vendor.

The Fortinet RADIUS vendor ID is 12365.

The FortiGate unit RADIUS VSA dictionary is supplied by Fortinet and is available through the Fortinet Knowledge Base (http://kb.forticare.com) or through Technical Support. Fortinet's dictionary for FortiOS 4.0 and up is configured this way:

```
##
Fortinet's VSA's
#
VENDOR fortinet 12356
BEGIN-VENDOR fortinet
ATTRIBUTE Fortinet-Group-Name   1   string
ATTRIBUTE Fortinet-Client-IP-Address   2   ipaddr
ATTRIBUTE Fortinet-Vdom-Name   3   string
ATTRIBUTE Fortinet-Client-IPv6-Address   4   octets
ATTRIBUTE Fortinet-Interface-Name   5   string
ATTRIBUTE Fortinet-Access-Profile   6   string
#
# Integer Translations
#
END-VENDOR Fortinet
```

Note that using the Fortinet-Vdom-Name, users can be tied to a specific VDOM on the FortiGate unit. See the documentation provided with your RADIUS server for configuration details.

Role Based Access Control

In Role Based Access Control (RBAC), network administrators and users have varying levels of access to network resources based on their role, and that role's requirement for access specific resources. For example, a junior accountant does not require access to the sales presentations, or network user account information.

There are three main parts to RBAC: role assignment, role authorization, and transaction authorization. Role assignment is accomplished when someone in an organization is assigned a specific role by a manager or HR. Role authorization is accomplished when a network administrator creates that user's RADIUS account and assigns them to the required groups for that role. Transaction authorization occurs when that user logs on and authenticates before performing a task.

RBAC is enforced when FortiOS network users are remotely authenticated via a RADIUS server. For users to authenticate, an identity-based security policy must be matched. That policy only matches a specific group of users. If VDOMs are enabled, the matched group will be limited to a specific VDOM. Using this method network administrators can separate users into groups that match resources, protocols, or VDOMs. It is even possible to limit users to specific FortiGate units if the RADIUS servers serve multiple FortiOS units.

For more information on identity-based policies, see "Authentication in security policies" on page 1246.

Configuring the FortiGate unit to use a RADIUS server

The information you need to configure the FortiGate unit to use a RADIUS server includes

- the RADIUS server's domain name or IP address
- the RADIUS server's shared secret key.

You can optionally specifiy the NAS IP or Called Station ID. When configuring the FortiGate to use a RADIUS server, the FortiGate is a Network Access Server (NAS). If the FortiGate interface has multiple IP addressses, or you want the RADIUS requests to come from a different address you can specify it here. Called Station ID applies to carrier networks. However, if the NAS IP is not included in the RADIUS configuration, the IP of the FortiGate unit interface that communicates with the RADIUS server is used instead.

A maximum of 10 remote RADIUS servers can be configured on the FortiGate unit. One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see "Creating users" on page 1224.

On the FortiGate unit, the default port for RADIUS traffic is 1812. Some RADIUS servers use port 1645. If this is the case with your server, you can either:

- Re-configure the RADIUS server to use port 1812. See your RADIUS server documentation for more information on this procedure.

or

- Change the FortiGate unit default RADIUS port to 1645 using the CLI:

```
config system global
  set radius_port 1645
end
```

One wildcard admin account can be added to the FortiGate unit when using RADIUS authentication. This uses the wildcard character to allow multiple admin accounts on RADIUS to use a single account on the FortiGate unit. See "Example — wildcard admin accounts - CLI" on page 1211.

To configure the FortiGate unit for RADIUS authentication - web-based manager

1 Go to *User* > *Remote* > *RADIUS* and select *Create New*.

2 Enter the following information and select OK.

Name	A name to identify the RADIUS server on the FortiGate unit.
Type	Select Query. Selecting a Type of *Dynamic Start* configures the Dynamic Profile feature. See "Dynamic profiles and end points" on page 1325.
Primary Server Name/IP	Enter the domain name (such as fgt.exmaple.com) or the IP address of the RADIUS server.
Primary Server Secret	Enter the server secret key, such as radiusSecret. This can be a maximum of 16 characters long. This must match the secret on the RADIUS primary server.
Secondary Server Name/IP	Optionally enter the domain name (such as fgt.exmaple.com) or the IP address of the secondary RADIUS server.
Secondary Server Secret	Optionally, enter the secondary server secret key, such as radiusSecret2. This can be a maximum of 16 characters long. This must match the secret on the RADIUS secondary server.
Authentication Scheme	If you know the RADIUS server uses a specific authentication protocol, select it from the list. Otherwise select Use Default Authentication Scheme. The Use Default option will usually work.
NAS IP/ Called Station ID	Enter the IP address to be used as an attribute in RADIUS access requests. **NAS-IP-Address** is RADIUS setting or IP address of FortiGate interface used to talk to RADIUS server, if not configured. **Called Station ID** is same value as NAS-IP Address but in text format.
Include in every User Group	When enabled this RADIUS server will automatically be included in all user groups. This is useful if all users will be authenticating with the remote RADIUS server.

For MAC OS and iOS devices to authenticate, you must use MS-CHAP-v2 authentication. In the CLI, the command is `set auth-type ms_chap_v2`.

3 Select *OK*.

To configure the FortiGate unit for RADIUS authentication - CLI example

```
config user radius
  edit ourRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret radiusSecret
  end
```

For more information about RADIUS server options, refer to the *FortiGate CLI Reference*.

Troubleshooting RADIUS

To test the connection to the RADIUS server use the following command:

```
diagnose test authserver radius-direct <server_name or IP> <port
    number> <secret>
```

For the port number, enter `-1` to use the default port. Otherwise enter the port number to check.

Additional RADIUS related troubleshooting is located at "Troubleshooting FSSO" on page 1318

LDAP servers

Lightweight Directory Access Protocol (LDAP) is an Internet protocol used to maintain authentication data that may include departments, people, groups of people, passwords, email addresses, and printers. LDAP consists of a data-representation scheme, a set of defined operations, and a request/response network.

The scale of LDAP servers range from big public servers such as BigFoot and Infospace, to large organizational servers at universities and corporations, to small LDAP servers for workgroups that may be using OpenLDAP. This document focuses on the institutional and workgroup applications of LDAP.

This section includes:

Components and topology

LDAP organization starts with directories. A directory is a set of objects with similar attributes organized in a logical and hierarchical way. Generally, an LDAP directory tree reflects geographic and organizational boundaries, with the Domain name system (DNS) names to structure the top level of the hierarchy. The common name identifier for most LDAP servers is `cn`, however some servers use other common name identifiers such as `uid`.

When LDAP is configured and a user is required to authenticate the general steps are:

1. The FortiGate unit contacts the LDAP server for authentication.
2. To authenticate with the FortiGate unit, the user enters a username and password.
3. The FortiGate unit sends this username and password to the LDAP server.
4. If the LDAP server can authenticate the user, the user is successfully authenticated with the FortiGate unit.
5. If the LDAP server cannot authenticate the user, the connection is refused by the FortiGate unit.

Binding

Binding is the step where the LDAP server authenticates the user. If the user is successfully authenticated, binding allows the user access to the LDAP server based on that user's permissions.

The FortiGate unit can be configured to use one of three types of binding:

- anonymous - bind using anonymous user search
- regular - bind using username/password and then search
- simple - bind using a simple password authentication without a search

You can use simple authentication if the user records all fall under one domain name (`dn`). If the users are under more than one `dn`, use the anonymous or regular type, which can search the entire LDAP database for the required username.

If your LDAP server requires authentication to perform searches, use the regular type and provide values for username and password.

Supported versions

The FortiGate unit supports LDAP protocol functionality defined in RFC 2251: Lightweight Directory Access Protocol v3, for looking up and validating usernames and passwords. FortiGate LDAP supports all LDAP servers compliant with LDAP v3, including FortiAuthenticator. In addition, FortiGate LDAP supports LDAP over SSL/TLS, which can be configured only in the CLI.

FortiGate LDAP does not support proprietary functionality, such as notification of password expiration, which is available from some LDAP servers. FortiGate LDAP does not supply information to the user about why authentication failed.

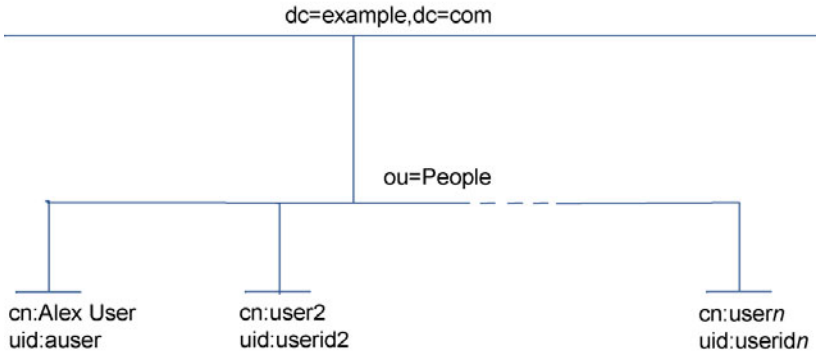
LDAP directory organization

To configure your FortiGate unit to work with an LDAP server, you need to understand the organization of the information on the server.

The top of the hierarchy is the organization itself. Usually this is defined as Domain Component (DC), a DNS domain. If the name contains a dot, such as `example.com`, it is written as two parts separated by a comma: `dc=example,dc=com`.

In this example, Common Name (CN) identifiers reside at the Organization Unit (OU) level, just below DC. The Distinguished Name (DN) is ou=People,dc=example,dc=com.

Figure 103: LDAP object hierarchy



In addition to the DN, the FortiGate unit needs an identifier for the individual person. Although the FortiGate unit GUI calls this the Common Name (CN), the identifier you use is not necessarily CN. On some servers, CN is the full name of a person. It might be more convenient to use the same identifier used on the local computer network. In this example, User ID (UID) is used.

Locating your identifier in the hierarchy

You need to determine the levels of the hierarchy from the top to the level that contain the identifier you want to use. This defines the DN that the FortiGate unit uses to search the LDAP database. Frequently used distinguished name elements include:

- uid (user identification)
- pw (password)
- cn (common name)
- ou (organizational unit)
- o (organization)
- c (country)

One way to test this is with a text-based LDAP client program. For example, OpenLDAP includes a client, `ldapsearch`, that you can use for this purpose.

Enter the following at the command line:

```
ldapsearch -x '(objectclass=*)'
```

The output is lengthy, but the information you need is in the first few lines:

```
version: 2
#
# filter: (objectclass=*)
# requesting: ALL

dn: dc=example,dc=com
dc: example
objectClass: top
objectClass: domain

dn: ou=People,dc=example,dc=com
ou: People
objectClass: top
objectClass: organizationalUnit
...
dn: uid=tbrown,ou=People,dc=example,dc=com
uid: tbrown
cn: Tom Brown
```

In the output above, you can see `tbrown` (uid) and `Tom Brown`(cn). Also note the dn is `ou=People, dc=example, dc=com`.

Configuring the FortiGate unit to use an LDAP server

After you determine the common name and distinguished name identifiers and the domain name or IP address of the LDAP server, you can configure the server on the FortiGate unit. The maximum number of remote LDAP servers that can be configured is 10.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see “Creating users” on page 1224.

To configure the FortiGate unit for LDAP authentication - web-based manager

1 Go to *User* > *Remote* > *LDAP* and select *Create New*.
2 Enter a name for the LDAP server.
3 In *Server Name/IP* enter the server's FQDN or IP address.
4 If the server does not use port 389, enter the port number in the *Server Port* field.
5 Enter the *Common Name Identifier* (20 characters maximum).

`cn` is the default, and is used by most LDAP servers.

6 In the *Distinguished Name* field, enter the base distinguished name for the server using the correct X.500 or LDAP format.

The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.

If you don't know the distinguished name, leave the field blank and select the Query icon to the right of the field. See the "Using the Query icon" on page 1211.

7 In *Bind Type*, select *Regular*.
8 In *User DN*, enter the LDAP administrator's distinguished name.
9 In *Password*, enter the LDAP administrator's password.
10 Select *OK*.

To verify your Distinguished Name field is correct, you can select the Query icon. If your DN field entry is valid, you will see the part of the LDAP database it defines. If your DN field entry is not valid, it will display an error message and return no information.

For detailed information about configuration options for LDAP servers, see the Online Help on your FortiGate unit or the FortiGate CLI Reference.

To configure the FortiGate unit for LDAP authentication - CLI example

```
config user ldap
  edit ourLDAPsrv
    set server 10.11.101.160
    set cnid cn
    set dn cn=users,dc=office,dc=example,dc=com
    set type regular
    set username
       cn=administrator,cn=users,dc=office,dc=example,dc=com
    set password w5AiGVMLkgyPQ
    set password-expiry-warning enable
    set password-renewal enable
  end
```

password-expiry-warning and password-renewal

In SSLVPN, when an LDAP user is connecting to the LDAP server it is possible for them to receive any pending password expiry or renewal warnings. When the password renewal or expiry warning exists, SSLVPN users will see a prompt allowing them to change their password.

`password-expiry-warning` allows FortiOS to detect from the LDAP server when a password is expiring or has expired using server controls or error codes.

`password-renewal` allows FortiOS to perform the online LDAP password renewal operations the LDAP server expects.

On an OpenLDAP server, when a user attempts to logon with an expired password they are allowed to logon on but only to change their password.

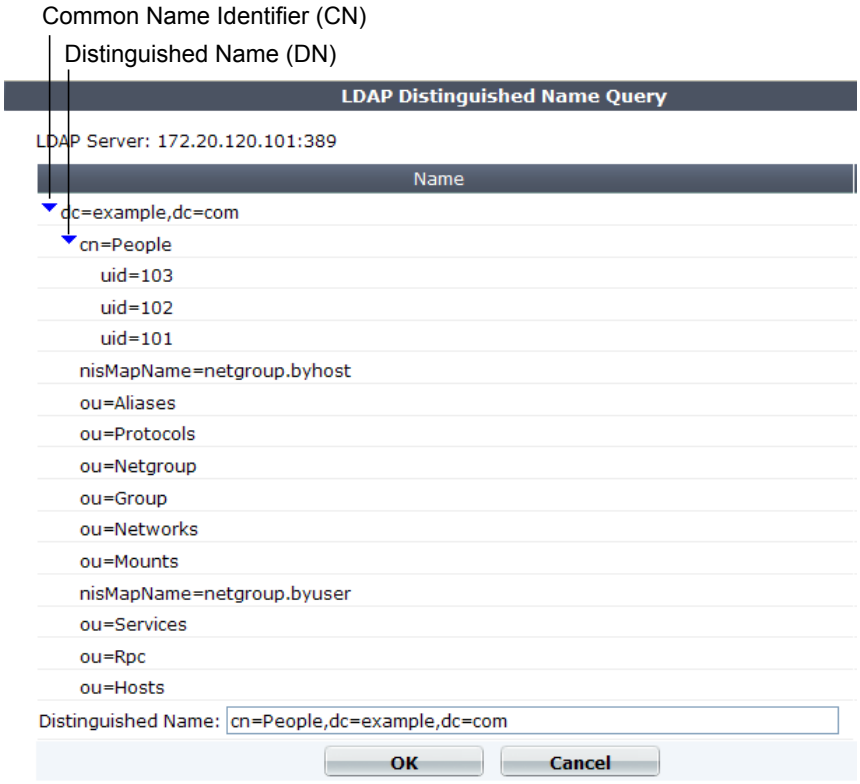
When changing passwords on a Windows AD system, the connection must be SSL-protected.

Using the Query icon

The LDAP Distinguished Name Query list displays the LDAP directory tree for the LDAP server connected to the FortiGate unit. This helps you to determine the appropriate entry for the DN field. To see the distinguished name associated with the Common Name identifier, select the Expand icon next to the CN identifier. Select the DN from the list. The DN you select is displayed in the Distinguished Name field. Select OK and the Distinguished Name you selected will be saved in the Distinguished Name field of the LDAP Server configuration.

To see the users within the LDAP Server user group for the selected Distinguished Name, expand the Distinguished Name in the LDAP Distinguished Name Query tree.

Figure 104: LDAP server Distinguished Name Query tree



Example — wildcard admin accounts - CLI

A wildcard admin account is an administrator account with the wildcard option enabled. This option allows multiple different remote administration accounts to match one local administration account, avoiding the need to set up individual admin accounts on the FortiGate unit. Instead multiple LDAP admin accounts will all be able to use one FortiGate admin account.

The initial benefit of wildcard admin accounts is fast configuration of the FortiGate unit's administration account to work with your LDAP network. The many to one ratio saves on effort, and potential errors.

The ongoing benefit is that as long as the users on the LDAP system belong to that group, and the test admin user settings don't change on the FortiGate unit, no other work is required. This point is important as it can help avoid manby system updates or changes that would otherwise require changes to the LDAP administrator account configuration. Even if a user is added to or removed from the LDAP group, no changes are required on the FortiGate unit.

Two potential issues with wildcard admin accounts are that multiple users may be logged on to the same account at the same time. This becomes an issue if they are changing the same information at the same time. The other potential issue is that security is reduced because multiple people have login access for the same account. If each user was assigned their own account, a hijacking of one account would not affect the other users.

Note that wildcard admin configuration also applies to RADIUS. When configuring for RADIUS, configure the RADIUS server, and RADUS user group instead of LDAP. When using web-based management, wildcard admin is the only type of remote administrator account that does not require you to enter a password on account creation. That password is normally used when the remote authentication server is unavailable during authentication.

In this example, default values are used where possible . If a specific value is not mentioned, it is set to its default value.

Configuring the LDAP server

The important parts of this configuration are the username and group lines. The username is the domain administrator account. The group binding allows only the group with the name `GRP` to access.

The `dn` used here is as an example only. On your network use your own domain name.

To configure LDAP server - CLI

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
    set dn "DC=example,DC=com,DC=au"
    set type regular
    set username "CN=Administrator,CN=Users,DC=example,DC=COM"
    set password *
    set group "CN=GRP,OU=training,DC=example,DC=COM"
    set filter ""
  next
end
```

To configure the user group and add the LDAP server - CLI

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
```

```
    edit 1
      set server-name "ldap"
      set group-name "TRUE"
    next
    end
  next
end
```

Configuring the admin account

The wildcard part of this example is only available in the CLI for admin configuration. When enabled, this allows all LDAP group members to login to the FortiGate unit without the need to create a separate admin account for each user. In effect the members of that group will each be able to login as “test”.

To configure the admin account - CLI

```
config system admin
  edit “test”
  set remote-auth enable
  set accprofile “super_admin”
  set wildcard enable
  set remote-group “ldap_grp”
  next
end
```

For troubleshooting, test that the admin account is operational, and see “Troubleshooting LDAP” on page 1214.

Example of LDAP to allow Dial-in through member-attribute - CLI

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to setup a VPN connection simply based on an attribute that is set to TRUE, instead of based on being part of a specific group.

In AD, the "Allow Dial-In" property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to "TRUE".

This same procedure can be used for other member attributes, as your system requires.

This example works with FortiOS 4.0 MR2. The filter command was removed in FortiOS 4.0 MR3.

Configuring LDAP member-attribute settings

To accomplish this with a FortiGate unit, the member attribute must be set. Setting member attributes can only be accomplished through the CLI using the `member-attr` keyword - the option is not available through the web-based manager.

Before configuring the FortiGate unit, the AD server must be configured and have the `msNPAllowDialin` attribute set to "TRUE" for the users in question. If not, those users will not be able to properly authenticate.

The dn used here is as an example only. On your network use your own domain name.

To configure user LDAP member-attribute settings - CLI

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
```

```
    set dn "DC=fortinet,DC=com,DC=au"
    set type regular
    set username "fortigate@example.com"
    set password ******
    set filter "(&(uid=%u)(msNPAllowDialin=TRUE))"
    set member-attr "msNPAllowDialin"
  next
end
```

Configuring LDAP group settings

A user group that will use LDAP must be configured. This example adds the member `ldap` to the group which is the LDAP server name that was configured earlier.

To configure LDAP group settings - CLI

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
    edit 1
      set server-name "ldap"
      set group-name "TRUE"
    next
    end
  next
end
```

Once these settings are in place, users can authenticate.

Troubleshooting LDAP

The examples in this section use the values from the previous example.

LDAP user test

A quick way to see if the LDAP configuration is correct is to run a diagnose CLI command with LDAP user information. The following command tests with a user called `netAdmin` and a password of `fortinet`. If the configuration is correct the test will be successful.

```
FGT# diag test authserver ldap ldap_server netAdmin fortinet
```

`'ldap_server' is not a valid ldap server name` — an LDAP server by that name has not been configured on the FortiGate unit, check your spelling.

`authenticate 'netAdmin' against 'ldap_server' failed!` — the user `netAdmin` does not exist on `ldap_server`, check your spelling of both the user and sever and ensure the user has been configured on the FortiGate unit.

LDAP authentication debugging

For a more in-depth test, you can use a `diag debug` command. The sample output from a shows more information about the authentication process that may prove useful if there are any problems.

Ensure the "Allow Dial-in" attribute is still set to "TRUE" and run the following CLI command. `fnbamd` is the Fortinet non-blocking authentication daemon.

```
FGT# diag debug enable
FGT# diag debug reset
FGT# diag debug application fnbamd -1
```

```
FGT# diag debug enable
```

The output will look similar to:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the "Allow Dial-in" attribute is not set but it is expected, the last line of the above output will instead be:

```
fnbamd_auth_poll_ldap-Failed group matching
```

TACACS+ servers

When users connect to their corporate network remotely, they do so through a remote access server. As remote access technology has evolved, the need for security when accessing networks has become increasingly important. This need can be filled using a Terminal Access Controller Access-Control System (TACACS+) server.

TACACS+ is a remote authentication protocol that provides access control for routers, network access servers, and other networked computing devices via one or more centralized servers. TACACS+ allows a client to accept a username and password and send a query to a TACACS+ authentication server. The server host determines whether to accept or deny the request and sends a response back that allows or denies the user access to the network.

TACACS+ offers fully encrypted packet bodies, and supports both IP and AppleTalk protocols. TACACS+ uses TCP port 49, which is seen as more reliable than RADIUS's UDP protocol.

There are several different authentication protocols that TACACS+ can use during the authentication process:

Protocol	Definition
ASCII	Machine-independent technique that uses representations of English characters. Requires user to type a username and password that are sent in clear text (unencrypted) and matched with an entry in the user database stored in ASCII format.
PAP	Password Authentication Protocol (PAP) Used to authenticate PPP connections. Transmits passwords and other user information in clear text.
CHAP	Challenge-Handshake Authentication Protocol (CHAP) Provides the same functionality as PAP, but is more secure as it does not send the password and other user information over the network to the security server.
MS-CHAP	MicroSoft Challenge-Handshake Authentication Protocol v1 (MSCHAP) Microsoft-specific version of CHAP.
default	The default protocol configuration, Auto, uses PAP, MS-CHAP, and CHAP, in that order.

Configuring a TACACS+ server on the FortiGate unit

A maximum of 10 remote TACACS+ servers can be configured for authentication.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see "Creating users" on page 1224.

To configure the FortiGate unit for TACACS+ authentication - web-based manager

1 Go to *User* > *Remote* > *TACACS+* and select *Create New*.

2 Enter the following information, and select *OK*.

Name	Enter the name of the TACACS+ server.
Server Name/IP	Enter the server domain name or IP address of the TACACS+ server.
Server Key	Enter the key to access the TACACS+ server.
Authentication Type	Select the authentication type to use for the TACACS+ server. *Auto* tries PAP, MSCHAP, and CHAP (in that order).

To configure the FortiGate unit for TACACS+ authentication - CLI

```
config user tacacs+
  edit <server_name>
    set auth-type {ascii | auto | chap | ms_chap | pap}
    set key <server_key>
    set tacacs+-port <tacacs+_port_num>
    set server <domain>
  end
```

FSSO servers

Novell and Microsoft Windows networks provide user authentication based on directory services: eDirectory for Novell, Active Directory for Windows. Users can log on at any computer in the domain and have access to resources as defined in their user account. The Fortinet Single Sign On (FSSO) agent enables FortiGate units to authenticate these network users for security policy or VPN access without asking them again for their username and password.

When a user logs in to the Windows or Novell domain, the FSSO agent sends the FortiGate unit the user's IP address and the names of the user groups to which the user belongs. The FortiGate unit uses this information to maintain a copy of the domain controller user group database. Because the domain controller authenticates users, the FortiGate unit does not perform authentication. It recognizes group members by their IP address.

In the FortiOS FSSO configuration, you specify the server where the FSSO Collector agent is installed. The Collector agent retrieves the names of the Novell or Active Directory user groups from the domain controllers on the domains, and then the FortiGate unit gets them from the Collector agent. You cannot use these groups directly. You must define FSSO type user groups on your FortiGate unit and then add the Novell or Active Directory user groups to them. The FSSO user groups that you created are used in security policies and VPN configurations to provide access to different services and resources.

FortiAuthenticator servers can replace the Collector agent when FSSO is using polling mode. The benefits of this is that FortiAuthenticator is a stand-alone server that has the necessary FSSO software pre-installed. For more information, see the *FortiAuthenticator Administration Guide*.

For more information about Directory Services and FSSO, see "FSSO integration with Windows AD or Novell" on page 1283.

RSA ACE (SecurID) servers

SecurID is a two-factor system that uses one-time password (OTP) authentication. It is produced by the company RSA. This system includes portable tokens carried by users, an RSA ACE/Server, and an Agent Host. In our configuration, the FortiGate unit is the Agent Host.

Components

When using SecurID, users carry a small device or "token" that generates and displays a random password. According to RSA, each SecurID authenticator token has a unique 64-bit symmetric key that is combined with a powerful algorithm to generate a new code every 60 seconds. The token is time-synchronized with the SecurID RSA ACE/Server.

The RSA ACE/Server is the management component of the SecurID system. It stores and validates the information about the SecurID tokens allowed on your network. Alternately the server could be an RSA SecurID 130 Appliance.

The Agent Host is the server on your network, in this case it is the FortiGate unit, that intercepts user logon attempts. The Agent Host gathers the user ID and password entered from their SecurID token, and sends that information to the RSA ACE/Server to be validated. If valid, a reply comes back indicating it is a valid logon and the FortiGate unit allows the user access to the network resources specified in the associated security policy.

Configuring the SecurID system

To use SecurID with a FortiGate unit, you need:

- to configure the RSA server and the RADIUS server to work with each other (see RSA server documentation)
- To configure the RSA SecurID 130 Appliance

  or
- To configure the FortiGate unit as an Agent Host on the RSA ACE/Server
- To configure the FortiGate unit to use the RADIUS server
- To create a SecurID user group and user
- To configure a security policy with SecurID authentication

The following instructions are based on RSA ACE/Server version 5.1, or RSA SecurID 130 Appliance, and assume that you have successfully completed all the external RSA and RADIUS server configuration steps listed above.

For this example, the RSA server is on the internal network, with an IP adress of 192.128.100.100. The FortiGate unit internal interface address is 192.168.100.3, RADIUS shared secret is fortinet123, RADIUS server is at IP address 192.168.100.102.

To configure the RSA SecurID 130 Appliance

1 Go to the IMS Console for SecurID and logon.

2 Go to *RADIUS* > *RADIUS Clients*, and select *Add New.*

3 Enter the following information to configure your FortiGate as a SecurID Client, and select Save.

RADIUS Client Basics	
Client Name	FortiGate
Associated RSA Agent	FortiGate
RADIUS Client Settings	
IP Address	192.168.100.3 The IP address of the FortiGate unit internal interface.
Make / Model	Select Standard Radius
Shared Secret	fortinet123 The RADIUS shared secret.
Accounting	Leave unselected
Client Status	Leave unselected

To configure the FortiGate unit as an Agent Host on the RSA ACE/Server

1 On the RSA ACE/Server computer, go to *Start* > *Programs* > *RSA ACE/Server*, and then *Database Administration - Host Mode*.

2 On the *Agent Host* menu, select *Add Agent Host*.

3 Enter and save the following information.

Name	FortiGate
Network Address	192.168.100.3 The IP address of the FortiGate unit.
Secondary Nodes	Optionally enter other IP addresses that resolve to the FortiGate unit.

If needed, refer to the RSA ACE/Server documentation for more information.

To configure the FortiGate unit to use the RADIUS server

1 Go to *User* > *Remote* > *RADIUS* and select *Create New*.

2 Enter the following information, and select OK.

Name	RSA
Type	Query
Primary Server Address	192.168.100.102 Optionally select Test to ensure the IP address is correct and the FortiGate can contact the RADIUS server.

Primary Server Secret	fortinet123
Authentication Scheme	Select *Use Default Authentication Scheme*.

To create a SecurID user group and user

1 Go to *User* > *User Group*, and select *Create New*.

2 Enter the following information, and select OK.

Name	RSA_group
Remote Authentication servers	Select the RSA server.

3 Go to *User* > *User* > *User*, and select *Create New*.

4 Enter the following information, and select OK.

User Name	wloman
Match User on RADIUS server	RSA
Add this user to groups	Select RSA_group

To test this configuration, on your FortiGate unit use the CLI command:

```
diag test auth rad RSA auto wloman 111111111
```

The series of 1s is the one time password that your RSA SecurID token generates and you enter.

Using the SecurID user group for authentication

You can use the SecurID user group in several FortiOS features that authenticate by user group including

- Security policy
- IPsec VPN XAuth
- PPTP VPN
- SSL VPN

The following sections assume the SecurID user group is called `securIDgrp` and has already been configured. Unless otherwise states, default values are used.

Security policy

To use SecurID in a security policy, you must include the SecurID user group in an identity-based security policy. This procedure will create a security policy that allows HTTP, FTP, and POP3 traffic from the `internal` interface to `wan1`. If these interfaces are not available on your FortiGate unit, substitute other similar interfaces.

To configure a security policy with SecurID authentication

1 Go to *Policy* > *Policy*.

2 Select *Create New*.

3 Select `internal` for *Source Interface/Zone*.

4 Select `wan1` for *Destination Interface/Zone.*

5 For both *Source Address* and *Destination Address* select *all*.

6 Select *Enable identity-based Policy* and select *Add*.

7 Move `securIDgrp` rom the *Available User Groups* to the list on the right.

8 Move `HTTP`, `FTP`, and `POP3` from *Available Services* to the list on the right.

9 Select OK.

You are returned to the security policy creation page, with the information you just entered in the identity-based policy (IBP) table as Rule ID 1.

10 Select OK.

The SecurID security policy is configured.

To generate usage reports on traffic authenticated with this policy, when you are adding the IBP rule, enable *Log Traffic*.

To either limit traffic or guarantee minimum bandwidth for traffic that uses the SecurID security policy, when you are adding the IBP rule, select traffic shaping and select one of the default shapers from the list such as `guarantee-100kbps`.

To customize any challenge pages or logon pages users will see when authenticating against this security policy, select *Customize Authentication Messages* and select the icon that appears. This takes you to the Edit Message page where you can customize the login challenge page, login failed page, and others.

For more details on configuring security policies, see the *FortiOS Handbook FortiGate Fundamentals chapter*.

IPsec VPN XAuth

Extended Authentication (XAuth) increases security by requiring additional user authentication information in a separate exchange at the end of the VPN Phase 1 negotiation. If the SecurID user group is used, this extended information will require users to enter their SecurID code. For more on XAuth, see "Configuring XAuth authentication" on page 1259.

This Phase 1 configuration will be named `securIDxAuth` and it will connect with IP address `10.11.101.155` on the `wan1` interface.

To configure IPsec VPN XAuth with SecurID authentication - web-based manager

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 1*.

3 Enter `securIDxAuth` for *Name*.

4 Select Dialup User for *Remote Gateway*.

5 Select Preshared Key for *Authentication Method*.

6 Enter `fortinet` for the *Pre-shared Key*.

7 Select *Advanced*.

8 For XAuth, select *Enable as Server*.

9 Select AUTO for Server Type.

10 Select `securIDgrp` for *User Group*.

11 Select *OK*.

PPTP VPN

PPTP VPN is configured in the CLI. In the PPTP configuration (`config vpn pptp`), set `usrgrp` to the SecurID user group.

SSL VPN

In the SecurID user group, select the appropriate web portal for these users. In the security policy for the SSL VPN, include the SecurID user group in the list of selected user groups.

Users and user groups

FortiGate authentication controls system access by user group. By assigning individual users to the appropriate user groups you can control each user's access to network resources. The members of user groups are user accounts, of which there are several types. Local users and peer users are defined on the FortiGate unit. User accounts can also be defined on remote authentication servers.

This section describes how to configure local users and peer users and then how to configure user groups. For information about configuration of authentication servers see "Authentication servers" on page 1201.

This section contains the following topics:

Users

A user is a user account consisting of username, password, and in some cases other information, configured on the FortiGate unit or on an external authentication server. Users can access resources that require authentication only if they are members of an allowed user group. There are several different types of user accounts with slightly different methods of authentication:

Table 78: How the FortiGate unit authenticates different types of users

User type	Authentication
Local user, password stored on the FortiGate unit	The username and password must match a user account stored on the FortiGate unit. Authentication by FortiGate security policy.
Local user, password stored on a remote server	The username must match a user account stored on the FortiGate unit and the username and password must match a user account stored on the remote authentication server.
Authentication server user	A FortiGate user group can include user accounts or groups that exist on a remote authentication server.
FSSO user	With Fortinet Single Sign On (FSSO), users on a Microsoft Windows or Novell network can use their network authentication to access resources through the FortiGate unit. Access is controlled through FSSO user groups which contain Windows or Novell user groups as their members.
Peer user with certificate authentication	A peer user is a digital certificate holder that authenticates using a client certificate. No password is required, unless two-factor authentication is enabled.

This section includes:

- PKI or peer users
- Two-factor authentication
- FortiToken
- Monitoring users

Local users

Local users are defined on the FortiGate unit. To define a local user you need:

- a username
- a password or the name of the authentication server that contains the user account

If the user is authenticated externally, the username on the FortiGate unit must be identical to the username on the authentication server. You may also still be prompted for a password. If the connection to the remote authentication server is interrupted during authentication the local password will be used if it exists to ensure access.

Local users are authenticated through authentication security policies. See

This section includes:

- Creating users
- Removing users
- Removing references to users

Creating users

Before configuring any authentication, except dynamic profiles, you must first create local users. For more about dynamic profiles, see “Configuring dynamic profile” on page 1332.

When creating a new user, there are only two differences between a local and a remote user:

- local users require a password to be configured
- remote users do not require a password, but do require a remote authentication server to be configured

To create a local user - web-based manager

1 Go to *User* > *User* and select *Create New*.

2 Enter the username in the *username* field.

- Select *Password* and type a password. Best practices dictate that the password be at least six characters long.

To authenticate this user using an external authentication server, select the *Match user* option for the appropriate type of server and select the server name. Password is not required. You must configure the remote server access first. See “Authentication servers” on page 1201.

3 Optionally select *Enable Two-factor Authentication* to use that option with this user.

When enabled, additional options will be displayed. Select one of the following options and configure it as stated.

- Select *FortiToken*, and choose the FortiToken serial number to associate with this user.
- Select *Email to* and enter the user's email address to email them the token code.
- Select *SMS* and enter the Mobile Provider from the list, and enter the user's mobile phone number that will receive the token code in a text message.

4 Select *OK*.

The Mobile Provider for SMS must be entered in the CLI using the `config user sms-provider` command before it will be available to select in the web-based manager.

To create a local user - CLI examples

Locally authenticated user

```
config user local
  edit user1
    set type password
    set passwd ljt_pj2gpepfdw
  end
```

User authenticated on an LDAP server

```
config user local
  edit user2
    set type ldap
    set ldap_server ourLDAPsrv
  end
```

User authenticated on a RADIUS server

```
config user local
  edit user3
    set type radius
    set radius_server ourRADIUSsrv
  end
```

User authenticated on a TACACS+ server

```
config user local
  edit user4
    set type tacacs+
    set tacacs+_server ourTACACS+srv
  end
```

User authenticated with a FortiToken

```
config user local
  edit user5
    set type password
    set passwd ljt_pj2gpepfdw
    set two_factor fortitoken
    set fortitoken 182937197
  end
```

User authenticated using email

```
config user local
  edit user6
    set type password
    set passwd ljt_pj4h7epfdw
    set two_factor email
    set email-to user6@sample.com
  end
```

User authenticated using SMS text message

```
config user sms-provider
  edit "Sample Mobile Inc"
    set mail-server mail.sample.com
  end

config user local
  edit user7
    set type password
    set passwd 3ww_pjt68dw
    set two_factor sms
    set sms-provider "Sample Mobile Inc"
    set sms-phone 2025551234
  end
```

Removing users

Best practices dictate that when a user account is no longer in use, it be deleted. Removing local and remote users from FortiOS involve the same steps.

If the user account is references by any configuration objects those references must be removed before the user can be deleted. See "Removing references to users" on page 1226.

To remove a user from the FortiOS configuration - web-based manager

1. Go to *User* > *User*.
2. Select the check box of the user that you want to remove.
3. Select *Delete*.
4. Select *OK*.

To remove a user from the FortiOS configuration - CLI example

```
config user local
  delete user4444
end
```

Removing references to users

You cannot remove a user that belongs to a user group. Remove the user from the user group first, and then delete the user.

To remove references to a user - web-based manager

1. Go to *User* > *User* > *User*.
2. If the number in the far right column for the selected user contains any number other than zero, select it.

3 A more detailed list of object references to this user is displayed. Use its information to find and remove these references to allow you to delete this user.

PKI or peer users

A PKI, or peer user, is a digital certificate holder. A PKI user account on the FortiGate unit contains the information required to determine which CA certificate to use to validate the user's certificate. Peer users can be included in firewall user groups or peer certificate groups used in IPsec VPNs. For more on certificates, see "Certificates overview" on page 1264.

To define a peer user you need:

- a peer username
- the text from the subject field of the user's certificate, or the name of the CA certificate used to validate the user's certificate

Creating a peer user

The configuration page for PKI users in the web-based manager is not available unless there is at least one peer user defined. Follow the CLI-based instructions to create the first peer user. Optionally, you can then logon to the web-based manager to configure additional PKI (peer) users.

To create a peer user for PKI authentication - CLI example

```
config user peer
  edit peer1
    set subject E=peer1@mail.example.com
    set ca CA_Cert_1
  end
```

If you create a PKI user in the CLI with no values in `subject` or `ca`, you will not be able to open the user's record in the web-based manager. The CLI will prompt you to add a value in *Subject* (`subject`) or *CA* (`ca`).

To create a peer user for PKI authentication - web-based manager

1 Go to *User* > *PKI* and select *Create New*.

2 Enter the user name.

3 Fill in at least one of the following fields:

Subject	The text string that appears in the Subject field of the user's certificate.
CA	Select the CA certificate that must be used to authenticate this peer user.

4 Optionally you can select Two-factor authentication. See "Two-factor authentication" on page 1228.

5 Select *OK*.

There are other configuration settings that can be added or modified for PKI authentication. For example, you can configure the use of an LDAP server to check access rights for client certificates. For information about the detailed PKI configuration settings only available through the CLI, see the *FortiGate CLI Reference*.

Two-factor authentication

The standard logon requires a username and password. This is one factor authentication—your password is one piece of information you need to know to gain access to the system.

Two factor authentication adds the requirement for another piece of information for you logon. Generally the two factors are something you know (password) and something you have (certificate, token, etc.). This makes it harder for a hacker to steal your logon information. For example if you have a FortiToken device, the hacker would need to both use it and know your password to gain entry to your account.

Two-factor authentication is available on both user and admin accounts. But before you enable two-factor authentication on an administrator account, you need toensure you have a second administrator account configured to guarantee administator access to the FortiGate unit if you are unable to authenticate on the main admin account for some reason.

Two-factor authentication does not work with explicit proxies.

The methods of two-factor authentication include:

- Certificate
- Email
- SMS
- FortiToken

Certificate

You can increase security by requiring both certificate and password authentication for PKI users. Certificates are installed on the user's computer. Requiring a password also protects against unauthorized use of that computer.

Optionally peer users can enter the code from their FortiToken instead of the certificate.

To create a peer user with two-factor authentication - web-based manager

While configuring a peer user (see "PKI or peer users" on page 1227), select *Require two-factor authentication* and enter a password.

To create a peer user with two-factor authentication - CLI example

```
config user peer
  edit peer1
    set subject E=peer1@mail.example.com
    set ca CA_Cert_1
    set two-factor enable
    set passwd fdktguefheygfe
  end
```

For more information on certificates, see "Certificates overview" on page 1264.

Email

Two-factor email authentication sends a randomly generated six digit numeric code to the specified email address. Enter that code when prompted at logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted.

A benefit is that you do not require mobile service to authenticate. However, a potential issue is if your email server does not deliver the email before the 60 second life of the token expires.

The code will be generated and emailed at the time of logon, so you must have email access at that time to be able to receive the code.

To enable email two-factor authentication - web-based manager

1. Go to the email server under *Log&Report->Log Config->Alert e-mail*.
2. Enter the SMTP Server and Email from address.
3. If applicable, enable Authentication on the SMTP server and enter the SMTP username and password to use.
4. Select *Apply*.
5. To modify an administrator account, go to *System* > *Admin* > *Administrators*. To modify a user account go to ***User > User***.
6. Select an existing account or select Create New.
7. Select *Enable Two-factor Authentication*.
8. Select *Email to*.
9. Enter the email address.
10. Select *OK*.

SMS

SMS two-factor authentication sends the token code in an SMS text message to the mobile device indicated when this user attempts to logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted. Enter this code when prompted at logon to be authenticated.

SMS two-factor authentication has the benefit that you do not require email service before logging on. A potential issue is if the mobile service provider does not send the SMS text message before the 60 second life of the token expires.

Before configuring SMS, you must configure the email server for sending email from the FortiGate unit and one or more SMS providers in the CLI.

To configure the SMTP email address for your FortiGate unit - web-based manager

1. Go to the email server under *Log&Report->Log Config->Alert e-mail*.
2. Enter the *SMTP Server* and *Email from* address.
3. If applicable, enable Authentication on the SMTP server and enter the SMTP username and password to use.
4. Select *Apply*.

To configure an SMS provider - CLI

```
config user sms-provider
  edit <provider_name>
    set mail-server <server_email>
  next
end
```

To configure SMS two-factor authentication - web-based manager

1 To modify an:
- administrator account, go to *System* > *Admin* > *Administrators, or*
- user account go to ***User > User***.

2 Select an existing account or select *Create New*.

3 Select *Enable Two-factor Authentication*.

4 Select SMS.

5 Choose the SMS provider from the drop down list.

6 Enter the phone number of the mobile device that will receive the SMS text messages.

If you have problems receiving the token codes via SMS messaging, contact your mobile provider to ensure you are using the correct phone number format to receive text messages and that your current mobile plan allows text messages.

FortiToken

FortiToken is a disconnected one-time password (OTP) generator. It is a small physical device with a button that when pressed displays a six digit authentication code. This code is entered with a user's username and password as two-factor authentication. The code displayed changes every 60 seconds, and when not in use the LCD screen is blanked to extend the battery life.

FortiTokens have a small hole in one end. This is intended for a lanyard to be inserted so the device can be worn around the neck, or easily stored with other electronic devices. Do not put the FortiToken on a key ring as the metal ring and other metal objects can damage it. The FortiToken is an electronic device like a cell phone and must be treated with similar care.

Any time information about the FortiToken is transmitted, it is encrypted. When the FortiGate unit receives the code that matches the serial number for a particular FortiToken, it is delivered and stored encrypted. This is in keeping with the Fortinet's commitment to keeping your network highly secured.

FortiTokens can be added to user accounts that are local, IPSec VPN, SSL VPN, and even Administrators. See "Associating FortiTokens with accounts" on page 1233.

A FortiToken can only be associated with one account at a time on a FortiGate unit. However, multiple FortiGate units can have the same FortiToken registered. This is useful for employees who travel between offices.

If a user loses their FortiToken, it can be locked out using the FortiGate so it will not be used to falsely access the network. Later if found, that FortiToken can be unlocked on the FortiGate to allow access once again. See "FortiToken maintenance" on page 1234.

There are three tasks to complete before FortiTokens can be used to authenticate accounts:

1 Adding FortiTokens to the FortiGate

2 Activating a FortiToken on the FortiGate

3 Associating FortiTokens with accounts

The FortiToken authentication process

The steps during FortiToken two-factor authentication are as follows.

1 User attempts to access a network resource.

2 FortiGate unit matches the traffic to an authentication security policy, and FortiGate unit prompts the user for username and password.

3 User enters their username and password.

4 FortiGate unit verifies their information, and if valid prompts the user for the FortiToken code.

5 User gets the current code from their FortiToken device.

6 User enters current code at the prompt.

7 FortiGate unit verifies the FortiToken code, and if valid allows access to the network resources such as the Internet.

The following steps are only if the time on the FortiToken has drifted from the time on the FortiGate unit and needs to be synchronized.

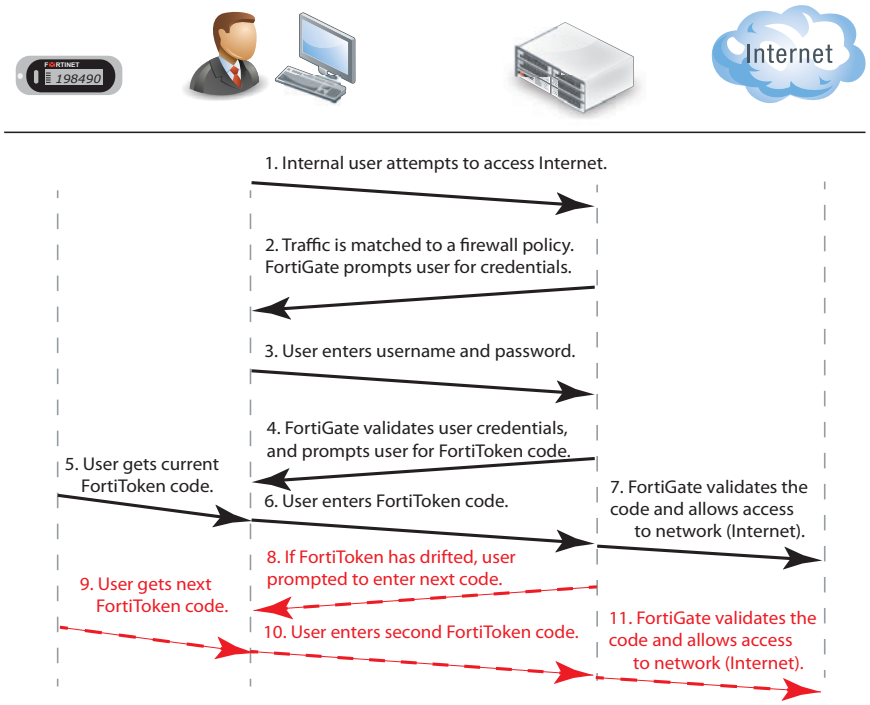
8 If time on FortiToken has drifted, FortiGate unit will prompt user to enter a second code to confirm.

9 User gets the next code from their FortiToken device

10 User enters the second code at the prompt.

11 FortiGate unit uses both codes to update its clock to match the FortiToken and then proceeds as in step 7.

Figure 105: FortiToken authentication process



When configured the FortiGate unit accepts the username and password, authenticates them either locally or remotely, and prompts the user for the FortiToken code. The FortiGate then authenticates the FortiToken code. When FortiToken authentication is enabled, the prompt field for entering the FortiToken code is automatically added to the authentication screens.

Even when an Administrator is logging in through a serial or Telnet connection and their account is linked to a FortiToken, that Administrator will be prompted for the token's code at each login.

If you have attempted to add invalid FortiToken serial numbers, there will be no error message. The serial numbers will simply not be added to the list.

Adding FortiTokens to the FortiGate

Before one or more FortiTokens can be used to authenticate logons, they must be added to the FortiGate. The import feature is used to enter many FortiToken serial numbers at one time.

One FortiToken can be added to multiple FortiGate units. This is useful for maintaining two-factor authentication for employees over multiple office locations, such as for employees who travel frequently between offices.

To manually add a FortiToken to the FortiGate - web-based manager

1 Go to *User* > *FortiToken* > *FortiToken*.
2 Select *Create New*.
3 Enter one or more serial numbers for the FortiToken or FortiTokens you have.
4 Select OK.

To import multiple FortiTokens to the FortiGate - web-based manager

1 Go to *User* > *FortiToken* > *FortiToken*.
2 Select *Import*.
3 Browse to the local file location on your local computer.
The file must be a text file with one FortiToken serial number per line.
4 Select OK.

To add two FortiTokens to the FortiGate - CLI

```
config user fortitoken
  edit <serial_number>
  next
  edit <serial_number2>
  next
end
```

Activating a FortiToken on the FortiGate

Once one or more FortiTokens have been added to the FortiGate unit, they must be activated before being available to be associated with accounts.The process of activation involves the FortiGate querying FortiGuard servers about the validity of each FortiToken. The serial number and information is encrypted before it is sent for added security.

A FortiGate unit requires a connection to FortiGuard servers to activate a FortiToken.

To activate a FortiToken on the FortiGate unit - web-based manager

1 Go to *User* > *FortiToken*.

2 Select one or more FortiTokens with a status of New.

3 Select *Activate*.

4 Refresh web browser. The status of selected FortiTokens will change to Activated.

The selected FortiTokens are now available for use with user and admin accounts.

To activate a FortiToken on the FortiGate unit - CLI

```
config user fortitoken
  edit <token_serial_num>
    set status activate
  next
end
```

Associating FortiTokens with accounts

The final step before using the FortiTokens to authenticate logons is associating a FortiToken with an account. The accounts can be local user or administrator accounts.

To add a FortiToken to a local user account - web-based manager

1 Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Activated.

2 Go to *User* > *User*, and select *Create New*.

3 Enter the username and password for this user account.

4 Select *Enable Two-factor Authentication*.

5 Select FortiToken, and select the serial number from the list that matches that user's FortiToken.

6 Select OK.

To add a FortiToken to a local user account - CLI

```
config user local
  edit <username>
    set type password
    set passwd "myPassword"
    set two-factor fortitoken
    set fortitoken <serial_number>
    set status enable
  next
  end
```

To add a FortiToken to an administrator account - web-based manager

1 Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Activated.

2 Go to *System* > *Admin* > *Administrators*, and select an admin account.

This account is assumed to be configured except for two-factor authentication.

3 Select *Enable Two-factor Authentication*.

4 Select FortiToken, and select the serial number from the list that matches that user's FortiToken.

5 Select OK.

To add a FortiToken to a local user account - CLI

```
config user local
  edit <username>
    set type password
    set passwd "myPassword"
    set two-factor fortitoken
    set fortitoken <serial_number>
    set status enable
  next
  end
```

The `fortitoken` keyword will not be visible until `fortitoken` is selected for the `two-factor` keyword.

Before a new FortiToken can be used, it may need to be synchronized due to clock drift.

FortiToken maintenance

Once FortiTokens are entered into the FortiGate unit, there are only two tasks to maintain them — changing the status,

To change the status of a FortiToken between Activated and Locked - CLI

```
config user fortitoken
  edit <token_serial_num>
    set status lock
  next
end
```

Any user attempting to login using this FortiToken will not be able to authenticate.

To list the drift on all FortiTokens configured on this FortiGate unit - CLI

```
# diag fortitoken drift
FORTITOKEN       DRIFT
```

This command lists the serial number and drift for each FortiToken configured on this FortiGate unit. This command is useful to check if it is necessary to synchronize the FortiGate and any particular FortiTokens.

Monitoring users

To monitor user activity in the web-based manager, go to *Users* > *Monitor* > *Firewall*. The list of users who are logged on is displayed with some information about them such as their user group, security policy ID, how long they have been logged on, their IP address, traffic volume, and their authentication method as one of FSSO, NTLM, or firewall (FW-auth).

From this screen you can de-authenticate all users who are logged on. The de-authenticate button is at the top left of this screen.

To see information about banned users go to *User* > *Monitor* > *Banned Users*. Displayed information about users who have been banned includes what application the triggered the ban (Application Protocol), the reason for the ban (Cause or rule), Created, and when the ban expires.

Filtering the list of users

When there are many users logged on, it can be difficult to locate a specific user or multiple users to analyze. Applying filters to the list allows you to organize the user list to meet your needs, or only display some the users that meet your current requirements.

Select *Column Settings* at the bottom of the screen to adjust columns that are displayed for users, including what order they are displayed in. This can be very helpful in locating information you are looking for.

The *username* column includes a green arrow to the right of the title. Select this arrow to sort the list of users by ordering them in ascending (down arrow) or descending order. This is the only column that allows this.

Each column heading has a grey filter icon. Click on the filter icon to configure a filter for the data displayed in that column. Each column has similar options including a field to enter the filtering information, a checkbox to select the negative of the text in the field, and the options to add more fields, apply the filter, clear all filters, or cancel without saving. To enter multiple terms in the field, separate each of them with a comma. To filter entries that contain a specific prefix, use an * (asterisk).

When removing existing filters, you must select *Apply* for the removal to take place.

For example, to create a filter to display only users with an IP address of `10.11.101.x` who authenticated using one of security policies five through eight, and who belong to the user group `Accounting`.

To configure a user monitor filter - web-based manager

1. Go to *User* > *Monitor* > *Firewall*.
2. Select filter icon for IP address.
3. Enter `10.11.101.0`.
4. Select *Add new filter*.
5. From the list of fields select *Policy ID* and enter `5-8`.
6. Select *Add new filter*.
7. From the list of fields select *User Group* and enter `Accounting`.
8. Select *Apply*.

User groups

A user group is a list of user identities. An identity can be:

- a local user account (username/password) stored on the FortiGate unit
- a local user account with the password stored on a RADIUS, LDAP, or TACACS+ server
- a PKI user account with digital client authentication certificate stored on the FortiGate unit

- a RADIUS, LDAP, or TACACS+ server, optionally specifying particular user groups on that server
- a user group defined on an FSSO server.

Identity-based policies and some types of VPN configurations allow access to specified user groups only. This restricted access enforces Role Based Access Control (RBAC) to your organization's network and its resources.Users must be in a group and that group must be part of the security policy.

You cannot change the type of a group unless the group is empty.

In most cases, the FortiGate unit authenticates users by requesting their username and password. The FortiGate unit checks local user accounts first. If a match is not found, the FortiGate unit checks the RADIUS, LDAP, or TACACS+ servers that belong to the user group. Authentication succeeds when a matching username and password are found. If the user belongs to multiple groups on a server, those groups will be matched as well.

FortiOS does not allow username overlaps between RADIUS, LDAP, or TACACS+ servers.

There are two types of FortiGate user groups: Firewall user groups, and FSSO user groups.

Firewall user groups

Firewall user groups are used locally as part of authentication and can contain any type of user identity except an FSSO group. When a user attempts to access resources controlled by an Identity-Based Policy (IBP), the FortiGate unit requires authentication from that user. If the user authenticates successfully and is a member of one of the permitted groups, the session is allowed to proceed.

This section includes:

- SSL VPN access
- IPsec VPN access
- Configuring a firewall user group
- User group timeouts
- Viewing, editing and deleting user groups

SSL VPN access

In any firewall user group, you can enable SSL VPN access and select the web-portal that the users can access. When the user connects to the FortiGate unit via HTTPS on the SSL VPN port (default 10443), the FortiGate unit requests a username and password.

SSL VPN access also requires an SSL VPN security policy (*Action* is *SSL VPN*) with an identity-based rule enabling access for the user group. For more information, see the *FortiOS Handbook SSL VPN chapter*.

IPsec VPN access

A firewall user group can provide access for dialup users of an IPsec VPN. In this case, the IPsec VPN phase 1 configuration uses the *Accept peer ID in dialup group* peer option. The user's VPN client is configured with the username as peer ID and the password as pre-shared key. The user can connect successfully to the IPsec VPN only if the username is a member of the allowed user group and the password matches the one stored on the FortiGate unit.

A user group cannot be used as a dialup group if any member of the group is authenticated using an external authentication server.

For more information, see the *FortiOS Handbook IPsec VPN chapter*.

Configuring a firewall user group

A user group can contain:

- local users, whether authenticated by the FortiGate unit or an authentication server
- PKI users
- authentication servers, optionally specifying particular user groups on the server

To create a Firewall user group - web-based manager

1. Go to *User* > *User Group* and select *Create New*.
2. Enter a name for the user group.
3. In *Type*, select *Firewall*.
4. From the *Available Users* list, select users and then select the right arrow button to move the names to the *Members* list.

   If you select an authentication server as a group member, by default all user accounts on the authentication server are members of this FortiGate user group. Follow steps 5 through 8 if you want to include only specific user groups from the authentication server. Otherwise, select *OK*.
5. Select *Add*.
6. To add a remote authentication server, select *Add* and select the authentication server from the drop down *Remote Server* list.

   The option to add remote servers is available only if at least one remote server has been configured.
7. In the *Group Name* field, either select *Any* to match all possible groups, or select *Specify* and enter the group name in the appropriate format for the type of server.

   For example, an LDAP server requires LDAP format, such as: cn=users,dn=office,dn=example,dn=com
8. Repeat steps 5 through 7 to add all the authentication server user groups that are required.
9. Select *OK*.

To create a firewall user group - CLI example

In this example, the members of `accounting_group` are `User1` and all of the members of `rad_accounting_group` on `myRADIUS` external RADIUS server.

```
config user group
  edit accounting_group
    set group-type firewall
    set member User1 myRADIUS
    config match
      edit 0
      set server-name myRADIUS
      set group-name rad_accounting_group
    end
end
```

Matching user group names from an external authentication server might not work if the list of group memberships for the user is longer than 8000 bytes. Group names beyond this limit are ignored.

`server_name` is the name of the RADIUS, LDAP, or TACACS+ server, but it must be a member of this group first and must also be a configured remote server on the FortiGate unit.

`group_name` is the name of the group on the RADIUS, LDAP, or TACACS+ server such as "engineering" or "cn=users,dc=test,dc=com".

Before using group matching with TACACS+, you must first enable authentication. For example if you have a configured TACACS+ server called myTACS, use the following CLI commands.

```
config user tacacs+
  edit myTACS
  set authorization enable
  next
end
```

For more information about user group CLI commands, see the *Fortinet CLI Guide*.

Multiple group enforcement support

Previously, when a user belonged to multiple user groups, this user could only access the group services that were within one group. With multiple group enforcement, a user can access the services within the groups that the user is part of.

For example, `userA` belongs to `user_group1`, `user_group2`, `user_group3`, and `user_group4`; previously `userA` could only access services within one of those four groups, typically the group that matches the first security policy. This can be annoying if HTTP access is in `user_group1`, FTP access is in `user_group2`, and email access is in `user_group3`. Now `userA` can access services within `user_group1`, `user_group2`, `user_group3`, and `user_group4`.

This feature is available only in the CLI and is enabled by default. It applies to RADIUS, LDAP, and TACACS+ servers. The new command for this feature is `auth-multi-group` found in `config user settings` and checks all groups a user belongs to for authentication.

User group timeouts

User groups can have timeout values per group in addition to FortiGate-wide timeouts. There are essentially three different types of timeouts that are configurable for user authentication on the FortiGate unit — idle timeout, hard timeout, and session timeout. These are in addition to any external timeouts such as those associated with RADIUS servers.

If VDOMs are enabled, the global level user setting `authtimeout` is the default all VDOMs inherit. If VDOMs are not enabled, user settings authtimeout is the default. The default timeout value is used when the `authtimeout` keyword for a user group is set to zero.

Each type of timeout will be demonstrated using the existing user group `example_group`. Timeout units are minutes. A value of zero indicates the global timeout is used.

Membership in multiple groups

When a user belongs to multiple groups in RADIUS groups, the group auth-timeout values are ignored. Instead the global timeout value is used. The default value is 5 minutes, but it can be set from 1 to 480 minutes.

```
config user setting
  set auth-timeout-type idle-timeout
  set auth-timeout 300
end
```

Idle timeout

The default type of timeout is idle timeout. When a user initiates a session, it starts a timer. As long as data is transferred in this session, the timer continually resets. If data flow stops, the timer is allowed to advance until it reaches its limit. At that time the user has been idle for too long, and the user is forced to re-authenticate before traffic is allowed to continue in that session.

To configure user group authentication idle timeout - CLI

```
config user settings
  set auth-timeout-type idle-timeout
end

config user group
  edit example_group
    set auth-timeout 480
  next
end
```

Hard timeout

Where the idle timeout is reset with traffic, the hard timeout is absolute. From the time the first session a user establishes starts, the hard timeout counter starts. When the timeout is reached, all the sessions for that user must be re-authenticated. This timeout is not affected by any event.

To configure user group authentication hard timeout - CLI

```
config user settings
  set auth-timeout-type hard-timeout
end
config user group
  edit example_group
    set auth-timeout 480
  next
```

```
end
```

Session timeout

The session timeout works much like the hard timeout in that its an absolute timer that can not be affected by events. However, when the timeout is reached existing sessions may continue but new sessions are not allowed until re-authentication takes place. The timeout can be set from 1 to 480 minutes. Setting the timeout value to zero removes the timeout value allowing the user to remain logged on without limit.

To configure a user group authentication new session hard timeout - CLI

```
config user setting
  set auth-timeout-type new-session
end

config user group
  edit example_group
    set authtimeout 30
  next
end
```

FSSO user groups

FSSO user groups are part of FSSO authentication and contain only Windows or Novell network users. No other user types are permitted as members. Information about the Windows or Novell user groups and the logon activities of their members is provided by the Fortinet Single Sign On (FSSO) which is installed on the network domain controllers.

You can specify FSSO user groups in identity-based security policies in the same way as you specify firewall user groups. FSSO user groups cannot have SSL VPN or dialup IPsec VPN access.

For information about configuring FSSO user groups, see “Creating Fortinet Single Sign-On (FSSO) user groups” on page 1312. For complete information about installing and configuring FSSO, see “FSSO integration with Windows AD or Novell” on page 1283.

Configuring Peer user groups

Peer user groups can only be configured using the CLI. Peers are digital certificate holders defined using the `config user peer` command. The peer groups you define here are used in dialup IPsec VPN configurations that accept RSA certificate authentication from members of a peer certificate group. For more information, see “Authenticating IPsec VPN users with security certificates” on page 1276.

To create a peer group - CLI example

```
config user peergrp
  edit vpn_peergrp1
    set member pki_user1 pki_user2 pki_user3
  end
```

Viewing, editing and deleting user groups

To view the list of FortiGate user groups, go to *User* > *User Group*.

Editing a user group

When editing a user group in the CLI you must set the type of group this will be — either a firewall group, or a Fortinet Single Sign-On Service group. Once the type of group is set, and members are added you cannot change the group type without removing the members.

In the web-based manager, if you change the type of the group any members will be removed automatically.

To edit a user group - web-based manager

1. Go to *User* > *User Group*.
2. Select the check box for the user group that you want to edit.
3. Select the *Edit* button.
4. Modify the user group as needed.
5. Select *OK*.

To edit a user group - CLI example

This example adds user3 to Group1. Note that you must re-specify the full list of users:

```
config user group
  edit Group1
  set group-type firewall
    set member user2 user4 user3
  end
```

Deleting a user group

Before you delete a user group, you must ensure there are no objects referring to, it such as security policies. If there are, you must remove those references before you are able to delete the user group.

To remove a user group - web-based manager

1. Go to *User* > *User Group*.
2. Select the check box for the user group that you want to remove.
3. Select the *Delete* button.
4. Select *OK*.

To remove a user group - CLI example

```
config user group
  delete Group2
end
```

Configuring authenticated access

When you have configured authentication servers, users, and user groups, you are ready to configure security policies and certain types of VPNs to require user authentication.

This section describes:

Authentication timeout

An important feature of the security provided by authentication is that it is temporary—a user must re-authenticate after logging out. Also if a user is logged on and authenticated for an extended period of time, it is a good policy to have them re-authenticate at set periods. This ensures a user's session is cannot be spoofed and used maliciously for extended periods of time — re-authentication will cut any spoof attempts short. Shorter timeout values are more secure.

Security authentication timeout

You set the security user authentication timeout to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 480 minutes (8 hours).

To set the security authentication timeout - web-based manager

1 Go to *User* > *User* > *Authentication*.

2 Enter the *Authentication Timeout* value in minutes.

The default authentication timeout is 5 minutes.

3 Select *Apply*.

SSL VPN authentication timeout

You set the SSL VPN user authentication timeout (*Idle Timeout*) to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 28 800 seconds. The default timeout is 300 seconds.

To set the SSL VPN authentication timeout - web-based manager

1 Go to *VPN* > *SSL* > *Config*.

2 Enter the *Idle Timeout* value (seconds).

3 Select *Apply*.

Password policy

Password authentication is effective only if the password is sufficiently strong and is changed periodically. By default, the FortiGate unit requires only that passwords be at least eight characters in length. You can set a password policy to enforce higher standards for both length and complexity of passwords. Password policies can apply to administrator passwords or IPsec VPN preshared keys.

To set a password policy in the web-based manager, go to *System* > *Admin* > *Settings*. In the CLI, use the `config system password-policy` command.

The default minimum password length on the FortiGate unit is eight characters, but up to 32 characters is permitted. Fortinet suggests a minimum length of 14 characters.

Users usually create passwords composed of alphabetic characters and perhaps some numbers. Password policy can require the inclusion of uppercase letters, lowercase letters, numerals or punctuation characters.

Configuring password minimum requirement policy (best practices)

Best practices dicatate that passwords include:

- one or more uppercase characters
- one or more lower care characters
- one or more of the numerals
- one or more non alphanumeric characters, such as punctuation marks.

The minimum number of each of these types of characters can be set in both the web-based manager and the CLI.

The following procedures show how to force administrator passwords to contain at least two uppercase, four lower care, two digits, and one non-alphanumeric characters. Leave the minimum length at the default of eight characters.

To change administrator password minimum requirements - web-based manager

1 Go to *System* > *Admin* > *Settings*.

2 Select *Enable Password Policy*.

3 Select *Must Contain*.

4 Enter the following information:

uppercase Letters	2
lower care Letters	4
Numerical Digits	2
Non-alphanumeric Letters	1

5 Under *Apply Password Policy to*, select *Admin Password*.

6 Select *Apply*.

To change administrator password minimum requirements - CLI

```
config system password-policy
  set status enable
  set apply-to admin-password
  set min-upper-case-letter 2
  set min-lower-case-letter 4
```

```
    set min-number 2
    set min-non-alphanumeric 1
    set change-4-characters enable
    next
  end
```

The `change-4-characters` option forces new passwords to change a minimum of four characters in the old password. Changing fewer characters results in the new password being rejected. This option is only available in the CLI.

Password best practices

In addition to length and complexity, there are security factors that cannot be enforced in a policy. Guidelines issued to users will encourage proper password habits.

Best practices dicate that password expiration also be enabled. This forces passwords to be changed on a regular basis. You can set the interval in days. The more sensitive the information this account has access to, the shorter the password expiration interval should be. For example 180 days for guest accounts, 90 days for users, and 60 days for administrators.

Avoid:

- real words found in any language dictionary
- numeric sequences, such as “12345”
- sequences of adjacent keyboard characters, such as “qwerty”
- adding numbers on the end of a word, such as “hello39”
- adding characters to the end of the old password, such as “hello39” to “hello3900”
- repeated characters
- personal information, such as your name, birthday, or telephone number.

Maximum logon attempts and blackout period

When you logon and fail to enter the correct password you could be a valid user, or a hacker attempting to gain access. For this reason, best practices dictate to limit the number of failed attempts to logon before a blackout period where you cannot logon.

To set a maximum of five failed authentication attempts before the blackout, using the following CLI command:

```
config user setting
  set auth-invalid-max 5
  next
end
```

To set the length of the blackout period to five minutes, or 300 seconds, once the maximum number of failed logon attempts has been reached, use the follwing CLI command:

```
config user setting
  set auth-blackout-time 300
  next
end
```

Authentication protocols

When user authentication is enabled on a security policy, the authentication challenge is normally issued for any of the four protocols, HTTP, HTTPS, FTP, and Telnet, which are dependent on the connection protocol. By making selections in the Protocol Support list, the user controls which protocols support the authentication challenge. The user must connect with a supported protocol first, so that they can subsequently connect with other protocols.

For example, if you have selected HTTP, FTP, or Telnet, a username and password-based authentication occurs. The FortiGate unit then prompts network users to input their security username and password. If you have selected HTTPS, certificate-based authentication (HTTPS, or HTTP redirected to HTTPS only) occurs.

FTP and Telnet authentication replacement messages cannot be customized. For HTTP and HTTPS replacement messages see "Authentication replacement messages" on page 1248.

For certificate-based authentication, you must install customized certificates on the FortiGate unit and on the browsers of network users. If you do not install certificates on the network user's web browser, the network users may see an SSL certificate warning message and have to manually accept the default FortiGate certificate. The network user's web browser may deem the default certificate as invalid.

When you use certificate authentication, if you do not specify any certificate when you create the security policy, the global settings are used. If you specify a certificate, the per-policy setting will overwrite the global setting. For more information about the use of certification authentication see "Certificate-based authentication" on page 1263.

To set the authentication protocols

1. Go to *User* > *User* > *Authentication*.
2. In *Protocol Support*, select the required authentication protocols.
3. If using HTTPS protocol support, in *Certificate*, select a Local certificate from the drop-down list.
4. Select *Apply*.

Authentication in security policies

Security policies control traffic between FortiGate interfaces, both physical interfaces and VLAN subinterfaces. Without authentication, a security policy enables access from one network to another for all users on the source network. Authentication enables you to allow access only for users who are members of selected user groups. To include authentication in a security policy, you must create an identity-based policy.

The style of the authentication method varies by the authentication protocol. If you have selected HTTP, FTP or Telnet, a username and password-based authentication occurs. The FortiGate unit prompts network users to input their security username and password. If you have selected HTTPS, certificate-based authentication (HTTPS or HTTP redirected to HTTPS only) occurs. You must install customized certificates on the FortiGate unit and on the browsers of network users, which the FortiGate unit matches.

You can configure user authentication for security policies only when *Action* is set to *Accept*. If the policy is set to *Deny*, *IPsec*, or *SSL VPN* the options will be different.

This section includes:

Enabling authentication protocols

Users can authenticate using FTP, HTTP, HTTPS, and Telnet. However, these protocols must be enabled first.

Another authentication option is to redirect any attempts to authenticate using HTTP to a more secure channel that uses HTTPS. This forces users to a more secure connection before entering their user credentials.

To enable support for authentication protocols - web-based manager

1 Go to *User* > *User* > *Authentication*.

2 Select one or more of HTTP, HTTPS, FTP, Telnet, or Redirect HTTP Challenge to a Secure Channel (HTTPS). Only selected protocols will be available for use in authentication.

3 Select the *Certificate* to use, for example `Fortinet_Factory`.

4 Select *Apply*.

To enable support for authentication protocols - CLI

```
config user setting
  set auth-type ftp http https telnet
  set auth-cert Fortinet_Factory
end
```

Authentication replacement messages

A replacement message is the body of a webpage containing a message about a blocked website message, a file too large message, a disclaimer, or even a login page for authenticating. The user is presented with this message instead of the blocked content.

Authentication replacement messages are the prompts a user sees during the security authentication process such as login page, disclaimer page, and login success or failure pages. These are different from most replacement messages because they are interactive requiring a user to enter information, instead of simply informing the user of some event as other replacement messages do.

Replacement messages have a system-wide default configuration, a per-VDOM configuration, and disclaimers can be customized for multiple security policies within a VDOM.

These replacement messages are used for authentication using HTTP and HTTPS. Authentication replacement messages are HTML messages. You cannot customize the security authentication messages for FTP and Telnet.

The authentication login page and the authentication disclaimer include replacement tags and controls not found on other replacement messages.

More information about replacement messages can be found in the `config system replacemsg` section of the *FortiOS CLI Reference*.

Table 79: List of authentication replacement messages

Replacement message name (CLI name)	Description
Login challenge page (auth-challenge-page)	This HTML page is displayed if security users are required to answer a question to complete authentication. The page displays the question and includes a field in which to type the answer. This feature is supported by RADIUS and uses the generic RADIUS challenge-access auth response. Usually, challenge-access responses contain a Reply-Message attribute that contains a message for the user (for example, “Please enter new PIN”). This message is displayed on the login challenge page. The user enters a response that is sent back to the RADIUS server to be verified. The Login challenge page is most often used with RSA RADIUS server for RSA SecurID authentication. The login challenge appears when the server needs the user to enter a new PIN. You can customize the replacement message to ask the user for a SecurID PIN. This page uses the %%QUESTION%% tag.

Table 79: List of authentication replacement messages

Replacement message name (CLI name)	Description
Disclaimer page (auth-disclaimer-page-1) (auth-disclaimer-page-2) (auth-disclaimer-page-3)	Prompts user to accept the displayed disclaimer when leaving protected network. The web-based manager refers to this as User Authentication Disclaimer, and it is enabled with a security policy that also includes at least one identity-based policy. When a security user attempts to browse a network through the FortiGate unit using HTTP or HTTPS this disclaimer page is displayed. The extra pages seamlessly extend the size of the page from 8 192 characters to 16 384 and 24 576 characters respectively. When configuring the disclaimer page in the web-based manager this is shown by its size being 24 576 characters. See “Disclaimer” on page 1251.
Email token page (auth-email-token-page)	The page prompting a user to enter their email token. See “Email” on page 1228.
FortiToken page (auth-fortitoken-page)	The page prompting a user to enter their FortiToken code. See “FortiToken” on page 1230.

Keepalive page (auth-keepalive-page)	The HTML page displayed with security authentication keepalive is enabled using the following CLI command:
	`config system global`
	`  set auth-keepalive enable`
	`end`
	Authentication keepalive keeps authenticated firewall sessions from ending when the authentication timeout ends. In the web-based manager, go to *User* > *Options* to set the *Authentication Timeout*.
	This page includes %%TIMEOUT%%.

Login failed page (auth-login-failed-page)	The Disclaimer page replacement message does not re-direct the user to a redirect URL or the security policy does not include a redirect URL. When a user selects the button on the disclaimer page to decline access through the FortiGate unit, the Declined disclaimer page is displayed.
Login page (auth-login-page)	The authentication HTML page displayed when users who are required to authenticate connect through the FortiGate unit using HTTP or HTTPS. Prompts the user for their username and password to login. This page includes %%USERNAMEID%% and %%PASSWORDID%% tags.
Declined disclaimer page (auth-reject-page)	The page displayed if a user declines the disclaimer page. See “Disclaimer” on page 1251.

Table 79: List of authentication replacement messages

Replacement message name (CLI name)	Description
SMS Token page (auth-sms-token-page)	The page prompting a user to enter their SMS token. See "SMS" on page 1229.
Success message (auth-success-msg)	The page displayed when a user successfully authenticates. Prompts user to attempt their connection again (as the first was interrupted for authentication).

Access to the Internet

A policy for accessing the Internet is similar to a policy for accessing a specific network, but the destination address is set to *all*. The destination interface is the one that connects to the Internet Service Provider (ISP). For general purpose Internet access, the Service is set to ANY.

Access to HTTP, HTTPS, FTP and Telnet sites may require access to a domain name service. DNS requests do not trigger authentication. You must configure a policy to permit unauthenticated access to the appropriate DNS server, and this policy must **precede** the policy for Internet access. Failure to do this will result in the lack of a DNS connection and a corresponding lack of access to the Internet.

Configuring authentication security policies

To include authentication in a security policy, you must create an identity-based policy. An identity-based policy can authenticate by certificate, FSSO, and NTLM. The two exceptions to this are dynamic profiles and FSSO Agents. See "Configuring dynamic profile" on page 1332, and "Introduction to FSSO" on page 1283.

Before creating an identity-based security policy, you need to configure one or more users and firewall user groups.For more information, see "Users and user groups" on page 1223.

Creating the security policy is the same as a regular security policy except you must select the action specific to your authentication method:

Table 80: Authentication methods allowed for each policy Action

Action	Authentication method	Where authentication is used
ACCEPT	FSSO Agent or identity-based policy — FSSO	See "FSSO integration with Windows AD or Novell" on page 1283.
	identity-based policy — NTLM	See "NTLM authentication" on page 1255.
	identity-based policy — Certificates	See "Configuring certificate-based authentication" on page 1275.
	Dynamic Profile	See "Configuring dynamic profile-based security policies" on page 1339.
IPSEC	IPsec Phase 1 and 2	See "Configuring authentication of remote IPsec VPN users" on page 1258.
SSL-VPN	SSL certificates	See "Configuring authentication of SSL VPN users" on page 1258.

Table 80: Authentication methods allowed for each policy Action

Action	Authentication method	Where authentication is used
DENY	none	none

Disclaimer

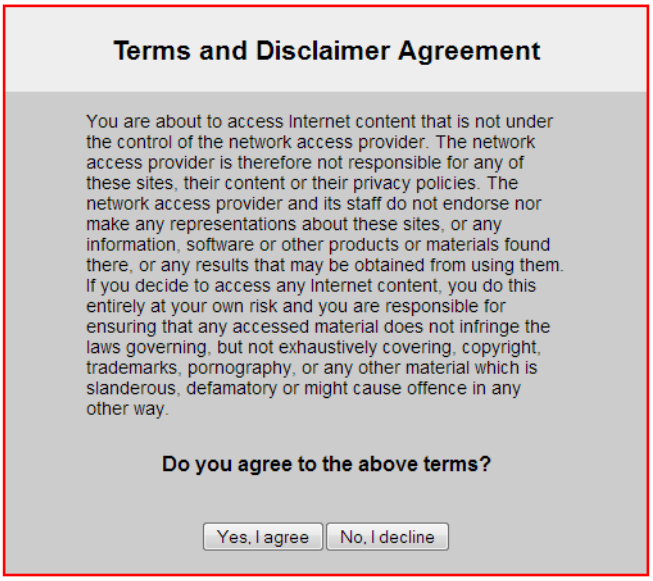
When configuring any authentication security policy, there is an option to enable a disclaimer. The disclaimer is a replacement message that when enabled, web traffic matching this policy will be presented with the disclaimer that the user must choose to agree or decline.

The default disclaimer contains a warning that any content the user is about to access is the responsibility of the user and not the company or owner of the network. It is presented in Figure 106. You can customize the text and the appearance to as required.

To change the disclaimer

1. Go to *System* > *Config* > *Replacement* messages.
2. Expand Authentication
3. Select Disclaimer page to edit.
4. Select the existing disclaimer text, and copy it to a separate file.
5. Make changes

Figure 106: Default disclaimer message



Customizing authentication replacement messages

Customizing disclaimers or other authentication replacement messages involves changing the text of the disclaimer message, and possibly the overall appearance of the message.

Disclaimers are useful in many situations. Often companies find it useful to brand the disclaimers with their specific company policy text, logo, and design. One example of this is at an Internet cafe where customers pay for usage and must accept terms of usage before accessing the internet. The cafe benefits from a customized disclaimer that alerts the customer to their online policies. The same is true for other authentication replacement messages such as the login page.

Changing the disclaimer at *System* > *Config* > *Replacement messages* is not the same as selecting to customize a disclaimer used in a policy. The *System* > *Config* location is the default message that all disclaimers inherit. The security policy location is a customized disclaimer that inherits the default format for the disclaimer message, but then can be customized for this policy.

If identity-based policy is enabled, the disclaimer option is not available. Instead Customize Authentication messages is available in the Enable identity-based Policy section. Selecting the Edit icon allows you to customize the listed authentication replacement messages which includes the disclaimer.

To customize the disclaimer for a security policy - web-based manager

1. Go to *Policy* > *Policy*. Either select an existing policy and edit or select *Create New*.
2. Enable *Disclaimer*, and select *Customize Disclaimer Message*.
3. Select the edit icon to edit the Disclaimer page, and change your text or layout as needed.

Enabling security logging

There are two types of logging that relate to authentication — event logging, and security logging.

When enabled, event logging records system events such as configuration changes, and authentication. To configure event logging, go to *Log&Report* > *Log Config* > *Log Setting* and in the *Event Log Settings* section, select the check box beside *Enable*. Select the events you want to log, such as authentication.

When enabled security logging will log UTM and security policy traffic

You must enable logging within a security policy, as well as the options that are applied to a security policy, such as UTM features. Event logs are enabled within the Event Log page,

For more information on logging, see the *FortiOS Log and Reporting chapter*.

For more information on specific types of log messages, see the *FortiOS Log Message Reference*.

You need to set the logging severity level to *Notification* when configuring a logging location to record traffic log messages .

To enable logging within an existing security policy - web-based manager

1. Go to *Policy* > *Policy*.
2. Expand to reveal the policy list of a policy.
3. Select the security policy you want to enable logging on and then select *Edit*.
4. To log all general firewall traffic, select the check box beside *Log Allowed Traffic*.
5. On the security policy's page, select the check box beside *UTM*.

6 Select the protocol option list from the drop-down list beside *Protocol Options*.

By default, the *Protocol Options* check box is selected. You must choose a list from the drop-down list.

7 For each row under *UTM*, select the check box beside each of the profiles and/or sensors that you want applied to the policy; then select the profile or sensor from the drop-down list as well.

8 To apply other options, such as application lists, repeat step 7 and choose the option from the drop-down list.

9 Select *OK*.

Identity-based policy

An identity-based policy (IBP) performs user authentication in addition to the normal security policy duties. If the user does not authenticate, access to network resources is refused. This enforces Role Based Access Control (RBAC) to your organization's network and resources.

User authentication can occur through any of the following supported protocols, including: HTTP, HTTPS, FTP, and Telnet. The authentication style depends on which of these protocols is included in the selected security services group and which of those enabled protocols the network user applies to trigger the authentication challenge.

For username and password-based authentication (HTTP, FTP, and Telnet) the FortiGate unit prompts network users to enter their username, password, and token code if two-factor authentication is selected for that user account. See "Two-factor authentication" on page 1228. For certificate-based authentication, including HTTPS or HTTP redirected to HTTPS only, see "Certificate authentication" on page 1256.

Enable identity-based Policy and *Enable Dynamic Profile* are mutually exclusive. When one of the two options is selected, the other is hidden. When both are not selected, both are visible again.

Set the ACCEPT *Action*, and select *Enable identity-based Policy*. In the web-based manager you can confirm this by changing *Action* from the default of ACCEPT to DENY. Note that nearly all of the fields are not available until you switch back to ACCEPT.

Set these commands in the CLI to see the other identity-based commands that were hidden before. In the following procedure, this is policy number 7.

```
config firewall policy
  edit 7
    set action ACCEPT
    set identity-based enable
  next
end
```

With identity-based policies, once the FortiGate unit matches the source and destination addresses, it processes the identity sub-policies for the user groups and services. This means unique security policies must be placed ***before*** an identity-based policy to be effective.

When the identity-based policy has been configured, the option to customize authentication messages is available. This allows you to change the text, style, layout, and graphics of the replacement messages associated with this firewall policy. When enabled, customizing these messages follows the same method as changing the disclaimer. See "Disclaimer" on page 1251.

The types of authentication available in identity-based policies are

- FSSO authentication
- NTLM authentication
- Certificate authentication

Identity-based sub-policies

Once IBP is enabled in a policy, a table appears. Selecting *Add* allows you to configure authentication rules which are added to this table as sub-policies.

Just as with regular security policies, with these identity-based sub-policies traffic is matched from the top of the list of sub-policies down until the criteria is met. If there is no matching policy packets are dropped, even if they have been authenticated. Each sub-policy has its own UTM profile fields, traffic shaping, logging, and so on that take effect when the User Group, Service and Schedule are matched.

The order of these sub-policies is just as important as with regular security policies. For example if a user is a member of two groups, and each group has a separate sub-policy entry, the top one in the list will be matched first.

FSSO authentication

Identity-based security policies are an integral part of any FSSO configuration. These policies are how user information is acquired to sent to the FSSO Collector agent and the AD domain controllers. See "FSSO authentication" on page 1254.

In the following procedure, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

To configure an FSSO authentication security policy - web-based manager

1 Go to *Policy* > *Policy.*

2 Select *Create New*.

3 Enter the following information.

Source Interface/Zone	port1
Source Address	company_network
Destination Interface/Zone	port2
Destination Address	all
Action	ACCEPT
Enable NAT	enabled

4 Select *Enable identity-based Policy*.

5 Select *Add* to add groups of users to this authentication policy.

6 Select the `fsso_group`, and the `FSSO_Guest_users` usergroups In the Available User Groups list and move them to the Selected User Groups list.

`FSSO_Guest_users` is a default user group enabled when FSSO is configured. It allows guest users on the network who do not have FSSO account to still authenticate and have access to network resources. See "Enabling guest access through FSSO security policies" on page 1315.

7 Select HTTP, HTTPS, FTP, and Telnet for in the *Available Services* list, and move them to the Selected Services list.

8 Select always for the *Schedule*.

9 Enable *Log Allowed Traffic*.

10 Select UTM, and enable default AntiVirus, IPS, Web Filter, an Email filter.

11 Select OK.

A new line of information will appear in the identity-based policy table. The table lists the ID, user group or groups, the service or services, schedule, UTM, and logging selected for the rule. Use this display to verify your information was entered correctly.

12 Select *Fortinet Single Sign-On (FSSO)*.

13 Optionally select *Customize Authentication messages* to change the default authentication messages to suit example.com's company design and policies.

14 Select OK.

15 Ensure the FSSO authentication policy is at the top of the list so it will be attempted to be matched before any other policy.

An Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet

NTLM authentication

The NT LAN Manager (NTLM) protocol is used when the MS Windows Active Directory (AD) domain controller can not be contacted. NTLM uses web browsers to send and receive authentication information. See "NTLM" on page 1167 and "NTLM authentication with FSSO" on page 1287.

NTLM authentication is enabled when you configure FSSO and enable NTLM in the identity-based policy (IBP). There must be at least one FSSO Collector agent configured on the FortiGate. Any users and user groups associated with the security policy will use NTLM to authenticate without further configuration. However some extra configuration in the CLI may be required for certain cases including guest access, and defining NTLM enabled browsers.

If there are multiple domains, a trust relation must exist between them. This is automatic if they are in a forest. With the trust relation, only one FSSO DC agent needs to be installed. Without the trust relation, FSSO DC agents must be installed on each domain controller.

NTLM guest access - CLI

Guest profile access may be granted to users failing NTLM authentication, such as visitors who have no user credentials on the network. To allow guest users in NTLM, use the following CLI command:

```
config firewall policy
  edit 8
    set action accept
    set identity-based enable
    set ntlm enable
    set ntlm-guest enable
  next
end
```

NTLM enabled browsers - CLI

User agent strings for NTLM enabled browsers allow the inspection of initial HTTP-User-Agent values, so that non-supported browsers are able to go straight to guest access without needlessly prompting the user for credentials that will fail. `ntlm-guest` must be enabled to use this option.

```
config firewall policy
  edit 9
    set action accept
    set identity-based enable
    set ntlm enable
    set ntlm-guest enable
    set ntlm-enabled-browsers <user_agent_string>
  next
end
```

`<user_agent_string>` is the name of the browser that is NTLM enabled. Examples of these values include “MSIE”, “Mozilla” (which includes FireFox), and “Opera”.

Value strings can be up to 63 characters in length, and may not contain cross site scripting (XSS) vulnerability characters such as brackets. The FortiGate unit prevents use of these characters to prevent exploit of cross site scripting (XSS) vulnerabilities.

Certificate authentication

Certificates can be used as part of an identity-based policy. A customized certificate must be installed on the FortiGate unit and in the web browser, which the FortiGate unit will attempt to match.

All users being authenticated against the policy are required to have the proper certificate, which must be imported into the FortiGate unit. See “Certificate-based authentication” on page 1263.

To require the user to accept a disclaimer to connect to the destination, select *Enable Disclaimer*. If the user is to be redirected after accepting the disclaimer, enter the URL in the *Redirect URL to* field. You can edit the User Authentication Disclaimer replacement message text in *System* > *Config* > *Replacement Messages*.

Certificate redirect authentication

Under *User* > *User* > *Authentication* select Redirect HTTP Challenge to a Secure Channel (HTTPS). This forces users to use secure connections to send their authentication information.

The following steps happen during a redirect:

1. User tries to access the Internet and the HTTP traffic hits the FortiGate security policy with authentication and HTTPS redirect enabled.
2. The FortiGate redirects the user with the HTTPS port and IP address of the interface connected to the user, such as internal.

3 User authenticates over the HTTPS connection as with normal authentication.

4 On successful authentication, the FortiGate provides access to the Internet as originally requested.

Dynamic profile

Only one security policy can be configured for dynamic profile in a VDOM. Also only one RADIUS server and one dynamic profile group can be configured per VDOM. When one dynamic profile security policy has been configured, the option is not visible when creating other policies. After deleting the dynamic profile security policy, the option is again visible when configuring other security policies.

Enable identity-based Policy and *Enable Dynamic Profile* are mutually exclusive. When one of the two options is selected, the other is hidden. When both are not selected, both are visible again.

By enabling the Dynamic Profile Users Only option, other non-dynamic profile users will not match this policy. This can be useful if you want to enforce all users to be part of the dynamic profile group—in which case you have a deny all profile after this one.

For more information, see "Configuring dynamic profile-based security policies" on page 1339.

Restricting number of concurrent user logons

Some users on your network may often have multiple account sessions open at one time either to the same network resource or accessing to the admin interface on the FortiGate unit.

While there are valid reasons for having multiple concurrent sessions open, hackers also do this to speed up their malicious work. Often a hacker is making multiple attempts to gain access to the internal network or the admin interface of the FortiGate unit, usually from different IP addresses to appear to the FortiGate unit as legitimate users. For this reason, the more concurrent sessions a hacker has open at once, the faster they will achieve their goal.

To help prevent this, you can limit concurrent user sessions to the same IP address. This allows valid users to continue their legitimate work while limiting hackers activity.

To enable administrator concurrent session restrictions - CLI

```
config system global
  set admin-concurrent enable
end
```

VPN authentication

All VPN configurations require users to authenticate. Authentication based on user groups applies to:

- SSL VPNs
- PPTP and L2TP VPNs
- an IPsec VPN that authenticates users using dialup groups
- a dialup IPsec VPN that uses XAUTH authentication (Phase 1)

You must create user accounts and user groups before performing the procedures in this section. If you create a user group for dialup IPsec clients or peers that have unique peer IDs, their user accounts must be stored locally on the FortiGate unit. You cannot authenticate these types of users using a RADIUS or LDAP server.

Configuring authentication of SSL VPN users

The general procedure for authenticating SSL VPN users is:

1 Configure user accounts.

2 Create one or more user groups for SSL VPN users.

See “Configuring user accounts and user groups for SSL VPN” in the *FortiOS Handbook SSL VPN chapter*.

3 Enable SSL VPN.

4 Optionally, set inactivity and authentication timeouts.

5 Configure a security policy with SSL VPN action. Add an identity-based rule to allow access for the user groups you created for SSL VPN users.

See “Configuring security policies” in the *FortiOS Handbook SSL VPN chapter*.

Configuring authentication timeout

By default, the SSL VPN authentication expires after 8 hours (28 800 seconds). You can change it only in the CLI, and the time entered must be in seconds. For example, to change this timeout to one hour, you would enter:

```
config vpn ssl settings
  set auth-timeout 3600
end
```

If you set the authentication timeout (`auth-timeout`) to 0 when you configure the timeout settings, the remote client does not have to re-authenticate unless they log out of the system. To fully take advantage of this setting, the value for `idle-timeout` has to be set to 0 also, so that the client does not time out if the maximum idle time is reached. If the `idle-timeout` is not set to the infinite value, the system will log out if it reaches the limit set, regardless of the `auth-timeout` setting.

Configuring authentication of remote IPsec VPN users

An IPsec VPN on a FortiGate unit can authenticate remote users through a dialup group. The user account name is the peer ID and the password is the pre-shared key.

Authentication through user groups is supported for groups containing only local users. To authenticate users using a RADIUS or LDAP server, you must configure XAUTH settings. See “Configuring XAuth authentication” on page 1259.

To configure user group authentication for dialup IPsec - web-based manager

1 Configure the dialup users who are permitted to use this VPN. Create a user group with Type:Firewall and add them to it.

For more information, see “Users and user groups” on page 1223.

2 Go to *VPN* > *IPsec* > *Auto Key (IKE)*, select *Create Phase 1* and enter the following information.

Name	Name for group of dialup users using the VPN for authentication.
Remote Gateway	List of the types of remote gateways for VPN. Select *Dialup User*.
Authentication Method	List of authentication methods available for users. Select *Preshared Key* and enter the preshared key.
Peer Options	Select *Accept peer ID in dialup group*. Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

The *Accept peer ID in dialup group* option does not support authentication of users through an authentication server. The user accounts must exist on the FortiGate unit.

3 Select *Advanced* to reveal additional parameters and configure other VPN gateway parameters as needed.

4 Select *OK*.

To configure user group authentication for dialup IPsec - CLI example

The `peertype` and `usrgrp` options configure user group-based authentication.

```
config vpn ipsec phase1
  edit office_vpn
    set interface port1
    set type dynamic
    set psksecret yORRAzltNGhzgtV32jend
    set proposal 3des-sha1 aes128-sha1
    set peertype dialup
    set usrgrp Group1
  end
```

Configuring XAuth authentication

Extended Authentication (XAuth) increases security by requiring additional user authentication information in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit asks the user for a username and password. It then forwards the user's credentials (the password is encrypted) to an external RADIUS or LDAP server for verification.

XAuth can be used in addition to or in place of IPsec phase 1 peer options to provide access security through an LDAP or RADIUS authentication server. You must configure a dialup user group whose members are all externally authenticated.

None of the users in this dialup user group can have their passwords stored on the FortiGate unit.

To configure authentication for a dialup IPsec VPN - web-based manager

1 Configure the users who are permitted to use this VPN. Create a user group and add the users to the group.

For more information, see "Users and user groups" on page 1223.

2 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

3 Select *Create Phase 1* and configure the basic VPN phase1 settings.

Remote Gateway must be *Dialup User*.

4 Select *Advanced* to reveal additional parameters and enter the following information.

XAuth	Select *Enable as Server*.
Server Type	Select *PAP*, *CHAP*, or *AUTO*. Use CHAP whenever possible. Use PAP with all implementations of LDAP and with other authentication servers that do not support CHAP, including some implementations of Microsoft RADIUS. Use AUTO with the Fortinet Remote VPN Client and where the authentication server supports CHAP but the XAuth client does not.
User Group	Select the user group that is to have access to the VPN. The list of user groups does not include any group that has members whose password is stored on the FortiGate unit.

5 Select *OK*.

For more information about XAUTH configuration, see the IPsec VPN chapter of this FortiOS Handbook.

To configure authentication for a dialup IPsec VPN - CLI example

The `xauthtype` and `authusrgrp` fields configure XAuth authentication.

```
config vpn ipsec phase1
  edit office_vpn
    set interface port1
    set type dynamic
    set psksecret yORRAzltNGhzgtV32jend
    set proposal 3des-sha1 aes128-sha1
    set peertype dialup
    set xauthtype pap
    set authusrgrp Group1
  end
```

Some parameters specific to setting up the VPN itself are not shown here. For detailed information about configuring IPsec VPNs, see the *FortiOS Handbook IPsec VPN chapter*.

Configuring authentication of PPTP VPN users and user groups

Configuration of a PPTP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

To configure authentication for a PPTP VPN

1 Configure the users who are permitted to use this VPN. Create a security user group and add them to it.

For more information, see "Users and user groups" on page 1223.

2 Configure the PPTP VPN in the CLI as in this example.

```
config vpn pptp
  set status enable
  set sip 192.168.0.100
  set eip 192.168.0.110
  set usrgrp PPTP_Group
end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to PPTP clients.

3 Configure a security policy. The source interface is the one through which the clients will connect. The source address is the PPTP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Configuring authentication of L2TP VPN users/user groups

Configuration of a L2TP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

To configure authentication for a PPTP VPN

1 Configure the users who are permitted to use this VPN. Create a user group and add them to it.

For more information, see “Users and user groups” on page 1223.

2 Configure the L2TP VPN in the CLI as in this example.

```
config vpn l2tp
  set status enable
  set sip 192.168.0.100
  set eip 192.168.0.110
  set usrgrp L2TP_Group
end
```

The `sip` and `eip` fields define a range of virtual IP addresses assigned to L2TP clients.

3 Configure a security policy. The source interface is the one through which the clients will connect. The source address is the L2TP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Certificate-based authentication

This section provides an overview of how the FortiGate unit verifies the identities of administrators, SSL VPN users, or IPsec VPN peers using X.509 security certificates.

The following topics are included in this section:

What is a security certificate?

A security certificate is a small text file that is part of a third-party generated public key infrastructure (PKI) to help guarantee the identity of both the user logging on and the website they where they are logging in.

A certificate includes identifying information such as the company and location information for the website, as well as the third-party company name, the expiry date of the certificate, and the encrypted public key.

FortiGate units use X.509 certificates to authenticate single sign-on (SSO) for users. The X.509 standard has been in use since before 2000, but has gained popularity with the Internet's increased popularity. X.509 v3 is defined in RFC 5280 and specifies standard formats for public key certificates, certificate revocation lists, and a certification path validation algorithm. The unused earlier X.509 version 1 was defined in RFC 1422.

The main difference between X.509 and PGP certificates is that where in PGP anyone can sign a certificate, for X.509 only a trusted authority can sign certificates. This limits the source of certificates to well known and trustworthy sources. Where PGP is well suited for one-on-one communications, the X.509 infrastructure is intended to be used in many different situations including one-to-many communications. Some common filename extensions for X.509 certificates are listed in Table 81.

Table 81: Common certificate filename extensions

Filetype	Format name	Description
.pem	Privacy Enhanced Mail (PEM)	Base64 encoded DER certificate, that uses "-----BEGIN CERTIFICATE-----" and "-----END CERTIFICATE-----"
.cer **.crt** **.der**	Security CERtificate	Usually binary DER form, but Base64-encoded certificates are common too.

Table 81: Common certificate filename extensions

.p7b **.p7c**	PKCS#7 SignedData	Structure without data, just certificates or CRLs. PKCS#7 is a standard for signing or encrypting (officially called "enveloping") data.
.p12	PKCS#12	May contain certificate(s) (public) and private keys (password protected)
.pfx	personal information exchange (PFX)	Older format. Came before PKCS#12. Usually today data is in PKCS#12 format.

Certificates overview

Certificates play a major role in authentication of clients connecting to network services via HTTPS, both for administrators and SSL VPN users. Certificate authentication is optional for IPsec VPN peers.

- Certificates and protocols
- IPsec VPNs and certificates
- Certificate types on the FortiGate unit

Certificates and protocols

There are a number of protocols that are commonly used with certificates including SSL and HTTPS, and other certificate-related protocols.

SSL and HTTPS

The secure HTTP (HTTPS) protocol uses SSL. Certificates are an integral part of SSL. When a web browser connects to the FortiGate unit via HTTPS, a certificate is used to verify the FortiGate unit's identity to the client. Optionally, the FortiGate unit can require the client to authenticate itself in return.

By default, the FortiGate unit uses a self-signed security certificate to authenticate itself to HTTPS clients. When the certificate is offered, the client browser displays two security messages.

- The first message prompts users to accept and optionally install the FortiGate unit's self-signed security certificate. If the user does not accept the certificate, the FortiGate unit refuses the connection. When the user accepts the certificate, the FortiGate login page is displayed, and the credentials entered by the user are encrypted before they are sent to the FortiGate unit. If the user chooses to install the certificate, the prompt is not displayed again.
- Just before the FortiGate login page is displayed, a second message informs users that the FortiGate certificate distinguished name differs from the original request. This message is displayed because the FortiGate unit redirects the connection (away from the distinguished name recorded in the self-signed certificate) and can be ignored.

Optionally, you can install an X.509 server certificate issued by a certificate authority (CA) on the FortiGate unit. You can then configure the FortiGate unit to identify itself using the server certificate instead of the self-signed certificate. For more information, see the *FortiOS Handbook SSL VPN chapter*. or "Authenticating SSL VPN users with security certificates" on page 1275.

After successful certificate authentication, communication between the client browser and the FortiGate unit is encrypted using SSL over the HTTPS link.

Certificate-related protocols

There are multiple protocols that are required for handling certificates. These include the Online Certificate Status Protocol (OCSP), Secure Certificate Enrollment Protocol (SCEP), and Server-based Certificate Validation Protocol (SCVP).

Online Certificate Status Protocol

Online Certificate Status Protocol (OCSP) allows the verification of X.509 certificate expiration dates. This is important to prevent hackers from changing the expiry date on an old certificate to a future date.

Normally certificate revocation lists (CRLs) are used, but OCSP is an alternate method available. However a CRL is a public list, and some companies may want to avoid the public exposure of their certificate structure even if it is only invalid certificates.

The OSCP check on the certificate's revocation status is typically carried out over HTTP with a request-response format. The authority responding can reply with a status of good, revoked, or unknown for the certificate in question.

Secure Certificate Enrollment Protocol

Secure Certificate Enrollment Protocol (SCEP) is an automated method of signing up for certificates. Typically this involves generating a request you send directly to the SCEP service, instead of generating a file request that may or may not be signed locally.

Server-based Certificate Validation Protocol

Server-based Certificate Validation Protocol (SCVP) is used to trace a certificate back to a valid root level certificate. This ensures that each step along the path is valid and trustworthy.

IPsec VPNs and certificates

Certificate authentication is a more secure alternative to preshared key (shared secret) authentication for IPsec VPN peers. Unlike administrators or SSL VPN users, IPsec peers use HTTP to connect to the VPN gateway configured on the FortiGate unit. The VPN gateway configuration can require certificate authentication before it permits an IPsec tunnel to be established. See "Authenticating IPsec VPN users with security certificates" on page 1276.

Certificate types on the FortiGate unit

There are different types of certificates available that vary depending on their intended use. FortiOS supports local, remote, CA, and CRL certificates.

Local certificates

Local certificates are issued for a specific server, or web site. Generally they are very specific, and often for an internal enterprise network. For example a personal web site for John Smith at www.example.com (such as http://www.example.com/home/jsmith) would have its own local certificate.

These can optionally be just the certificate file, or also include a private key file and PEM passphrase for added security.

Remote certificates

Remote certificates are public certificates without a private key. For dynamic certificate revocation, you need to use an Online Certificate Status Protocol (OCSP) server. The OCSP is configured in the CLI only. Installed Remote (OCSP) certificates are displayed in the Remote Certificates list.

CA root certificates

CA root certificates are similar to local certificates, however they apply to a broader range of addresses or to whole company; they are one step higher up in the organizational chain. Using the local certificate example, a CA root certificate would be issued for all of www.example.com instead of just the smaller single web page.

Certificate revocation list

Certificate revocation list (CRL) is a list of certificates that have been revoked and are no longer usable. This list includes certificates that have expired, been stolen, or otherwise compromised. If your certificate is on this list, it will not be accepted. CRLs are maintained by the CA that issues the certificates and includes the date and time when the next CRL will be issued as well as a sequence number to help ensure you have the most current version of the CRL.

Certificate signing

The trust in a certificate comes from the authority that signs it. For example if VeriSign signs your CA root certificate, it is trusted by everyone. While these certificates are universally accepted, it is cumbersome and expensive to have all certificates on a corporate network signed with this level of trust.

With self-signed certificates nobody, except the other end of your communication, knows who you are and therefore they do not trust you as an authority. However this level is useful for encryption between two points — neither point may care about who signed the certificate, just that it allows both points to communicate. This is very useful for internal networks and communications.

A general rule is that CA signed certificates are accepted and sometimes required, but it is easier to self-sign certificates when you are able.

For more on the methods of certificate signing see “Generating a certificate signing request” on page 1267.

Managing X.509 certificates

Managing security certificates is required due to the number of steps involved in both having a certificate request signed, and then distributing the correct files for use.

You use the FortiGate unit or CA software such as OpenSSL to generate a certificate request. That request is a text file that you send to the CA for verification, or alternately you use CA software to self-validate. Once validated, the certificate file is generated and must be imported to the FortiGate unit before it can be used. These steps are explained in more detail later in this section.

This section provides procedures for generating certificate requests, installing signed server certificates, and importing CA root certificates and CRLs to the FortiGate unit.

For information about how to install root certificates, CRLs, and personal or group certificates on a remote client browser, refer to your browser’s documentation.

This section includes:

Generating a certificate signing request

Whether you create certificates locally with a software application or obtain them from an external certificate service, you will need to generate a certificate signing request (CSR).

When you generate a CSR, a private and public key pair is created for the FortiGate unit. The generated request includes the public key of the FortiGate unit and information such as the FortiGate unit's public static IP address, domain name, or email address. The FortiGate unit's private key remains confidential on the FortiGate unit.

After you submit the request to a CA, the CA will verify the information and register the contact information on a digital certificate that contains a serial number, an expiration date, and the public key of the CA. The CA will then sign the certificate, and you install the certificate on the FortiGate unit.

The Certificate Request Standard is a public key cryptography standard (PKCS) published by RSA, specifically PKCS10 which defines the format for CSRs. This is defined in RFC 2986.

To generate a certificate request in FortiOS - web-based manager

1 Go to *System* > *Certificates* > *Local Certificates*.

2 Select *Generate*.

3 In the *Certificate Name* field, enter a unique meaningful name for the certificate request. Typically, this would be the hostname or serial number of the FortiGate unit or the domain of the FortiGate unit such as example.com.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

4 Enter values in the *Subject Information* area to identify the FortiGate unit:

- If the FortiGate unit has a static IP address, select *Host IP* and enter the public IP address of the FortiGate unit. If the FortiGate unit does not have a public IP address, use an email address (or fully qualified domain name (FQDN) if available) instead.
- If the FortiGate unit has a static IP address and subscribes to a dynamic DNS service, use a FQDN if available to identify the FortiGate unit. If you select *Domain Name*, enter the FQDN of the FortiGate unit. Do not include the protocol specification (http://) or any port number or path names.

If a domain name is not available and the FortiGate unit subscribes to a dynamic DNS service, an "unable to verify certificate" type message may be displayed in the user's browser whenever the public IP address of the FortiGate unit changes.

- If you select *E-Mail*, enter the email address of the owner of the FortiGate unit.

5 Enter values in the *Optional Information* area to further identify the FortiGate unit.

Organization Unit	Name of your department. You can enter a series of OUs up to a maximum of 5. To add or remove an OU, use the plus (+) or minus (-) icon.
Organization	Legal name of your company or organization.
Locality (City)	Name of the city or town where the FortiGate unit is installed.
State/Province	Name of the state or province where the FortiGate unit is installed.
Country	Select the country where the FortiGate unit is installed.
e-mail	Contact email address.

6 From the *Key Size* list, select *1024 Bit*, *1536 Bit* or *2048 Bit*. Larger keys are slower to generate but more secure.

7 In *Enrollment Method*, you have two methods to choose from. Select *File Based* to generate the certificate request, or *Online SCEP* to obtain a signed SCEP-based certificate automatically over the network. For the SCEP method, enter the URL of the SCEP server from which to retrieve the CA certificate, and the CA server challenge password.

8 Select *OK*.

The request is generated and displayed in the *Local Certificates* list with a status of `PENDING`.

9 Select the *Download* button to download the request to the management computer.

10 In the *File Download* dialog box, select *Save* and save the Certificate Signing Request on the local file system of the management computer.

11 Name the file and save it on the local file system of the management computer.

The certificate request is ready for the certificate to be generated.

Generating certificates with CA software

CA software allows you to generate unmanaged certificates and CA certificates for managing other certificates locally without using an external CA service. Examples of CA software include ssl-ca from OpenSSL (available for Linux, Windows, and Mac) or gensslcert from SuSE, MS Windows Server 2000 and 2003 come with a CA as part of their certificate services, and in MS Windows 2008 CA software can be installed as part of the Active Directory installation. See “Example — Generate and Import CA certificate with private key pair on OpenSSL” on page 1278.

The general steps for generating certificates with CA software are

1 Install the CA software as a stand-alone root CA.

2 Provide identifying information for your self-administered CA.

While following these steps, the methods vary slightly when generating server certificates, CA certificates, and PKI certificates.

Server certificate

1 Generate a Certificate Signing Request (CSR) on the FortiGate unit.

2 Copy the CSR base-64 encoded text (PKCS10 or PKCS7) into the CA software and generate the certificate.

   PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.

3 Export the certificate as a X.509 DER encoded binary file with .CER extension

4 Upload the certificate file to the FortiGate unit Local Certificates page (type is Certificate).

CA certificate

1 Retrieve the CA Certificate from the CA software as a DER encoded file.

2 Upload the CA certificate file to the FortiGate unit CA Certificates page at *System* > *Certificates* > *CA Certificates*.

PKI certificate

1 Generate a Certificate Signing Request (CSR) on the FortiGate unit.

2 Copy the CSR base-64 encoded text (PKCS#10 or PKCS#7) into the CA software and generate the certificate.

   PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.

3 Export the certificate as a X.509 DER encoded binary file with .CER extension.

4 Install the certificate in the user's web browser or IPsec VPN client as needed.

Obtaining a signed server certificate from an external CA

To obtain a signed server certificate for a FortiGate unit, you must send a request to a CA that provides digital certificates that adhere to the X.509 standard. The FortiGate unit provides a way for you to generate the request.

To submit the certificate signing request (file-based enrollment)

1 Using the web browser on the management computer, browse to the CA web site.

2 Follow the CA instructions for a base-64 encoded PKCS#10 certificate request and upload your certificate request.

3 Follow the CA instructions to download their root certificate and CRL.

   When you receive the signed server certificate from the CA, install the certificate on the FortiGate unit.

To install or import the signed server certificate - web-based manager

1 On the FortiGate unit, go to *System* > *Certificates* > *Local Certificates*.

2 Select *Import*.

3 From *Type*, select *Local Certificate*.

4 Select *Browse*, browse to the location on the management computer where the certificate was saved, select the certificate, and then select *Open*.

5 Select *OK*, and then select *Return*.

Installing a CA root certificate and CRL to authenticate remote clients

When you apply for a signed personal or group certificate to install on remote clients, you can obtain the corresponding root certificate and CRL from the issuing CA. When you receive the signed personal or group certificate, install the signed certificate on the remote client(s) according to the browser documentation. Install the corresponding root certificate (and CRL) from the issuing CA on the FortiGate unit according to the procedures given below.

FortiGate IPSec VPNs do not support CRL lookups.

To install a CA root certificate

1. After you download the root certificate of the CA, save the certificate on the management computer. Or, you can use online SCEP to retrieve the certificate.
2. On the FortiGate unit, go to *System* > *Certificates* > *CA Certificates*.
3. Select *Import*.
4. Do one of the following:
   - To import using SCEP, select *SCEP*. Enter the URL of the SCEP server from which to retrieve the CA certificate. Optionally, enter identifying information of the CA, such as the filename.
   - To import from a file, select *Local PC*, then select *Browse* and find the location on the management computer where the certificate has been saved. Select the certificate, and then select *Open*.
5. Select *OK*, and then select *Return*.

The system assigns a unique name to each CA certificate. The names are numbered consecutively (CA_Cert_1, CA_Cert_2, CA_Cert_3, and so on).

To import a certificate revocation list

A Certificate Revocation List (CRL) is a list of the CA certificate subscribers paired with certificate status information. The list contains the revoked certificates and the reason(s) for revocation. It also records the certificate issue dates and the CAs that issued them.

When configured to support SSL VPNs, the FortiGate unit uses the CRL to ensure that the certificates belonging to the CA and remote peers or clients are valid. You must download the CRL from the CA web site on a regular basis.

1. After you download the CRL from the CA web site, save the CRL on the management computer.
2. Go to *System* > *Certificates* > *CRL*.
3. Select *Import*.

4 Do one of the following:
   - To import using an HTTP server, select *HTTP* and enter the URL of the HTTP server.
   - To import using an LDAP server, select *LDAP* and select the LDAP server from the list.
   - To import using an SCEP server, select *SCEP* and select the Local Certificate from the list. Enter the URL of the SCEP server from which the CRL can be retrieved.
   - To import from a file, select *Local PC*, then select *Browse* and find the location on the management computer where the CRL has been saved. Select the CRL and then select *Open*.
5 Select *OK*, and then select *Return*.

Troubleshooting certificates

There are times when there are problems with certificates — a certificate is seen as expired when its not, or it can't be found. Often the problem is with a third party website, and not FortiOS. However, some problems can be traced back to ForitOS such as DNS or routing issues.

Certificate is reported as expired when it is not

Certificates often are issued for a set period of time such as a day or a month, depending on their intended use. This ensures everyone is using up-to-date certificates. It is also more difficult for hackers to steal and use old certificates.

Reasons a certificate may be reported as expired include:

- It really has expired based on the "best before" date in the certificate
- The FortiGate unit clock is not properly set. If the FortiGate clock is fast, it will see a certificate as expired before the expiry date is really here.
- The requesting server clock is not properly set. A valid example is if your certificate is 2 hours from expiring, a server more than two time zones away would see the certificate as expired. Otherwise, if the server's clock is set wrongly it will also have the same effect.
- The certificate was revoked by the issuer before the expiry date. This may happen if the issuer belives a certificate was either stolen or misused. Its possible it is due to reasons on the issuer's side, such as a sytem change or such. In either case it is best to contact the certifcate issuer to deteriminewhat is happening and why.

A secure connection cannot be completed (Certificate cannot be found)

Everyone who uses a browser has encountered a message such as *This connection is untrusted*. Normally when you try to connect securly to a website, that website will present its valid certificate to prove their identity is valid. When the website's certificate cannot be verified as valid, the message appears stating *This connection is untrusted* or something similar. If you usually connect to this website without problems, this error could mean that someone is trying to impersonate or hijack the website, and best practices dictates you not continue.

Reasons a website's certificate cannot be validated include:

- The website uses an unrecognized self-signed certificate. These are not secure because anyone can sign them. If you accept self-signed certificates you do so at your own risk. Best practices dictate that you must confirm the ID of the website using some other method before you accept the certificate.

- The certificate is valid for a different domain. A certificate is valid for a specific location, domain, or sub-section of a domain such as one certificate for `support.example.com` that is not valid for `marketing.example.com`. If you encounter this problem, contact the webmaster for the website to inform them of the problem.
- There is a DNS or routing problem. If the website's certificate cannot be verified, it will not be accepted. Generally to be verified, your system checks with the third party certificate signing authority to verifiy the certificate is valid. If you cannot reach that third party due to some DNS or routing error, the certificate will not be verified.
- Firewall is blocking required ports. Ensure that any firewalls between the requesting computer and the website allow the secure traffic through the firewall. Otherwise a hole must be opened to allow it through. This includes ports such as 443 (HTTPS) and 22 SSH).

Online updates to certificates and CRLs

If you obtained your local or CA certificate using SCEP, you can configure online renewal of the certificate before it expires. Similarly, you can receive online updates to CRLs.

Local certificates

In the `config vpn certificate local` command, you can specify automatic certificate renewal. The relevant fields are:

`scep-url <URL_str>`	The URL of the SCEP server. This can be HTTP or HTTPS.
`scep-password <password_str>`	The password for the SCEP server.
`auto-regenerate-days <days_int>`	How many days before expiry the FortiGate unit requests an updated local certificate. The default is `0`, no auto-update.
`auto-regenerate-days-warning <days_int>`	How many days before local certificate expiry the FortiGate generates a warning message. The default is `0`, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate local
  edit mycert
    set scep-url http://scep.example.com/scep
    set scep-server-password my_pass_123
    set auto-regenerate-days 3
    set auto-regenerate-days-warning 2
  end
```

CA certificates

In the `config vpn certificate ca` command, you can specify automatic certificate renewal. The relevant fields are:

`scep-url <URL_str>`	The URL of the SCEP server. This can be HTTP or HTTPS.
`auto-update-days <days_int>`	How many days before expiry the FortiGate unit requests an updated CA certificate. The default is `0`, no auto-update.
`auto-update-days-warning <days_int>`	How many days before CA certificate expiry the FortiGate generates a warning message. The default is `0`, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate ca
  edit mycert
    set scep-url http://scep.example.com/scep
    set auto-update-days 3
    set auto-update-days-warning 2
  end
```

Certificate Revocation Lists

If you obtained your CRL using SCEP, you can configure online updates to the CRL using the `config vpn certificate crl` command. The relevant fields are:

Variable	Description
`http-url <http_url>`	URL of the server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
`scep-cert <scep_certificate>`	Local certificate used for SCEP communication for CRL auto-update.
`scep-url <scep_url>`	URL of the SCEP CA server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
`update-interval <seconds>`	How frequently, in seconds, the FortiGate unit checks for an updated CRL. Enter `0` to update the CRL only when it expires.
`update-vdom <update_vdom>`	VDOM used to communicate with remote SCEP server for CRL auto-update.

In this example, an updated CRL is requested only when it expires.

```
config vpn certificate crl
  edit cert_crl
    set http-url http://scep.example.com/scep
    set scep-cert my-scep-cert
    set scep-url http://scep.ca.example.com/scep
    set update-interval 0
    set update-vdom root
  end
```

Backing up and restoring local certificates

The FortiGate unit provides a way to export and import a server certificate and the FortiGate unit's personal key through the CLI. If required (to restore the FortiGate unit configuration), you can import the exported file through the *System* > *Certificates* > *Local Certificates* page of the web-based manager.

As an alternative, you can back up and restore the entire FortiGate configuration through the *System* > *Maintenance* > *Backup & Restore* page of the web-based manager. The backup file is created in a FortiGate-proprietary format.

To export a server certificate and private key - CLI

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate unit before you enter the command.

1 Connect to the FortiGate unit through the CLI.

2 Type the following command:

```
execute vpn certificate local export tftp <cert_name> <exp_filename>
  <tftp_ip>
```

where:

- `<cert_name>` is the name of the server certificate; typing `?` displays a list of installed server certificates.
- `<exp_filename>` is a name for the output file.
- `<tftp_ip>` is the IP address assigned to the TFTP server host interface.

3 Move the output file from the TFTP server location to the management computer for future reference.

To import a server certificate and private key - web-based manager

1 Go to *VPN* > *Certificates* > *Local Certificates* and select *Import*.

2 In *Type*, select *PKCS12 Certificate*.

3 Select *Browse*. Browse to the location on the management computer where the exported file has been saved, select the file, and then select *Open*.

4 In the *Password* field, type the password needed to upload the exported file.

5 Select *OK*, and then select *Return*.

To import separate server certificate and private key files - web-based manager

Use the following procedure to import a server certificate and the associated private key file when the server certificate request and private key were not generated by the FortiGate unit. The two files to import must be available on the management computer.

1 Go to *VPN* > *Certificates* > *Local Certificates* and select *Import*.

2 In *Type*, select *Certificate*.

3 Select the *Browse* button beside the *Certificate file* field. Browse to the location on the management computer where the certificate file has been saved, select the file, and then select *Open*.

4 Select the *Browse* button beside the *Key file* field. Browse to the location on the management computer where the key file has been saved, select the file, and then select *Open*.
5 If required, in the *Password* field, type the associated password, and then select *OK*.
6 Select *Return*.

Configuring certificate-based authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users.

In Microsoft Windows 7, you can use the certificate manager to keep track of all the different certiticates on your local computer. To access certificate manager, in Windows 7 press the Windows key, enter “certmgr.msc” at the search prompt, and select the displayed match. Remember that in addition to these system certificates, many applications require you to register certificates with them directly.

To see FortiClient certificates, open the FortiClient Console, and select VPN. The VPN menu has options for My Certificates (local or client) and CA Certificates (root or intermediary certificate authorities). Use Import on those screens to import certificate files from other sources.

Authenticating administrators with security certificates

You can install a certificate on the management computer to support strong authentication for administrators. When a personal certificate is installed on the management computer, the FortiGate unit processes the certificate after the administrator supplies a username and password.

To enable strong administrative authentication:

- Obtain a signed personal certificate for the administrator from a CA and load the signed personal certificate into the web browser on the management computer according to the browser documentation.
- Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see “Installing a CA root certificate and CRL to authenticate remote clients” on page 1270).
- Create a PKI user account for the administrator.
- Add the PKI user account to a firewall user group dedicated to PKI-authenticated administrators.
- In the administrator account configuration, select *PKI* as the account *Type* and select the *User Group* to which the administrator belongs.

Authenticating SSL VPN users with security certificates

While the default self-signed certificates can be used for HTTPS connections, it is preferable to use the X.509 server certificate to avoid the redirection as it can be misinterpreted as possible session hijacking. However, the server certificate method is more complex than self-signed security certificates. Also the warning message is typically displayed for the initial connection, and future connections will not generate these messages.

X.509 certificates can be used to authenticate IPsec VPN peers or clients, or SSL VPN clients. When configured to authenticate a VPN peer or client, the FortiGate unit prompts the VPN peer or client to authenticate itself using the X.509 certificate. The certificate supplied by the VPN peer or client must be verifiable using the root CA certificate installed on the FortiGate unit in order for a VPN tunnel to be established.

To enable certificate authentication for an SSL VPN user group

1 Install a signed server certificate on the FortiGate unit and install the corresponding root certificate (and CRL) from the issuing CA on the remote peer or client.
2 Obtain a signed group certificate from a CA and load the signed group certificate into the web browser used by each user. Follow the browser documentation to load the certificates.
3 Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see "Installing a CA root certificate and CRL to authenticate remote clients" on page 1270).
4 Create a PKI user for each SSL VPN user. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
5 Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the SSL VPN users who are authenticated by certificate.
6 Go to *VPN* > *SSL* > *Config*.
7 Select *Enable SSL-VPN*.
8 Go to *Policy*.
9 Select the *Edit* icon in the row that corresponds to the SSL-VPN security policy for traffic generated by holders of the group certificate.
10 Select *SSL Client Certificate Restrictive*.
11 Select *OK*.

Authenticating IPsec VPN users with security certificates

To require VPN peers to authenticate by means of a certificate, the FortiGate unit must offer a certificate to authenticate itself to the peer.

To enable the FortiGate unit to authenticate itself with a certificate:

1 Install a signed server certificate on the FortiGate unit.
See "To install or import the signed server certificate - web-based manager" on page 1269.
2 Install the corresponding CA root certificate on the remote peer or client. If the remote peer is a FortiGate unit, see "To install a CA root certificate" on page 1270.
3 Install the certificate revocation list (CRL) from the issuing CA on the remote peer or client. If the remote peer is a FortiGate unit, see "To import a certificate revocation list" on page 1270.
4 In the VPN phase 1 configuration, set *Authentication Method* to *RSA Signature* and from the *Certificate Name* list select the certificate that you installed in Step 1.

To authenticate a VPN peer using a certificate, you must install a signed server certificate on the peer. Then, on the FortiGate unit, the configuration depends on whether there is only one VPN peer or if this is a dialup VPN that can he multiple peers.

To configure certificate authentication of a single peer

1 Install the CA root certificate and CRL.

2 Create a PKI user to represent the peer. Specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.

3 In the VPN phase 1 *Peer Options*, select *Accept this peer certificate only* and select the PKI user that you created.

To configure certificate authentication of multiple peers (dialup VPN)

1 Install the corresponding CA root certificate and CRL.

2 Create a PKI user for each remote VPN peer. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.

3 Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the PKI users who will use the IPsec VPN.

In the VPN phase 1 *Peer Options*, select *Accept this peer certificate group only* and select the peer group that you created.

FortiGate IPSec VPNs do not support CRL lookups.

Example — Generate a CSR on the FortiGate unit

This example follows all the steps required to create and install a local certificate on the FortiGate unit, without using CA software.

The FortiGate unit is called myFortiGate60, and is located at 10.11.101.101 (a private IP address) and http://myfortigate.example.com. Mr. John Smith (john.smith@myfortigate.example.com) is the IT administrator for this FortiGate unit,a nd the unit belongs to the Sales department located in Greenwich, London, England.

To generate a certificate request on the FortiGate unit - web-based manager

1 Go to *System* > *Certificates* > *Local Certificates*.

2 Select *Generate*.

3 In the *Certificate Name* field, enter `myFortiGate60`.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

Since the IP address is private, we will use the FQDN instead.

4 Select *Domain Name*, and enter `http://myfortigate.example.com`.

5 Enter values in the *Optional Information* area to further identify the FortiGate unit.

Organization Unit	Sales.
Organization	Example.com
Locality (City)	Greenwhich
State/Province	London

Country	England
e-mail	john.smith@myfortigate.example.com

6 From the *Key Size* list, select *2048 Bit* or the most secure option available to you.

7 In *Enrollment Method*, select *File Based* to generate the certificate request

8 Select *OK*.

The request is generated and displayed in the *Local Certificates* list with a status of PENDING.

9 Select the *Download* button to download the request to the management computer.

10 In the *File Download* dialog box, select *Save* and save the Certificate Signing Request on the local file system of the management computer.

11 Name the file and save it on the local file system of the management computer.

Example — Generate and Import CA certificate with private key pair on OpenSSL

This example explains how to generate a certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

Assumptions

Before starting this procedure, ensure that you have downloaded and installed OpenSSL on Windows. One source is http://www.slproweb.com/products/Win32OpenSSL.html.

Generating and importing the CA certificate and private key

The two following procedures will generate a CA certificate file and private key file, and then import it to the FortiGate unit as a local certificate.

To generate the private key and certificate

1 At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

```
cd c:\OpenSSL-Win32\bin
```

2 Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet123.

```
openssl genrsa -des3 -out fgtcapriv.key 2048
```

This command generates an RSA DES3 2038-bit encryption key.

3 The following command will generate the certificate using the key from the previous step.

```
openssl req -new -x509 -days 3650 -extensions v3_ca -key
   fgtcapriv.key -out fgtca.crt
```

This step generates an X509 CA certificate good for 10 years that uses the key generated in the previous step. The certificate filename is `fgtca.crt`.

You will be prompted to enter information such as PEM Pass Phrase from the previous step, Country Name, State, Organization Name, Organizational Unit (such as department name), Common Name (the FQDN), and Email Address.

To import the certificate to the FortiGate unit - web-based manager

1 Go to *System* > *Certificates* > *Local Certificates*.

2 Select *Import*.

3 Select Certificate for Type.

Fields for Certificate file, Key file, and Password are displayed.

4 For Certificate file, enter `c:\OpenSSL-Win32\bin\fgtca.crt`.

5 For Key file, enter `c:\OpenSSL-Win32\bin\fgtcapriv.key`.

6 For Password, enter the PEM Pass Phrase you entered earlier, such as fortinet123.

7 Select OK.

The Certificate will be added to the list of Local Certificates and be ready for use. It will appear in the list as the filename you uploaded — `fgtca`.You can add comments to this certificate to make it clear where its from and how it is intended to be used. If you download the certificate from FortiOS, it is a .CER file.

It can now be used in "Authenticating IPsec VPN users with security certificates" on page 1276, and "Authenticating SSL VPN users with security certificates" on page 1275.

Optionally, you can install the certificate as a CA Certificate. CA certificates are used in HTTPS proxy/inspection. To do this, under CA Certificates select Import. Select Local PC and enter the certificate file `c:\OpenSSL-Win32\bin\fgtca.crt`. Then select OK. This certificate will be displayed in the CA Certificate list under the name `CA_Cert_1`.

Example — Generate an SSL certificate in OpenSSL

This example explains how to generate a CA signed SSL certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

This example includes:

- Assumptions
- Generating a CA signed SSL certificate
- Generating a self-signed SSL certificate
- Import the SSL certificate into FortiOS

Assumptions

- Before starting this procedure, ensure that you have downloaded and installed OpenSSL on MS Windows. One download source is http://www.slproweb.com/products/Win32OpenSSL.html.

Generating a CA signed SSL certificate

This procedure assumes:

- you have already completed "Example — Generate and Import CA certificate with private key pair on OpenSSL" on page 1278 successfully.

To generate the CA signed SSL certificate

1 At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

```
cd c:\OpenSSL-Win32\bin
```

2 Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.

```
openssl genrsa -des3 -out fgtssl.key 2048
```

This command generates an RSA DES3 2038-bit encryption key.

3 Create a certificate signing request for the SSL certificate. This step requires you to enter the information listed in step 3 of the previous example — "To generate the private key and certificate" on page 1278. You can leave the Challenge Password blank.

```
openssl req -new -key fgtssl.key -out fgtssl.csr
```

4 Using the CSR from the previous step, you can now create the SSL certificate using the CA certificate that was created in "Example — Generate and Import CA certificate with private key pair on OpenSSL" on page 1278.

```
openssl x509 -req -days 365 -in fgtssl.csr -CA fgtca.crt -
   CAkey fgtcapriv.key -set_serial 01 -out fgtssl.crt
```

This will generate an X.509 certificate good for 365 days signed by the CA certificate fgtca.crt .

Generating a self-signed SSL certificate

This procedures does not require any existing certificates.

1 At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

```
cd c:\OpenSSL-Win32\bin
```

2 Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.

```
openssl genrsa -des3 -out fgtssl.key 2048
openssl req -new -key fgtssl.key -out fgtssl.csr
openssl x509 -req -days 365 -in fgtssl.csr -signkey fgtssl.key
   -out fgtssl.crt
```

These commands:

- generate an RSA 3DES 2048-bit private key,
- generate an SSL certificate signing request, and
- sign the CSR to generate an SSL .CRT certificate file.

Import the SSL certificate into FortiOS

To import the certificate to FortiOS- web-based manager

1 Go to *System* > *Certificates* > *Local Certificates*.

2 Select *Import*.

3 Select Certificate for Type.

Fields for Certificate file, Key file, and Password are displayed.

4 For Certificate file, enter `c:\OpenSSL-Win32\bin\fgtssl.crt`.

5 For Key file, enter `c:\OpenSSL-Win32\bin\fgtssl.key`.

6 For Password, enter the PEM Pass Phrase you entered, such as fortinet.

7 Select OK.

The SSL certificate you just uploaded can be found under `System > Certificates > Local Certificates` under the name of the file you uploaded — `fgtssl`.

To confirm the certificate is uploaded properly - CLI

```
config vpn certificate local
  edit fgtssl
    get
  end
```

The get command will display all the certificate's information. If it is not there or the information is not correct, you will need to remove the corrupted certificate (if it is there) and upload it again from your PC.

To use the new SSL certificate - CLI

```
config vpn ssl settings
  set servercert fgtssl
end
```

This assigns the fgtssl certificate as the SSL server certificate. For more information see the *FortiOS Handbook SSL VPN chapter*.

FSSO integration with Windows AD or Novell

This chapter provides information, installation instructions, and troubleshooting for Fortinet Single Sign On (FSSO) agent. Earlier versions of this product were named Fortinet Server Authentication Extension (FSAE).

The following topics are included:

Introduction to FSSO

The Fortinet Single Sign On (FSSO) agent connects FortiGate Fortinet security appliances to the corporate authentication servers, such as Microsoft Active Directory and Novell E-Directory, allowing security policies to be defined on the FortiGate unit based on the user information residing on the corporate authentication servers. FSSO, a component installed on the authentication server or a standalone server, provides user authentication information to the FortiGate unit so users can automatically gain access to the permitted resources with a single sign on. Older versions were called Fortinet Server Authentication Extension (FSAE).

On a Microsoft Windows or Novell network, users authenticate with the Active Directory or Novell eDirectory at logon. It would be inconvenient if users then had to enter another username and password for network access through the FortiGate unit. FSSO provides authentication information to the FortiGate unit so that users automatically get access to permitted resources.

There are several mechanisms for passing user authentication information to the FortiGate unit:

- FSSO software installed on a Windows AD network monitors user logons and sends the required information to the FortiGate unit. The FSSO software can obtain this information by polling the AD domain controllers or by using an FSSO agent on each AD domain controller that monitors user logons in real time. Optionally, a FortiGate unit running FortiOS 3.0 MR6 or later can obtain group information directly from AD using Lightweight Directory Access Protocol (LDAP). See “Using FSSO in a Windows AD environment” on page 1284.

- On a Windows AD network, the FSSO software can also serve NT LAN Manager (NTLM) requests coming from client browsers (forwarded by the FortiGate unit) with only one or more Controller agents installed. See "NTLM authentication with FSSO" on page 1287.
- FSSO software installed on a Novell network monitors user logons and sends the required information to the FortiGate unit. The FSSO software can obtain information from the Novell eDirectory using either the Novell API or LDAP. See "Using FSSO in a Novell eDirectory environment" on page 1290.
- A FortiAuthenticator server can act as a replacement for the Collector agent in polling mode in a Windows AD network. FortiAuthenticator can also be configured with internal or external LDAP and RADIUS servers. For more information, see the *FortiAuthenticator Administration Guide*.

Consult the latest FortiOS and FSSO Release Notes for operating system compatibility information.

Using FSSO in a Windows AD environment

FSSO installed in a Windows AD environment can provide two kinds of services:

- Monitor user logon activity and send the information to FortiGate unit so that the FortiGate unit can support Single user Sign On (SSO).
- Provide NTLM authentication service for requests coming from FortiGate.

SSO is very convenient for users, but may not be supported across all platforms. NTLM is not as convenient, but it enjoys wider support.

FSSO is certified for the Microsoft Windows Server 2003 (32- and 64-bit editions) and is supported on the Microsoft Windows Server 2008 (32- and 64-bit editions) operating systems.

FSSO security

When the different components of FSSO are communicating there are some inherent security features.

FSSO installation requires an account with network admin privileges. The security inherent in these types of accounts helps ensure access to FSSO configurations is not tampered with.

User passwords are never sent between FSSO components. The information that is sent is information to identify a user including the username, group or groups, and IP address.

NTLM uses base-64 encoded packets, and uses a unique randomly generated challenge nonce to avoid sending user information and password between the client and the server. For more information on NTLM, see "NTLM authentication with FSSO" on page 1287.

FSSO Controller agent (CA)

The FSSO Controller agent (CA), or FSSO agent, is a service installed on a Windows computer that has access to both the FortiGate unit and each of the domain controller agents (DC agents).

The CA is responsible for DNS lookups, group verification, workstation checks, and as mentioned FortiGate updates of logon records. The FSSO Collector Agent sends Domain Local Security Group and Global Security Group information to FortiGate units. The CA communicates with the FortiGate over TCP port 8000 and it listens on UDP port 8002 for updates from the DC agents.

The FortiGate unit can have up to five CAs configured for redundancy. If the first on the list is unreachable, the next is attempted, and so on down the list until one is contacted. See "Configuring FSSO on FortiGate units" on page 1308.

All DC agents must point to the correct Collector agent port number and IP address on domains with multiple DCs.

See "Configuring Collector agent settings" on page 1296.

FSSO user logon event monitoring

A FSSO agent installed in a Windows AD environment monitors which users logon to which workstations and pass that information to the FortiGate unit. The FortiGate uses that information to apply its security policies.

When a Windows AD user logs on at a workstation in a monitored domain, FSSO

- detects the logon event and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- uses Active Directory to determine which groups the user belongs to,
- sends the user logon information, including IP address and groups list, to the FortiGate unit
- creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. The selection consist of matching the FSSO group or groups the user belongs to with the security policy or policies that match that group. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

With Windows AD, FSSO can use one of two different working modes to monitor user logon activity: DC Agent mode or Polling mode.

Table 82: FSSO DC Agent mode versus Polling mode

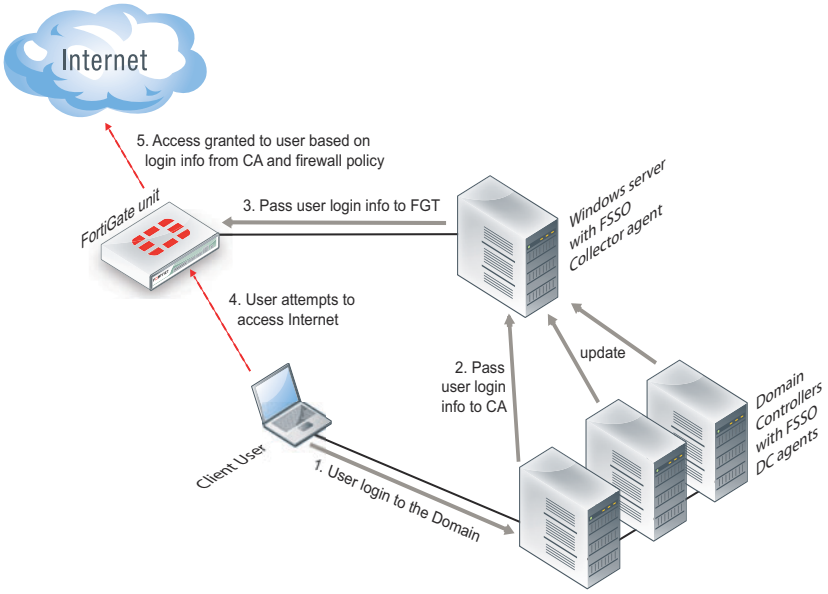
	DC Agent mode	Polling Mode
Installation	Complex — Multiple installations: one agent per DC plus Controller agent, requires a reboot	Easy — only Controller agent installation, no reboot required
Resources	Shares resources with DC system	Has own resources
Network load	Each DC agent requires minimum 64kpbs bandwidth, adding to network load	Increase polling period during busy period to reduce network load
Level of Confidence	Captures all logons	Potential to miss a login if polling period is too great

DC Agent mode

DC Agent mode is the standard mode for FSSO. In DC Agent mode (see Figure 107), a Fortinet authentication agent is installed on each domain controller. These DC agents monitor user logon events and pass the information to the Collector agent, which stores the information and sends it to the FortiGate unit.

The DC agent installed on the domain controllers is not a service like the Collector agent — it is a DLL file called `dcagent.dll` and is installed in the `Windows\system32` directory. It must be installed on all domain controllers of the domains that are being monitored.

Figure 107: FSSO in DC agent mode



DC Agent mode provides reliable user logon information, however you must install a DC agent on every domain controller. A reboot is needed after the agent is installed. Each installation requires some maintenance as well. For these reasons it may not be possible to use the DC Agent mode.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality. You can optionally configure traffic shapers on the FortiGate unit to ensure this minimum bandwidth is guaranteed for the domain controller connections.

Polling mode

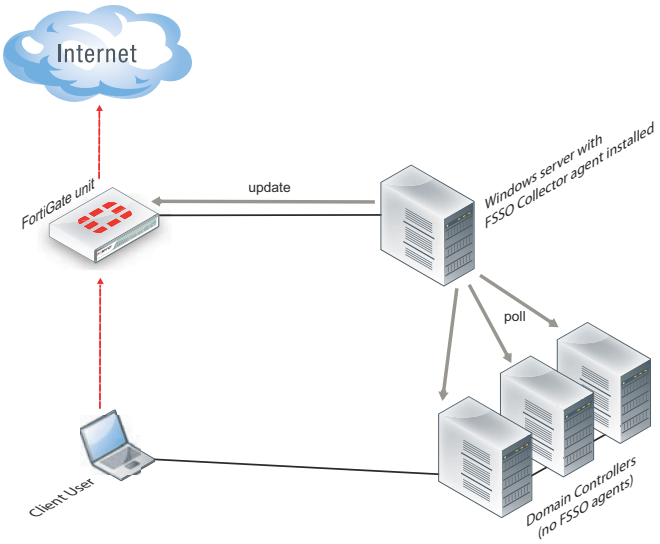
In Polling mode there are two options — NetAPI polling, and Event log polling. Both share the advantages of being transparent and agentless.

NetAPI polling is used to retrieve server logon sessions. This includes the logon event information for the Controller agent. NetAPI runs faster than Event log polling but it may miss some user logon events under heavy system load. It requires a query round trip time of less than 10 seconds.

Event log polling may run a bit slower, but will not miss events, even when the installation site has many users that require authentication. It does not have the 10 second limit or NetAPI polling. Event log polling requires fast network links. Event log polling is required if there are Mac OS users logging into Windows AD.

In Polling mode (see Figure 108), the Collector agent polls port 445 of each domain controller for user logon information every few seconds and forwards it to the FortiGate unit. There are no DC Agents installed, so the Collector agent polls the domain controllers directly.

Figure 108: FSSO in Polling mode



A major benefit of Polling mode is that no FSSO DC Agents are required. If it is not possible to install FSSO DC Agents on your domain controllers, this is the alternate configuration available to you. Polling mode results in a less complex install, and reduces ongoing maintenance. The minimum permissions required in Polling mode are to read the event log or call NetAPI. To install FSSO with minimum permissions, see "Installing FSSO without using an administrator account" on page 1293.

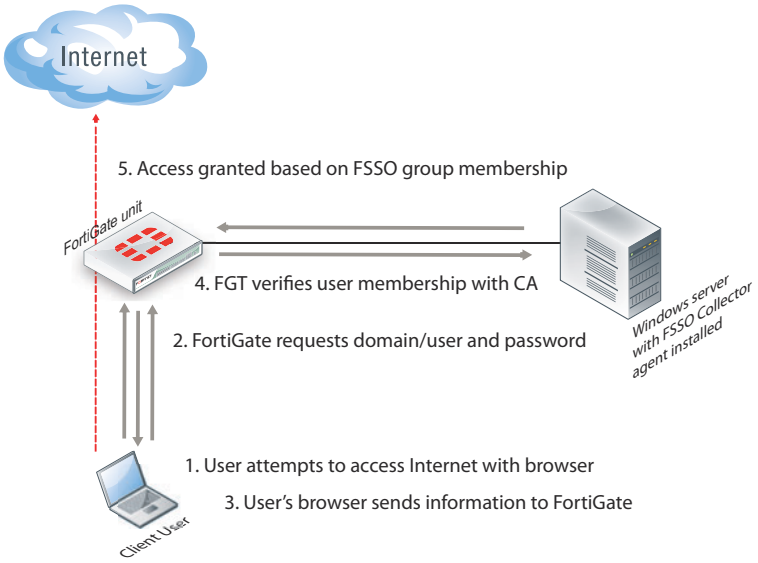
NTLM authentication with FSSO

In a Windows AD network, FSSO can also provide NTLM authentication service to the FortiGate unit. When the user makes a request that requires authentication, the FortiGate unit initiates NTLM negotiation with the client browser. The FortiGate unit does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service to process.

NTLM has the benefit of not requiring an FSSO agent, but it is not transparent to users, and the user's web browser must support NTLM.

The NTLM protocol protects the user's password by not sending it over the network. Instead, the server sends the client a random number that the client must encrypt with the hash value of the user's password. The server compares the result of the client's encryption with the result of its own encryption. The two will match only if both parties used the same password.

Figure 109: NTLM authentication



If the NTLM authentication with the Windows AD network is successful, and the user belongs to one of the groups permitted in the applicable security policy, the FortiGate unit allows the connection.

Fortinet has tested NTLM authentication with Internet Explorer and Firefox browsers.

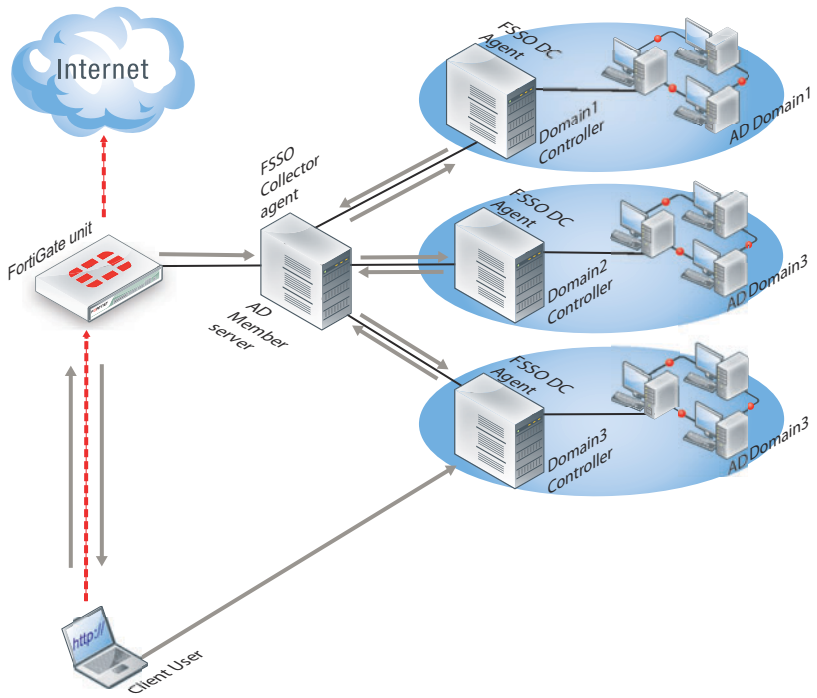
NTLM in a multiple domain environment

In a multiple domain environment for NTLM, the important factor is that there is a trust relation between the domains. In a forest, this relation is automatically created. So you can install FSSO agent on one of the domain controllers without worry.

But in case of multiple domains that are not in a forest, you need to create a trust relation between the domains. If you do not want to have a trust relation between your multiple domains, you need to use FSAE 4.0 MR1 and the DC agent needs to be installed once on each domain. Then you can use security policies to configure server access.

In Figure 110, three domains are shown connected to the FSSO Collector agent server. The Client logs on to their local Domain Controller, which then sends the user logon event information to the Collector Agent. When the Client attempts to access the Internet, the FortiGate unit contacts the Collector Agent for the logon information, sees the Client is authenticated, and allows access to the Internet. There are multiple domains each with a domain controller agent (DCagent) that sends logon information to the Collector agent. If the multiple domains have a trust relationship, only one DCagent is required instead of one per domain.

Figure 110: FSSO NTLM with multiple domains not in a forrest



Understanding the NTLM authentication process

1. The user attempts to connect to an external (internet) HTTP resource. The client application (browser) on the user's computer issues an unauthenticated request through the FortiGate unit.
2. The FortiGate is aware that this client has not authenticated previously, so responds with a `401 Unauthenticated` status code, and tells the client which authentication method to reply with in the header: `Proxy-Authenticated: NTLM`. Then the initial session is dismantled.
3. The client application connects again to the FortiGate, and issues a GET-request, with a `Proxy-Authorization: NTLM <negotiate string>` header. `<negotiate-string>` is a base64-encoded NTLM Type 1 negotiation packet.
4. The FortiGate unit replies with a `401 "proxy auth required"` status code, and a `Proxy-Authenticate: NTLM <challenge string>` (a base 64-encoded NTLM Type 2 challenge packet). In this packet is the challenge nonce, a random number chosen for this negotiation that is used once and prevents replay attacks.

The TCP connection must be kept alive, as all subsequent authentication-related information is tied to the TCP connection. If it is dropped, the authentication process must start again from the beginning.

5. The client sends a new GET-request with a header: `Proxy-Authenticate: NTLM <authenticate string>`, where `<authenticate string>` is a NTLM Type 3 Authentication packet that contains:
   - username and domain
   - the challenge nonce encoded with the client password (it may contain the challenge nonce twice using different algorithms).

6 If the negotiation is successful and the user belongs to one of the groups permitted in the security policy, the connection is allowed, Otherwise, the FortiGate unit denies the authentication by issuing a 401 return code and prompts for a username and password. Unless the TCP connection is broken, no further credentials are sent from the client to the proxy.

If the authentication policy reaches the authentication timeout period, a new NTLM handshake occurs.

Using FSSO in a Novell eDirectory environment

FSSO in a Novell eDirectory environment works similar to the FSSO Polling mode in the Windows AD environment. The eDirectory agent polls the eDirectory servers for user logon information and forwards it to the FortiGate unit.

When a user logs on at a workstation, FSSO:

- detects the logon event by polling the eDirectory server and records the IP address and user ID,
- looks up in the eDirectory which groups this user belongs to,
- sends the IP address and user groups information to the FortiGate unit.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

FSSO is supported on the Novell E-Directory 8.8 operating system

FSSO for Windows AD

This section explains what the FSSO components are for Windows AD, how to install them, and how to configure them.

- FSSO components for Windows AD
- Standard versus Advanced mode
- Installing FSSO for Windows AD
- Configuring Fortinet Single Sign On with Windows AD

FSSO components for Windows AD

FSSO has two components, or agents, to install on your network:

- the Collector agent must be installed on one or more network computers
- the Domain Controller (DC) agent must be installed on every domain controller if you will use DC Agent mode, but is not required if you use Polling mode.

FSSO is supported on Microsoft Windows Server 2003 (32- and 64-bit editions) and Microsoft Windows Server 2008 (32- and 64-bit editions) operating systems.

FSSO Installation

The FSSO installer first installs the Collector agent. You can then continue with installation of the DC agent, or you can install it later by going to *Start* > *Programs* > *Fortinet* > *Fortinet Server Authentication Extension* > *Install DC Agent*. The installer will install a DC agent on the domain controllers of all of the trusted domains in your network.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality.Traffic shapers configured on the FortiGate can help guarantee these minimum bandwidths.

You can create a redundant configuration if you install the Collector agent on two or more servers. This provides improved reliability. If the current Collector agent fails, the FortiGate unit will switch to the next Collector agent in its list. The list can have up to five Collector agents.

In Windows 2008 by default, you do not have administrative user rights if you are logged on as a user other than as the built-in administrator, even if you were added to the local Administrators group on the computer.

Ensure you have administrative rights on the servers where you are installing FSSO. Best practices dictate that you install FSSO using the built-in local administrator account. If you are logged on to another account and try to install FSSO, you may see a security alert dialog box requesting your permission to use or install the program.

Best practices dictate that before installing FSSO, you create a dedicated account with administrator privileges and a password that does not expire. Optionally, you can install FSSO without an admin account. See "Installing FSSO without using an administrator account" on page 1293.

Standard versus Advanced mode

Part of installing FSSO for Windows is choosing Standard or Advanced mode. The main difference between Standard and Advanced mode is the naming convention used when referring to username information.

Standard mode uses regular Windows convention: Domain\Username. Advanced mode uses LDAP convention: CN=User, OU=Name, DC=Domain.

If there is no special requirement to use LDAP— best practices dictate you setup FSSO in Standard mode. This mode is easier to setup, and is usually easier to maintain and troubleshoot.

Standard and advanced modes have the same level of functionality with the following exceptions:

1. Users have to create Group filters on the Collector agent. This differs from Advanced mode where Group filters are configured from the FortiGate unit. Fortinet strongly encourages users to create filters from CA.
2. Advanced mode supports nested or inherited groups. This means that users may be a member of multiple monitored groups. Standard mode does not support nested groups so a user must be a direct member of the group being monitored.

Installing FSSO for Windows AD

To install FSSO, you must obtain the FSSO Setup file from the Fortinet Support web site. Then you follow these two installation procedures on the server that will run the Collector agent. This can be any server or domain controller that is part of your network. These procedures also installs the DC Agent on all of the domain controllers in your network.

To install the Collector agent

1 Create an account with administrator privileges and a password that does not expire. See Microsoft Advanced Server documentation for help with this task.

To use a non-admin read only account, see "Installing FSSO without using an administrator account" on page 1293.

2 logon to the account that you created in Step 1.

3 Double-click the `FSSOSetup.exe` file.

The FSSO InstallShield Wizard starts.

4 Select *Next*. Optionally, you can change the installation location.

5 Select *Next*.

This procedure will install using the currently running account. If you want FSSO to use another existing admin account, change the *username:* field in the InstallShield Wizard to the correct username using the format DomainName \ UserName. For example if the account is `jsmith` and the domain is *example_corp* you would enter `example_corp\jsmith` in the *UserName:* field.

6 In the *Password* field, enter the password for the account listed in the *username* field. This is the account you are logged onto currently.

7 Select *Next*.

8 By default, FSSO authenticates users both by monitoring logons and by accepting authentication requests using the NTLM protocol.

If you want to support only NTLM authentication

- Clear the *Monitor user logon events and send the information to Fortinet* check box.
- Select the *Serve NTLM authentication requests coming from FortiGate* check box.

If you do not want to support NTLM authentication

- Clear the *Serve NTLM authentication requests coming from FortiGate* check box.
- Select the *Monitor user logon events and send the information to Fortinet* check box.

You can change these options after installation.

9 Select the access method to use for Windows Directory:

- Select *Standard* to use Windows domain and username credentials.
- Select *Advanced* if you will set up LDAP access to Windows Directory.

See "Standard versus Advanced mode" on page 1291.

10 Select *Next* and then select *Install*.

11 For DC Agent mode, when the FSSO InstallShield Wizard completes Collector agent installation, ensure that *Launch DC Agent Install Wizard* is selected and then select *Finish*.

If you see an error such as Service Fortinet Single Sign On agent (service_FSAE) failed to start, there are two possible reasons for this. Verify the user account you selected has sufficient privileges to run the FSSO service. Also verify the computer system you are attempting to install on is a supported operating system and version.

To install the DC Agent

1 If you have just installed the Collector agent, the FSSO - Install DC Agent wizard starts automatically. Otherwise, go to *Start* > *Programs* > *Fortinet* > *Fortinet Single Sign On* > *Install DC Agent*.

2 Verify the *Collector agent IP address*.

If the Collector agent computer has multiple network interfaces, ensure that the one that is listed is on your network. The listed *Collector agent listening port* is the default. Only change this if the port is already used by another service.

3 Select *Next*.

4 Select the domains to monitor and select *Next*.

If any of your required domains are not listed, cancel the wizard and set up the proper trusted relationship with the domain controller. Then run the wizard again by going to *Start* > *Programs* > *Fortinet* > *Fortinet Single Sign On* > *Install DC Agent*.

5 Optionally, select users that you do not want monitored. These users will not be able to authenticate to FortiGate units using FSSO. You can also do this later. See "Configuring Fortinet Single Sign On with Windows AD" on page 1295.

6 Select *Next*.

7 Optionally, clear the check boxes of domain controllers on which you do not want to install the DC Agent.

8 Select the *Working Mode* as DC Agent Mode. While you can select Polling Mode here, in that situation you would not be installing a DC Agent. For more information, see "DC Agent mode" on page 1285 and "Polling mode" on page 1286.

9 Select *Next*.

10 Select *Yes* when the wizard requests that you reboot the computer.

If you reinstall the FSSO software on this computer, your FSSO configuration is replaced with default settings.

If you want to create a redundant configuration, repeat the procedure "To install the Collector agent" on page 1292 on at least one other Windows AD server.

When you start to install a second Collector agent, cancel the Install Wizard dialog appears the second time. From the configuration GUI, the monitored domain controller list will show your domain controllers un-selected. Select the ones you wish to monitor with this Collector agent, and select *Apply*.

Before you can use FSSO, you need to configure it on both Windows AD and on the FortiGate units. The next section and "Configuring FSSO on FortiGate units" on page 1308 will help you accomplish these two tasks.

Installing FSSO without using an administrator account

Normally when installing services in Windows, it is best to use the Domain Admin account, as stated earlier. This ensures installation goes smoothly and uninterrupted, and when using the FSSO agent there will be no permissions issues. However, it is possible to install FSSO with a non-admin account in Windows 2003 or 2008 AD.

The following instructions for Windows 2003 are specific to the event log polling mode only. Do not use this procedure with other FSSO configurations.

Windows 2003

There are two methods in Windows 2003 AD for installing FSSO without an admin account — add the non-admin user to the security log list, and use a non-admin account with read-only permissions. A problem with the first method is that full rights (read, write, and clear) are provided to the event log. This can be a problem when audits require limited or no write access to logs. In those situations, the non-admin account with read-only permissions is the solution.

To add the non-admin user account to the Windows 2003 security log list

1. *Go to Default Domain Controller Security Settings > Security Settings > User Rights Assignment > Manage auditing and security log*.
2. Add the user account to this list.
3. Repeat these steps on every domain controller in Windows 2003 AD.
4. A reboot is required.

To use a non-admin account with read-only permissions to install FSSO on Windows 2003

The following procedure provides the user account specified with read only access to the Windows 2003 AD Domain Controller Security Event Log which allows FSSO to function.

1. Find out the SID of the account you intend to use.

   Tools for this can be downloaded for free from http://technet.microsoft.com/en-us/sysinternals/bb897417.
2. Then create the permission string. For example:

   `(A;;0x1;;;S-1-5-21-4136056096-764329382-1249792191-1107)`

   `A` means Allow,

   `0x1` means Read, and

   `S-1-5-21-4136056096-764329382-1249792191-1107` is the SID.
3. Then, append it to the registry key
4. `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Eventlog\Security\CustomSD`.
5. Repeat these steps on every domain controller in Windows 2003 AD.
6. A reboot is required.

Windows 2008

In Windows 2008 AD, if you do not want to use the Domain Admin account then the user account that starts the FSSO agent needs to be added to the Event Log Readers group.

When the user is added to the Event Log Readers group, that user is now allowed to have read only access to the event log and this is the minimal rights required for FSSO to work.

Updating FSSO with Windows AD

After FSSO is installed on your network, you may want to upgrade to a newer version. The following procedure helps ensure you have a trouble free upgrade. How you update FSSO depends on if you are using polling mode or DCAgent mode.

For polling mode, since there are no DC agents you only need to upgrade the Collector. However in DCAgent mode, each DC Agent must be updated as well.

To update FSSO in DCAgent mode

1 Go to the system32 directory on all DC's and rename the `dcagent.dll` file to `dcagent.dll.old`.

This ensures the when the upgrade is pushed to the DC it does not overwrite the old file. If there are any problems this makes it easy to revert to the old version.

2 Run the FSSO setup .exe file to update the collector. When this is completed, ignore any reboot message.

3 Go to *Programs* > *Fortinet* > *Fortinet Single Sign On* > *Install DC Agent* and push the DC agent out to all servers. All DC's will now need to be rebooted so that the new dll file is loaded.

4 After the reboot, go to all DC's and delete the `dcagent.dll.old` files.

Configuring Fortinet Single Sign On with Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate units.

To avoid this problem, you can configure the Fortinet Single Sign On Collector agent to send logon information only for groups named in the FortiGate unit's security policies. See "Configuring FortiGate group filters" on page 1301.

On each server with a Collector agent, you will be

- Configuring Windows AD server user groups
- Configuring Collector agent settings, including the domain controllers to be monitored
- Configuring Directory Access settings
- Configuring the Ignore User List
- Configuring FortiGate group filters for each FortiGate unit
- Configuring FSSO ports
- Configuring alternate user IP address tracking

In some environments where user IP addresses change frequently, it might be necessary to configure the alternate IP address tracking method. For more information, see "Configuring alternate user IP address tracking" on page 1303.

Configuring Windows AD server user groups

FortiGate units control network resource access at the group level. All members of a user group have the same network access as defined in FortiGate security policies.

You can use existing Windows AD user groups for authentication to FortiGate units if you intend that all members within each group have the same network access privileges.

Otherwise, you need to create new user groups for this purpose.

If you change a user's group membership, the change does not take effect until the user logs off and then logs on again.

The FSSO Agent sends only Domain Local Security Group and Global Security Group information to FortiGate units. You cannot use Distribution group types for FortiGate access. No information is sent for empty groups.

Refer to Microsoft documentation for information about creating and managing Windows AD user groups.

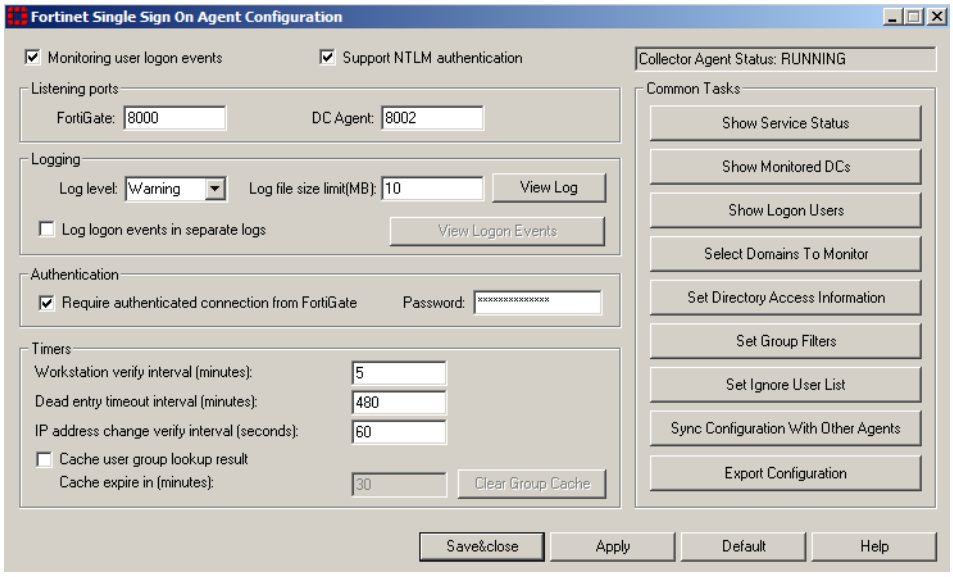
Configuring Collector agent settings

You need to configure which domain controllers the Collector agent will use and which domains to monitor for user logons. You can also alter default settings and settings you made during installation. These tasks are accomplished by configuring the FSSO Collector Agent, and selecting either Apply to enable the changes.

At any time to refresh the FSSO Agent settings, select Apply.

To configure the Collector agent

1 From the Start menu, select *Programs* > *FortiNet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.



2 Enter the following information and then select *Save&Close*.

Monitoring user logon events		Select to automatically authenticate users as they logon to the Windows domain.
Support NTLM authentication		Select to facilitate logon of users who are connected to a domain that does not have the FSSO DC Agent installed.
Collector Agent Status		Shows RUNNING when Collector agent is active.
Listening ports		You can change FSSO Collector Agent related port numbers if necessary.
	FortiGate	TCP port for FortiGate units. Default 8000.
	DC Agent	UDP port for DC Agents. Default 8002.
Logging		
	Log level	Select the minimum severity level of logged messages.
	Log file size limit (MB)	Enter the maximum size for the log file in MB.
	View Log	View all Fortinet Single Sign On agent logs.
	Log logon events in separate logs	Record user login-related information separately from other logs. The information in this log includes data received from DC agents user logon/logoff information workstation IP change information data sent to FortiGate units
	View Logon Events	If *Log logon events in separate logs* is enabled, you can view user login-related information.
Authentication		
	Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the Collector agent.
	Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 16 characters. The default password is “fortinetcanada”.

Timers		
	Workstation verify interval (minutes)	Enter the interval in minutes at which the Fortinet Single Sign On Collector agent connects to client computers to determine whether the user is still logged on. The default is every 5 minutes. The interval may be increased if your network has too much traffic. ***Note:*** This verification process creates security log entries on the client computer. If ports 139 or 445 cannot be opened on your network, set the interval to 0 to prevent checking. See "Configuring FSSO ports" on page 1302.
	Dead entry timeout interval	Enter the interval in minutes after which Fortinet Single Sign On Agent purges information for user logons that it cannot verify. The default is 480 minutes (8 hours). Dead entries usually occur because the computer is unreachable (such as in standby mode or disconnected) but the user has not logged off. A common reason for this is when users forget to logoff before leaving the office for the day. You can also prevent dead entry checking by setting the interval to 0.
	IP address change verify interval	Fortinet Single Sign On Agent periodically checks the IP addresses of logged-in users and updates the FortiGate unit when user IP addresses change. IP address verification prevents users from being locked out if they change IP addresses, as may happen with DHCP assigned addresses. Enter the verification interval in seconds. The default is 60 seconds. You can enter 0 to prevent IP address checking if you use static IP addresses. This does not apply to users authenticated through NTLM.
Cache user group lookup result		Enable caching. Caching can reduce group lookups and increase performance.
	Cache expire in (minutes)	Fortinet Single Sign On Agent caches group information for logged-in users. Enter the duration in minutes after which the cache entry expires. If you enter 0, the cache never expires. A long cache expire interval may result in more stale user group information. This can be an issue when a user's group information is changed.
	Clear Group Cache	Clear group information of logged-in users. This affects all logged-in users, and may force them to re-logon.

Common Tasks		
	Show Service Status	View information about the status of the Collector agent and connected FortiGate units. See "Viewing FSSO component status" on page 1303.
	Show Monitored DCs	Shows detailed information about connected Domain Controller agents. Use the *Select DC to Monitor* button to select domain controllers to monitor and choose *Working Mode*. See "Selecting Domain Controllers and working mode for monitoring" on page 1304.
	Show Logon Users	View a list of currently logged-in users. Select the column headers to sort the list.
	Select Domains to Monitor	Select this button to remove domains that you do not want to monitor. From the *Domain Filter* dialog box that displays, clear check boxes for unwanted domains and select *OK*.
	Set Directory Access Information	See "Configuring Directory Access settings" on page 1299.
	Set Group Filters	Configure group filtering for each FortiGate unit. See "Configuring FortiGate group filters" on page 1301.
	Set Ignore User List	Exclude users such as system accounts that do not authenticate to any FortiGate unit. See "Configuring the Ignore User List" on page 1300.
	Sync Configuration With Other Agents	Copy this Collector agent's Ignore User List and Group Filters to the other Collector agents to synchronize the configuration. You are asked to confirm synchronization for each Collector agent.
	Export Configuration	Export Fortinet Single Sign On Agent configuration to a text file. The file is named `saved_config.txt` and is saved in the Fortinet Single Sign On Agent program directory.
Save & Close		Save the modified settings and exit.
Apply		Apply changes now.
Default		Change all settings to the default values.
Help		View the online Help.

To view the version and build number information for your FSSO Collector Agent configuration, selecting the Fortinet icon in the upper left corner of the Collector agent Configuration screen and select *About Fortinet Single Sign On Agent configuration.*

Configuring Directory Access settings

The FSSO Collector Agent can access Windows Active Directory in one of two modes:

- Standard — the FSSO Collector Agent receives group information from the Collector agent in the *domain\user* format. This option is available on FortiOS 3.0 and later.

- Advanced — the FSSO Collector Agent obtains user group information using LDAP. The benefit of this method is that it is possible to nest groups within groups. This is option is available on FortiOS 3.0 MR6 and later. The group information is in standard LDAP format.

If you change AD access mode, you must reconfigure your group filters to ensure that the group information is in the correct format.

To configure Directory Access settings

1 From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.

2 In the *Common Tasks* section, select *Set Directory Access Information*.

The *Set Directory Access Information* dialog box opens.

3 From the *AD access mode* list, select either *Standard* or *Advanced*.

4 If you selected Advanced AD access mode, select *Advanced Setting* and configure the following settings and then select *OK*:

AD server address	Enter the address of your network's global catalog server.
AD server port	The default AD server port is 3268. This must match your server port.
BaseDN	Enter the Base distinguished name for the global catalog. This is the point in the tree that will be considered the starting point by default.
username	If the global catalog accepts your Fortinet Single Sign On Agent agent's credentials, you can leave these fields blank. Otherwise, enter credentials for an account that can access the global catalog.
Password	

BaseDN example

An example DN for Training Fortinet, Canada is `DN = ou=training, ou=canada, dc=fortinet, dc=com`. If you set the *BaseDN* to `ou=canada, dc=fortinet, dc=com` then when Fortinet Single Sign On Agent is looking up user credentials, it will only search the Canada organizational unit, instead of all the possible countries in the company. Its a short cut to entering less information and faster searches.

However, you may have problems if you narrow the BaseDN too much when you have international employees from the company visiting different offices. If someone from Fortinet Japan is visiting the Canada office in the example above, their account credentials will not be matched because they are in `DN = ou=japan, dc=fortinet, dc=com` instead of the BaseDN `ou=canada, dc=fortinet, dc=com`. The easy solution is to change the BaseDN to simply be `dc=fortinet, dc=com`. Then any search will check all the users in the company.

Configuring the Ignore User List

The Ignore User List excludes users that do not authenticate to any FortiGate unit, such as system accounts. The logons of these users are not reported to FortiGate units. This reduces the amount of required resources on the FortiGate unit especially when logging logon events to memory.

To configure the Ignore User List

1 From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.

2 In the *Common Tasks* section, select *Set Ignore User List*.

The current list of ignored users is displayed. To view ignored usernames, expand each domain.

3 Do any of the following:

- To remove a user from the list, select the check box beside the username and then select *Remove*. The user's login is no longer ignored.
- To add users to be ignored, select *Add*, select the check box beside each required username, and then select *Add*.

4 Select *OK*.

Configuring FortiGate group filters

FortiGate group filters actively control which user logon information is sent to each FortiGate unit. You need to configure the group filter list so that each FortiGate unit receives the correct user logon information for the user groups that are named in its security policies. These group filters help limit the traffic sent to the FortiGate unit, and help limit the logon events logged.

The maximum number of Windows AD user groups allowed on a FortiGate depends on the model. Low end models up to 300A support 256 Windows AD user groups, where mid and high end models support 1024 groups. This is per VDOM if VDOMs are enabled on the FortiGate unit.

You do not need to configure a group filter on the Collector agent if the FortiGate unit retrieves group information from Windows AD using LDAP. In that case, the Collector agent uses the list of groups you selected on the FortiGate unit as its group filter.

The filter list is initially empty. You need to configure filters for your FortiGate units using the Add function. At a minimum, create a default filter that applies to all FortiGate units without a defined filter.

If no filter is defined for a FortiGate unit and there is no default filter, the Collector agent sends all Windows AD group and user logon events to the FortiGate unit. While this normally is not a problem, limiting the amount of data sent to the FortiGate unit improves performance by reducing the amount of memory the unit uses to store the group list and resulting logs.

To configure a FortiGate group filter

1 From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.

2 In the *Common Tasks* section, select *Set Group Filters*.

The FortiGate Filter List opens. It has the following columns:

FortiGate SN	The serial number of the FortiGate unit to which this filter applies.
Description	An optional description of the role of this FortiGate unit.
Monitored Groups	The Windows AD user groups that are relevant to the security policies on this FortiGate unit.
Add	Create a new filter.

Edit	Modify the filter selected in the list.
Remove	Remove the filter selected in the list.
OK	Save the filter list and exit.
Cancel	Cancel changes and exit.

3 Select *Add* to create a new filter. If you want to modify an existing filter, select it in the list and then select *Edit*.

4 Enter the following information and then select *OK*.

Default filter	Select to create the default filter. The default filter applies to any FortiGate unit that does not have a specific filter defined in the list.
FortiGate Serial Number	Enter the serial number of the FortiGate unit to which this filter applies. This field is not available if Default is selected.
Description	Enter a description of this FortiGate unit's role in your network. For example, you could list the resources accessed through this unit. This field is not available if Default is selected.
Monitor the following groups	The Collector agent sends to the FortiGate unit the user logon information for the Windows AD user groups in this list. Edit this list using the Add, Advanced and Remove buttons.
Add	In the preceding single-line field, enter the Windows AD domain name and user group name, and then select Add. If you don't know the exact name, use the Advanced button instead. The format of the entry depends on the AD access mode (see "Configuring Directory Access settings" on page 1299): Standard: Domain\Group Advanced: cn=group, ou=corp, dc=domain
Advanced	Select *Advanced*, select the user groups from the list, and then select *Add*.
Remove	Remove the user groups selected in the monitor list.

Configuring FSSO ports

For FSSO to function properly a small number of TCP and UDP ports must be open through all firewalls on the network. There ports listed in this section assume the default FSSO ports are used.

TCP ports for FSSO agent with client computers

Windows AD records when users log on but not when they log off. For best performance, Fortinet Single Sign On Agent monitors when users log off. To do this, Fortinet Single Sign On Agent needs read-only access to each client computer's registry over TCP port 139 or 445. Open at least one of these ports — ensure it is not blocked by firewalls.

If it is not feasible or acceptable to open TCP port 139 or 445, you can turn off Fortinet Single Sign On Agent logoff detection. To do this, set the Collector agent workstation verify interval to 0. The FSSO Collector Agent assumes that the logged on computer remains logged on for the duration of the Collector agent dead entry timeout interval — by default this is eight hours.

Configuring ports on the Collector agent computer

On the computer where you install the Collector agent, you must make sure that the firewall does not block the listening ports for the FortiGate unit and the DC Agent. By default, these are TCP port 8000 and UDP port 8002. For more information about setting these ports, see "Configuring Collector agent settings" on page 1296.

Configuring alternate user IP address tracking

In environments where user IP addresses change frequently, you can configure Fortinet Single Sign On Agent to use an alternate method to track user IP address changes. Using this method, Fortinet Single Sign On Agent responds more quickly to user IP address changes because it directly queries workstation IP addresses to match users and IP addresses.

This feature requires FSAE version 3.5.27 or later, Fortinet Single Sign On Agent any version, and FortiOS 3.0 MR7 or later.

To configure alternate user IP address tracking

1. On the computer where the Collector agent is installed, go to *Start* > *Run*.
2. Enter `regedit` or `regedt32` and select *OK*.

   The Registry Editor opens.
3. Find the registry key HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\collectoragent.
4. Set the supportFSAEauth value (dword) to 00000001.
5. Close the Registry Editor.
6. From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.
7. Select *Apply*.

   The Fortinet Single Sign On Agent service restarts with the updated registry settings.

Viewing FSSO component status

It is important to know the status of both your Collector agents and DC agents.

Viewing Collector agent status

Use the *Show Service Status* to view your Collector agent information in the Status window. The Status window displays:

- the version of the software
- the status of the service
- the number of connected FortiGate units
- connected FortiGate information such as serial number, IP address, and time connected

To view Collector agent status

1. From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.
2. In the *Common Tasks* section, select *Show Service Status*.

The Fortinet Single Sign On Collector agent Status window opens.

Optionally select *Get NTLM statistics* in the Status window to display NTLM information such as number of messages received, processed, failed, in the queue.

Viewing DC agent status

Use the *Show Monitored DCs* to view the status of DC agents.

To view domain controller agent status

1 From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.

2 In the *Common Tasks* section, select *Show Monitored DCs*.

For each DC Agent, the following information is displayed:

- IP address
- number of logon events received
- the last logon event
- when last logon was received.

To change which DC agents are monitored or change the working mode for logon event monitoring, select *Select DC to Monitor*.

Selecting Domain Controllers and working mode for monitoring

You can change which DC agents are monitored or change the working mode for logon event monitoring between DC agent mode and polling mode.

When polling mode is selected, it will poll port 445 of the domain controller every few seconds to see who is logged on.

1 From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.

2 In the *Common Tasks* section, select *Show Service Status*.

3 Select *Select DC to Monitor.*

Working Mode	
	DC Agent mode — a Domain Controller agent monitors user logon events and passes the information to the Collector agent. This provides reliable user logon information, however you must install a DC agent on every domain controller in the domain.
	Polling mode — the Collector agent polls each domain controller for user logon information. Under heavy system load this might provide information less reliably. However installing a DC agent on each domain controller is not required in this mode.

FSSO for Novell eDirectory

The components you need to install depend on whether you are installing FSSO on Windows AD or Novell eDirectory. FSSO supports the Novell E-Directory 8.8 operating system.
This section includes:

- FSSO components for Novell eDirectory
- Installing FSSO for Novell

FSSO components for Novell eDirectory

For a Novell network, there is only one FSSO component to install — the eDirectory agent. In some cases, you also need to install the Novell Client.

Installing FSSO for Novell

To install FSSO, you must obtain the FSAE_Setup_eDirectory file from the Fortinet Support web site. Perform the following installation procedure on the computer that will run the eDirectory agent. This can be any server or domain controller that is part of your network.

This section includes:

- Configuring the eDirectory agent
- Adding an eDirectory server
- Configuring a group filter

To install the FSSO eDirectory agent

1. Create an account with administrator privileges and a password that does not expire. See Novell documentation for more information.
2. logon to the account that you created in Step 1.
3. Double-click the FSSO_Setup_edirectory.exe file.

   The Fortinet eDirectory Agent InstallShield Wizard starts.
4. Optionally, fill in the *username* and *Organization* fields.
5. Select the *Anyone who uses this computer (all users)* option.
6. Select *Next*.
7. Optionally, enter any of the following information:

eDirectory Server		
	Server Address	Enter the IP address of the eDirectory server.
	Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
	Search Base DN	Enter the base Distinguished Name for the user search.
eDirectory Authentication		
	username	Enter a username that has access to the eDirectory, using LDAP format.
	User password	Enter the password.

8. Select *Next*.
9. Select *Install*.

Configuring Fortinet Single Sign On with Novell networks

You need to configure the eDirectory agent for it to communicate with eDirectory servers. You may have provided some of this information during installation.

This section includes:

- Configuring the eDirectory agent

- Adding an eDirectory server
- Configuring a group filter

Configuring the eDirectory agent

You need to configure the eDirectory agent for it to communicate with eDirectory servers.

To configure the eDirectory agent

1 From the Start menu select *Programs* > *Fortinet* > *eDirectory Agent* > *eDirectory Config Utility*.

2 The eDirectory Agent Configuration Utility dialog opens.Enter the following information and select *OK*.

eDirectory Authentication	
username	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.
Listening port	Enter the TCP port on which Fortinet Single Sign On Agent listens for connections from FortiGate units. The default is 8000. You can change the port if necessary.
Refresh interval	Enter the interval in seconds between polls of the eDirectory server to check for new logons. The default is 30 seconds.
FortiGate Connection Authentication	
Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the eDirectory Agent.
Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 16 characters. The default password is “FortinetCanada”.
User logon info search method	Select how the eDirectory agent accesses user logon information: *LDAP* or *Native* (Novell API). LDAP is the default. If you select *Native*, you must also have the Novell Client installed on the PC.
Logging	
Log level	Select *Debug, Info*, *Warning* or *Error* as the minimum severity level of message to log or select *None* to disable logging.
Log file size limit (MB)	Enter the maximum size for the log file in MB.
View Log	View the current log file.
Dump Session	List the currently logged-on users in the log file. This can be useful for troubleshooting.

eDirectory server list		If you specified an eDirectory server during installation, it appears in this list.
	Add	Add an eDirectory server. See .
	Delete	Delete the selected eDirectory server.
	Edit	Modify the settings for the selected server.
	Group Filter	Select the user groups whose user logons will be reported to the FortiGate unit. This is used only if user groups are not selected on the FortiGate unit.

Adding an eDirectory server

Once the eDirectory agent is configured, you add one or more eDirectory servers.

To add an eDirectory server

1 In the eDirectory Agent Configuration Utility dialog box (see the preceding procedure, "Configuring the eDirectory agent"), select *Add*.

2 The eDirectory Setup dialog box opens.Enter the following information and select OK:

eDirectory Server Address		Enter the IP address of the eDirectory server.
Port		If the eDirectory server does not use the default port 389, clear the Default check box and enter port number.
Use default credential		Select to use the credentials specified in the eDirectory Configuration Utility. See . Otherwise, leave the check box clear and enter a username and Password below.
	username	Enter a username that has access to the eDirectory, using LDAP format.
	User password	Enter the password.
Use secure connection (SSL)		Select to connect to the eDirectory server using SSL security.
Search Base DN		Enter the base Distinguished Name for the user search.

Configuring a group filter

The eDirectory agent sends user logon information to the FortiGate unit for all user groups unless you either configure an LDAP server entry for the eDirectory on the FortiGate unit and select the groups that you want to monitor configure the group filter on the eDirectory agent.

If both the FortiGate LDAP configuration and the eDirectory agent group filter are present, the FortiGate user group selections are used.

To configure the group filter

1 From the Start menu select *Programs* > *Fortinet* > *eDirectory Agent* > *eDirectory Config Utility*.

2 Select *Group Filter*.

3 Do one of the following:
   - Enter group names, then select *Add*.
   - Select *Advanced*, select groups, and then select *Add*.
4 Select *OK*.

Configuring FSSO on FortiGate units

To configure your FortiGate unit to operate with either a Windows AD or a Novell eDirectory FSSO install, you

- Configure LDAP access to the Novell eDirectory or Windows AD global catalog. Skip this step if you are using FSSO Standard mode. See “Configuring LDAP server access” on page 1308.
- Specify the Collector agent or Novell eDirectory agent that will provide user logon information. See “Specifying your Collector agents or Novell eDirectory agents” on page 1310.
- Add Active Directory user groups to FortiGate user groups. See “Selecting Windows user groups (LDAP only)” on page 1311.
- Create security policies for FSSO-authenticated groups. See “Creating Fortinet Single Sign-On (FSSO) user groups” on page 1312 and “Creating security policies” on page 1312.
- Optionally, specify a guest protection profile to allow guest access. See “Enabling guest access through FSSO security policies” on page 1315.

Configuring LDAP server access

LDAP access is required if your network has a Novell eDirectory agent or a Collector agent using Windows Advanced AD access mode. If you are using FSSO Standard mode, go to “Specifying your Collector agents or Novell eDirectory agents” on page 1310.

The LDAP configuration on the FortiGate unit not only provides access to the LDAP server, it sets up the retrieval of Windows AD user groups for you to select in FSSO. The LDAP Server configuration (in *User* > *Remote* > *LDAP*) includes a function to preview the LDAP server’s response to your distinguished name query. If you already know the appropriate Distinguished Name (DN) and User DN settings, you may be able to skip some of the following steps.

1 Go to *User* > *Remote* > *LDAP* and select *Create New*.
2 Select the *Query distinguished name* button to the right of the *Distinguished Name* field.

   A new window opens.
3 If more than one name is listed, you might need to explore each name following the steps below to determine which one is relevant to your needs.
4 Copy the name string to the *Distinguished Name* field and select *OK*.

   This closes the window and copies the name string to the *Distinguished Name* field of the LDAP Server configuration.
5 Set *Bind Type* to *Regular.*
6 In the *User DN* field, enter the administrative account name that you created for FSSO.

   For example, if the account is FSSO_Admin, enter “cn=FSSO_Admin,cn=users”.

7 Make sure that the *User DN* entry ends with a comma and append the string from the *Distinguished Name* field to the end of it.

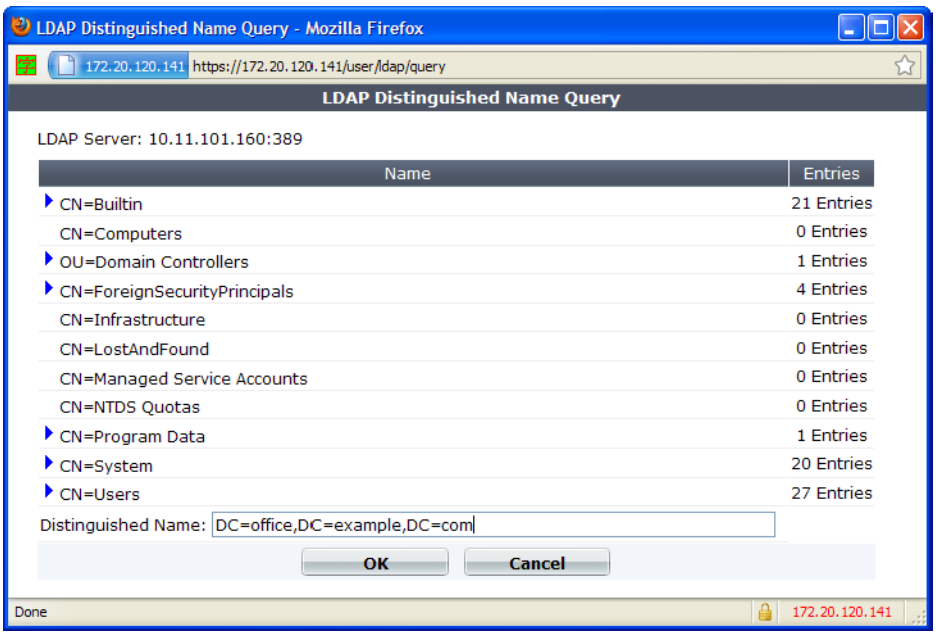
Example: cn=FSSO_Admin,cn=users,dc=office,dc=example,dc=com

8 Enter the administrative account password in the *Password* field.

9 Select the *Query distinguished name* button again.

The LDAP Distinguished Name Query window opens:

Figure 111: Authenticated DN query



You can expand any of the DNs that contain entries. When you select an expandable DN, the *Distinguished Name* field is updated. Look for the DN that contains the users or groups whose logon you want to monitor.

10 Select the DN that you want to monitor and then select *OK*.

This closes the window and updates the *Distinguished Name* field of the LDAP Server configuration with the selected Domain Name Identifier (DNI).

11 Check the following fields and select OK:

Name	Enter a name to identify the LDAP server.
Common Name Identifier	The default common name identifier is `cn`. This is correct for most LDAP servers. However some servers use other identifiers such as `uid`.
Secure Connection	Do not select. The Collector agent does not support secure connection.

To configure LDAP for FSSO - CLI example

```
config user ldap
  edit "ADserver"
    set server "10.11.101.160"
    set cnid "cn"
    set dn "cn=users,dc=office,dc=example,dc=com"
```

```
    set type regular
    set username
       "cn=administrator,cn=users,dc=office,dc=example,dc=com"
    set password set_a_secure_password
  next
end
```

Specifying your Collector agents or Novell eDirectory agents

You need to configure the FortiGate unit to access at least one Collector agent or Novell eDirectory agent. You can specify up to five servers on which you have installed a Collector or eDirectory agent. The FortiGate unit accesses these servers in the order that they appear in the list. If a server becomes unavailable, the next one in the list is tried.

To specify Collector agents - web-based manager

1 Go to *User* > *FSSO* > *FSSO Agent* and select *Create New*.

2 Enter a Name for the Windows AD server. This name appears in the list of Windows AD servers when you create user groups.

3 Enter the following information for each of up to five collector agents and select *OK*:

	FSSO Agent IP/Name	Enter the IP address or the name of the server where this agent is installed. Maximum name length is 63 characters.
	Port	Enter the TCP port used for FSSO. You must enter the port number for the server. This must be the same as the FortiGate listening port specified in the Novell eDirectory or Collector agent configuration. TCP port 8000 is used by default. See “Configuring Collector agent settings” on page 1296 .
	Password	Enter the password for the Collector agent or eDirectory agent. For the Collector agent, this is required only if you configured the agent to require authenticated access.
LDAP Server		For Novell eDirectory, enable. For Windows AD, enable if the Collector agent is configured to use Advanced AD access mode. Select the LDAP server you configured previously. See “Configuring LDAP server access” on page 1308.

To specify the FSSO Collector agent - CLI

```
config user fsso
  edit WinGroups
  set ldap-server ADserver
  set password ENC
     G7GQV7NEqilCM9jKmVmJJFVvhQ2+wtNEe9T0iYA5Sa+EqT2J8zhOrbkJFD
     r0RmY3c4LaoXdsoBczA1dONmcGfthTxxwGsigzGpbJdC71spFlQYtj
  set server 10.11.101.160
  set port 8000
end
```

Selecting Windows user groups (LDAP only)

If the Collector agent uses Advanced AD access mode, the FortiGate unit obtains user group information using LDAP. You need to select the Windows user groups that you want to monitor. These user group names are then available to add to FSSO user groups.

To select Windows user groups - web-based manager

1 Go to *User* > *FSSO* > *FSSO Agent*.

The list of FSSO agent servers is displayed.

2 Select the *Edit Users/Groups* icon.

The FortiGate unit performs an LDAP query and displays the result.

3 Select the check boxes of the user groups that you want to monitor and then select *OK*.

You can also use the Add User/Group icon to select a group by entering its distinguished name.

Viewing information imported from the Windows AD server

You can view the domain and group information that the FortiGate unit receives from the AD Server. Go to *User* > *FSSO* > *FSSO Agent*. The display differs for Standard and Advanced AD access mode.

Figure 112: List of groups from Active Directory server (Standard AD access mode)

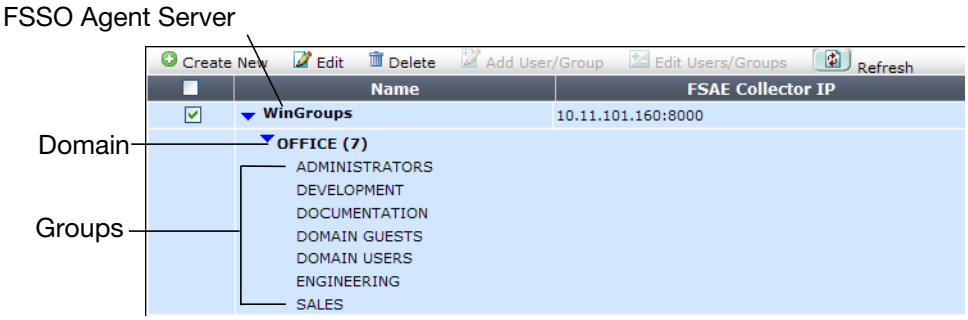


Figure 113: List of monitored groups (Advanced AD access mode)

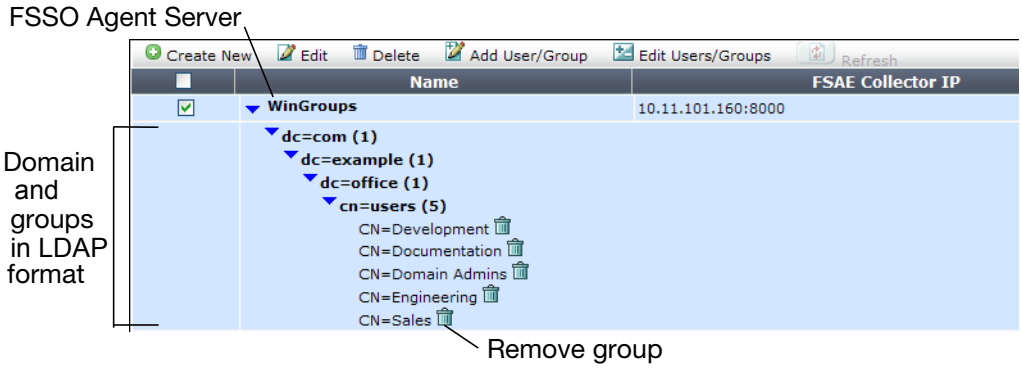

Create New		Add a new FSSO agent server.
Name		
	Server	The name defined for the FSSO agent server.

	Domain	Domain name imported from the FSSO agent server.
	Groups	The group names imported from the FSSO agent server.
FSSO Collector IP		The IP address of the FSSO agent on the server
Delete icon		Delete this server definition.
Edit icon		Edit this server definition.
Refresh icon		Get user group information from the FSSO agent server.
Add User/Group		Add a user or group to the list. You must know the distinguished name for the user or group. This is available for Windows AD in Advanced AD access mode only.
Edit Users/Groups		Select users and groups to add to the list. See "Selecting Windows user groups (LDAP only)" on page 1311. This is available in Advanced AD access mode only.

Creating Fortinet Single Sign-On (FSSO) user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

To create a user group for FSSO authentication - web-based manager

1 Go to *User* > *User Group*.
2 Select *Create New*.
The New User Group dialog box opens.
3 In the *Name* box, enter a name for the group, FSSO_Internet_users for example.
4 In *Type*, select *Fortinet Single Sign-On (FSSO)*.
5 From the *Available Members* list, select the required *FSSO* groups.
Using the CTRL or SHIFT keys, you can select multiple groups.
6 Select the green right arrow button to move the selected groups to the *Members* list.
7 Select *OK*.

To create the FSSO_Internet-users user group - CLI

```
config user group
  edit FSSO_Internet_users
    set group-type fsso-service
    set member
       CN=Engineering,cn=users,dc=office,dc=example,dc=com
       CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

To configure an FSSO authentication security policy - web-based manager

1 Go to *Policy* > *Policy.*

2 Select *Create New*.

3 Enter the following information.

Source Interface/Zone	port1
Source Address	company_network
Destination Interface/Zone	port2
Destination Address	all
Action	ACCEPT
Enable NAT	enabled

4 Select *Enable identity-based Policy*.

5 Select *Add* to add groups of users to this authentication policy.

6 Select the `fsso_group`, and the `FSSO_Guest_users` usergroups in the *Available User Groups* list and move them to the *Selected User Groups* list.

`FSSO_Guest_users` is a default user group enabled when FSSO is configured. It allows guest users on the network who do not have FSSO account to still authenticate and have access to network resources. See "Enabling guest access through FSSO security policies" on page 1315.

7 Select HTTP, HTTPS, FTP, and Telnet for in the *Available Services* list, and move them to the Selected Services list.

8 Select always for the *Schedule*.

9 Enable *Log Allowed Traffic*.

Logging FSSO logon events helps troubleshoot any FSSO related issues.

10 Select UTM, and enable default AntiVirus, IPS, Web Filter, an Email filter.

11 Select OK.

A new line of information will appear in the identity-based policy table. The table lists the ID, user group or groups, the service or services, schedule, UTM, and logging selected for the rule. Use this display to verify your information was entered correctly.

12 Select *Fortinet Single Sign-On (FSSO)*.

13 Optionally select *Customize Authentication messages* to change the default authentication messages to suit example.com's company design and policies.

14 Select OK.

15 Ensure the FSSO authentication policy is at the top of the list so it will be attempted to be matched before any other policy.

To create a security policy for FSSO authentication - CLI

```
config firewall policy
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr company_network
    set dstaddr all
    set action accept
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule any
        set groups company_network FSSO_guest_users
        set service HTTP HTTPS FTP TELNET
      end
  end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

Users belonging to multiple groups

Before FSSO 4.0 MR3, if a user belonged to multiple user groups, the first security policy to match any group that user belonged too was the only security policy applied. If that specific group did not have access to this protocol or resource where another group did, the user was still denied access. For example, `test_user` belongs to `group1` and `group2`. There are two FSSO authentication policies — one matches `group1` to authenticate FTP traffic and one matches `group2` to authenticate email traffic. The `group1` policy is at the top of the list of policies. If `test_user` wants to access an email server, the first policy encountered for a group `test_user` belongs to is the `group1` policy which does not allow email access and `test_user` is denied access. This is despite the next policy allowing access to email. If the order was reversed in this case, the traffic would be matched and the user's traffic would be allowed through the firewall. However if the policy order was reversed, FTP traffic would not be matched.

As of FSSO 4.0 MR3, if a user belongs to multiple groups multiple then attempts to match the group are attempted if applicable. Using the above example, when the attempt to match the `group1` policy is made and fails, the next policy with a group that `test_user` is a member of is attempted. In this case, the next policy is matched and access is granted to the email server.

When configuring this example the only difference between the policies is the services that are listed and the FSSO user group name.

Authenticating through multiple groups allows administrators to assign groups for specific services, and users who are members of each group have access to those services. For example there could be an FTP group, an email group, and a Telnet group.

Resolve usernames Using FSSO Agent

When configuring a security policy, there is an option to enable the feature *Resolve usernames Using FSSO Agent* without configuring an identity-based policy.

If an FSSO server and user group are configured, but no identity-based policy is enabled then logon events do not generate a log entry — essentially the logon event goes unnoticed by the FortiGate unit.

If this option is enabled then when there is no identity-based policy configured, the logon event will still be logged on the traffic log along with the username. The username will be resolved from the FSSO information.

Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to the Windows AD or Novell network and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `FSSO_Guest_Users`. Specify the services, schedule and protection profile that apply to guest users — typically guests receive reduced access to a reduced set of services. See "Creating security policies" on page 1312.

FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see "Enabling security logging" on page 1252. For more information on logging, see the *FortiOS Handbook Log and Reporting chapter*.

This section includes:

Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events need, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged. While this extra information is useful, you must

To enable event logging

1 Go to *Log&Report* > *Log Config* > *Log Setting*.

2 In the *Event Log Settings* section, select the check box beside *Enable*.

3 You must select the following events:

System activity event	All system-related events, such as ping server failure and gateway status.
Admin event	All administration events, such as user logins, resets, and configuration updates.
Firewall authentication event	All firewall-related events, such as user authentication.
CPU & memory usage (every 5 min)	Real-time CPU and memory events only, at 5-minute intervals.

Optionally you can enable any or all of the other logging event options.

4 Select *Apply*.

5 Select *OK*.

Viewing FSSO log messages

If you have configured logging to a FortiAnalyzer unit, FortiGate unit's local disk or system memory, you can view log messages from either the web-based manager or CLI. The following procedures explain how to view log messages from the Log Access menu in the web-based manager, and how to view log messages from within the CLI.

Figure 114 on page 1317 shows the event log filtered for authentication log entries, and the display columns customized.

Table 83 on page 1317 lists the log message IDs and descriptions for FSSO related log messages. Use this table to help identify FSSO log messages on the FortiGate unit. Note that for the log messages to be displayed, the Minimum Log Level must be set to the Severity or lower for the log entry to be logged.

When viewing log messages in the Raw format in *Memory*, the ten-digit log ID number is used; however, when viewing the same log messages, in Raw format, in *Disk*, the five-digit log ID number is used (except for traffic logs which have only one-digit log IDs). This five-digit log identification number is used because of log size reduction that occurred in FortiOS 4.0 MR1.

To view log messages - web-based manager

1 Go to *Log&Report* > *Log & Archive Access*.

2 Select the log menu that you want to view log messages in.

For example, the attack log messages in *Log&Report* > *Log & Archive Access* > *Traffic Log*.

3 Within the page, use any one of the following to view each log message:

- *Download Raw Log* – downloads the log file to your PC. *Column Settings* – customize what columns display on the page.
- *Filter Settings* – filter the information within the page.
- *Detailed Information* – display the log table on the right side of the page, at the bottom (default), or hide the log table.

For more on viewing logs, see the *FortiOS Handbook Log and Reporting chapter*.

4 To display current log messages on the page, select *Refresh*.

To view log messages - CLI

1 Enter the following to configure how the log messages will be displayed, as well as what log messages you want to display:

```
execute log filter category <category_number>
execute log filter start-line <line_number>
execute log filter view-lines <lines_per_view>
```

2 Enter the following to display the logs messages within the CLI:

```
execute log display
```

3 Log messages appear and stop when the maximum number of view-lines is reached.

Figure 114: Authentication log messages

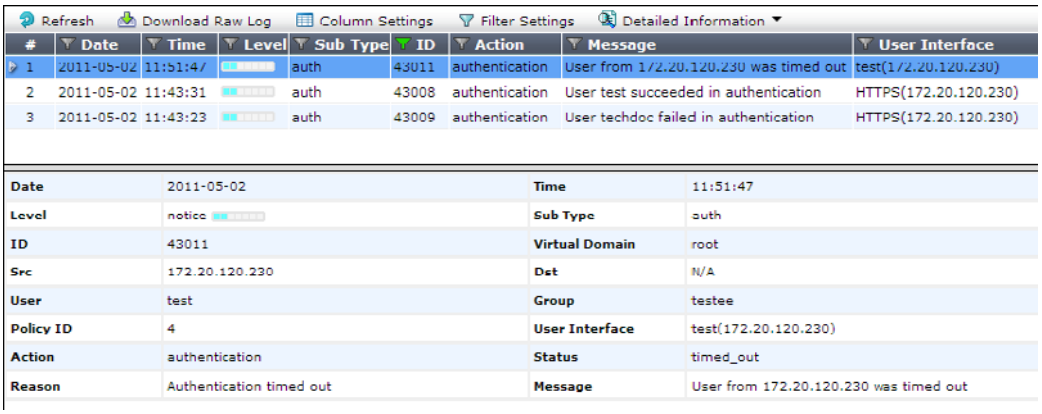

Table 83: List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the *FortiOS Handbook Log and Reporting chapter*.

Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see "Troubleshooting FSSO" on page 1318.

1 Logon to one of the stations on the FSSO domain, and access an Internet resource.

2 Connect to the CLI of the FortiGate unit, and if possible log the output.

3 Enter the following command:

```
diagnose debug authd fsso list
```

4 Check the output. If FSSO is functioning properly you will see something similar to the following:

```
----FSSO logons----
IP: 192.168.1.230  User: ADMINISTRATOR  Groups: VLAD-AD/DOMAIN
   USERS
IP: 192.168.1.240  User: ADMINISTRATOR  Groups: VLAD-AD/DOMAIN
   USERS
Total number of users logged on: 2
----end of FSSO logons----
```

The exact information will vary based on your installation.

5 Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field. For a list of FSSO log message IDs, see Table 83 on page 1317.

6 To check server connectivity, run the following commands from the CLI:

```
FGT# diagnose debug enable
FGT# diagnose debug authd fsso server-status
FGT# Server Name           Connection Status
     -----------           -----------------
     SBS-2003              connected
```

Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- General troubleshooting tips for FSSO
- User status “Not Verified” on the Collector agent
- After initial configuration, there is no connection to the Collector agent
- FortiGate performance is slow on a large network with many users
- Users from the Windows AD network are not able to access the network
- Users on a particular computer (IP address) can not access the network
- Guest users do not have access to network
- Can’t find the DCagent service
- User logon events not received by FSSO Collector agent
- User list from Windows AD is empty
- Mac OS X users can’t access external resources after waking from sleep mode

General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- To help locate the problem, configure a sniffer policy to capture FSSO logon messages along with other information.

  If FSSO is in use the log messages captured by a sniffer policy will include a user name if the IP address in the log message corresponds to the IP address if a user who has been authenticated with FSSO.

- Ensure all firewalls are allowing the FSSO required ports through.

  FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP) 8000, and 8002.

- Ensure the Collector agent has at least 64kbps bandwidth to the FortiGate unit.

  If not the Collector agent does not have this amount of bandwidth, information FSSO information may not reach the FortiGate unit resulting in outages. The best solution is to configure traffic shaping between the FortiGate unit and the Collector agent to ensure that minimum bandwidth is always available.

User status “Not Verified” on the Collector agent

When selecting “Show logon Users” in the Collector agent, some users may have their status set as “Not Verified”.

The Collector agent receives logon events for users from the DC agents, but Windows does not generate log out events. As such, the Collector agent needs to verify that the user is still logged on by checking the registry on that host.

If the Collector agent cannot connect to the host on ports 139 and 445 to perform this check, the host status is set to “Not Verified” and a log entry will be added to the Collector agent logs:

```
"01/01/2010 01:23:45 [ 1884] name_ip_match: failed to connect to
   workstation: <Workstation Name> (192.168.1.1)"
```

Solution

There are a few things that can cause the Collector agent not to be able to connect to the user's work station. Below is a list of the most common causes:

- Most commonly, a host firewall on the user's workstation or a router on the network prevents remote access on ports 139 and/or 445. Try opening the ports on the host firewall.
- If the remote registry service is not running on the user's workstation, the Collector agent will not be able to connect to the registry remotely. Make sure the remote registry service is running.
- This problem may also be caused by a known MS upgrade issue.

  Using `Regedit.exe`, edit “`HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurePipeServers`”, set permissions for winreg and allow Local Service with R and W permissions.

After initial configuration, there is no connection to the Collector agent

The Collector Agent has been configured but now cannot be contacted. This may be a regular connectivity problem. The section *Troubleshooting Connectivity* in the *FortiOS Handbook Troubleshooting chapter* will help locate and identify any network problems. Other solutions specific to FSSO are listed here.

Solution

If there are no network problems that can be identified, try the following solutions.

- The Windows AD network must be configured before configuring the FortiGate unit. This includes the domain controller agents, and Collector agents.
- Ensure the DC agents point to the correct collector agent port and IP address.

- Ensure that TCP port 8000, and UDP port 8002 are not blocked.
- FSSO is very dependent on DNS, ensure the forward DNS zone has no stale records and after adding it to the domain if the DNS entry is not in the zone add it.
- An error in the DNI field on the FortiGate unit will prevent connections. Select the browse button next to the field to confirm it can connect correctly to the Windows AD server and return information. See
- If the secure check box is selected, ensure that LDAP v3 is being used since earlier LDAP does not support secure TLS connections.
- Ensure that the default LDAP ports are not being blocked on the network. These ports include port 389, and port 636. If you change the default ports, ensure both the FortiGate unit and the Windows AD server are using the same port numbers and that those ports are allowed through all firewalls on your network.
- If you are using FSSO in polling mode, ensure that port 445 is not blocked by firewalls.

Collector Agent service freezing and shutting down

FSSO problem.

Solution

-

FortiGate performance is slow on a large network with many users

FSSO sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate units. Logon tracking is logged to memory, and may reduce performance in extreme situations.

To avoid this problem, you can configure the Collector agent to send logon information only for groups named in the FortiGate unit's security policies. Also you can configure the Ignore User list on the FortiGate unit to avoid tracking unnecessary logons.

Also logging to memory can consume large amounts of FortiGate system memory. To lessen the memory used, change the logging from the default level of Information to a less frequent level such as Error or Warning. This results in less information being logged and frees system memory to improve overall FortiGate system performance. However, if you are trying to troubleshoot a problem one of the first things to do is to change the logging severity to Information or possibly even Debug to provide you with additional information while solving your problem.

Solution

Add users to the Ignore User list. This a best practice for admin accounts whose logon information will not be sent to the FortiGate unit. This is useful for automated accounts that may logon many times. Examples of accounts in this category include:

- IIS services
- AV
- other system accounts

For more information on configuring the Ignore users list, see "Configuring the Ignore User List" on page 1300.

Users from the Windows AD network are not able to access the network

If nobody can access the network and your network has only one Collector agent, when it goes offline no users will have access. However if only some users can not access the network, it is likely that user group changes were made recently that are causing the problems.

Solutions

- If there is only one Collector agent, configure additional Collector agents in the domain to act as backups. They will provide the redundancy required if the original collector goes offline. Remember to add them to the FortiGate FSSO entry under *User* > *FSSO* > *FSSO Agent* on the web-based manager or `config user fsso` in the CLI. If the server and port for the new agent are not in the list, it will not be contacted.
- Ensure the Collector agent has at least 64kbps bandwidth to the FortiGate unit. If not, information FSSO information may not reach the FortiGate unit resulting in outages. The best solution is to configure traffic shaping between the FortiGate unit and the Collector agent to ensure that minimum bandwidth is always available.
- If some users can not connect, verify their Windows AD records to find groups in common, and investigate the state of those groups focusing on any recent changes. It may be a group or permission change is the reason.
- There may be a a problem with the user list. See "User list from Windows AD is empty" on page 1322.

Users on a particular computer (IP address) can not access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer_1 is actually trying to access computer_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediate logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

Guest users do not have access to network

A group of guest users was created, but they don't have access.

Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called `FSSO_Guest_Users`. Ensure that group is part of an identity-based security policy to allow traffic.

Can’t find the DCagent service

The DCagent service can’t be found in the list of regular windows services. This is because it has no associated Windows service.

Instead DCagent is really `dcagent.dll` and is located in the `Windows\system32` folder. This DLL file is loaded when windows boots up and it intercepts all logon events processed by the domain controller to send these events to the Collector agent (CA).

Solution

To verify that the DCagent is installed properly

1. Check that DCagent.dll exists in `%windir%\system32` folder.
2. Check that the registry key exists:
   `[HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\dcagent]`

If both exist, the DCagent is properly installed.

User logon events not received by FSSO Collector agent

When a a warning dialog is present on the screen on the Collector agent computer, the Collector agent will not receive any logon events. Once the dialog has been closed normal operation will resume.

If polling mode is enabled, it is possible the polling interval is too large. Use a shorter polling interval to ensure the collector agent is capturing all logon events.

If NetAPI polling mode is enabled, consider switching to Event log polling as it provides letter accuracy.

User list from Windows AD is empty

FSSO server is configured. I have received a list of windows AD groups. However, a user list is empty.

Solution

There could be 2 problems:

In most cases, the FortiGate receives login information, but can't translate the Windows AD group into the protection profile. Make sure that all the required Windows AD groups are included in the FortiGate user groups and that all FortiGate user groups are included into the authentication security policy.

There may be a problem with AD FSSO service running on the Windows AD server.

To ensure the problem is on windows side

1. Go to *Log&Report* > *Log Config*.
2. Enable firewall authentication event logging and debug level logging on the FortiGate.
3. Ask one or more users to log in into windows.
4. Check the FortiGate logs for the logon event from the Windows AD server.

If there is no new logon event entry in the logs, the problem is with Windows side. Use MS Windows AD documentation to troubleshoot the problem.

Mac OS X users can’t access external resources after waking from sleep mode

When client computers running Mac OS X (10.6.X and higher) wake up from sleep mode, the user must authenticate again to be able to access external resources. If the user does not re-authenticate, the user will maintain access to internal web sites, but will be unable to access any external resources.

This issue is caused by Mac OS X not providing sufficient information to the FSAE. This results in the FortiGate blocking access to the user because they cannot be authenticated.

Solution

The security settings on client computer(s) must be configured to require that a username and password be entered when exiting sleep mode or screen saver. With this feature enabled in Mac OS X, the FortiGate will receive the authentication information it requires to authenticate the user and allow them access.

Note that if the user reverts their settings to disable the password requirement, this will cause the issue to reappear.

Dynamic profiles and end points

This section explains how to set up the FortiOS dynamic profile and end point features to identify users and communication sessions. This section also describes configuring FortiOS Carrier HTTP header options, and end points.

This section describes:

Overview

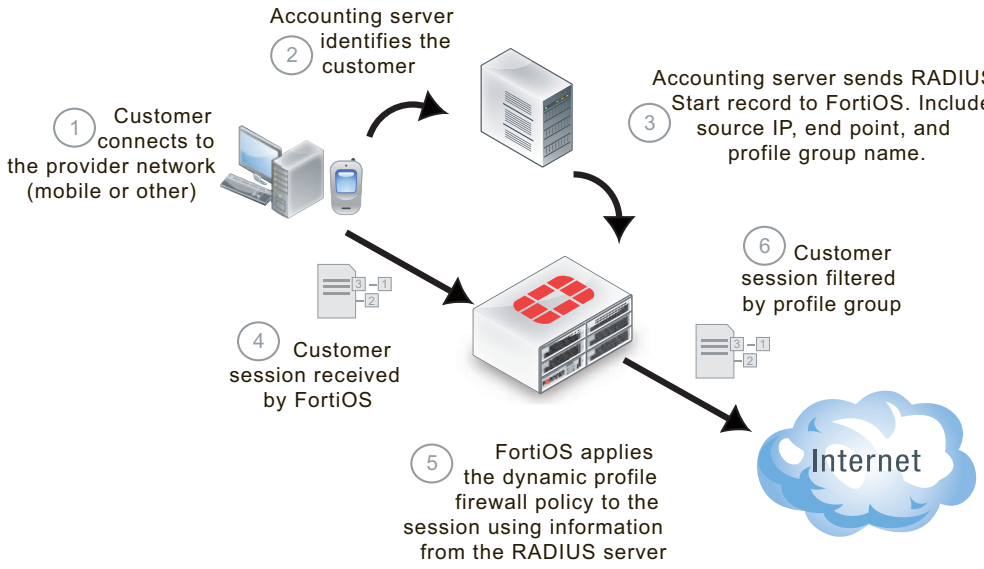
Network administrators can add customer identifying information and profile group names to their RADIUS server accounts. In response to a user connecting to the company network, if the RADIUS server successfully authenticates that user it sends a RADIUS Start record to FortiOS. In real time, FortiOS can extract identifying information and profile group names from these RADIUS Start records and match the identifying information with the customer communication session. FortiOS can then dynamically select and apply the profile group named in the RADIUS Start record to the communication session.

The application of parental-type controls to user sessions at a school is a useful example of the dynamic profile and multiple profile groups with different levels of access. Administrators can create profile groups that provide different levels of parental controls. Then these different levels of controls can be applied to communication sessions; the level of parental control depending on the profile group name added to the user account in the accounting system. This would allow teachers and student accounts to have different parental control settings. It would also allow teachers and students to logon to the school network from different locations, with different IP addresses, and still have the same restrictions for their level of account. It would also allow for difference between younger and older student controls, as appropriate.

Another example is on a mobile phone network with a mobile service provider. The mobile phone may access the network from many physical or network locations. With FortiOS Carrier dynamic profiles enabled on the provider network, that user will be identified as the same user and given the same privileges no matter where they logon. This makes it easier for mobile providers to track customers and provide extended services where warranted, or block access to some resources as may also be warranted. It also allows carriers to treat customers from other carriers who are using their network differently according to any agreements that might exist between carriers or even countries.

While FortiOS Carrier dynamic profiles and end points are very similar to those objects defined in FortiOS, in FortiOS Carrier there are some differences. These differences will be noted in the documentation. For definitions of carrier related terms, see the *FortiOS Handbook Carrier chapter*.

Figure 115: Information flow between customers, the accounting system, and FortiOS



When to use FSSO or dynamic profiles

FSSO and dynamic profiles have much in common. Both use RADIUS servers for authentication and accounting. Both are single sign on (SSO) solutions. For these and other reasons its valid to wonder why use one method over the other.

There are three main points FSSO and dynamic profiles differ on.

When to use FFSO

1. ***Your large network has a complex Windows AD authentication server already configured.*** FSSO is designed to work with an established Windows AD or Novell eDirectory network. Its agent software installations sit on the various servers to help send the required information to the FortiGate unit for authentication. Dynamic profiles does not require this extra software to be installed, but its performance may suffer as a result on large networks.
2. You have multiple authentication groups that require different levels of access. FSSO can be configured to work with 512 groups or more (depending on your FortiGate model). Dynamic profiles allows one group per VDOM.

3 Dynamic profiles requires no user or user group configuration. For Dynamic profile, configure the RADIUS server, and security policy. FSSO requires more configuration, but as a result allows more flexibility as well.

End points

The term for customer identifying information is an ***end point***. An end point can be any information the service provider uses to identify a customer and the device that the customer is using to connect to the network. For example, if the customer is using a mobile phone, the end point could be the phone's MSISDN number. The end point information must be included in the RADIUS Start record and must be available in the customer communication session (for example, in the HTTP header).

This is not the Endpoint Control feature referred to in other parts of FortiOS — that is a different feature for application control. End points in this chapter are used with the dynamic profile feature and RADIUS records to identify users.

In most cases, FortiOS Carrier can find the end point and IP address in customer communication sessions. An important exception is WAP traffic. Because WAP traffic may have the source IP address changed from the customer's IP address to the IP address of the WAP server, extra configuration may be required to extract the end point and source IP address from WAP traffic. See *FortiOS Handbook Carrier chapter* for information on configuring FortiOS Carrier for WAP traffic.

Without the end point, customers can only be identified by the IP address of the device that they are using. Because IP addresses may not be permanent or multiple users may be behind a NAT device and sharing a single IP address, the additional end point information is a more reliable and accurate way to identify individual customers. See "Configuring end points" on page 1341.

Dynamic profiles and security policies

For FortiOS to use the dynamic profile, you must add a security policy that includes the feature. Then all traffic that matches that profile will be authenticated by the configured RADIUS server.

Dynamic profile and identity-based policy are mutually exclusive options. When one is enabled, the other is hidden.

You can configure a maximum of one dynamic profile security policy per VDOM.

The general steps to configure a dynamic profile security policy are:

1 Create a new UTM profile group with a name that matches the dynamic profile group name that will be in the RADIUS attribute.

2 Create a new security policy and set the required fields (source, destination, schedule, service and action) as normal.

3 Enable *Dynamic Profile*, and select the dynamic profile from the list.

4 Enable *Dynamic Profile Users Only*.

5 Select other optional fields as required, and select OK when done.

Dynamic profile UTM profile groups

UTM profile groups allow you to create a group of UTM services and associate them together for a specific purpose. This group is then applied to one or more security policies. The benefit of this method is that you can have multiple configurations for AntiVirus, IPS, Application control and such, but only select the versions or services you require. To make changes in the future you change that IPS configuration for example and all UTM profile groups that use that IPS configuration will be updated as well.

When creating a dynamic profile UTM profile group, the group name must match the RADIUS server profile group name that was specified in the RADIUS server configuration. This group name is used to match traffic.

To create a dynamic profile UTM profile group - web-based manager

1 Go to *UTM* > *Profile Group*.

If this options is not visible, go to *System* > *Admin* > *Settings* and enable firewall related displays.

2 Select *Create New*.

3 Enter the *Name*. For example, `my_dyn_prof_group`. The name has to be the same as the dynamic profile group name used when configuring the RADIUS server for dynamic profiles. See "RADIUS server configuration for dynamic profiles" on page 1333.

4 Select default for the various UTM services. All entries have at least a default entry, and may have additional entries if they have been configured. For additional UTM configuration details, see the *FortiOS Handbook UTM chapter*.

5 Select the web and email protocols to apply dynamic profile to. This can include any or all of HTTP, HTTPS, FTP, IMAP, POP3, SMTP, IM, and NNTP. Best practices dictate that if you do not use some of these protocols, do not configure those ones. For all protocols selected, enable monitor to ensure statistics are collected for the Dashboard.

6 Select *OK*.

To create a dynamic profile UTM profile group - CLI

```
config firewall profile-group
  edit my_dyn_prof_group
    set av_profile default
    set profile_protocol_options default
    set webfilter-profile default
    set spamfilter-profile default
    set ips-sensor default
  next
end
```

Dynamic security policies

The following procedures use a dynamic profile group called `my_dyn_prof_group` to create a security policy to allow traffic between `wan1` and `internal` for all traffic at any time of day. It allows a group of services called `allowed_protocols` that includes protocols for web traffic, email, and other useful business applications.

Even though you have configured a UTM profile with AV, webfilter, spam, and IPS you must also configure UTM in the security policy. The UTM profile is used to match the dynamic profile group name on the RADIUS server. Configuring UTM within the security policy ensures that level UTM will be applied to any users who fail the dynamic profile authentication check. Otherwise those users would be left without any UTM, which can leave a gap in your security depending how those users are handled.

When this policy has been created, place it at the top of the security policy list to ensure it will be matched first. Otherwise it is possible another pollicy will match the users but without Authentication resulting in an unsecure user gaining access. Ensure there are policies lower in the list to catch any traffic that needs access through the FortiGate unit without requiring Authentication, as well as the final implicit deny policy at the bottom. You may have to enable *Display Implicit security Policies* under *System* > *Admin* > *Settings* to see it.

To create a dynamic profile security policy - web-based manager

1 Go to *Policy*.

2 Select Create New.

3 Enter the following information.

Source Interface/Zone	wan1
Source Address	all
Destination Interface/Zone	internal
Destination Address	all
Action	ACCEPT

4 Select *Enable Dynamic Profile*.

5 Select `my_dyn_prof_group` for Profile.

This is the UTM profile group created earlier.

6 Select UTM, and enable default configuration for AntiVirus, IPS, Web Filter, Email Filter, and Protocol Options.

7 Add the comment “Dynamic Profile policy” to help identify this security policy in a list of policies.

8 Select *OK*.

To create a dynamic profile security policy - CLI

```
config firewall policy
  edit 0
    set srcintf wan1
    set srcaddr any
    set dstintf internal
    set dstaddr any
    set action accept
    set dynamic-profile enable
    set dynamic-profile-access http imap pop3 smtp
    set dynamic-profile-group my_dyn_prof_group
    set utm-status enable
    set av-profile default
    set webfilter-profile default
    set spamfilter-profile default
```

```
    set ips-sensor default
    set profile-protocol-options default
    set comments "Dynamic Profile policy"
  next
  end
```

Accounting system RADIUS configuration

You can configure FortiOS dynamic profiles to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system before you can use dynamic profiles.

- Add a profile group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the FortiOS unit. Profile group names do not need to be added for all users, only to the accounts of customers who will use the dynamic profile feature on the FortiOS unit. If a profile group is not found in a RADIUS Start record regular RADIUS authentication will be used instead of dynamic profile if the user is configured for that type of authentication. See "RADIUS authentication with a FortiGate unit" on page 1202.
- Configure your accounting system to send RADIUS Start records to the FortiOS unit. You can send the RADIUS Start records to any FortiOS network interface. If your FortiOS unit is operating with virtual domains (VDOMs) enabled, the RADIUS Start records must be sent to a network interface in the management VDOM.

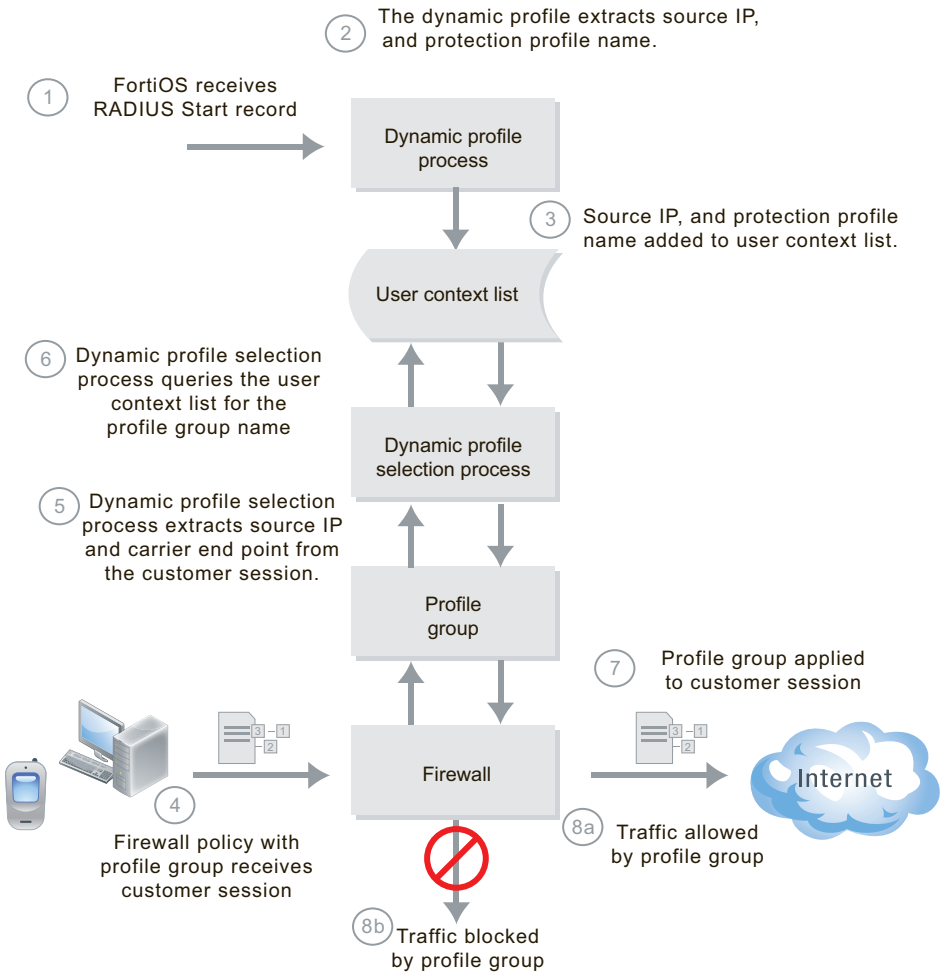
User context list

FortiOS maintains a dynamic ***user context list***—a list of current end points, IP addresses, and the profile group name received in RADIUS Start records. FortiOS uses timeouts to make sure that the list contains only current information, removing entries that are no longer needed (see "Timeout options" on page 1349).

FortiOS can also remove entries from the user context list if the accounting system sends a RADIUS Stop record when a customer finishes a communication session. When FortiOS receives a RADIUS Stop record, the end point in the record is removed from the user context list. The RADIUS Stop records are optional, but they make sure FortiOS maintains an accurate user context list.

Figure 116: FortiOS dynamic profile information flow

You can use the IP Filter list to block access through FortiOS for end points. To use this feature, add end points to the list and select block traffic. FortiOS uses the user context list to look up an end point in the IP filter list to find the find source IP address that the end point is using. Then at the IP level, FortiOS blocks all sessions from the source IP address.



Accepting sessions only from dynamic profile users

Extracting an end point from the content of a communication session creates extra processing overhead for the FortiOS unit. This extra overhead is acceptable for communication sessions where you want to apply dynamic profiles because of the ability to examine the content of the communication session.

However, communication sessions that do not have an end point in the user context list also create the same extra processing overhead only to be dropped when no match is found. In some cases you can reduce the amount of processing overhead by adding specific source and destination addresses to a dynamic profile security policy so that the policy matches fewer sessions. However, this may or may not work depending on factors such as your network design and security policy.

A better solution is to select *Dynamic Profile Users Only* in the security policy. If this option is selected, the dynamic profile policy only accepts sessions with source addresses that are in the user context list. Sessions with source addresses that are not in the user context list do not match the policy. For sessions that don't match the policy, the FortiOS unit continues searching down the policy list for a match.

You can add policies below the dynamic profile policy to apply various FortiOS features to non-dynamic profile sessions. For example:

- To block all non-dynamic profile sessions, make the next policy in the list a deny policy that matches all traffic. You could select *Log Violation Traffic* in this policy to log all non-dynamic profile sessions.
- To use traffic shaping to reduce the bandwidth available for non-dynamic profile sessions, apply a restrictive traffic shaper to the policy below the dynamic profile policy.

Dynamic Profile Users Only option

The *Dynamic Profile Users Only* option also allows you to differentiate between dynamic profile and regular sessions without including a profile group in the dynamic profile policy. You can use this property to apply a profile group only to non-dynamic profile traffic by adding a profile group to the next policy in the list. All dynamic profile sessions would use the dynamic profile policy and all non-dynamic profile sessions would use the next policy.

One example use of this configuration would be if you can assume that your dynamic profile users are not a security risk and you want to give them the benefit of enhanced performance of firewall sessions that do not apply a profile group.

With *Dynamic Profile User Only* selected, the FortiOS unit does not wait for the *User Context Creation Timeout* to see if a matching entry is added to the user context list. If there is a delay in receiving the RADIUS record and adding entries to the user context list, it is possible that sessions may not be matched with the dynamic profile security policy when as expected. If users experience this problem you may need to improve the performance of your RADIUS server, network, or FortiOS Carrier unit. For more information about the *User Context Creation Timeout*, see "Timeout options" on page 1349.

Configuring dynamic profile

For dynamic profile to work, your RADIUS accounting system needs to send all the user information to the FortiOS unit which will then match the user session to a dynamic profile security policy. The users do not need to be configured on the FortiOS unit as they are being authenticated by the RADIUS server. Once the RADIUS server authenticates the user, its just a matter of the security policy allowing the type of traffic in the session—just like an identity-based security policy after the user has authenticated.

You can configure one dynamic profile RADIUS server and one dynamic profile security policy per VDOM on your FortiOS unit. If you provide services to multiple networks by using VDOMs, this allows you to provide each network with their own dynamic profile configuration. Alternately you can configure a separate profile group in each VDOM's RADIUS server configuration to provide different levels of service to different user groups.

To enable dynamic profiles, the following configuration is required:

- ensure dynamic profile is visible in web-based manager
- configure the single RADIUS server for dynamic profiles under *User* > *Remote* > *RADIUS*
- optionally configure UTM Profile Group
- configure dynamic profile security policy

This section includes:

- Make dynamic profiles visible
- RADIUS server configuration for dynamic profiles

Make dynamic profiles visible

Dynamic profiles are not required by everyone, and the extra information displayed in the web-based manager may be confusing. For this reason, dynamic profiles can optionally be hidden.

If you want to configure dynamic profiles, you must first ensure dynamic profiles are not hidden in FortiOS.

To make dynamic profiles visible - web-based manager

1 Go to *System* > *Admin* > *Settings*.

2 Enable *Dynamic Profile Support on GUI*.

3 Select Apply.

To make dynamic profiles visible in GUI - CLI

```
config global
  config system global
    set gui-dynamic-profile-display enable
end
```

RADIUS server configuration for dynamic profiles

A RADIUS server must be configured on FortiOS for dynamic profile to work. If it is not, then the FortiOS unit does not listen for the RADIUS start record it needs for notification that the user was authenticated.

Restrictions and requirements

There are no restrictions on which brand of RADIUS servers can be used with FortiOS. The only requirements are that your RADIUS server supports the configuration FortiOS requires. Read this configuration section to ensure your RADIUS server can be properly configured using the documentation for your RADIUS server. This documentation does not explain how to configure your RADIUS server.

Only one RADIUS server can be configured for dynamic profiles per VDOM. Once one server is configured, the option to create more in the web-based manager is grayed-out and in the CLI attempting to enable the feature returns an error.

Profile group name

The profile group name is a means to identify which users on the RADIUS server are valid for the FortiOS unit and which are not. For example some users may have internal only access or be for automated processes that are internal network only. These users do not need to access resources outside their subnet, and will not use the FortiOS unit firewall. Using this method, FortiOS enforces Role Based Access Control (RBAC).

Also the profile group name allows multiple FortiOS units to share the Same RADIUS server by assigning each FortiOS unit a different group name and possibly even use a different RADIUS attribute as well. This can be useful if you only have one RADIUS server on your networks but have multiple FortiOS units protecting different network segments—for security reasons different users may have different levels of access to different parts of the network.

This example uses a RADIUS server called `myRADIUS.example.com`. This server uses “Login-IP Host” for both endpoint attribute and endpoint blocking. It uses “Vendor-Specific” for profile along with a value of “forti_dyn_prof”. This means when dynamic profile is trying to match the profile group, the group name it is looking to match will be in the *Vendor-Specific* RADIUS attribute and the value will be `forti_dyn_prof`. You may use different attributes for your configuration as is required.

The RADIUS server configuration will use the default settings where possible. This procedure assumes there is no existing dynamic profile server already configured.

To configure a dynamic profile RADIUS server - web-based manager

1. Go to User > *Remote* > *Radius.*
2. Select Create New.
3. For *Name*, enter `myRADIUS.example.com`. This is the name of the RADIUS server on the network.
4. For *Type*, select Dynamic Start. This enables dynamic profiles.

5 Enter the following information, and select OK:

Endpoint Attribute	Select the RADIUS attribute “Login-IP Host” from drop-down list. This attribute will be used to uniquely identify the user and enable extraction of endpoint information. Some RADUIS attributes are only for use with FortiOS Carrier and carrier networks. These attributes relate to mobile devices such as `*-Station-Id`.
Profile Attribute	Select the RADIUS attribute “Vendor-Specific” from drop-down list. This attribute will be used to uniquely identify the user and enable extraction of security profile information. RBAC is enabled with Vendor-Specific attributes. See “Role Based Access Control” on page 1204. Some RADUIS attributes are only for use with FortiOS Carrier and carrier networks. These attributes relate to mobile devices such as `*-Station-Id`.
Endpoint Blocking Attribute	Select the RADIUS attribute “Login-IP Host” from drop-down list. This attribute will be used to uniquely identify the user and enable extraction of endpoint blocking information. Some RADUIS attributes are only for use with FortiOS Carrier and carrier networks. These attributes relate to mobile devices such as `*-Station-Id`.
Send RADIUS Response	Select this option. FortiOS will send RADIUS responses after receiving RADIUS Start and Stop records. This setting may be required by your accounting system.
Validate RADIUS Secret	Select to use RADIUS shared secret for responses and validating requests for dynamic profile.
Flush IP sessions on STOP	Select to terminate all firewall TCP and UDP sessions associated with an IP after recieving a RADIUS STOP message for a dynamic profile. If left open it can result in unwanted traffic from an earlier user being assinged to a new user if the same IP address was assinged.
Profile Key	For this example, enter “forti_dyn_prof”, short for (fortios dynamic profile).Contains the profile group name to be matched in Profile Attribute. This is the profile group from the RADIUS server that the user belongs to. The profile group is how RADIUS users can be divided into different groups and access levels.
Log All Events	Select to log all possible dynamic profile related events. To select individual events, go to the CLI command `dp-log-dyn_flags` and select individual events to log. See “Advanced dynamic profile RADIUS server configuration - CLI” on page 1336.

Dynamic profiles always use the RADIUS `framed-ip-addr` field to get the IP address associated with the end point.

Advanced dynamic profile RADIUS server configuration - CLI

In the CLI, the following keywords are specific to configuring a RADIUS server for dynamic profile. The CLI keywords provide more in-depth options than found in the web-based manager. In the following example the RADIUS server uses `secret123` for the server secret, and the server is located at the IP address of `10.21.101.10`.

The dynamic profile RADIUS server keywords are found under `config user radius`.

To repeat the example above:

```
config vdom
edit root
config user radius
edit myRADIUS.example.com
  set dynamic_profile enable
  set auth-type auto
  set server myRADIUS.example.com
  set secret secret123
  set source-ip 10.21.101.10
  set use-management-vdom enable
  set dp-context-timeout 7200
  set dp-log-dyn-flags accounting-event accounting-stop-missed
     context-missing endpoint-block profile-missing protocol-
     error radiusd-other
  set dp-profile-attribute Vendor-Specific
  set dp-profile-attribute-key "forti_dyn_prof"
  set dp-radius-response enable
  next
end
```

`nas-ip` defines the station ID, commonly used with FortiOS Carrier, and is not used in this example.

`use-management-vdom` ensures that all requests are sent over the management VDOM instead of the current VDOM. When multiple VDOMs are enabled, the management VDOM always has access to servers such as FortiGuard which may help ensure connections to RADIUS servers as well. If each VDOM sends its own requests, changes to that VDOM may unknowingly cause problems with the sending of RADIUS requests.

`dp-context-timeou`t defines how long before the user context is cleared from the table. The default is eight hours (28 800 seconds) which is generally OK. However, in this example we are using two hours (7 200 seconds). This is more secure, but may require clients to reconnect if they maintain an open connection for periods longer than two hours.

`dp-log-dyn-flags` allows you to set which dynamic profile related events you want to log. In the example, all flags were selected. This customizing allows you to ensure all the necessary information is logged while also allowing you to remove any unused events from the log to save space and time. Available log events include `accounting-event`, `accounting-stop-missed`, `ontext-missing`, `endpoint-block`, `none`, `profile-missing`, `protocol-error`, and `radiusd-other`. See "Log settings" on page 1350.

`dp-profile-attribute` and `dp-profile-attribute-key` work together. Essentially the first field tells FortiOS which RADIUS attribute will contain the name of the profile group (such as Fortinet-Group-Name in the Vendor Specific Attribute), and the second field has the group name, or profile group name, to look for.

It is likely that different users will have different strings in the selected RADIUS attribute, but FortiOS is only concerned with the one string that identifies its users. This is the same name as the UTM profile that is applied to the dynamic profile in the security policy. Role based access control is accomplished this way. See "Dynamic profiles and security policies" on page 1327.

`dp-radius-response` tells FortiOS to send a response when the system receives a RADIUS start message. Some RADIUS servers require this to be enabled. It allows the RADIUS server to ensure the Start Record was received, which will prevent retries and such which will in turn improve system performance overall.

For additional dynamic profile configuration, see the *FortiOS CLI reference*.

Carrier endpoints

When you are configuring the dynamic profile RADIUS server in the CLI, you have the option of configuring carrier endpoints as well. If you `set endpoint-translation enable`, this enables the endpoint series of CLI commands. See "Configuring end points" on page 1341.

`dynamic_profile`	Enable dynamic profile feature. Default is disable. Note that identity-based policy and dynamic profile are mutual exclusive — when one is enabled, the other is hidden. When disabled, all related keywords (dp-*) are hidden.
`dp-carrier-endpoint-attribute`	Enter the RADIUS Attribute used to hold End Point name. By default this value is Calling-Station-Id.
`dp-carrier-endpoint-block-attribute`	Select "Login-IP Host". This is the RADIUS Attribute used to hold the endpoint to block. The list of available attributes to use is extensive. By default this value is Calling-Station-Id. Some RADIUS attributes are only for use with FortiOS Carrier and carrier networks. These attributes relate to mobile devices such as `*-Station-Id`.
`dp-context-timeout`	Timeout value in seconds for user context table entries (0 = infinite). Default is 28 800 seconds. See "Timeout options" on page 1349.
`dp-flush-ip-session`	Enable to flush user IP asessions on RADIUS accounting stop. By default this is set to disabled.
`dp-hold-time`	Enter the time in seconds to hold in proxy connection state to receive RADIUS START. Default time is 5 seconds.

dp-log-dyn_flags	Select one or more dynamic profile events to log. Events available include: • accounting-event • accounting-stop-missed • context-missing • endpoint-block • none • profile-missing • protocol-error • radiusd-other By default, all event types are enabled except none.
dp-log-period	Enter the minimum time period in seconds to use for event logs. Default is 0.
dp-mem-percent	Enter the maximum percentage of system memory to use for context tables. The default for this is set to 4%.
dp-profile-attribute	Select “Vendor-Specific”. This is the RADIUS Attribute used to hold the security profile group name. By default this is set to Class. To extract a profile group name from the RADIUS Start record, set this field to the name of the RADIUS attribute that contains the profile group name. Some RADUIS attributes are only for use with FortiOS Carrier and carrier networks. These attributes relate to mobile devices such as *-Station-Id.
dp-profile-attribute-key	Enter a string in this field if the *Profile Attribute* always contains the same text string directly before the profile group name. For example, if the *Profile Attribute* always includes the string profile_name= before the profile group name (for example, profile_name=<profile_name_str>), set the *Profile Key* to profile_name. FortiOS uses the string in the *Profile Key* to extract the profile name from the complete *Profile Attribute* string.
dp-radius-response	Enable to send RADIUS response packets. By default this is set to disable.
dp-radius-server-port	If required, change the UDP port number used by the RADIUS accounting server for sending RADIUS records. The default is 1813. FortiOS Carrier listens for RADIUS Start and Stop records on this port.

dp-secret	Enter the RADIUS shared secret for responses and validating requests for dynamic profile by the RADIUS accounting server.
dp-validate-request-secret	Enable to validate RADIUS request shared secret. Select if you want FortiOS Carrier to verify that the RADIUS secret matches the RADIUS secret in the RADIUS Start or End record. You can use the RADIUS secret to verify that the RADIUS record is valid.

Configuring dynamic profile-based security policies

Only one security policy can be configured for dynamic profile in a VDOM. Also only one RADIUS server and one dynamic profile group can be configured per VDOM. When one dynamic profile security policy has been configured, the option is not visible when creating other policies. After deleting the dynamic profile security policy, the option is again visible when configuring other security policies.

By enabling the *Dynamic Profile Users Only* option, other non-dynamic profile users will not match this policy. This can be useful if you want to enforce all users to be part of the dynamic profile group—in which case you have a deny all profile after this one.

If you want to allow all users access to the resources this security policy allows, do not enable the *Dynamic Profile Users Only* option.

To create dynamic profile-based security policies - web-based manager

1. Go to *Policy* > *Policy*.
2. Select *Create New*.
3. Enter the Source, Destination, Schedule, Service and Action information as you would for any security policy.
4. Select *Enable Dynamic Profile*.

   If this option does not appear, another security policy has dynamic profile enabled already.
5. Select *Profile Group*, and choose a configured group from the list.

   The dynamic profile Profile Group uses the UTM Profile Group list, located under *UTM* > *Profile Group* > *Profile Group*.
6. Optionally select *Dynamic Profile Users Only*. See “Accepting sessions only from dynamic profile users” on page 1331 and “Dynamic Profile Users Only option” on page 1332.
7. Select UTM, Traffic Shaping, Endpoint Security, and other settings as you would for any other security policy.
8. Select OK.

If the RADIUS server and users have been configured, you can now start authenticating users with dynamic profile.
chapter of FortiOS Handbook

In FortiOS Carrier, while creating or editing the identity based policy the service list includes MMS as an option.

Configuration concepts

Between identity-based policies, dynamic profiles, and traffic shaping there are many possible ways to configure your security policies to work with dynamic profiles. A few common ideas are presented here.

While many security options such as AV, webfiltering, and endpoint control are not mentioned here they are perfectly valid for use with dynamic profile security policies and are critical to maintaining network security.

These concepts include:

- Only allow dynamic profile users
- Only allow dynamic profile users, but traffic shape protocols
- Allow multiple dynamic profile groups
- Promote dynamic profile users
- Schedule-based policies

Only allow dynamic profile users

In this security policy configuration, there are only two policies needed. The first one will allow all dynamic profile authenticated users, and the second will deny everyone else.

This can be a problem for guest users visiting the office. It may also prove to be too restrictive in other ways as well.

Only allow dynamic profile users, but traffic shape protocols

This configuration is the same as the last one with one change. Different protocols (HTTPS, HTTP, telnet, ftp, etc.) will have different bandwidths allotted to each of them, and each will need its own security policy and traffic shaper to implement this. Each policy will be an IBP allow policy.

This is useful to ensure that important protocols or applications have the needed bandwidth to function properly. An example is VoIP applications that require a minimum level of bandwidth to guarantee a level of service.

Allow multiple dynamic profile groups

This configuration is the same as the last one, but uses multiple VDOMs to allow one profile group per VDOM. This configuration can be useful if you provide services to multiple networks with multiple VDOMs, or if you have one network with multiple levels of user access and want to differentiate between different dynamic profile users.

Promote dynamic profile users

It is possible that non-dynamic profile users are allowed on your network, but they will not have the same amount of resources available to them. This configuration is the same as the last one, but for the traffic shaping protocols there is no identity-based policy involved.

It is possible to have the users still authenticate if you want, by using IBPs and certificates.This would maintain a higher level of security on your network by requiring all users to authenticate in some form or another.

Schedule-based policies

Up to now, no mention has been made of scheduling. It is possible to have a policy only active at certain times of the day, or certain days of the week. This would allow a school to configure “during class” and “after school” schedules that may vary. Or at a company, different policies might be used over the lunch hour, for example relaxing company Internet browsing policies.

Schedules can be used by any security policy, but remember when that policy is offline you likely want a different policy in place allowing some traffic through. If you deny all traffic at times, you may run into problems with blocking even administrator access and be forced to use the console interface to access the FortiOS unit.

Configuring end points

An end point contains enough information about a user to be unique. This includes the IP address, profile, and group the user belongs to at a minimum. The end point information must be included in the RADIUS Start record and must be available in the customer communication session (for example, in the HTTP header).

Note that while the feature name is carrier end point, the feature is common to both FortiOS and FortiOS Carrier except where noted in the text.

This section includes:

Configuring end points - CLI

Dynamic profile end points are configured per RADIUS user that will be authentication using the dynamic profile. End points are only configurable in the CLI.

The following CLI keywords are specific to configuring end points. The end point keywords are found under `config user radius`, when `set dynamic-profile` is enabled.

`endpoint-translation`	Enable/disable endpoint-translation configure. Default is disabled. When disabled, all carrier endpoint translation related keywords (ep-*) are hidden. The example dynamic profile in Figure expects the end point to be in the Calling-Station-ID attribute. For details about RADIUS attributes see *RFC 2138* and *RFC 2866*.
`ep-carrier-endpoint-convert-hex`	Enable to enable converting end point to and from HEX string.
`ep-carrier-endpoint-header`	Enable to allow custom information to be added to HTTP headers. This option is commonly used on carrier networks. Default is `x-up-calling-line-id`.

ep-carrier-endpoint-header-suppress	Select Enable to prevent use of HTTP headers
ep-carrier-endpoint-prefix	Enable to prefix end point values with additional information
ep-ip-header-suppress	Enable/disable HTTP header suppression.
ep-missing-header-fallback	Specify either the policy-profile or the session-ip address to act as a backup when the extracted header is not present. Default is policy-profile.
ep-profile-query-type	Specify the type of dynamic profile query as one of • extract-carrier-endpoint • extract-ip • session-ip Use the IP address when the full carrier endpoint information is not available. The default is session-ip.

Controlling MMS service access based on a user's end point - FortiCarrier Only

You can control access to MMS services for users according to their end point by configuring *end point filtering* (also called end point blocking). End point filtering can filter MM1, MM3, MM4, and MM7 messages according to the end points in the *From* or *To* addresses of the messages. For a definition of end points, see "End points" on page 1327.

You configure end point filtering by creating an end point filter list containing end point patterns. A end point pattern can match one end point or can use wildcards or regular expressions to match multiple end points.

For each pattern, you select the action that FortiOS Carrier takes on a message when the pattern matches a end point in the message. Actions include blocking the message, exempting the message from mass MMS scanning and exempting the message from all scanning. You can also intercept the message and archive the message to a FortiAnalyzer unit.

To apply an end point filter list, you need to add the list to the *MMS Scanning* > *Carrier End Point Block* section of an MMS protection profile.

Configuring end point filtering - FortiOS Carrier only

To apply end point filtering- web-based manager

1. Go to *UTM* > *Carrier* > *Carrier End point Filter Lists*.
2. Add or edit an end point filter list.
3. Add or edit end point patterns in the list. See "Configuring end point filter lists" on page 1343.
4. Go to *UTM* > *Carrier* > *MMS Profile* and add or edit an MMS protection profile.
5. Expand *MMS Scanning* and select *Carrier End Point Block*.
6. Select the MMS protocols to apply the end point filter list to—one or more of MM1, MM3, MM4 and MM7.
7. Select the end point filter list to apply.

8 Add the MMS protection profile to a protection profile.

9 Add the protection profile to the dynamic profile security policy that accepts the MMS messages that you want to filter.

Configuring end point filter lists

To configure an end point filter list - web-based manager

1 Go to *UTM* > *Carrier* > *Carrier End Point Filter Lists*.

2 Select Create New.

3 Enter the following information and select OK.

Name		Name of the end point filter list. You select this name in an MMS protection profile.
Comments		Optional description of the end point filter list.
Check/Uncheck All		Select the check box to enable all end point patterns in the MMS filter list. Clear the check box to disable all entries on the MMS filter list. You can also select or clear individual check boxes to enable or disable individual end point patterns.
Pattern		The pattern that FortiOS Carrier uses to match with end points. The pattern can be a single end point or consist of wildcards or Perl regular expressions that will match more than one end point. See “Regular expression vs. wildcard match pattern” on page 1344.
Action		Select the action taken by FortiOS Carrier for messages from a carrier end point that matches the end point pattern: **None -** No action is taken. **Block -** MMS messages from the end point are not delivered and FortiOS Carrier records a log message. **Exempt from mass MMS -** MMS messages from the end point are delivered and are exempt from mass MMS filtering. Mass MMS filtering is configured in MMS protection profiles and is also called MMS Bulk Email Filtering and includes MMS message flood protection and MMS duplicate message detection. **Exempt from all scanning -** MMS messages from the end point are delivered and are exempt from all MMS protection profile scanning. MMS messages are not subject to protection profile filtering, just MMS protection profile filtering.
	Content Archive	MMS messages from the end point are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
	Intercept	MMS messages from the end point are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.

Pattern Type	The pattern type: *Wildcard*, *Regular Expression*, or *Single end point*. See *"Using wildcards and Perl regular expressions"* in the *FortiOS Handbook UTM chapter*.
Enable	Select to enable this end point filter pattern.

Regular expression vs. wildcard match pattern

A wildcard character is a special character that represents one or more other characters. The most commonly used wildcard characters are the asterisk (*), which typically represents zero or more characters in a string of characters, and the question mark (?), which typically represents any one character.

In Perl regular expressions, the '.' character refers to any single character. It is similar to the '?' character in wildcard match pattern. As a result:

- fortinet.com not only matches fortinet.com but also fortinetacom, fortinetbcom, fortinetccom, and so on.

To add a question mark (?) character to a regular expression from the FortiGate CLI, enter Ctrl+V followed by ?. To add a single backslash character (\) to a regular expression from the CLI you must add precede it with another backslash character. For example, `fortinet\\.com`.

To match a special character such as '.' and '*' use the escape character '\'. For example:

- To match fortinet.com, the regular expression will be: fortinet\.com

In Perl regular expressions, '*' means match 0 or more times of the character before it, not 0 or more times of any character. For example:

- forti*.com matches fortiiii.com but does not match fortinet.com

To match any character 0 or more times, use '.*' where '.' means any character and the '*' means 0 or more times. For example, the wildcard match pattern forti*.com will therefore be fort.*\.com.

Blocking access to the network based on end points - FortiOS Carrier only

You can use end point IP filtering to block traffic from source IP addresses associated with end points. You can also configure FortiOS Carrier to record log messages whenever end point IP filtering blocks traffic. End point IP filtering blocks traffic at the IP level, before the traffic is accepted by a security policy..

To configure end point IP filtering, go to *UTM* > *Carrier* > *IP Filter* and add end points to the IP filter list. For each end point you can enable or disable both blocking traffic and logging blocked traffic.

You cannot add end point patterns to the end point IP filter list. You must enter complete and specific end points that are valid for your network.

The only action available is block. You cannot use end point IP filtering to exempt end points from IP filtering or to content archive or quarantine communication sessions.

FortiOS Carrier looks in the current user context list for the end points in the IP filter list and extracts the source IP addresses for these end points. Then any communication session with a source IP address that matches one of these IP addresses is blocked at the IP level, before the communication session is accepted by a security policy.

FortiOS Carrier dynamically updates the list of IP addresses to block as the user context list changes. Only these updated IP addresses are blocked by end point IP filtering.

Carrier Endpoint Filter Lists

A carrier end point filter list contains carrier end point patterns. A pattern can match one carrier end point or can use wildcards or regular expressions to match multiple carrier end points. For each pattern, you select the action that the unit takes on a message when the pattern matches a carrier end point in the message. Actions include blocking the message, exempting the message from MMS scanning, and exempting the message from all scanning. You can also configure the pattern to intercept the message and content archive the message to a FortiAnalyzer unit.

Viewing and defining an end point IP filter list

To view the end point IP filter list, go to *UTM* > *Carrier* > *IP Filter*.

You define a end point IP filter list by adding IP addresses to it. From this list, you can select *Create New* to add a new IP address or select the *Edit* icon beside an entry that you want to change.

There is only one IP filter list, and each entry can be blocked or allowed. The single list prevents configuration issues by applying all IP filters to all MMS protection profiles that use IP filtering.

Once the IP filters are configured, it is applied to all Carrier Endpoints as their traffic hits the security policies.

Carrier end point IP filter list		
	Create New	Add a end point to the end point IP filter list.
	Edit	Edit the IP filter list entry. You can change the end point, enable or disable blocking, and enable or disable logging blocked traffic. If multiple entries are selected, Edit is not available.
	Delete	Delete one or more selected end points from the list.
	Enable	Select an end point entry, and select enable to enable blocking for that entry. The Enable icon will be green with a checkmark.
	Disable	Select an end point entry, and select disable to disable blocking for that entry. This effectively turns off this entry. The Enable Icon will be grey with an X.
	Remove All Entries	Remove all entries from the end point IP filter list.

	Check / uncheck all entries on this page	Select the check box to enable all entries on the end point IP filter list. FortiOS Carrier will then block all communication sessions from source IP addresses associated with these end points. Clear the check box to disable all entries on the IP filter list. Disabling all entries disables end point IP filtering. You can also select or clear individual check boxes to enable or disable individual end points.
Create new entry		
	Adding or modifying a carrier end point pattern	Select *Create New* to add a new end point IP address or select *Edit* to change an existing address. The end point and logging selections will appear in the end point filter list.
	Carrier End Point	Enter the end point. You must enter a single end point and not a end point pattern.
	Log Blocked Traffic	Select to record a log message when carrier end point IP filtering blocks a communication session.
	Block Traffic	Select to block traffic from the carrier end point. *Block Traffic* is selected by default.

Example

You can use IP filtering on Carrier Endpoints when a handheld on your carrier network is known to be sending spam or malware. You can easily use IP filtering to block the traffic from that unit, log it, or both. This allows you to escalate your response, and even monitor afterwards as well.

In this example the hand held IP address is 10.11.101.99 and since they are sending malware this IP address will be both logged and blocked.

To create an IP filter list entry to block an address - web-based manager

1 Go to *UTM* > *Carrier* > *IP Filter*.

2 Select *Create New*.

3 Enter `10.11.101.199` for the *Carrier End Point*.

4 Select *Log Blocked Traffic* and *Block Traffic*.

5 Select *OK*.

Adding additional blocked IP addresses

In the future, additional IP filters can be added both to the Carrier End Point filtering list, and to the firewall address list. To add additional filters to the filtering list, repeat the procedure *To create an IP filter list entry to block an address* for each new additional IP address to be filtered.

To add additional firewall addresses to be matched in the security policy, enter each additional new IP address as a separate firewall address, and in the security policy for the address select multiple and then select all the IP_Filter_xx addresses. Using a logical naming convention for additional IP filters such as `IP_Filter_02`, `IP_Filter_xx`, etc. will help with configuration.

Extracting carrier end points for notifications - FortiOS Carrier only

The sender's carrier end point is used to provide logging and reporting details to the mobile operator and to identify the sender of infected content.

When MMS messages are transmitted, the *From* field may or may not contain the sender's address. When the address is not included, the sender information will not be present in the logs and the FortiOS Carrier unit will not be able to notify the user if the message is blocked unless the sender's address is made available elsewhere in the request. One reason for this is if multiple users are behind the same NAT device.

Beyond logging, the sender address is also important for billing, end point control, and applying security policies. It is also important for differing levels of URL access.

FortiOS Carrier can extract the sender's address from an extended HTTP header field in the HTTP request. This field must be added to the HTTP request before it is received by FortiOS Carrier. If this field is present, it will be used instead of the sender's address in the MMS message for logging and notification. If this header field is present when a message is retrieved, it will be used instead of the *To* address in the message. If this header field is not present the content of the *To* header field is used instead.

Alternatively, FortiOS Carrier can extract the sender's address from a cookie. The cookie is sent as part of the HTTP header.

You can configure MMS address translation to extract the sender's carrier end point so that it can be added to log and notification messages. You can configure MMS address translation settings to extract carrier end points from HTTP header fields or from cookies. You can also configure MMS address translation to add an end point prefix to the extracted carrier end points.

To configure MMS address translation, go to *Firewall* > *MMS Profile*. Select *Create New* or select the *Edit* icon beside an existing profile. Expand *MMS Address Translation*. Complete the fields as described in the following table and select *OK*.

Configuring MMS address translation - FortiOS Carrier only

MMS address translation changes the address from using the one embedded in the MMS message to using the additional HTTP Header Field (if present) or a cookie to get the address.

This applies to MM1 and MM7 messages — messages sent to or from handsets, and messages sent to or from content providers. These are the only message types that use the HTTP headers that enable this feature.

To configure MMS address translation - web-based manager

1. Go to *UTM* > *Carrier* > *MMS Profile*.
2. Select *Create New*.
3. Expand *MMS Address Translation*.
4. Select settings for MM1 and MM7 as required.

5 Select *OK*.

Sender Address Source		Select to extract the sender's address from the *HTTP Header Field* or a *Cookie*. You must also specify the identifier that contains the carrier end point.

Sender Address Identifier		Enter the sender address identifier that includes the carrier end point. The default identifier is `x-up-calling-line-id`.
		If the *Sender Address Source* is *HTTP Header Field*, the address and its identifier in the HTTP request header takes the format:
		`<Sender Address Identifier>: <MSISDN_value>`
		If the *Sender Address Source* is Cookie, the address and its identifier in the HTTP request header's `Cookie` field takes the format of attribute-value pairs:
		`Cookie: id=<cookie-id>;`
		`<Sender Address Identifier>=<MSISDN Value>`

Convert Sender Address From / To Hex		Select to convert the sender address from ASCII to hexadecimal or from hexadecimal to ASCII. This is required by some applications.
Add End Point Prefix for Logging / Notification		
	Enable	Select to enable adding the country code to the extracted carrier end point, such as the MSISDN, for logging and notification purposes. You can limit the number length for the test numbers used for internal monitoring without a country code.
	Prefix	Enter a carrier end point prefix that will be added to all carrier end points. Use the prefix to add extra information to the carrier end point in the log entry.
	Minimum Length	Enter the minimum length of the number. If this and Maximum Length are set to zero (`0`), length is not limited.
	Maximum Length	Enter the maximum length of the number. If this and Minimum Length are set to zero (`0`), length is not limited.

HTTP header field example

For this example, in FortiOS Carrier we are concerned about MMS traffic between content providers — MM7 traffic only. The default `x-up-calling-line-id` will be used in the HTTP header along with a country code of `9811`. The *Sender Address* does need converting from hex. The prefix will be added to *Logging/Notification* using the MSISDN for the prefix.

To configure MMS address translation using HTTP header field

1 Go to *UTM* > *Carrier* > *MMS Profile*.

2 Select *Create New*.

3 Enter `MMS_addr_http_header` for the *Profilename*.

4 Expand *MMS Address Translation*.

5 Under MM7, select `HTTP Header Field` for *Sender Address Source.*

6 Under MM7, enter `x-up-calling-line-id` for *Sender Address Identifier*.

7 Under MM7, select *Convert Sender Address From / To HEX*.

8 Select Enable for *Add End Point Prefix for Logging / Notification*.

9 Enter `9811` for *Prefix*.

10 Select *OK*.

If the Sender Address Source is HTTP Header Field, the address and its identifier in the HTTP request header takes the format:

```
<Sender Address Identifier>: <MSISDN_value>
```

Where the <MSISDN_value> is the carrier end point. For example, the HTTP header might contain:

```
x-up-calling-line-id: 9811301234
```

where `x-up-calling-line-id` would be the Sender Address Identifier, and `9811301234` would be the MSISDN.

Cookie example

If you want the address to persist, then use a cookie. Keep in mind that cookies are a less secure method than the HTTP header field option because of their persistence.

For this example we are concerned about traffic to and from handsets and will only be using MM1. A non-standard field for Sender Address Identifier will be used: `x-up-calling-cookie`, and a country code of `467`. The *Sender Address* does not need converting from hex. The prefix will be added to *Logging/Notification* using the MSISDN for the prefix.

To configure MMS address translation using cookies - web-based manager

1 Go to *UTM* > *Carrier* > *MMS Profile*.

2 Select *Create New*.

3 Enter `MMS_addr_cookie` for the *Profilename*.

4 Expand *MMS Address Translation*.

5 Under MM1, select `Cookie` for *Sender Address Source.*

6 Under MM1, enter `x-up-calling-cookie` for *Sender Address Identifier*.

7 Select Enable for *Add End Point Prefix for Logging / Notification*.

8 Enter `467` for *Prefix*.

9 Select *OK*.

For MM1 messages, a cookie can now be referenced for the Sender's address. Any messages that trigger logging or notification that use this address translation will include the `467` prefix for added identification.

A sample HTTP request header resulting from this configuration would be:

```
Cookie: id=0123jf!a; x-up-calling-cookie=467301297
```

where `0123jf!a` is the cookie id, `x-up-calling-cookie` is the Sender Address Identifier, and `467301297` is the MSISDN.

Timeout options

Dynamic profile timeouts control how long FortiOS keeps entries in the user context list. Entries are removed when a RADIUS stop record is received by FortiOS, but otherwise entries remain in the context list until they timeout.

Usually you would not want entries staying in the user context list if they are not being used. A smaller list is easier and more efficient for FortiOS to manage. As well, because user context information can change, a smaller list means incorrect or out-of-date information is more likely to be removed.

However, some situations may benefit from keeping the entries in the user context list for a longer period of time. This may reduce network load and provide other benefits, but the security risk must be kept in mind as well.

User Context Entry Timeout	Enter the number of seconds that a user context entry can remain in the list without FortiOS Carrier receiving a communication session from the end point. If a user context entry is not being looked up, then the user must no longer be connected to the network. This timeout is only required if FortiOS Carrier does not receive the RADIUS Stop record. However, even if the accounting system does send RADIUS Stop records, this timeout must be set in case FortiOS Carrier misses one. The default user context entry timeout is 28800 seconds (8 hours). You can keep this timeout relatively high because it is not usually a problem to have a long list. But a timeout is usually required because FortiOS Carrier normally removes entries that are no longer used. You might want to reduce this timeout if the accounting server does not send RADIUS Stop records. Also, if customer IP addresses change often, you might want to set this timeout lower so that out-of-date entries are removed from the list. Avoid entering a setting that is too low. FortiOS Carrier may remove user context entries for users who are still connected. Set the timeout to 0 if you do not want FortiOS Carrier to remove entries from the list except in response to RADIUS Stop messages.
User Context Creation Timeout	If FortiOS Carrier receives a communication session and can't find a corresponding end point and IP address in the user context list, the system waits for the *User Context Creation Timeout*. If a match is not found after this timeout, FortiOS Carrier applies the profile group in the security policy to the communication session. The default user context creation timeout is 5 seconds. You might want to increase this timeout if the default profile group, instead of the dynamic profile, is being applied to users. This could be happening if there is a delay before FortiOS Carrier receives the RADIUS Start record from the accounting server. If you set this timeout to 0, FortiOS Carrier blocks communication sessions that do not have a matching entry in the user context list.

Log settings

You can use Log settings to configure FortiOS Carrier to record event log messages for dynamic profile events. You can also set a log message period to group log messages.

When using a dynamic profile. RADIUS attributes are included in the log information including framed IP address, radius username, and profile group.

Log Message Period	Enter the time in seconds to group event log messages for dynamic profile events. For example, if the log message period is 30 seconds, FortiOS Carrier generates groups of single-event log messages every 30 seconds instead of generating event log messages continuously. The grouped log messages generated each period contain a count of how many events of that type occurred. If you set this period to 0, FortiOS Carrier generates all event log messages in real time.
Protocol Errors	Select to have FortiOS generate event log messages if RADIUS protocol errors occur. One example could be a RADIUS record containing a RADIUS secret that does not match the one added to the dynamic profile.
Missing Profile Errors	Select to have FortiOS generate an event log message whenever FortiOS Carrier cannot find a profile group name in a RADIUS start message that matches the name of a profile group added to FortiOS Carrier.
Missing Context Errors	Select to have FortiOS generate an event log message whenever a user context creation timeout expires indicating that FortiOS Carrier was not able to match a communication session because a matching entry was not found in the user context list.
Missed Accounting 'Stop' Events	Select to have FortiOS generate an event log message whenever a user context entry timeout expires indicating that FortiOS Carrier removed an entry from the user context list without receiving a RADIUS Stop message.
Accounting Events	Select to have FortiOS generate an event log message when FortiOS Carrier does not find the expected information in a RADIUS record. This may happen, for example, if a RADIUS record contains more than the expected number of addresses.
Other Log Messages	Select to have FortiOS generate event log messages for other events. The event is described in the log message. For example, a log message may be generated if the memory limit for the user context list is reached and the oldest entries in the table have been dropped.

Carrier end point filters and blocking

Carrier end points are available on FortiOS units as well as FortiOS Carrier units. However, only FortiOS Carrier units can handle MMS traffic. In the following section, any reference to MMS messages is FortiOS Carrier only material.

This section includes:

Controlling access to MMS services based on a user's carrier end point

You can control access to MMS services for users according to their carrier end point by configuring *carrier end point filtering* (also called carrier end point blocking). Carrier end point filtering can filter MM1, MM3, MM4, and MM7 messages according to the carrier end points in the *From* or *To* addresses of the messages.

For a definition of carrier end points, see "End points" on page 1327.

You configure carrier end point filtering by creating a carrier end point filter list containing carrier end point patterns. A carrier end point pattern can match one carrier end point or can use wildcards or regular expressions to match multiple carrier end points.

For each pattern, you select the action that FortiOS Carrier takes on a message when the pattern matches a carrier end point in the message. Actions include blocking the message, exempting the message from mass MMS scanning and exempting the message from all scanning. You can also intercept the message and archive the message to a FortiAnalyzer unit.

To apply a carrier end point filter list, you need to add the list to the *MMS Scanning* > *Carrier End Point Block* section of an MMS protection profile.

Filtering MMS flows from selected carrier end points

You may want to block specific MMS protocols or block all of them depending on the situation. For example if you wanted to block traffic from selected handsets, you only need to select MM1 traffic. The benefit of this is a more specific match allows you to create individual security policies for each situation on your network. Extending the example you would have one policy for MM1 handset traffic, another policy for Internet MM3 traffic, another policy for Content Provider MM7 traffic, and another policy for inter-provider MM4 traffic.

Dividing traffic into smaller groups enables focused logging and reporting, while providing a more secure and customized firewall solution for your specific needs. When something changes, its easier to update a specific smaller security policy than to update a single large complex rambling policy.

Configuring carrier end point filtering

To apply carrier end point filtering- web-based manager

1. Go to *UTM* > *Carrier End Point* > *Carrier End point Filter Lists*.
2. Add or edit a carrier end point filter list.
3. Add or edit carrier end point patterns in the list.
4. Go to *UTM* > *Carrier* > *MMS Profile* and add or edit an MMS protection profile.
5. Expand *MMS Scanning* and select *Carrier End Point Block*.
6. Select the MMS protocols to apply the carrier end point filter list to (MM1, MM3, MM4 and MM7).
7. Select the carrier end point filter list to apply.
8. Add the MMS protection profile to a protection profile.
9. Add the protection profile to a security policy that accepts the MMS messages that you want to filter.

To configure a carrier end point filter list - web-based manager

To configure a carrier end point filter list go to *UTM* > *Carrier* > *Carrier End Point Filter Lists*.

Name		Name of the carrier end point filter list. You select this name in an MMS protection profile.
Comments		Optional description of the carrier end point filter list.
Check/Uncheck All		Select the check box to enable all carrier end point patterns in the MMS filter list. Clear the check box to disable all entries on the MMS filter list. You can also select or clear individual check boxes to enable or disable individual carrier end point patterns.
Pattern		The pattern that FortiOS Carrier uses to match with carrier end points. The pattern can be a single carrier end point or consist of wildcards or Perl regular expressions that will match more than one carrier end point. See *"Using wildcards and Perl regular expressions"* in the *FortiOS Handbook UTM chapter*.
Action		Select the action taken by FortiOS Carrier for messages from a carrier end point that matches the carrier end point pattern: **None -** No action is taken. **Block -** MMS messages from the carrier end point are not delivered and FortiOS Carrier records a log message. **Exempt from mass MMS -** MMS messages from the carrier end point are delivered and are exempt from mass MMS filtering. Mass MMS filtering is configured in MMS protection profiles and is also called MMS Bulk Email Filtering and includes MMS message flood protection and MMS duplicate message detection. **Exempt from all scanning -** MMS messages from the carrier end point are delivered and are exempt from all MMS protection profile scanning. MMS messages are not subject to protection profile filtering, just MMS protection profile filtering.
	Content Archive	MMS messages from the carrier end point are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
	Intercept	MMS messages from the carrier end point are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
Pattern Type		The pattern type: *Wildcard*, *Regular Expression*, or *Single Carrier End Point*. See *"Using wildcards and Perl regular expressions"* in the *FortiOS Handbook UTM chapter*.
Enable		Select to enable this carrier end point filter pattern.

Blocking network access for IP addresses based on carrier end points

You can use carrier end point IP filtering to block traffic from source IP addresses associated with carrier end points. You can also configure FortiOS Carrier to record log messages whenever carrier end point IP filtering blocks traffic. Carrier end point IP filtering blocks traffic at the IP level, before the traffic is accepted by a security policy.

For a definition of carrier end points, see "End points" on page 1327.

To configure carrier end point IP filtering, go to *UTM* > *Carrier* > *IP Filter* and add carrier end points to the IP filter list. For each carrier end point you can enable or disable both blocking traffic and logging blocked traffic.

You cannot add carrier end point patterns to the carrier end point IP filter list. You must enter complete and specific carrier end points that are valid for your network.

The only action available is block. You cannot use carrier end point IP filtering to exempt carrier end points from IP filtering or to content archive or quarantine communication sessions.

FortiOS Carrier looks in the current user context list for the carrier end points in the IP filter list and extracts the source IP addresses for these carrier end points. Then any communication session with a source IP address that matches one of these IP addresses is blocked at the IP level, before the communication session is accepted by a security policy.

FortiOS Carrier dynamically updates the list of IP addresses to block as the user context list changes. Only these updated IP addresses are blocked by carrier end point IP filtering.

Configuring end point IP filtering includes:

- Viewing and defining a carrier end point IP filter list
- Adding additional blocked IP addresses

Viewing and defining a carrier end point IP filter list

To view the carrier end point IP filter list, go to *UTM* > *Carrier* > *IP Filter*.

You define a carrier end point IP filter list by adding IP addresses to it. From this list, you can select *Create New* to add a new IP address or select the *Edit* icon beside an entry that you want to change.

There is only one IP filter list, and each entry can be blocked or allowed. The single list prevents configuration issues by applying all IP filters to all MMS protection profiles that use IP filtering.

Once the IP filters are configured, it is applied to all Carrier Endpoints as their traffic hits the security policies.

Carrier end point IP filter list		
	Create New	Add a carrier end point to the carrier end point IP filter list.
	Edit	Edit the IP filter list entry. You can change the carrier end point, enable or disable blocking, and enable or disable logging blocked traffic. If multiple entries are selected, Edit is not available.

	Delete	Delete one or more selected carrier end points from the list.
	Enable	Select an end point entry, and select enable to enable blocking for that entry. The Enable icon will be green with a checkmark.
	Disable	Select an end point entry, and select disable to disable blocking for that entry. This effectively turns off this entry. The Enable Icon will be grey with an X.
	Remove All Entries	Remove all entries from the carrier end point IP filter list.
	Check / uncheck all entries on this page	Select the check box to enable all entries on the carrier end point IP filter list. FortiOS Carrier will then block all communication sessions from source IP addresses associated with these carrier end points. Clear the check box to disable all entries on the IP filter list. Disabling all entries disables carrier end point IP filtering. You can also select or clear individual check boxes to enable or disable individual carrier end points.
Create new entry		
	Adding or modifying a carrier end point pattern	**Select** *Create New* **to add a new carrier end point IP address or select** *Edit* **to change an existing address. The carrier end point and logging selections will appear in the carrier end point filter list.**
	Carrier End Point	Enter the carrier end point. You must enter a single carrier end point and not a carrier end point pattern.
	Log Blocked Traffic	Select to record a log message when carrier end point IP filtering blocks a communication session.
	Block Traffic	Select to block traffic from the carrier end point. *Block Traffic* is selected by default.

Example

You can use IP filtering on Carrier Endpoints when a handheld on your carrier network is known to be sending spam or malware. You can easily use IP filtering to block the traffic from that unit, log it, or both. This allows you to escalate your response, and even monitor afterwards as well.

In this example the hand held device IP address is 10.11.101.99 and since they are sending malware this IP address will be both logged and blocked. The following general steps are required.

1. Create an IP filter list entry to block an address
2. Create an MMS protection profile to use this IP filter list
3. Create a firewall address for the blocked IP address, and create incoming and outgoing security policies that use the firewall address and MMS profile.

Firewall configuration is not explained here. See the Fundamentals Handbook chapter.

To create an IP filter list entry to block an address - web-based manager

1 Go to *UTM* > *Carrier* > *IP Filter*.
2 Select *Create New*.
3 Enter `10.11.101.199` for the *Carrier End Point*.
4 Select *Log Blocked Traffic* and *Block Traffic*.
5 Select *OK*.

To create an MMS protection profile to use the IP filter

1 Go to *UTM* > *Carrier* > *MMS profile*.
2 Select Create New.
3 Enter `ipFilteringProfile` as the *Profilename*.
4 Expand *MMS Scanning*.
5 Select all MMS protocols for *Carrier End Point Block*.
6 Select `my IP filter list` from the *Option* menu for *Carrier End Point Block*.
7 Select any other settings as required for this MMS protection profile.
8 Select *OK*.

Adding additional blocked IP addresses

In the future, additional IP filters can be added both to the Carrier End Point filtering list, and to the firewall address list. To add additional filters to the filtering list repeat general step 1 for each new additional IP address to be filtered. To add additional firewall addresses to be matched in the security policy, enter each additional new IP address as a separate firewall address, and in the security policy for the address select multiple and then select all the IP_Filter_xx addresses. Using a logical naming convention for additional IP filters such as `IP_Filter_02`, `IP_Filter_xx`, etc. will help with configuration.

Troubleshooting dynamic profiles

This section provides you with some commands and methods for troubleshooting dynamic profile issues.

This section includes:

General dynamic profile troubleshooting

When you are troubleshooting, work your way down the list. The first solution is more general, and each solution becomes more specific as you move down the list.

- If dynamic profiles are not displayed anywhere in the web-based manager they must un-hidden. Go to *System* > *Admin* > *Settings* and select *Dynamic Profile Support on GUI*. If VDOMs are enabled, this is at the global level.
- Dynamic server option does not appear in RADIUS server configuration. This means there is already one dynamic RADIUS server configured. To configure another you must first locate and remove the original configuration.

- Dynamic profile option is not displayed in security policies. There are two possible reasons for this. The first is that there is already another security policy with dynamic profile enabled—this must be removed before you can configure another dynamic security policy. Second, when identity-based policy is selected in a security policy dynamic profile is not displayed. For dynamic profile option to reappear, un-select identity-based profile.
- Valid users not being authenticated. It is possible that it is taking too long for the FortiOS unit to receive the RADIUS start record, and the security policy is failing from lacking that information.

Dynamic profile related diag commands

You can use the following FortiOS diagnose commands to debug communication between the RADIUS server and FortiOS:

`diag test application radiusd 2`

Clears the user context list. This is similar to having all users log off.

`diag test application radiusd 3`

Shows the user context list (`user`, `profile`, `ip`)

`diag test application radiusd 5`

Displays RADIUS statistics such as the number of RADIUS Start and Stop packets received, the number of packet errors and so on.

`diag dynamic-profile query ip 10.0.0.1`

A filter that displays the same kind of information as `diagnose test application radiusd 3`.

`diag dynamic-profile query profile-usage <vdom_name>`

Displays a summary of profile usage for the named VDOM.

`diag debug application radiusd 3`

Displays carrier end points and their associated profile group names. An example entry for carrier end point `5551231234` and profile group name `profile_name` could be:

```
<000.000000> [49]: received from radiusd -- msgId=41,
profile=profile_name, endpoint=5551231234 [49]: delayed setup
for profile profile_name)
```

In the following example, the command `diagnose test application radiusd 3` displays three entries in the user context list. In this example, the carrier end points are listed under endpoint and they are all email addresses. This example output uses example IP addresses and domain names.

```
index,"time left (hh:mm:ss)",ip,endpoint,profile,rc,"Default
Profile?",Blacklist?
1,07:08:07,"192.168.23.7","33example@example.com","PackageVAS2",1,
No,No
2,07:23:32,"192.168.33.112","45example@example.com","PackageVAS2",
```

```
1,No,No
3,07:28:32,"172.20.123.71","332example@example.com","PackageVAS1",
1,No,No
```

Monitoring authenticated users

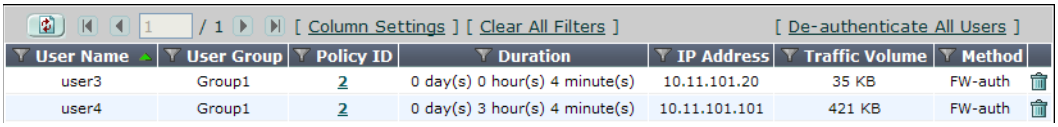
This section describes how to view lists of currently logged-in firewall and VPN users. It also describes how to disconnect users.

The following topics are included in this section:

Monitoring firewall users

To monitor firewall users, go to *User* > *Monitor* > *Firewall*>

Figure 117: Firewall users listed in monitor



You can de-authenticate a user by selecting the Delete icon for that entry.

You can filter the list of displayed users either by selecting the funnel icon for one of the column titles or selecting *Filter Settings*.

Select *Column Settings* to add or remove columns to the display, or rearrange the order of the columns displayed.

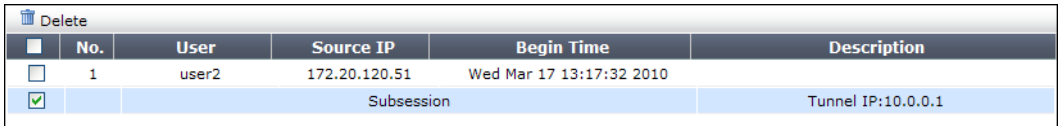
Optionally, you can select *De-authenticate all users*. Best practices dictate that this only be used in extreme cases since all users will momentarily loose their network resource connections.

Monitoring SSL VPN users

You can monitor web-mode and tunnel-mode SSL VPN users by username and IP address.

To monitor SSL VPN users, go to *VPN* > *Monitor* > SSL-VPN Monitor. To disconnect a user, select the user and then select the *Delete* icon.

Figure 118: Monitoring SSL VPN users



The first line, listing the username and IP address, is present for a user with either a web-mode or tunnel-mode connection. The Subsession line is present only if the user has a tunnel mode connection. The *Description* column displays the virtual IP address assigned to the user's tunnel-mode connection.

For more information about SSL VPN, see the *FortiOS Handbook SSL VPN chapter.*

To monitor SSL VPN users - CLI

To list all of the SSL VPN sessions and their index numbers:

```
execute vpn sslvpn list
```

The output looks like this:

```
SSL-VPN Login Users:
 Index   User   Auth Type     Timeout         From      HTTPS in/out
 0       user1  1              256    172.20.120.51    0/0

SSL-VPN sessions:
 Index   User     Source IP      Tunnel/Dest IP
 0       user2    172.20.120.51  10.0.0.1
```

You can use the Index value in the following commands to disconnect user sessions:

To disconnect a tunnel-mode user

```
execute vpn sslvpn del-tunnel <index>
```

To disconnect a web-mode user

```
execute vpn sslvpn del-web <index>
```

You can also disconnect multiple users:

To disconnect all tunnel-mode SSL VPN users in this VDOM

```
execute vpn ssl del-all tunnel
```

To disconnect all SSL VPN users in this VDOM

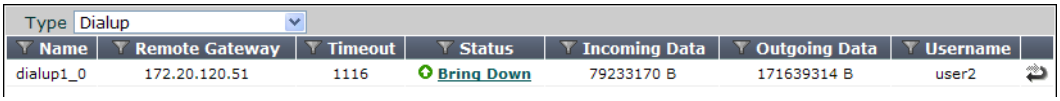
```
execute vpn ssl del-all
```

Monitoring IPsec VPN users

To monitor IPsec VPN tunnels in the web-based manager, go to *VPN* > *Monitor* > IPsec Monitor. usernames are available only for users who authenticate with XAuth.

You can close a tunnel by selecting its *Bring Down* link in the *Status* column.

Figure 119: Monitoring dialup VPN users



For more information, see the *FortiOS Handbook IPsec chapter*.

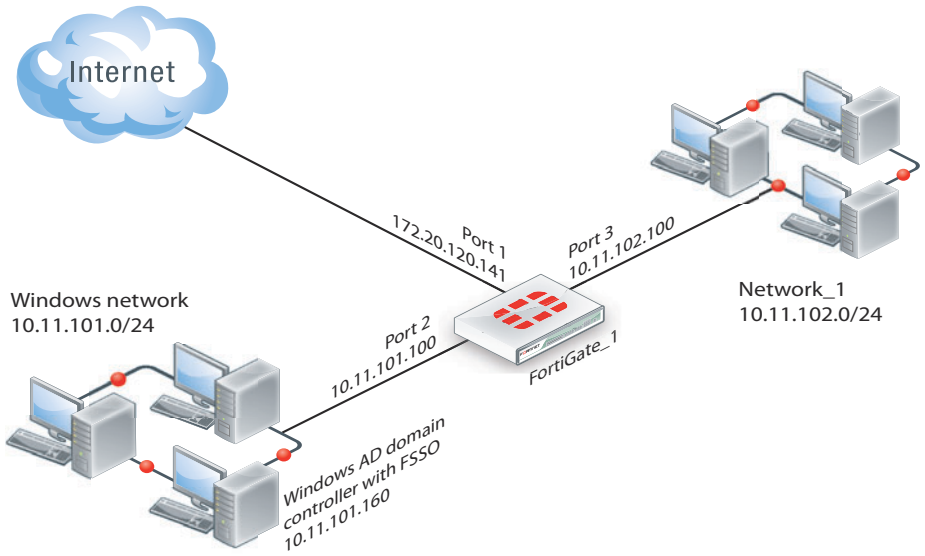
Examples and Troubleshooting

This chapter provides an example of a FortiGate unit providing authenticated access to the Internet for both Windows network users and local users.

The following topics are included in this section:

Firewall authentication example

Figure 120: Example configuration



Overview

In this example, there is a Windows network connected to Port 2 on the FortiGate unit and another LAN, Network_1, connected to Port 3.

All Windows network users authenticate when they logon to their network. Members of the Engineering and Sales groups can access the Internet without entering their authentication credentials again. The example assumes that the Fortinet Single Sign On (FSSO) has already been installed and configured on the domain controller.

LAN users who belong to the Internet_users group can access the Internet after entering their username and password to authenticate. This example shows only two users, User1 is authenticated by a password stored on the FortiGate unit, User2 is authenticated on an external authentication server. Both of these users are referred to as local users because the user account is created on the FortiGate unit.

Creating a locally-authenticated user account

User1 is authenticated by a password stored on the FortiGate unit. It is very simple to create this type of account.

To create a local user - web-based manager

1 Go to *User* > *User* and select *Create New*.

2 Enter the following information: username, Password.

username	User1
Password	hardtoguess

3 Select *OK*.

To create a local user - CLI

```
config user local
  edit user1
    set type password
    set passwd hardtoguess
  end
```

Creating a RADIUS-authenticated user account

To authenticate users using an external authentication server, you must first configure the FortiGate unit to access the server.

To configure the remote authentication server - web-based manager

1 Go to *User* > *Remote* > *RADIUS* and select *Create New*.

2 Enter the following information and select *OK*:

Name	OurRADIUSsrv
Primary Server Name/IP	10.11.101.15
Primary Server Secret	OurSecret
Authentication Scheme	Select *Use Default Authentication Scheme*.

To configure the remote authentication server - CLI

```
config user radius
  edit OurRADIUSsrv
    set server 10.11.102.15
    set secret OurSecret
    set auth-type auto
  end
```

Creation of the user account is similar to the locally-authenticated account, except that you specify the RADIUS authentication server instead of the user's password.

To configure a remote user - web-based manager

1 Go to *User* > *User* and select *Create New*.

2 Enter the following information and select *OK*:

username	User2
RADIUS	Select *Match user on RADIUS server* and then select OurRADIUSsrv from the list.

To configure a remote user - CLI

```
config user local
  edit User2
    set name User2
    set type radius
    set radius-server OurRADIUSsrv
  end
```

Creating user groups

There are two user groups: an FSSO user group for FSSO users and a firewall user group for other users. It is not possible to combine these two types of users in the same user group.

Creating the FSSO user group

For this example, assume that FSSO has already been set up on the Windows network and that it uses Advanced mode, meaning that it uses LDAP to access user group information. You need to

- configure LDAP access to the Windows AD global catalog
- specify the collector agent that sends user logon information to the FortiGate unit
- select Windows user groups to monitor
- select and add the Engineering and Sales groups to an FSSO user group

To configure LDAP for FSSO - web-based manager

1 Go to *User* > *Remote* > *LDAP* and select *Create New*.

2 Enter the following information:

Name	ADserver
Server Name / IP	10.11.101.160
Distinguished Name	dc=office,dc=example,dc=com
Bind Type	Regular
User DN	cn=FSSO_Admin,cn=users,dc=office,dc=example,dc=com
Password	set_a_secure_password

Leave other fields at their default values.

3 Select *OK*.

To configure LDAP for FSSO - CLI

```
config user ldap
  edit "ADserver"
    set server "10.11.101.160"
    set dn "cn=users,dc=office,dc=example,dc=com"
    set type regular
    set username
       "cn=administrator,cn=users,dc=office,dc=example,dc=com"
    set password set_a_secure_password
  next
end
```

To specify the collector agent for FSSO - web-based manager

1 Go to *User* > *FSSO* and select *Create New*.

2 Enter the following information and select *OK*:

Name		WinGroups
Enter on one line		
	Collector IP/Name	10.11.101.160
	Port	8000
	Password	fortinet_canada
LDAP Server		ADserver

To specify the collector agent for FSSO - CLI

```
config user fsso
  edit "WinGroups"
  set ldap-server "ADserver"
  set password ENC
     G7GQV7NEqilCM9jKmVmJJFVvhQ2+wtNEe9T0iYA5Sa+EqT2J8zhOrbkJFD
     r0RmY3c4LaoXdsoBczA1dONmcGfthTxxwGsigzGpbJdC71spFlQYtj
  set server "10.11.101.160"
end
```

To select Windows user groups to monitor - web-based manager

1 Go to *User* > *FSSO* > *FSSO Agent*.

2 Expand *WinGroups*, then select the *Edit Users/Groups* icon.

3 Select the Engineering and Sales groups and then select *OK*.

To create the FSSO_Internet-users user group - web-based manager

1 Go to *User* > *User Group* and select *Create New*.

2 Enter the group name, FSSO_Internet_users.

3 Select *Fortinet Single Sign-On (FSSO)*.

4 In the *Available Members* list, select the Engineering and Sales groups and then select the right arrow button to move them to the *Members* list.

5 Select *OK*.

To create the FSSO_Internet-users user group - CLI

```
config user group
  edit FSSO_Internet_users
    set group-type directory-service
    set member
       CN=Engineering,cn=users,dc=office,dc=example,dc=com
       CN=Sales,cn=users,dc=office,dc=example,dc=com
end
```

Creating the Firewall user group

The non-FSSO users need a user group too. In this example, only two users are shown, but additional members can be added easily.

To create the firewall user group - web-based manager

1 Go to *User* > *User Group* and select *Create New*.

2 Enter the following information and then select *OK*:

Name	Internet_users
Type	Firewall
Members	User1, User2

To create the firewall user group - CLI

```
config user group
  edit Internet_users
    set group-type firewall
    set member User1 User2
  end
```

Defining policy addresses

Go to *Firewall Objects* > *Address* and create the following addresses:

Address Name	Internal_net
Type	Subnet / IP Range
Subnet / IP Range	10.11.102.0/24
Interface	Port 3

Address Name	Windows_net
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0/24
Interface	Port 2

Creating security policies

Two security policies are needed: one for firewall group who connect through port3 and one for FSSO group who connect through port2.

To create a security policy for FSSO authentication - web-based manager

1 Go to *Policy* > *Policy* and select *Create New*.

2 Enter the following information:

Source interface	Port2
Source address	Windows_net
Destination interface	Port1
Destination address	all
Action	ACCEPT
NAT	Enable

3 Select *Enable identity-based Policy* and then select *Add*.

In the *New Authentication Rule* window, enter the following information, and then select OK:

User Group	FSSO_Internet_users
Service	ANY
Schedule	always
UTM	Optionally, enable UTM options.

4 Select OK.

To create a security policy for FSSO authentication - CLI

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr Windows_net
    set dstaddr all
    set action accept
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule always
        set groups FSSO_Internet_users
        set service ANY
      end
  end
```

To create a security policy for local user authentication - web-based manager

1 Go to *Policy* > *Policy* and select *Create New*.

2 Enter the following information:

Source interface	Port3
Source address	Internal_net
Destination interface	Port1
Destination address	all

Action	ACCEPT
NAT	Enable

3 Select *Enable identity-based Policy* and then select *Add*.

In the *New Authentication Rule* window, enter the following information, and then select OK:

User Group	Internet_users
Service	ANY
Schedule	always
UTM	Optionally, enable UTM options.

4 Select OK.

To create a security policy for local user authentication - CLI

```
config firewall policy
  edit 0
    set srcintf port3
    set dstintf port1
    set srcaddr internal_net
    set dstaddr all
    set action accept
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule always
        set groups Internet_users
        set service ANY
      end
  end
```

LDAP Dial-in using member-attribute

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to setup a VPN connection simply based on an attribute that is set to TRUE, instead of based on the group they are in like normal. In AD the "Allow Dialin" property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to "TRUE".

This same procedure can be used for other member attributes, as your system requires.

To accomplish this with a FortiGate unit, member-attribute must be set. This can only be accomplished through the CLI - the option is not available through the web-based manager.

Before configuring the FortiGate unit, ensure the AD server has the `msNPAllowDialin` attribute set to "TRUE" for the users in question. If not, those users will not be able to authenticate.

To configure user LDAP member-attribute settings - CLI

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
```

```
    set cnid "sAMAccountName"
    set dn "DC=fortilabanz,DC=com,DC=au"
    set type regular
    set username "fortigate@sample.com"
    set password ******
    set filter "(&(uid=%u)(msNPAllowDialin=TRUE))"
    set member-attr "msNPAllowDialin"
  next
end
```

To configure LDAP group settings - CLI

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
    edit 1
      set server-name "ldap"
      set group-name "TRUE"
    next
    end
  next
end
```

Once these settings are in place, users that are a member of the `ldap` user group will be able to authenticate.

To ensure your settings are correct, here is the sample output from a diag debug command that shows the authentication process.

When the "Allow Dial-in" attribute is set to "TRUE" the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the attribute is not set but it is expected, the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='FALSE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Failed group matching
```

The only difference between these two outputs is the last line which is either passed or failed based on if the member-attribute is set to the expected value or not.

Dynamic Profile example

A common dynamic profile topology involves a medium sized company network of users connecting to the Internet through the FortiGate unit, and authenticating with a RADIUS server. Dynamic profile authentication was selected because it is fast and relatively easy to configure.

This section includes:

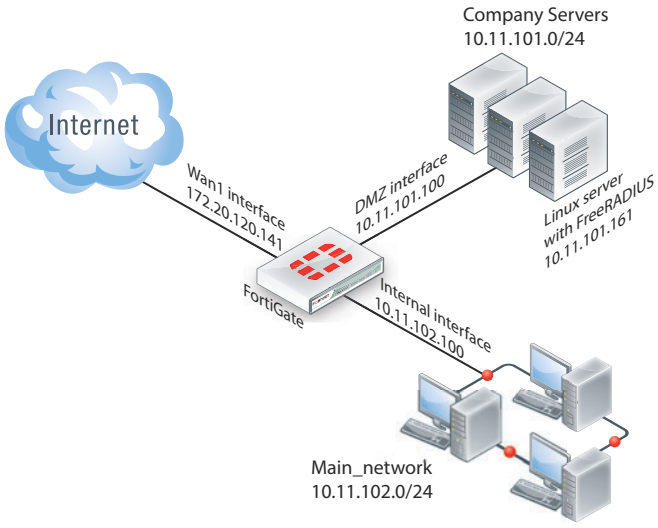
Assumptions

- VDOMs are not enabled
- The admin super_admin administrator account will be used for all FortiGate unit configuration.
- Any other devices on the network do not affect the topology of this example, and therefore are not included.
- Anywhere settings are not described, they are assumed to be default values.
- third-party RADIUS server is installed on a server box.
- BGP is used for any dynamic routing.
- Authentication event logging under Log&Report has been configured.

Topology

Example.com has an office with 20 users on the internal network. These users need access to the Internet to do their jobs. The office network is protected by a FortiGate-60C unit with access to the Internet through the wan1 interface, the user network on the internal interface, and all the servers are on the DMZ interface. This includes an Ubuntu Linux server running FreeRADIUS. For this example only two users will be configured — Pat Lee with an account name `plee`, or `plee@example.com`, and Kelly Green with an account name `kgreen`, or `kgreen@example.com`.

Figure 121: Dynamic Profile topology



General configuration

1. Configuring RADIUS with users, user group, and FortiGate information.
2. Configuring FortiGate interfaces
3. Configuring dynamic profile RADIUS server on FortiGate
4. Configuring FortiGate regular and dynamic profile security policies

Configuring RADIUS

Configuring RADIUS includes configuring the RADIUS server such as FreeRADIUS, a radius client on user's computers, and configuring users in the system. For this example the two users will be Pat Lee, and Kelly Green. They belong to a group called `exampledotcom_employees`. When it is all configured, the RADIUS daemon needs to started.

The users have a RADIUS client installed on their PCs that allows them to authenticate through the RADIUS server.

FreeRADIUS can be found on the freeradius.org website. For any problems installing FreeRADIUS, see the FreeRADIUS documentation.

Configuring FortiGate interfaces

Before configuring the dynamic profile security policy, configure FortiGate interfaces. This includes defining DHCP servers for the dmz and internal networks as these networks typically use DHCP. However, wan1 is assigned a static IP address by the ISP and does not need a DHCP server.

Table 84: FortiGate interfaces used in this example

Interface	Subnet	Act as DHCP Server	Devices
wan1	172.20.120.141	No	Internet Service Provider
dmz	10.11.101.100	Yes: x.x.x.110-.250	Servers, including RADIUS server
internal	10.11.102.100	Yes: x.x.x.110-.250	Internal user network

To configure FortiGate interfaces - web-based manager

1 Go to *System* > *Network* > *Interface*.

2 Select wan1 to edit.

3 Enter the following information and select OK.

Alias	Internet
Addressing Mode	Manual
IP/Netmask	172.20.120.141/255.255.255.0
Administrative Access	HTTPS, SSH
Comments	Internet
Administrative Status	Up

4 Select dmz to edit.

5 Enter the following information and select OK.

Alias	Servers
Addressing Mode	Manual
IP/Netmask	10.11.101.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING, SNMP
Comments	Servers
Administrative Status	Up

6 Select internal to edit.

7 Enter the following information and select OK.

Alias	Internal network
Addressing Mode	Manual
IP/Netmask	10.11.102.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING
Comments	Internal network
Administrative Status	Up

To configure DHCP servers - web-based manager

1 Go to *System* > *Network* > *DHCP Server*.

2 Select Create New.

3 Enter the following information and select OK.

Interface Name	dmz
Mode	Server

Enable	Select
Type	Regular
IP	10.11.101.110 - 10.11.101.250
Network mask	255.255.255.0
Default Gateway	10.11.101.100
DNS Service	Use System DNS Setting

4 Select Create New.

5 Enter the following information and select OK.

Interface Name	internal
Mode	Server
Enable	Select
Type	Regular
IP	10.11.102.110 - 10.11.102.250
Network mask	255.255.255.0
Default Gateway	10.11.102.100
DNS Service	Use System DNS Setting

Configuring dynamic profile RADIUS server on FortiGate

The FortiGate unit needs the RADIUS server information to be able to properly connect to it. Only one entry can be configured. If you cannot create one, ensure there is not already one configured.

The *Profile Key* entry must match the group name for users on the RADIUS server to be validated. Enable all logging if possible as it will assist with troubleshooting.

To configure the dynamic profile RADIUS server

1 Go to *User* > *Remote* > *RADIUS*, and *Create New*.

2 Enter the following information, and select OK.

Name	dynamic_profile_server
Type	Dynamic Start
Endpoint Attribute	Vendor-Specific
Profile Attribute	Vendor-Specific
Endpoint Blocking Attribute	Vendor-Specific
Send RADIUS Response	enable
Validate Radius Secret	enable
Profile Key	my_dyn_prof_group
Log All Events	enable

Configuring FortiGate regular and dynamic profile security policies

With the RADIUS server and FortiGate interfaces configured, security policies can be configured. This includes both dynamic profile and regular policies, as well as addresses and address groups. All policies require NAT to be enabled.

Table 85: security policies needed for dynamic profile

Seq. No.	From -> To	Type	Schedule	Description
1	internal -> wan1	dynamic profile	business hours	Authenticate outgoing user traffic.
2	internal -> wan1	regular	always	Allow essential network services and VoIP.
3	dmz -> wan1	regular	always	Allow servers to access Internet.
4	internal -> dmz	regular	always	Allow users to access servers.
5	any -> any	deny	always	Implicit deny all traffic that hasn't been matched

The dynamic profile policy must be placed at the top of the policy list so it is matched first. The only exception to this is if you have a policy to deny access to a list of banned users. In this case, that policy must go at the top so the dynamic profile does not mistakenly match a banned user or IP address.

This section includes:

- Schedules, address groups, and services groups
- Configuring regular security policies
- Configuring dynamic profile security policy

Schedules, address groups, and services groups

This section lists the lists that need to be configured before security policies are created. Creating these lists is straight forward, so the essential information has been provided here but not step by step instructions. For more information on firewall related details, see

Schedules

Only one schedule needs to be configured — `business_hours`. This is a fairly standard Monday to Friday 8am to 5pm schedule, or whatever days and hours covers standard work hours at the company.

Address groups

The following address groups need to be configured before the security policies.

Address group Name	Interface	Address range included
internal_network	internal	10.11.102.110 to 10.11.102.250
company_servers	dmz	10.11.101.110 to 10.11.101.250

Service groups

The following service groups need to be configured before the security policies. Note that the services listed are suggestions and may include more or less as required.

Service group Name	Interface	Description of services to be included
essential_network_services	internal	Any network protocols required for normal network operation such as DNS, NTP, BGP.
essential_server_services	dmz	All the protocols required by the company servers such as BGP, HTTP, HTTPS, FTP, IMAP, POP3, SMTP, IKE, SQL, MYSQL, NTP, TRACEROUTE, SOCKs, and SNMP.
dynamic_profile_services	internal	Any protocols required by users HTTP, HTTP, FTP,

The following security policy configurations are basic and only include logging, and default AV and IPS.

Configuring regular security policies

Regular security policies allow or deny all non-dynamic profile traffic. This is essential as there are network services—such as DNS, NTP, and FortiGuard—that require access to the Internet.

To configure regular security policies - web-based manager

1 Go to *Policy* > *Policy*, and select Create New.

2 Enter the following information, and select OK.

Source Interface/Zone	Internal
Source Address	internal_network
Destination Interface/Zone	wan1
Destination Address	all
Schedule	always
Service	essential_network_services
Action	ACCEPT
Log Allowed Traffic	enable
Enable NAT	enable
UTM	enable
Enable Antivirus	enable Default
Enable IPS	enable Default
Enable VoIP	enable Default
Comments	Essential network services

3 Select Create New, enter the following information, and select OK.

Source Interface/Zone	dmz
Source Address	company_servers
Destination Interface/Zone	wan1

Destination Address	all
Schedule	always
Service	essential_server_services
Action	ACCEPT
Log Allowed Traffic	enable
Enable NAT	enable
UTM	enable
Enable Antivirus	enable Default
Enable IPS	enable Default
Comments	Company servers accessing the Internet

4 Select Create New, enter the following information, and select OK.

Source Interface/Zone	Internal
Source Address	internal_network
Destination Interface/Zone	dmz
Destination Address	company_servers
Schedule	always
Service	all
Action	ACCEPT
Log Allowed Traffic	enable
Enable NAT	enable
UTM	enable
Enable Antivirus	enable Default
Enable IPS	enable Default
Comments	Access company servers

Configuring dynamic profile security policy

A dynamic profile security policy has less configuration than a regular security policy. Before configuring the policy, you must configure a UTM Profile Group. This group name must match the RADIUS user group name.

If *UTM* > *Profile Group* is not visible, to go *System* > *Admin* > *Settings* and display it on the GUI.

To configure UTM profile group

1 Go to *UTM* > *Profile Group* > *Profile Group*, and select *Create New*.

2 Enter the name `exampledotdcom_employees`.

3 Enable default Antivirus, IPS, Web Filter, Email Filter, and Protocol Options.

4 Select OK.

To configure dynamic profile security policy

1 Go to *Policy* > *Policy*, and select *Create New*.

2 Enter the following information, and select OK.

Source Interface/Zone	Internal
Source Address	internal_network
Destination Interface/Zone	wan1
Destination Address	all
Schedule	business_hours
Service	all
Action	ACCEPT
Log Allowed Traffic	enable
Enable NAT	enable
Enable Dynamic Profile	Enable
Profile Group	exampledotcom_employees
Dynamic Profile Users Only	enable
UTM	enable
Enable Antivirus	enable Default
Enable IPS	enable Default
Enable Web Filter	enable Default
Enable Email Filter	enable Default
Comments	Access company servers

Testing

Once configured, a user only needs to logon to their PC using their RADIUS account. After that when they attempt to access an Internet website, the FortiGate unit will use their session information to get their RADIUS information. Once the user is verified, they are allowed access to the website.

To test the configuration perform the following steps.

1 Have user plee logon to their PC, and try to access an Internet website.

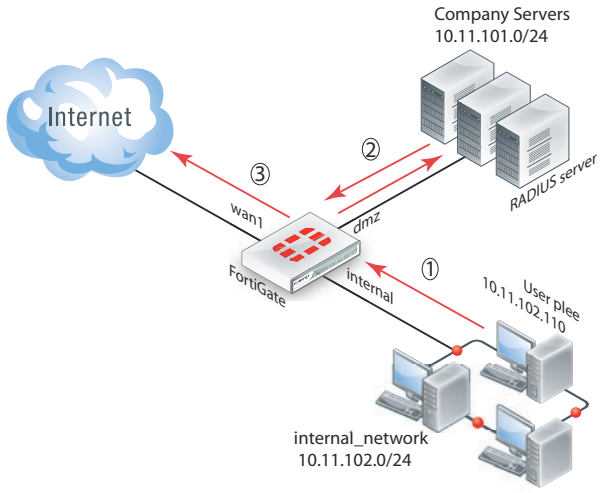
2 The FortiGate unit will contact the RADUS server for user plee's information.

3 Once confirmed, plee will have access to the website.

Each step generates log entries that enable you to verify that each step was successful.

If a step is unsuccessful, confirm your configuration is correct and see "Troubleshooting dynamic profiles" on page 1356.

Figure 122: Dynamic profile test



Troubleshooting

In the web-based manager, a good tool for troubleshooting is the packet counter column on the security policy page (*Policy* > *Policy*). This column displays the number of packets that have passed through this security policy. Its value when you are troubleshooting is that when you are testing your configuration (end to end connectivity, user authentication, policy use) watching the packet count for an increase confirms any other methods you may be using for troubleshooting. It provides the key of which policy is allowing the traffic, useful information if you expect a user to require authentication and it never happens. For more information about authentication security policies, see "Authentication in security policies" on page 1246.

This section addresses how to get more information from the CLI about users and user authentication attempts to help troubleshoot failed authentication attempts.

```
diag firewall iprope authuser
```

Shows the IP of where your computer is connected from. This is useful to confirm authorization and VPN settings.

```
diag firewall iprope resetauth
```

Clear all authorized users from the current list. Useful to force users to re-authenticate after system or group changes. However, this command may easily result in many users having to re-authenticate, so use carefully.

```
diag firewall auth list
```

List all the authorized users on this system.

```
diag debug disable
diag application auth 1
diag debug enable
```

See the stream of authentication system messages displayed enter the following commands. Best practices dictate the use of a terminal program that logs output so you can save the system messages to analyze later.

For more information on troubleshooting specific features, go to that section of this document. Most sections have troubleshooting information at the end of the section. In addition to that information, see the *FortiOS Handbook Troubleshooting chapter* for general troubleshooting information.

Chapter 8 IPsec VPNs

This FortiOS Handbook chaptercontains the following sections:

IPsec VPN concepts explains the basic concepts that you need to understand about virtual private networks (VPNs).

IPsec VPN Overview provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

IPsec VPN in the web-based manager describes the IPsec VPN menu of the web-based manager interface.

Gateway-to-gateway configurations explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN. In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks.

Hub-and-spoke configurations describes how to set up hub-and-spoke IPsec VPNs. In a hub-and-spoke configuration, connections to a number of remote peers and/or clients radiate from a single, central FortiGate hub.

Dynamic DNS configuration describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a dynamic IP address and a domain name.

FortiClient dialup-client configurations guides you through configuring a FortiClient dialup-client IPsec VPN. In a FortiClient dialup-client configuration, the FortiGate unit acts as a dialup server and VPN client functionality is provided by the FortiClient Endpoint Security application installed on a remote host.

FortiGate dialup-client configurations explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit with a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

Supporting IKE Mode config clients explains how to set up a FortiGate unit as either an IKE Mode Config server or client. IKE Mode Config is an alternative to DHCP over IPsec.

Internet-browsing configuration explains how to support secure web browsing performed by dialup VPN clients, and hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

Redundant VPN configurations discusses the options for supporting redundant and partially redundant tunnels in an IPsec VPN configuration. A FortiGate unit can be configured to support redundant tunnels to the same remote peer if the FortiGate unit has more than one interface to the Internet.

Transparent mode VPNs describes two FortiGate units that create a VPN tunnel between two separate private networks transparently. In transparent mode, all FortiGate unit interfaces except the management interface are invisible at the network layer.

Manual-key configurations explains how to manually define cryptographic keys to establish an IPsec VPN tunnel. If one VPN peer uses specific authentication and encryption keys to establish a tunnel, both VPN peers must use the same encryption and authentication algorithms and keys.

IPv6 IPsec VPNs describes FortiGate unit VPN capabilities for networks based on IPv6 addressing. This includes IPv4-over-IPv6 and IPv6-over-IPv4 tunnelling configurations. IPv6 IPsec VPNs are available in FortiOS 3.0 MR5 and later.

L2TP and IPsec (Microsoft VPN) explains how to support Microsoft Windows native VPN clients.

GRE over IPsec (Cisco VPN) configurations explains how to interoperate with Cisco VPNs that use Generic Routing Encapsulation (GRE) protocol with IPsec.

Protecting OSPF with IPsec provides an example of protecting OSPF links with IPsec.

Auto Key phase 1 parameters provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The basic phase 1 parameters identify the remote peer or clients and support authentication through preshared keys or digital certificates. You can increase VPN connection security further using methods such as extended authentication (XAuth).

Phase 2 parameters provides detailed step-by-step procedures for configuring an IPsec VPN tunnel. During phase 2, the specific IPsec security associations needed to implement security services are selected and a tunnel is established.

Defining VPN security policies explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN tunnel, and how to define a security encryption policy. Security policies control all IP traffic passing between a source address and a destination address.

Hardware offloading and acceleration explains how to make use of FortiASIC network processor IPsec accelerated processing capabilities.

Monitoring and troubleshooting provides VPN monitoring and testing procedures

IPsec VPN concepts

Virtual Private Network (VPN) technology enables remote users to connect to private computer networks to gain access to their resources in a secure way. For example, an employee traveling or working from home can use a VPN to securely access the office network through the Internet.

Instead of remotely logging on to a private network using an unencrypted and unsecure Internet connection, the use of a VPN ensures that unauthorized parties cannot access the office network and cannot intercept any of the information that is exchanged between the employee and the office. It is also common to use a VPN to connect the private networks of two or more offices.

Fortinet offers VPN capabilities in the FortiGate Unified Threat Management (UTM) appliance and in the FortiClient Endpoint Security suite of applications. A FortiGate unit can be installed on a private network, and FortiClient software can be installed on the user's computer. It is also possible to use a FortiGate unit to connect to the private network instead of using FortiClient software.

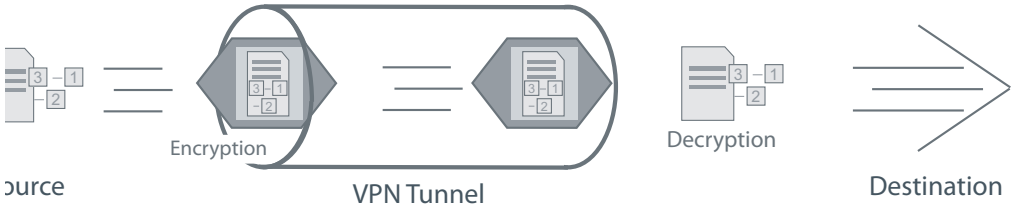
This chapter discusses VPN terms and concepts including:

VPN tunnels

The data path between a user's computer and a private network through a VPN is referred to as a tunnel. Like a physical tunnel, the data path is accessible only at both ends. In the telecommuting scenario, the tunnel runs between the FortiClient application on the user's PC, or a FortiGate unit or other network device and the FortiGate unit on the office private network.

Encapsulation makes this possible. IPsec packets pass from one end of the tunnel to the other and contain data packets that are exchanged between the local user and the remote private network. Encryption of the data packets ensures that any third-party who intercepts the IPsec packets can not access the data.

Figure 123: Encoded data going through a VPN tunnel



You can create a VPN tunnel between:

- a PC equipped with the FortiClient application and a FortiGate unit
- two FortiGate units
- third-party VPN software and a FortiGate unit

Third-party VPN software is not covered in this document. Refer to the Fortinet Knowledge Base for more information on this topic.

VPN gateways

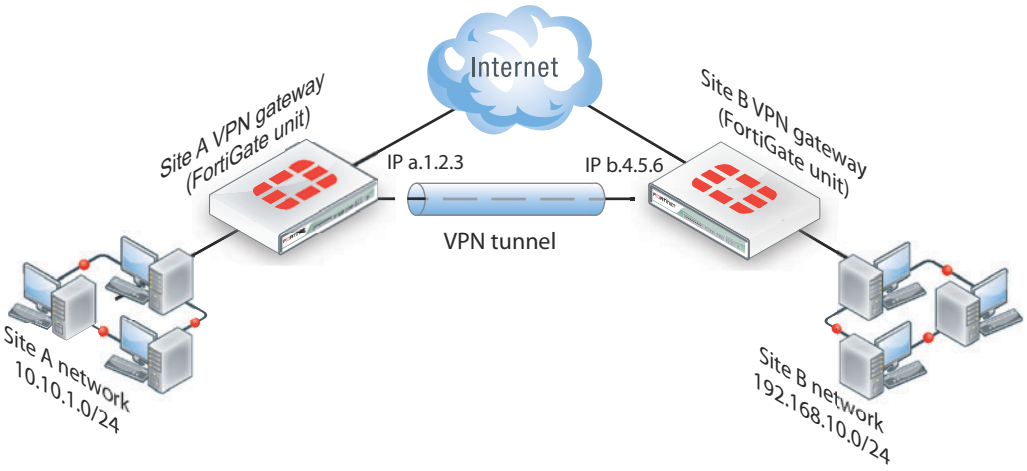
A gateway is a router that connects the local network to other networks. The default gateway setting in your computer's TCP/IP properties specifies the gateway for your local network.

A VPN gateway functions as one end of a VPN tunnel. It receives incoming IPsec packets, decrypts the encapsulated data packets and passes the data packets to the local network. Also, it encrypts data packets destined for the other end of the VPN tunnel, encapsulates them, and sends the IPsec packets to the other VPN gateway. The VPN gateway is a FortiGate unit because the private network behind it is protected, ensuring the security of the unencrypted VPN data. The gateway can also be FortiClient software running on a PC since the unencrypted data is secure on the PC.

The IP address of a VPN gateway is usually the IP address of the network interface that connects to the Internet. Optionally, you can define a secondary IP address for the interface and use that address as the local VPN gateway address. The benefit of doing this is that your existing setup is not affected by the VPN settings.

The following diagram shows a VPN connection between two private networks with FortiGate units acting as the VPN gateways. This configuration is commonly referred to as Gateway-to-Gateway IPsec VPN.

Figure 124: VPN tunnel between two private networks



Although the IPsec traffic may actually pass through many Internet routers, you can visualize the VPN tunnel as a simple secure connection between the two FortiGate units.

Users on the two private networks do not need to be aware of the VPN tunnel. The applications on their computers generate packets with the appropriate source and destination addresses, as they normally do. The FortiGate units manage all the details of encrypting, encapsulating and sending the packets to the remote VPN gateway.

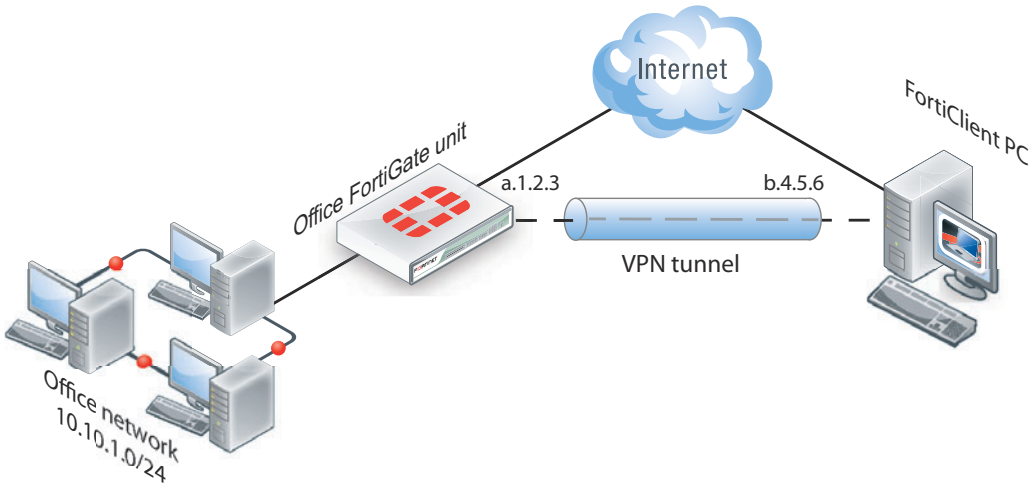
The data is encapsulated in IPsec packets only in the VPN tunnel between the two VPN gateways. Between the user's computer and the gateway, the data is on the secure private network and it is in regular IP packets.

For example User1 on the Site A network, at IP address 10.10.1.7, sends packets with destination IP address 192.168.10.8, the address of User2 on the Site B network. The Site A FortiGate unit is configured to send packets with destinations on the 192.168.10.0 network through the VPN, encrypted and encapsulated. Similarly, the Site B FortiGate unit is configured to send packets with destinations on the 10.10.1.0 network through the VPN tunnel to the Site A VPN gateway.

In the site-to-site, or gateway-to-gateway VPN shown in Figure 124, the FortiGate units have static (fixed) IP addresses and either unit can initiate communication.

You can also create a VPN tunnel between an individual PC running FortiClient and a FortiGate unit, as shown below. This is commonly referred to as Client-to-Gateway IPsec VPN.

Figure 125: VPN tunnel between a FortiClient PC and a FortiGate unit



On the PC, the FortiClient application acts as the local VPN gateway. Packets destined for the office network are encrypted, encapsulated into IPsec packets, and sent through the VPN tunnel to the FortiGate unit. Packets for other destinations are routed to the Internet as usual. IPsec packets arriving through the tunnel are decrypted to recover the original IP packets.

Clients, servers, and peers

A FortiGate unit in a VPN can have one of the following roles:

- ***server*** — responds to a request to establish a VPN tunnel.
- ***client*** — contacts a remote VPN gateway and requests a VPN tunnel.
- ***peer*** — brings up a VPN tunnel or responds to a request to do so.

The site-to-site VPN shown in Figure 124 is a peer-to-peer relationship. Either FortiGate unit VPN gateway can establish the tunnel and initiate communications. The FortiClient-to-FortiGate VPN shown in Figure 125 is a client-server relationship. The FortiGate unit establishes a tunnel when the FortiClient PC requests one.

A FortiGate unit cannot be a VPN server if it has a dynamically-assigned IP address. VPN clients need to be configured with a static IP address for the server.

A FortiGate unit acts as a server only when the remote VPN gateway has a dynamic IP address or is a client-only device or application, such as FortiClient.

As a VPN server, a FortiGate unit can also offer automatic configuration for FortiClient PCs. The user needs to know only the IP address of the FortiGate VPN server and a valid user name/password. FortiClient downloads the VPN configuration settings from the FortiGate VPN server. For information about configuring a FortiGate unit as a VPN server, see the *FortiClient Administration Guide*.

Encryption

Encryption mathematically transforms data to appear as meaningless random numbers. The original data is called plaintext and the encrypted data is called ciphertext. The opposite process, called decryption, performs the inverse operation to recover the original plaintext from the ciphertext.

The process by which the plaintext is transformed to ciphertext and back again is called an algorithm. All algorithms use a small piece of information, a key, in the arithmetic process of converted plaintext to ciphertext, or vice-versa. IPsec uses symmetrical algorithms, in which the same key is used to both encrypt and decrypt the data.

The security of an encryption algorithm is determined by the length of the key that it uses. FortiGate IPsec VPNs offer the following encryption algorithms, in descending order of security:

AES256	A 128-bit block algorithm that uses a 256-bit key.
AES192	A 128-bit block algorithm that uses a 192-bit key.
AES128	A 128-bit block algorithm that uses a 128-bit key.
3DES	Triple-DES, in which plain text is DES-encrypted three times by three keys.
DES	Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key

The default encryption algorithms provided on FortiGate units make recovery of encrypted data almost impossible without the proper encryption keys.

There is a human factor in the security of encryption. The key must be kept secret, known only to the sender and receiver of the messages. Also, the key must not be something that unauthorized parties might easily guess, such as the sender's name, birthday or simple sequence such as `123456`.

Authentication

In addition to protecting data through encryption, a VPN must ensure that only authorized users can access the private network. You must use either a preshared key on both VPN gateways or RSA X.509 security certificates. The examples in this guide use only preshared key authentication. Refer to the Fortinet Knowledge Base for articles on RSA X.509 security certificates.

Preshared keys

A preshared key contains at least six random alphanumeric characters. Users of the VPN must obtain the preshared key from the person who manages the VPN server and add the preshared key to their VPN client configuration.

Although it looks like a password, the preshared key, also known as a shared secret, is never sent by either gateway. The preshared key is used in the calculations at each end that generate the encryption keys. As soon as the VPN peers attempt to exchange encrypted data, preshared keys that do not match will cause the process to fail.

Additional authentication

To increase security, you can require additional means of authentication from users:

- an identifier, called a peer ID or a local ID
- extended authentication (XAUTH) which imposes an additional user name/password requirement

A Local ID is an alphanumeric value assigned in the Phase 1 configuration. The Local ID of a peer is called a Peer ID.

Phase 1 and Phase 2 settings

A VPN tunnel is established in two phases: Phase 1 and Phase 2. Several parameters determine how this is done. Except for IP addresses, the settings simply need to match at both VPN gateways. There are defaults that are appropriate for most cases.

FortiClient distinguishes between Phase 1 and Phase 2 only in the VPN Advanced settings and uses different terms. Phase 1 is called the IKE Policy. Phase 2 is called the IPsec Policy.

Phase 1

In Phase 1, the two VPN gateways exchange information about the encryption algorithms that they support and then establish a temporary secure connection to exchange authentication information.

When you configure your FortiGate unit or FortiClient application, you must specify the following settings for Phase 1:

Remote Gateway	The remote VPN gateway's address. FortiGate units also have the option of operating only as a server by selecting the "Dialup User" option.
Preshared key	This must be the same at both ends. It is used to encrypt phase 1 authentication information.
Local interface	The network interface that connects to the other VPN gateway. This applies on a FortiGate unit only.

All other Phase 1 settings have default values. These settings mainly configure the types of encryption to be used. The default settings on FortiGate units and in the FortiClient application are compatible. The examples in this guide use these defaults.

For more detailed information about Phase 1 settings, see the "Auto Key phase 1 parameters" on page 1407.

Phase 2

Similar to the Phase 1 process, the two VPN gateways exchange information about the encryption algorithms that they support for Phase 2. You may choose different encryption for Phase 1 and Phase 2. If both gateways have at least one encryption algorithm in common, a VPN tunnel can be established. Keep in mind that more algorithms each phase does not share with the other gateway, the longer negotiations will take. In extreme cases this may cause timeouts during negotiations.

To configure default Phase 2 settings on a FortiGate unit, you need only select the name of the corresponding Phase 1 configuration. In FortiClient, no action is required to enable default Phase 2 settings.

For more detailed information about Phase 2 settings, see "Phase 2 parameters" on page 1425.

Security Association

The establishment of a Security Association (SA) is the successful outcome of Phase 1 negotiations. Each peer maintains a database of information about VPN connections. The information in each SA can include cryptographic algorithms and keys, keylife, and the current packet sequence number. This information is kept synchronized as the VPN operates. Each SA has a Security Parameter Index (SPI) that is provided to the remote peer at the time the SA is established. Subsequent IPsec packets from the peer always reference the relevant SPI. It is possible for peers to have multiple VPNs active simultaneously, and correspondingly multiple SPIs.

IPsec VPN Overview

This section provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

The following topics are included in this section:

- Types of VPNs
- Planning your VPN
- General preparation steps
- How to use this guide to configure an IPsec VPN

VPN configurations interact with the firewall component of the FortiGate unit. There must be a security policy in place to permit traffic to pass between the private network and the VPN tunnel.

Security policies for VPNs specify:

- the FortiGate interface that provides the physical connection to the remote VPN gateway, usually an interface connected to the Internet
- the FortiGate interface that connects to the private network
- IP addresses associated with data that has to be encrypted and decrypted
- optionally, a schedule that restricts when the VPN can operate
- optionally, the services (types of data) that can be sent

When the first packet of data that meets all of the conditions of the security policy arrives at the FortiGate unit, a VPN tunnel may be initiated and the encryption or decryption of data is performed automatically afterward. For more information, see “Defining VPN security policies” on page 1431.

Types of VPNs

FortiGate unit VPNs can be policy-based or route-based. There is little difference between the two types. In both cases, you specify phase 1 and phase 2 settings. However there is a difference in implementation. A route-based VPN creates a virtual IPsec network interface that applies encryption or decryption as needed to any traffic that it carries. That is why route-based VPNs are also known as interface-based VPNs. A policy-based VPN is implemented through a special security policy that applies the encryption you specified in the phase 1 and phase 2 settings.

Route-based VPNs

For a route-based VPN, you create two security policies between the virtual IPsec interface and the interface that connects to the private network. In one policy the virtual interface is the source. In the other policy the virtual interface is the destination. The Action for both policies is Accept. This creates bidirectional policies that ensure traffic will flow in both directions over the VPN.

Policy-based VPNs

For a policy-based VPN, one security policy enables communication in both directions. You must select IPSEC as the Action and then select the VPN tunnel you defined in the phase 1 settings. You can then enable inbound and outbound traffic as needed within that policy, or create multiple policies of this type to handle different types of traffic differently. For example HTTPS traffic may not require the same level of scanning as FTP traffic.

Comparing policy-based or route-based VPNs

For both VPN types you create phase 1 and phase 2 configurations. Both types are handled in the stateful inspection security layer, assuming there is no IPS or AV. For more information on the security layers, see "Life of a Packet" on page 699.

The main difference is in the security policy.

You create a policy-based VPN by defining an IPSEC security policy between two network interfaces and associating it with the VPN tunnel (phase 1) configuration.

You create a route-based VPN by enabling IPsec interface mode in the VPN phase 1 configuration. This creates a virtual IPsec interface. You then define a regular ACCEPT security policy to permit traffic to flow between the virtual IPsec interface and another network interface. And lastly, configure a static route to allow traffic over the VPN.

Where possible, you should create route-based VPNs. Generally, route-based VPNs are more flexible and easier to configure than policy-based VPNs — by default they are treated as interfaces. However, these two VPN types have different requirements that limit where they can be used.

Table 86: Comparison of policy-based and route-based VPNs

Features	Policy-based	Route-based
• Both NAT and transparent modes available	• Yes	• NAT mode only
• L2TP-over-IPsec supported	• Yes	• No
• GRE-over-IPsec supported	• No	• Yes
• security policy requirements	• Requires a security policy with IPSEC action that specifies the VPN tunnel	• Requires only a simple security policy with ACCEPT action
• Number of policies per VPN	• One policy controls connections in both directions	• A separate policy is required for connections in each direction

Planning your VPN

It is a good idea to plan the VPN configuration ahead of time. This will save time later and be help you configure your VPN correctly.

All VPN configurations comprise a number of required and optional parameters. Before you begin, you need to determine:

- where does the IP traffic originate and where does it need to be delivered
- which hosts, servers, or networks to include in the VPN

- which VPN devices to include in the configuration
- through which interfaces the VPN devices communicate
- through which interfaces do private networks access the VPN gateways

Once you have this information, you can select a VPN topology that meets the requirements of your situation.

Network topologies

The topology of your network will determine how remote peers and clients connect to the VPN and how VPN traffic is routed. You can read about various network topologies and find the high-level procedures needed to configure IPsec VPNs in one of these sections.

Table 87: VPN network topologies and brief descriptions

Topology	Description
Gateway-to-gateway configurations	Standard one-to-one VPN between two FortiGate units. See "Gateway-to-gateway configurations" on page 1437.
Hub-and-spoke configurations	One central FortiGate unit has multiple VPNs to other remote FortiGate units. See "Hub-and-spoke configurations" on page 1453.
Dynamic DNS configuration	One end of the VPN tunnel has a changing IP address and the other end must go to a dynamic DNS server for the current IP address before establishing a tunnel. See "Dynamic DNS configuration" on page 1469.
FortiClient dialup-client configurations	Typically remote FortiClient dialup-clients use dynamic IP addresses through NAT devices. The FortiGate unit acts as a dialup server allowing dialup VPN connections from multiple sources. See "FortiClient dialup-client configurations" on page 1483.
FortiGate dialup-client configurations	Similar to FortiClient dialup-client configurations but with more gateway-to-gateway settings such as unique user authentication for multiple users on a single VPN tunnel. See "FortiGate dialup-client configurations" on page 1501.
Internet-browsing configuration	Secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. See "Internet-browsing configuration" on page 1515.
Redundant VPN configurations	Options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches. See "Redundant VPN configurations" on page 1519.
Transparent mode VPNs	In transparent mode, the FortiGate acts as a bridge with all incoming traffic being broadcast back out on all other interfaces. Routing and NAT must be performed on external routers. See "Transparent mode VPNs" on page 1543.
Manual-key configurations	Manually define cryptographic keys to establish an IPsec VPN, either policy-based or route-based. See "Manual-key configurations" on page 1551.
L2TP and IPsec (Microsoft VPN)	Configure VPN for Microsoft Windows dialup clients using the built in L2TP software. Users do not have to install any See "L2TP and IPsec (Microsoft VPN)" on page 1567.

These sections contain high-level configuration guidelines with cross-references to detailed configuration procedures. If you need more detail to complete a step, select the cross-reference in the step to drill-down to more detail. Return to the original procedure to complete the procedure. For a general overview of how to configure a VPN, see "General preparation steps" below.

General preparation steps

A VPN configuration defines relationships between the VPN devices and the private hosts, servers, or networks making up the VPN. Configuring a VPN involves gathering and recording the following information. You will need this information to configure the VPN.

- **The private IP addresses of participating hosts, servers, and/or networks.** These IP addresses represent the source addresses of traffic that is permitted to pass through the VPN. A IP source address can be an individual IP address, an address range, or a subnet address.
- **The public IP addresses of the VPN end-point interfaces.** The VPN devices establish tunnels with each other through these interfaces.
- **The private IP addresses associated with the VPN-device interfaces to the private networks.** Computers on the private networks behind the VPN gateways will connect to their VPN gateways through these interfaces.

How to use this guide to configure an IPsec VPN

This guide uses a task-based approach to provide all of the procedures needed to create different types of VPN configurations. Follow the step-by-step configuration procedures in this guide to set up the VPN.

The following configuration procedures are common to all IPsec VPNs:

1. Define the phase 1 parameters that the FortiGate unit needs to authenticate remote peers or clients and establish a secure a connection. See "Auto Key phase 1 parameters" on page 1407.
2. Define the phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with a remote peer or dialup client. See "Phase 2 parameters" on page 1425.
3. Specify the source and destination addresses of IP packets that are to be transported through the VPN tunnel. See "Defining policy addresses" on page 1431.
4. Create an IPsec security policy to define the scope of permitted services between the IP source and destination addresses. See "Defining VPN security policies" on page 1432.

These steps assume you configure the FortiGate unit to generate unique IPsec encryption and authentication keys automatically. In situations where a remote VPN peer or client requires a specific IPsec encryption and authentication key, you must configure the FortiGate unit to use manual keys instead of performing Steps 1 and 2. For more information, see "Manual-key configurations" on page 1551.

IPsec VPN in the web-based manager

The IPsec VPN menu in FortiOS provides settings to configure an IPsec VPN. IPsec VPNs that are configured by using the general procedure:

1 Define phase 1 parameters to authenticate remote peers and clients for a secure connection. See “Phase 1 configuration” on page 1394.

2 Define phase 2 parameters to create a VPN tunnel with a remote peer or dialup client. See “Phase 2 configuration” on page 1399.

With these steps, your FortiGate unit will automatically generate unique IPsec encryption and authentication keys. If a remote VPN peer or client requires a specific IPsec encryption or authentication key, you must configure your FortiGate unit to use manual keys instead. See “Manual Key” on page 1403.

3 Create a security policy to permit communication between your private network and the VPN. Policy-based VPNs have an action of IPSEC, where for interface-based VPNs the security policy action is ACCEPT. See “Defining VPN security policies” on page 1431.

The FortiGate unit implements the Encapsulated Security Payload (ESP) protocol. Internet Key Exchange (IKE) is performed automatically based on pre-shared keys or X.509 digital certificates. As an option, you can specify manual keys. Interface mode, supported in NAT mode only, creates a virtual interface for the local end of a VPN tunnel.

This topic contains the following:

Auto Key (IKE)

You can configure VPN peers (or a FortiGate dialup server and a VPN client) to generate unique Internet Key Exchange (IKE) keys automatically during the IPsec phase 1 and phase 2 exchanges.

When you define phase 2 parameters, you can choose any set of phase 1 parameters to set up a secure connection for the tunnel and authenticate the remote peer. Auto Key configuration applies to both tunnel-mode and interface-mode VPNs.

To configure VPN peers go to *VPN* > *IPsec* > *Auto Key (IKE)*.

Auto Key (IKE) page	
Create Phase 1	Creates a new phase 1 tunnel configuration. For more information, see "Phase 1 configuration" on page 1394.
Create Phase 2	Creates a new phase 2 configuration. For more information, see "Phase 2 configuration" on page 1399.
Create FortiClient VPN	Creates a new FortiClient VPN. For more information, see "FortiClient VPN" on page 1402.

If you want to control how the IKE negotiation process controls traffic when there is no traffic, as well as the length of time the FortiGate unit waits for negotiations to occur, use the `negotiation-timeout` and `auto-negotiation` commands in the CLI.

Phase 1 configuration

The basic phase 1 settings associate IPsec phase 1 parameters with a remote gateway, if a pre-shared key or digital certificate will be used, and if a special identifier will be used to identify the remote VPN peer or client.

New Phase 1 page	
Name	Type a name for the phase 1 definition. The maximum name length is 15 characters for an interface mode VPN, 35 characters for a policy-based VPN. If *Remote Gateway* is *Dialup User*, the maximum name length is further reduced depending on the number of dialup tunnels that can be established: by 2 for up to 9 tunnels, by 3 for up to 99 tunnels, 4 for up to 999 tunnels, and so on. For a tunnel mode VPN, the name normally reflects where the remote connection originates. For a route-based tunnel, the FortiGate unit also uses the name for the virtual IPsec interface that it creates automatically.
Remote Gateway	Select the category of the remote connection: • *Static IP Address* — If the remote peer has a static IP address. • *Dialup User* — If one or more FortiClient or FortiGate dialup clients with dynamic IP addresses will connect to the FortiGate unit. • *Dynamic DNS* — If a remote peer that has a domain name and subscribes to a dynamic DNS service will connect to the FortiGate unit.
IP Address	If you selected *Static IP Address*, enter the IP address of the remote peer.
Dynamic DNS	If you selected *Dynamic DNS*, enter the domain name of the remote peer.

Local Interface	This option is available in NAT mode only. Select the name of the interface through which remote peers or dialup clients connect to the FortiGate unit. By default, the local VPN gateway IP address is the IP address of the interface that you selected. Optionally, you can specify a unique IP address for the VPN gateway in the *Advanced* settings.
Mode	Select *Main (ID Protection)* or *Aggressive*: • *Main mode* — the phase 1 parameters are exchanged in multiple rounds with encrypted authentication information. • *Aggressive mode* — the phase 1 parameters are exchanged in single message with authentication information that is not encrypted. When the remote VPN peer has a dynamic IP address and is authenticated by a pre-shared key, you must select Aggressive mode if there is more than one dialup phase1 configuration for the interface IP address. When the remote VPN peer has a dynamic IP address and is authenticated by a certificate, you must select Aggressive mode if there is more than one phase 1 configuration for the interface IP address and these phase 1 configurations use different proposals.
Authentication Method	Select *Preshared Key* or *RSA Signature*.
Pre-shared Key	If you selected *Pre-shared Key*, enter the pre-shared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during phase 1 negotiations. You must define the same key at the remote peer or client. The key must contain at least 6 printable characters. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.
Certificate Name	If you selected *RSA Signature*, select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during phase 1 negotiations. For information about obtaining and loading the required server certificate, see the *FortiOS User Authentication guide*.
Peer Options	Peer options are available to authenticate VPN peers or clients, depending on the *Remote Gateway* and *Authentication Method* settings.
Accept any peer ID	Accept the local ID of any remote VPN peer or client. The FortiGate unit does not check identifiers (local IDs). You can set *Mode* to *Aggressive* or *Main*. You can use this option with RSA Signature authentication. But, for highest security, configure a PKI user/group for the peer and set *Peer Options* to *Accept this peer certificate only*.

Accept this peer ID	This option is available when *Aggressive Mode* is enabled. Enter the identifier that is used to authenticate the remote peer. This identifier must match the Local ID that the remote peer's administrator has configured. If the remote peer is a FortiGate unit, the identifier is specified in the *Local ID* field of the Advanced phase 1 configuration. If the remote peer is a FortiClient user, the identifier is specified in the *Local ID* field, accessed by selecting *Config* in the *Policy* section of the VPN connection's *Advanced Settings*.
Accept peer ID in dialup group	Authenticate multiple FortiGate or FortiClient dialup clients that use unique identifiers and unique pre-shared keys (or unique pre-shared keys only) through the same VPN tunnel. You must create a dialup user group for authentication purposes. Select the group from the list next to the *Accept peer ID in dialup group* option. You must set *Mode* to *Aggressive* when the dialup clients use unique identifiers and unique pre-shared keys. If the dialup clients use unique pre-shared keys only, you can set *Mode* to *Main* if there is only one dialup phase 1 configuration for this interface IP address.
Advanced	Defines advanced phase 1 parameters. For more information, see Phase 1 advanced configuration settings.

Phase 1 advanced configuration settings

You use the advanced parameters to select the encryption and authentication algorithms that the FortiGate unit uses to generate keys for the IKE exchange. You can also select these advanced settings to ensure the smooth operation of phase 1 negotiations.

To configure Phase 1settings, go to *VPN* > *Auto Key (IKE)* and select *Create Phase 1*.

Advanced section of the New Phase 1 page	
Enable IPsec Interface Mode	This is available in NAT mode only. Create a virtual interface for the local end of the VPN tunnel. Select this option to create a route-based VPN, clear it to create a policy-based VPN.
IKE Version	Select the version of IKE to use. This is available only if *IPsec Interface Mode* is enabled. For more information about IKE v2, refer to RFC 4306. IKE v2 is not available if *Mode* is *Aggressive*. When *IKE Version* is *2*, *Mode* and *XAUTH* are not available.
IPv6 Version	Select if you want to use IPv6 addresses for the remote gateway and interface IP addresses. This is available only when *Enable IPsec Interface Mode* is selected and IPv6 Support is enabled in the administrative settings (*System* > *Admin* > *Settings*).

Local Gateway IP	If you selected *Enable IPsec Interface Mode*, specify an IP address for the local end of the VPN tunnel. Select one of the following: • *Main Interface IP* — The FortiGate unit obtains the IP address of the interface from the network interface settings. • *Specify* — Enter a secondary address of the interface selected in the phase 1 *Local Interface* field. For more information, see "Local Interface" on page 1395. You cannot configure Interface mode in a transparent mode VDOM.
P1 Proposal	Select the encryption and authentication algorithms used to generate keys for protecting negotiations and add encryption and authentication algorithms as required. You need to select a minimum of one and a maximum of three combinations. The remote peer or client must be configured to use at least one of the proposals that you define.
	Select one of the following symmetric-key encryption algorithms: • *DES* — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. • *3DES* — Triple-DES, in which plain text is encrypted three times by three keys. • *AES128* — a 128-bit block Cipher Block Chaining (CBC) algorithm that uses a 128-bit key. • *AES192* — a 128-bit block Cipher Block Chaining (CBC) algorithm that uses a 192-bit key. • *AES256* — a 128-bit block Cipher Block Chaining (CBC) algorithm that uses a 256-bit key.
	Select either of the following authentication message digests to check the authenticity of messages during phase 1 negotiations: • *MD5* — Message Digest 5, the hash algorithm developed by RSA Data Security. • *SHA1* — Secure Hash Algorithm 1, which produces a 160-bit message digest. • *SHA256* — Secure Hash Algorithm 2, which produces a 256-bit message digest. To specify a third combination, use the *Add* button beside the fields for the second combination.
DH Group	Select one or more Diffie-Hellman groups from DH group 1, 2, 5 and 14. At least one of the *DH Group* settings on the remote peer or client must match one the selections on the FortiGate unit. Failure to match one or more DH groups will result in failed negotiations.
Keylife	Enter the time (in seconds) that must pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172 800 seconds.

Local ID	If the FortiGate unit will act as a VPN client and you are using peer IDs for authentication purposes, enter the identifier that the FortiGate unit will supply to the VPN server during the phase 1 exchange. If the FortiGate unit will act as a VPN client, and you are using security certificates for authentication, select the distinguished name (DN) of the local server certificate that the FortiGate unit will use for authentication purposes. If the FortiGate unit is a dialup client and will not be sharing a tunnel with other dialup clients (that is, the tunnel will be dedicated to this FortiGate dialup client), set *Mode* to *Aggressive*. Note that this Local ID value must match the peer ID value given for the remote VPN peer's Peer Options.
XAuth	This option supports the authentication of dialup clients. It is available for IKE v1 only. • *Disable* — Select if you do not use XAuth. • *Enable as Client* — If the FortiGate unit is a dialup client, enter the user name and password that the FortiGate unit will need to authenticate itself to the remote XAuth server. • *Enable as Server* — This is available only if *Remote Gateway* is set to *Dialup User*. Dialup clients authenticate as members of a dialup user group. You must first create a user group for the dialup clients that need access to the network behind the FortiGate unit. You must also configure the FortiGate unit to forward authentication requests to an external RADIUS or LDAP authentication server. Select a *Server Type* setting to determine the type of encryption method to use between the FortiGate unit, the XAuth client and the external authentication server, and then select the user group from the User Group list.
Username	Enter the user name that is used for authentication.
Password	Enter the password that is used for authentication.
NAT Traversal	Select the check box if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared) to connect reliably.

Keepalive Frequency	If you enabled *NAT-traversal*, enter a keepalive frequency setting.
Dead Peer Detection	Select this check box to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. You can use this option to receive notification whenever a tunnel goes up or down, or to keep the tunnel connection open when no traffic is being generated inside the tunnel. For example, in scenarios where a dialup client or dynamic DNS peer connects from an IP address that changes periodically, traffic may be suspended while the IP address changes. With *Dead Peer Detection* selected, you can use the `config vpn ipsec phase1` (tunnel mode) or `config vpn ipsec phase1-interface` (interface mode) CLI command to optionally specify a retry count and a retry interval.

Phase 2 configuration

After IPsec phase 1 negotiations end successfully, you begin phase 2. You configure the phase 2 parameters to define the algorithms that the FortiGate unit may use to encrypt and transfer data for the remainder of the session. During phase 2, you select specific IPsec security associations needed to implement security services and establish a tunnel.

The basic phase 2 settings associate IPsec phase 2 parameters with the phase 1 configuration that specifies the remote end point of the VPN tunnel. In most cases, you need to configure only basic phase 2 settings.

To configure Phase 2 settings, go to *VPN* > *Auto Key (IKE)* and select *Create Phase 2*.

New Phase 2 page	
Name	Type a name to identify the phase 2 configuration.
Phase 1	Select the phase 1 tunnel configuration. For more information on configuring phase 1, see "Phase 1 configuration" on page 1394. The phase 1 configuration describes how remote VPN peers or clients will be authenticated on this tunnel, and how the connection to the remote peer or client will be secured.
Advanced	Define advanced phase 2 parameters. For more information, see "Phase 2 advanced configuration settings" on page 1399.

Phase 2 advanced configuration settings

In phase 2, the FortiGate unit and the VPN peer or client exchange keys again to establish a secure communication channel between them. You select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). These are called P2 Proposal parameters. The keys are generated automatically using a Diffie-Hellman algorithm.

You can use a number of additional advanced phase 2 settings to enhance the operation of the tunnel.

Advanced section of New Phase 2 page	
P2 Proposal	Select the encryption and authentication algorithms that will be proposed to the remote VPN peer. You can specify up to three proposals. To establish a VPN connection, at least one of the proposals that you specify must match configuration on the remote peer. Initially there are two proposals. *Add* and *Delete* icons are next to the second *Authentication* field. It is invalid to set both *Encryption* and *Authentication* to NULL.
Encryption	Select one of the following symmetric-key algorithms: • *NULL* — Do not use an encryption algorithm. • *DES* — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. • *3DES* — Triple-DES, in which plain text is encrypted three times by three keys. • *AES128* — a 128-bit block Cipher Block Chaining (CBC) algorithm that uses a 128-bit key. • *AES192* — a 128-bit block CBC algorithm that uses a 192-bit key. • *AES256* — a 128-bit block CBC algorithm that uses a 256-bit key.
Authentication	Select one of the following message digests to check the authenticity of messages during an encrypted session: • *NULL* — Do not use a message digest. • *MD5* — Message Digest 5, the hash algorithm developed by RSA Data Security. • *SHA1* — Secure Hash Algorithm 1, which produces a 160-bit message digest. • *SHA256* — Secure Hash Algorithm 2, which produces a 256-bit message digest. • *SHA384* — Secure Hash Algorithm 2, which produces a 384-bit message digest. • *SHA512* — Secure Hash Algorithm 2, which produces a 512-bit message digest.
Enable replay detection	Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.
Enable perfect forward secrecy (PFS)	Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.
DH Group	Select one Diffie-Hellman group (1, 2, 5 or 14). This must match the DH Group that the remote peer or dialup client uses.
Keylife	Select the method for determining when the phase 2 key expires: *Seconds*, *KBytes*, or *Both*. If you select *Both*, the key expires when either the time has passed or the number of KB have been processed.

Autokey Keep Alive	Select the check box if you want the tunnel to remain active when no data is being processed.
DHCP-IPSec	Provide IP addresses dynamically to VPN clients. This is available for phase 2 configurations associated with a dialup phase 1 configuration. You also need configure a DHCP server or relay on the private network interface. You must configure the DHCP parameters separately. If you configure the DHCP server to assign IP addresses based on RADIUS user group attributes, you must also set the Phase 1 *Peer Options* to *Accept peer ID in dialup group* and select the appropriate user group. See "Phase 1 configuration" on page 1394. If the FortiGate unit acts as a dialup server and you manually assigned FortiClient dialup clients VIP addresses that match the network behind the dialup server, selecting the check box will cause the FortiGate unit to act as a proxy for the dialup clients.
Quick Mode Selector	Specify the source and destination IP addresses to be used as selectors for IKE negotiations. If the FortiGate unit is a dialup server, keep the default value of 0.0.0.0/0 unless you need to circumvent problems caused by ambiguous IP addresses between one or more of the private networks making up the VPN. You can specify a single host IP address, an IP address range, or a network address. You may optionally specify source and destination port numbers and a protocol number. If you are editing an existing phase 2 configuration, the *Source address* and *Destination address* fields are unavailable if the tunnel has been configured to use firewall addresses as selectors. This option exists only in the CLI.
Source address	If the FortiGate unit is a dialup server, enter the source IP address that corresponds to the local senders or network behind the local VPN peer (for example, `172.16.5.0/24` or `172.16.5.0/255.255.255.0` for a subnet, or `172.16.5.1/32` or `172.16.5.1/255.255.255.255` for a server or host, or `192.168.10.[80-100]` or `192.168.10.80-192.168.10.100` for an address range). A value of `0.0.0.0/0` means all IP addresses behind the local VPN peer. If the FortiGate unit is a dialup client, source address must refer to the private network behind the FortiGate dialup client.
Source port	Enter the port number that the local VPN peer uses to transport traffic related to the specified service (protocol number). The range is from 0 to 65535. To specify all ports, type `0`.
Destination address	Enter the destination IP address that corresponds to the recipients or network behind the remote VPN peer (for example, `192.168.20.0/24` for a subnet, or `172.16.5.1/32` for a server or host, or `192.168.10.[80-100]` for an address range). A value of `0.0.0.0/0` means all IP addresses behind the remote VPN peer.
Destination port	Enter the port number that the remote VPN peer uses to transport traffic related to the specified service (protocol number). To specify all ports, enter `0`.
Protocol	Enter the IP protocol number of the service. To specify all services, enter `0`.

FortiClient VPN

Use the FortiClient VPN configuration settings when configuring an IPsec VPN for FortiClient. When configuring a FortiClient VPN connection, the settings for phase 1 and phase 2 settings are automatically configured by the FortiGate unit. They are set to:

- Remote Gateway — Dialup User
- Mode — Aggressive
- IPSec Interface Mode — Enabled
- Default settings for P1 and P2 Proposal
- XAUTH Enable as Server (Auto)
- IKE mode-config will be enabled
- Peer Option — "Accept any peer ID"

The remainder of the settings use the current FortiGate defaults. Note that FortiClient settings need to match these FortiGate defaults.

If you need to configure advanced settings for the FortiClient VPN, select *Edit* on the Auto Key (IKE) page (Go to *VPN* > *IPsec* > *Auto Key (IKE)*) and configure the peer options or advanced options.

New FortiClient VPN page	
Name	Enter a name for the FortiClient VPN.
Local Outgoing Interface	Select the local outgoing interface for the VPN.
Authentication Method	Select the type of authentication used when logging in to the VPN.
Preshared Key	If *Pre-shared Key* was selected in *Authentication Method*, enter the pre-shared key in the field provided.
User Group	Select a user group. You can also create a user group from the drop-down list by selecting *Create New*.
Address Range Start IP	Enter the start IP address for the DHCP address range for the client.
Address Range End IP	Enter the end IP address for the address range.
Subnet Mask	Enter the subnet mask.
Enable IPv4 Split Tunnel	Enabled by default, this option enables the FortiClient user to use the VPN to access internal resources while other Internet access is not sent over the VPN, alleviating potential traffic bottlenecks in the VPN connection. Disable this option to have all traffic sent through the VPN tunnel.
DNS Server	Select which DNS server to use for this VPN: • *Use System DNS* — Use the same DNS servers as the FortiGate unit. These are configured at System > Interface > DNS. This is the default option. • *Specify* — Specify the IP address of a different DNS server.

Manual Key

Use manual keys only if it is unavoidable. There are potential difficulties in keeping keys confidential and in propagating changed keys to remote VPN peers securely.

If required, you can manually define cryptographic keys for establishing an IPsec VPN tunnel. You would define manual keys in situations where:

- you require prior knowledge of the encryption or authentication key (that is, one of the VPN peers requires a specific IPsec encryption or authentication key).
- you need to disable encryption and authentication.

In both cases, you do not specify IPsec phase 1 and phase 2 parameters; you define manual keys by going to *VPN* > *IPsec* > *Manual Key* instead.

Manual key configuration settings

If you are not familiar with the security policies, SAs, selectors, and SA databases for your particular installation, do not attempt these procedures without qualified assistance.

If one of the VPN devices is manually keyed, the other VPN device must also be manually keyed with the identical authentication and encryption keys. In addition, it is essential that both VPN devices be configured with complementary Security Parameter Index (SPI) settings. The administrators of the devices need to cooperate to achieve this.

Each SPI identifies a Security Association (SA). The value is placed in ESP datagrams to link the datagrams to the SA. When an ESP datagram is received, the recipient refers to the SPI to determine which SA applies to the datagram. You must manually specify an SPI for each SA. There is an SA for each direction, so for each VPN you must specify two SPIs, a local SPI and a remote SPI, to cover bidirectional communications between two VPN devices.

To add a manual key, go to *VPN* > *IPsec* > *Manual Key* and select *Create New*.

New Manual Key page	
Name	Type a name for the VPN tunnel. The maximum name length is 15 characters for an interface mode VPN, 35 characters for a policy-based VPN.
Local SPI	Type a hexadecimal number (up to 8 characters, 0-9, a-f) that represents the SA that handles outbound traffic on the local FortiGate unit. The valid range is from `0x100` to `0xffffffff`. This value must match the Remote SPI value in the manual key configuration at the remote peer.
Remote SPI	Type a hexadecimal number (up to 8 characters, 0-9, a-f) that represents the SA that handles inbound traffic on the local FortiGate unit. The valid range is from `0x100` to `0xffffffff`. This value must match the Local SPI value in the manual key configuration at the remote peer.
Remote Gateway	Enter the IP address of the public interface to the remote peer. The address identifies the recipient of ESP datagrams.

Local Interface	This option is available in NAT mode only. Select the name of the interface to which the IPsec tunnel will be bound. The FortiGate unit obtains the IP address of the interface from the network interface settings.
Encryption Algorithm	Select one of the following symmetric-key encryption algorithms: • *NULL* — Do not use an encryption algorithm. • *DES* — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. • *3DES* — Triple-DES, where plain text is encrypted three times by three keys. • *AES128* — a 128-bit block Cipher Block Chaining algorithm that uses a 128-bit key. • *AES192* — a 128-bit block Cipher Block Chaining) algorithm that uses a 192-bit key. • *AES256* — a 128-bit block Cipher Block Chaining algorithm that uses a 256-bit key. **Note:** The algorithms for encryption and authentication cannot both be NULL.
Authentication Algorithm	Select one of the following message digests: • *NULL* **—** Do not use a message digest. • *MD5* — Message Digest 5 algorithm, which produces a 128-bit message digest. • *SHA1* — Secure Hash Algorithm 1, which produces a 160-bit message digest. • *SHA256* — Secure Hash Algorithm 2, which produces a 256-bit message digest. • *SHA384* – Secure Hash Algorithm 2, which produces a 384-bit message digest. • *SHA512 – Secure Has Algorithm 2, which produces a 512-bit message digest.* **Note:** The Algorithms for encryption and authentication cannot both be NULL.
IPsec Interface Mode	Create a virtual interface for the local end of the VPN tunnel. Select this check box to create a route-based VPN, clear it to create a policy-based VPN. This is available only in NAT mode.

Concentrator

In a hub-and-spoke configuration, policy-based VPN connections to a number of remote peers radiate from a single, central FortiGate unit. Site-to-site connections between the remote peers do not exist; however, you can establish VPN tunnels between any two of the remote peers through the FortiGate unit's "hub".

In a hub-and-spoke network, all VPN tunnels terminate at the hub. The peers that connect to the hub are known as "spokes". The hub functions as a concentrator on the network, managing all VPN connections between the spokes. VPN traffic passes from one tunnel to the other through the hub.

You define a concentrator to include spokes in the hub-and-spoke configuration. You create the concentrator in *VPN* > *IPSec* > *Concentrator* and select *Create New*. A concentrator configuration specifies which spokes to include in an IPsec hub-and-spoke configuration.

New VPN Concentrator page	
Concentrator Name	Type a name for the concentrator.
Available Tunnels	A list of defined IPsec VPN tunnels. Select a tunnel from the list and then select the right arrow.
Members	A list of tunnels that are members of the concentrator. To remove a tunnel from the concentrator, select the tunnel and select the left arrow.

IPsec Monitor

You can use the IPsec Monitor to view activity on IPsec VPN tunnels and start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels, including tunnel mode and route-based (interface mode) tunnels.

To view the IPsec monitor, go to *VPN* > *Monitor* > *IPsec Monitor*.

For dialup VPNs, the list provides status information about the VPN tunnels established by dialup clients, and their IP addresses.

For static IP or dynamic DNS VPNs, the list provides status and IP addressing information about VPN tunnels, active or not, to remote peers that have static IP addresses or domain names. You can also start and stop individual tunnels from the list.

Auto Key phase 1 parameters

This chapter provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The phase 1 parameters identify the remote peer or clients and support authentication through preshared keys or digital certificates. You can increase access security further using peer identifiers, certificate distinguished names, group names, or the FortiGate extended authentication (XAuth) option for authentication purposes.

For more information on phase 1 parameters in the web-based manager, see "Phase 1 configuration" on page 1394.

The information and procedures in this section do not apply to VPN peers that perform negotiations using manual keys. Refer to "Manual-key configurations" on page 1551 instead.

The following topics are included in this section:

Overview

To configure IPsec phase 1 settings, go to *VPN* > *IPsec* > *Auto Key (IKE)* and select *Create Phase 1*. IPsec phase 1 settings define:

- the remote and local ends of the IPsec tunnel
- if phase 1 parameters are exchanged in multiple rounds with encrypted authentication information (main mode) or in a single message with authentication information that is not encrypted (aggressive mode)
- if a preshared key or digital certificates will be used to authenticate the FortiGate unit to the VPN peer or dialup client
- if the VPN peer or dialup client is required to authenticate to the FortiGate unit. A remote peer or dialup client can authenticate by peer ID or, if the FortiGate unit authenticates by certificate, it can authenticate by peer certificate.
- the IKE negotiation proposals for encryption and authentication
- optional XAuth authentication, which requires the remote user to enter a user name and password. A FortiGate VPN server can act as an XAuth server to authenticate dialup users. A FortiGate unit that is a dialup client can also be configured as an XAuth client to authenticate itself to the VPN server.

For all the phase 1 web-based manager fields, see "Phase 1 configuration" on page 1394.

If you want to control how the IKE negotiation process controls traffic when there is no traffic, as well as the length of time the unit waits for negotiations to occur, use the `negotiation-timeout` and `auto-negotiation` commands in the CLI.

Defining the tunnel ends

To begin defining the phase 1 configuration, go to *VPN* > *IPsec* > *Auto Key* (IKE) and select *Create Phase 1*. Enter a descriptive name for the VPN tunnel. This is particularly important if you will create several tunnels.

The phase 1 configuration mainly defines the ends of the IPsec tunnel. The remote end is the remote gateway with which the FortiGate unit exchanges IPsec packets. The local end is the FortiGate interface that sends and receives IPsec packets.

The remote gateway can be:

- a static IP address
- a domain name with a dynamic IP address
- a dialup client

A statically addressed remote gateway is the simplest to configure. You specify the IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer has a domain name and subscribes to a dynamic DNS service, you need to specify only the domain name. The FortiGate unit performs a DNS query to determine the appropriate IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer is a dialup client, only the dialup client can bring up the tunnel. The IP address of the client is not known until it connects to the FortiGate unit. This configuration is a typical way to provide a VPN for client PCs running VPN client software such as the FortiClient Endpoint Security application.

The local end of the VPN tunnel, the Local Interface, is the FortiGate interface that sends and receives the IPsec packets. This is usually the public interface of the FortiGate unit that is connected to the Internet. Packets from this interface pass to the private network through a security policy.

The local Interface for a Phase 1 cannot not be a loopback interface. By design, the IPSec tunnel will not be established if this happens.

By default, the local VPN gateway is the IP address of the selected Local Interface. If you are configuring an interface mode VPN, you can optionally use a secondary IP address of the Local Interface as the local gateway.

Choosing main mode or aggressive mode

The FortiGate unit and the remote peer or dialup client exchange phase 1 parameters in either Main mode or Aggressive mode. This choice does not apply if you use IKE version 2, which is available only for route-based configurations.

- In Main mode, the phase 1 parameters are exchanged in multiple rounds with encrypted authentication information
- In Aggressive mode, the phase 1 parameters are exchanged in single message with authentication information that is not encrypted.

Although Main mode is more secure, you must select Aggressive mode if there is more than one dialup phase 1 configuration for the interface IP address, and the remote VPN peer or client is authenticated using an identifier local ID). Descriptions of the peer options in this guide indicate whether Main or Aggressive mode is required.

Choosing the IKE version

If you create a route-based VPN, you have the option of selecting IKE version 2. Otherwise, IKE version 1 is used.

IKEv2, defined in RFC 4306, simplifies the negotiation process that creates the security association (SA).

If you select IKEv2:

- There is no choice in Phase 1 of Aggressive or Main mode.
- FortiOS does not support Peer Options or Local ID.
- Extended Authentication (XAUTH) is not available.
- You can select only one DH Group.

Authenticating the FortiGate unit

The FortiGate unit can authenticate itself to remote peers or dialup clients using either a pre-shared key or an RSA Signature (certificate).

Authenticating the FortiGate unit with digital certificates

To authenticate the FortiGate unit using digital certificates, you must have the required certificates installed on the remote peer and on the FortiGate unit. The signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer. If you use certificates to authenticate the FortiGate unit, you can also require the remote peers or dialup clients to authenticate using certificates.

For more information about obtaining and installing certificates, see the *FortiOS User Authentication guide*.

To authenticate the FortiGate unit using digital certificates

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Create a new phase 1 configuration or edit an existing phase 1 configuration.

3 Include appropriate entries as follows:

Name	Enter a name that reflects the origination of the remote connection. For interface mode, the name can be up to 15 characters long.
Remote Gateway	Select the nature of the remote connection. Each option changes the available fields you must configure. For more information, see “Defining the tunnel ends” on page 1408.

Local Interface	Select the interface that is the local end of the IPsec tunnel. For more information, see "Defining the tunnel ends" on page 1408. This interface cannot be a loopback interface.
Mode	Select amode. It is easier to use aggressive mode. • In Main mode, parameters are exchanged in multiple encrypted rounds. • In Aggressive mode, parameters are exchanged in a single unencrypted message. Aggressive mode must be used when the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID). For more information, see "Choosing main mode or aggressive mode" on page 1408.
Authentication Method	Select *RSA Signature*.
Certificate Name	Select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during phase 1 negotiations. You must obtain and load the required server certificate before this selection. See the *FortiOS User Authentication guide.* If you have not loaded any certificates, use the certificate named `Fortinet_Factory`.
Peer Options	Peer options define the authentication requirements for remote peers or dialup clients. They are not for your FortiGate unit itself. See "Authenticating remote peers and clients" on page 1412.
Advanced	You can use the default settings for most phase 1 configurations. Changes are required only if your network requires them. These settings includes IKE version, DNS server, P1 proposal encryption and authentication settings, and XAuth settings. See "Defining IKE negotiation parameters" on page 1417.

4 If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters in the Advanced section. See "Using the FortiGate unit as an XAuth server" on page 1422.

5 Select *OK*.

Authenticating the FortiGate unit with a pre-shared key

The simplest way to authenticate a FortiGate unit to its remote peers or dialup clients is by means of a pre-shared key. This is less secure than using certificates, especially if it is used alone, without requiring peer IDs or extended authentication (XAuth). Also, you need to have a secure way to distribute the pre-shared key to the peers.

If you use pre-shared key authentication alone, all remote peers and dialup clients must be configured with the same pre-shared key. Optionally, you can configure remote peers and dialup clients with unique pre-shared keys. On the FortiGate unit, these are configured in user accounts, not in the phase_1 settings. For more information, see "Enabling VPN access with user accounts and pre-shared keys" on page 1415.

The pre-shared key must contain at least 6 printable characters and best practices dictate that it be known only to network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.

If you authenticate the FortiGate unit using a pre-shared key, you can require remote peers or dialup clients to authenticate using peer IDs, but not client certificates.

To authenticate the FortiGate unit with a pre-shared key

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Create a new phase 1 configuration or edit an existing phase 1 configuration.

3 Include appropriate entries as follows:

Name	Enter a name that reflects the origination of the remote connection.
Remote Gateway	Select the nature of the remote connection. For more information, see "Defining the tunnel ends" on page 1408.
Local Interface	Select the interface that is the local end of the IPsec tunnel. For more information, see "Defining the tunnel ends" on page 1408.
Mode	Select Main or Aggressive mode. • In Main mode, the phase 1 parameters are exchanged in multiple rounds with encrypted authentication information. • In Aggressive mode, the phase 1 parameters are exchanged in single message with authentication information that is not encrypted. When the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID), you must select Aggressive mode if there is more than one dialup phase 1 configuration for the interface IP address. For more information, see "Choosing main mode or aggressive mode" on page 1408.
Authentication Method	Select *Pre-shared Key*.
Pre-shared Key	Enter the preshared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during phase 1 negotiations. You must define the same value at the remote peer or client. The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.

Peer options	Peer options define the authentication requirements for remote peers or dialup clients, not for the FortiGate unit itself. You can require the use of peer IDs, but not client certificates. For more information, see "Authenticating remote peers and clients" on page 1412.
Advanced	You can retain the default settings unless changes are needed to meet your specific requirements. See "Defining IKE negotiation parameters" on page 1417.

4 If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters. See "Using the FortiGate unit as an XAuth server" on page 1422.

5 Select *OK*.

Authenticating remote peers and clients

Certificates or pre-shared keys restrict who can access the VPN tunnel, but they do not identify or authenticate the remote peers or dialup clients. You have the following options for authentication:

Table 88: Methods of authenticating remote VPN peers

Certificates or Pre-shared key	Local ID	User account pre-shared keys	Reference
Certificates			See "Enabling VPN access for specific certificate holders" on page 1412
Either	X		See "Enabling VPN access by peer identifier" on page 1414
Pre-shared key		X	See "Enabling VPN access with user accounts and pre-shared keys" on page 1415
Pre-shared key	X	X	See "Enabling VPN access with user accounts and pre-shared keys" on page 1415

For authentication of users of the remote peer or dialup client device, see "Using XAuth authentication" on page 1422.

Enabling VPN access for specific certificate holders

When a VPN peer or dialup client is configured to authenticate using digital certificates, it sends the DN of its certificate to the FortiGate unit. This DN can be used to allow VPN access for the certificate holder. That is, a FortiGate unit can be configured to deny connections to all remote peers and dialup clients except the one having the specified DN.

Before you begin

The following procedures assume that you already have an existing phase 1 configuration (see "Authenticating the FortiGate unit with digital certificates" on page 1409). Follow the procedures below to add certificate-based authentication parameters to the existing configuration.

Before you begin, you must obtain the certificate DN of the remote peer or dialup client. If you are using the FortiClient application as a dialup client, refer to *FortiClient online Help* for information about how to view the certificate DN. To view the certificate DN of a FortiGate unit, see "To view server certificate information and obtain the local DN" on page 1413.

Use the `config user peer` CLI command to load the DN value into the FortiGate configuration. For example, if a remote VPN peer uses server certificates issued by your own organization, you would enter information similar to the following:

```
config user peer
  edit DN_FG1000
    set cn 192.168.2.160
    set cn-type ipv4
  end
```

The value that you specify to identify the entry (for example, DN_FG1000) is displayed in the Accept this peer certificate only list in the IPsec phase 1 configuration when you return to the web-based manager.

If the remote VPN peer has a CA-issued certificate to support a higher level of credibility, you would enter information similar to the following:

```
config user peer
  edit CA_FG1000
    set ca CA_Cert_1
    set subject FG1000_at_site1
  end
```

The value that you specify to identify the entry (for example, CA_FG1000) is displayed in the Accept this peer certificate only list in the IPsec phase 1 configuration when you return to the web-based manager. For more information about these CLI commands, see the "user" chapter of the *FortiGate CLI Reference*.

A group of certificate holders can be created based on existing user accounts for dialup clients. To create the user accounts for dialup clients, see the "User" chapter of the *FortiGate Administration Guide*. To create the certificate group afterward, use the `config user peergrp` CLI command. See the "user" chapter of the *FortiGate CLI Reference*.

To view server certificate information and obtain the local DN

1 Go to *System* > *Certificates* > *Local Certificates*.

2 Note the CN value in the *Subject* field (for example, `CN = 172.16.10.125`, `CN = info@fortinet.com`, or `CN = www.example.com`).

To view CA root certificate information and obtain the CA certificate name

1 Go to *System* > *Certificates* > *CA Certificates*.

2 Note the value in the *Name* column (for example, `CA_Cert_1`).

Configuring certificate authentication for a VPN

With peer certificates loaded, peer users and peer groups defined, you can configure your VPN to authenticate users by certificate.

To enable access for a specific certificate holder or a group of certificate holders

1 At the FortiGate VPN server, go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 In the list of defined configurations, select the phase 1 configuration and edit it.

3 From the *Authentication Method* list, select *RSA Signature*.

4 From the *Certificate Name* list, select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client

5 Under *Peer Options*, select one of these options:

- To accept a specific certificate holder, select *Accept this peer certificate only* and select the name of the certificate that belongs to the remote peer or dialup client. The certificate DN must be added to the FortiGate configuration through CLI commands before it can be selected here. See "Before you begin" on page 1412.
- To accept dialup clients who are members of a certificate group, select *Accept this peer certificate group only* and select the name of the group. The group must be added to the FortiGate configuration through CLI commands before it can be selected here. See "Before you begin" on page 1412.

6 If you want the FortiGate VPN server to supply the DN of a local server certificate for authentication purposes, select *Advanced* and then from the *Local ID* list, select the DN of the certificate that the FortiGate VPN server is to use.

7 Select *OK*.

Enabling VPN access by peer identifier

Whether you use certificates or pre-shared keys to authenticate the FortiGate unit, you can require that remote peers or clients have a particular peer ID. This adds another piece of information that is required to gain access to the VPN. More than one FortiGate/FortiClient dialup client may connect through the same VPN tunnel when the dialup clients share a preshared key and assume the same identifier.

A peer ID, also called local ID, can be up to 63 characters long containing standard regular expression characters. Local ID is set in phase1 Aggressive Mode configuration.

You cannot require a peer ID for a remote peer or client that uses a pre-shared key and has a static IP address.

To authenticate remote peers or dialup clients using one peer ID

1 At the FortiGate VPN server, go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 In the list, select a phase 1 configuration and edit its parameters.

3 Select *Aggressive* mode in any of the following cases:

- the FortiGate VPN server authenticates a FortiGate dialup client that uses a dedicated tunnel
- a FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service
- FortiGate/FortiClient dialup clients sharing the same preshared key and local ID connect through the same VPN tunnel

4 Select *Accept this peer ID* and type the identifier into the corresponding field.

5 Select *OK*.

To assign an identifier (local ID) to a FortiGate unit

Use this procedure to assign a peer ID to a FortiGate unit that acts as a remote peer or dialup client.

1 Go to *VPN* > *IPsec* > *Auto Key (IKE*).

2 In the list, select a phase 1 configuration and edit its parameters.

3 Select *Advanced*.

4 In the *Local ID* field, type the identifier that the FortiGate unit will use to identify itself.

5 Set *Mode* to *Aggressive* if any of the following conditions apply:
   - The FortiGate unit is a dialup client that will use a unique ID to connect to a FortiGate dialup server through a dedicated tunnel.
   - The FortiGate unit has a dynamic IP address, subscribes to a dynamic DNS service, and will use a unique ID to connect to the remote VPN peer through a dedicated tunnel.
   - The FortiGate unit is a dialup client that shares the specified ID with multiple dialup clients to connect to a FortiGate dialup server through the same tunnel.
6 Select *OK*.

To configure the FortiClient application

Follow this procedure to add a peer ID to an existing FortiClient configuration:

1 Start the FortiClient application.
2 Go to *VPN* > *Connections*, select the existing configuration.
3 Select *Advanced* > *Edit* > *Advanced*.
4 Under *Policy*, select *Config*.
5 In the *Local ID* field, type the identifier that will be shared by all dialup clients. This value must match the *Accept this peer ID* value that you specified previously in the phase 1 gateway configuration on the FortiGate unit.
6 Select *OK* to close all dialog boxes.
7 Configure all dialup clients the same way using the same preshared key and local ID.

Enabling VPN access with user accounts and pre-shared keys

You can permit access only to remote peers or dialup clients that have pre-shared keys and/or peer IDs configured in user accounts on the FortiGate unit.

If you want two VPN peers (or a FortiGate unit and a dialup client) to accept reciprocal connections based on peer IDs, you must enable the exchange of their identifiers when you define the phase 1 parameters.

The following procedures assume that you already have an existing phase 1 configuration (see "Authenticating the FortiGate unit with digital certificates" on page 1409). Follow the procedures below to add ID checking to the existing configuration.

Before you begin, you must obtain the identifier (local ID) of the remote peer or dialup client. If you are using the FortiClient Endpoint Security application as a dialup client, refer to the *Authenticating FortiClient Dialup Clients Technical Note* to view or assign an identifier. To assign an identifier to a FortiGate dialup client or a FortiGate unit that has a dynamic IP address and subscribes to a dynamic DNS service, see "To assign an identifier (local ID) to a FortiGate unit" on page 1414.

If required, a dialup user group can be created from existing user accounts for dialup clients. To create the user accounts and user groups, see the *User Authentication*chapter of The Handbook.

The following procedure supports FortiGate/FortiClient dialup clients that use unique preshared keys and/or peer IDs. The client must have an account on the FortiGate unit and be a member of the dialup user group.

The dialup user group must be added to the FortiGate configuration before it can be selected. For more information, see the *User Authentication*chapter of The Handbook.

The FortiGate dialup server compares the local ID that you specify at each dialup client to the FortiGate user-account user name. The dialup-client preshared key is compared to a FortiGate user-account password.

To authenticate dialup clients using unique preshared keys and/or peer IDs

1 At the FortiGate VPN server, go to *VPN* > *IPsec* > *Auto Key (IKE)*.
2 In the list, select the *Edit* icon of a phase 1 configuration to edit its parameters.
3 If the clients have unique peer IDs, set *Mode* to *Aggressive*.
4 Clear the *Pre-shared Key* field.

   The user account password will be used as the preshared key.
5 Select *Accept peer ID in dialup group* and then select the group name from the list of user groups.
6 Select *OK*.

Follow this procedure to add a unique pre-shared key and unique peer ID to an existing FortiClient configuration.

To configure FortiClient - pre-shared key and peer ID

1 Start the FortiClient Endpoint Security application.
2 Go to *VPN* > *Connections*, select the existing configuration.
3 Select *Advanced* > *Edit*.
4 In the *Preshared Key* field, type the FortiGate password that belongs to the dialup client (for example, `1234546`).

   The user account password will be used as the preshared key.
5 Select *Advanced*.
6 Under *Policy*, select *Config*.
7 In the *Local ID* field, type the FortiGate user name that you assigned previously to the dialup client (for example, `FortiC1ient1`).
8 Select *OK* to close all dialog boxes.

Configure all FortiClient dialup clients this way using unique preshared keys and local IDs.

Follow this procedure to add a unique pre-shared key to an existing FortiClient configuration.

To configure FortiClient - preshared key only

1 Start the FortiClient Endpoint Security application.
2 Go to *VPN* > *Connections*, select the existing configuration
3 Select *Advanced* > *Edit*.
4 In the *Preshared Key* field, type the user name, followed by a “+” sign, followed by the password that you specified previously in the user account settings on the FortiGate unit (for example, `FC2+1FG6LK`)
5 Select *OK* to close all dialog boxes.

Configure all the FortiClient dialup clients this way using their unique peer ID and pre-shared key values.

Defining IKE negotiation parameters

In phase 1, the two peers exchange keys to establish a secure communication channel between them. As part of the phase 1 process, the two peers authenticate each other and negotiate a way to encrypt further communications for the duration of the session. For more information see “Authenticating remote peers and clients” on page 1412. The P1 Proposal parameters select the encryption and authentication algorithms that are used to generate keys for protecting negotiations.

The IKE negotiation parameters determine:

- which encryption algorithms may be applied for converting messages into a form that only the intended recipient can read
- which authentication hash may be used for creating a keyed hash from a preshared or private key
- which Diffie-Hellman group (DH Group) will be used to generate a secret session key

Phase 1 negotiations (in main mode or aggressive mode) begin as soon as a remote VPN peer or client attempts to establish a connection with the FortiGate unit. Initially, the remote peer or dialup client sends the FortiGate unit a list of potential cryptographic parameters along with a session ID. The FortiGate unit compares those parameters to its own list of advanced phase 1 parameters and responds with its choice of matching parameters to use for authenticating and encrypting packets. The two peers handle the exchange of encryption keys between them, and authenticate the exchange through a preshared key or a digital signature.

Generating keys to authenticate an exchange

The FortiGate unit supports the generation of secret session keys automatically using a Diffie-Hellman algorithm. These algorithms are defined in RFC 2409. The *Keylife* setting in the *P1 Proposal* area determines the amount of time before the phase 1 key expires. Phase 1 negotiations are rekeyed automatically when there is an active security association. See “Dead peer detection” on page 1421.

You can enable or disable automatic rekeying between IKE peers through the `phase1-rekey` attribute of the `config system global` CLI command. For more information, see the “system” chapter of the *FortiGate CLI Reference*.

When in FIPS-CC mode, the FortiGate unit requires DH key exchange to use values at least 3072 bits long. However most browsers need the key size set to 1024. You can set the minimum size of the DH keys in the CLI.

```
config system global
  set dh-params 3072
end
```

When you use a preshared key (shared secret) to set up two-party authentication, the remote VPN peer or client and the FortiGate unit must both be configured with the same preshared key. Each party uses a session key derived from the Diffie-Hellman exchange to create an authentication key, which is used to sign a known combination of inputs using an authentication algorithm (such as HMAC-MD5, HMAC-SHA-1, or HMAC-SHA-256). Hash-based Message Authentication Code (HMAC) is a method for calculating an authentication code using a hash function plus a secret key, and is defined in RFC 2104. Each party signs a different combination of inputs and the other party verifies that the same result can be computed.

SHA-256, SHA-384 and SHA-512 are not accelerated by some FortiASIC processors (including FortiASIC network processors and security processors). As a result, using SHA-256, SHA-384 and SHA-512 may reduce the performance of the FortiGate unit more significantly than SHA-1 which is accelerated by all FortiASIC processors.

When you use preshared keys to authenticate VPN peers or clients, you must distribute matching information to all VPN peers and/or clients whenever the preshared key changes.

As an alternative, the remote peer or dialup client and FortiGate unit can exchange digital signatures to validate each other's identity with respect to their public keys. In this case, the required digital certificates must be installed on the remote peer and on the FortiGate unit. By exchanging certificate DNs, the signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer.

The following procedure assumes that you already have a phase 1 definition that describes how remote VPN peers and clients will be authenticated when they attempt to connect to a local FortiGate unit. For information about the Local ID and XAuth options, see "Enabling VPN access with user accounts and pre-shared keys" on page 1415 and "Using the FortiGate unit as an XAuth server" on page 1422. Follow this procedure to add IKE negotiation parameters to the existing definition.

Defining IKE negotiation parameters

1. Go to *VPN* > *IPsec* > *Auto Key (IKE)*.
2. In the list, select the *Edit* button to edit the phase 1 parameters for a particular remote gateway.

3 Select *Advanced* and include appropriate entries as follows:

P1 Proposal	Select the encryption and authentication algorithms that will be used to generate keys for protecting negotiations. Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define. You can select any of the following symmetric-key algorithms: • DES-Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. • 3DES-Triple-DES, in which plain text is encrypted three times by three keys. • AES128-A 128-bit block algorithm that uses a 128-bit key. • AES192-A 128-bit block algorithm that uses a 192-bit key. • AES256-A 128-bit block algorithm that uses a 256-bit key. You can select one of the following message digests to check the authenticity of messages during phase 1 negotiations: • MD5-Message Digest 5, the hash algorithm developed by RSA Data Security. • SHA1-Secure Hash Algorithm 1, which produces a 160-bit message digest. • SHA-256 Secure Hash Algorithm 256, which produces a 256-bit message digest • SHA-384 Secure Hash Algorithm 384, which produces a 384-bit message digest • SHA-512 Secure Hash Algorithm 512, which produces a 512-bit message digest To specify a third combination, use the add button beside the fields for the second combination. SHA-256, SHA-384 and SHA-512 are not accelerated by some FortiASIC processors (including FortiASIC network processors and security processors). As a result, using SHA-256, SHA-384 and SHA-512 may reduce the performance of the FortiGate unit more significantly than SHA-1 which is accelerated by all FortiASIC processors.

DH Group	Select one or more Diffie-Hellman groups from DH group 1, 2, and 5. When using aggressive mode, DH groups cannot be negotiated. If both VPN peers (or a VPN server and its client) have static IP addresses and use aggressive mode, select a single DH group. The setting on the FortiGate unit must be identical to the setting on the remote peer or dialup client. When the remote VPN peer or client has a dynamic IP address and uses aggressive mode, select up to three DH groups on the FortiGate unit and one DH group on the remote peer or dialup client. The setting on the remote peer or dialup client must be identical to one of the selections on the FortiGate unit. If the VPN peer or client employs main mode, you can select multiple DH groups. At least one of the settings on the remote peer or dialup client must be identical to the selections on the FortiGate unit.
Keylife	Type the amount of time (in seconds) that will be allowed to pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172800 seconds.
Nat-traversal	Enable this option if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared). When in doubt, enable NAT-traversal. See “NAT traversal” on page 1420.
Keepalive Frequency	If you enabled NAT traversal, enter a keepalive frequency setting. The value represents an interval from 0 to 900 seconds where the connection will be maintained with no activity. For additional security this value must be as low as possible. See “NAT keepalive frequency” on page 1421.
Dead Peer Detection	Enable this option to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. This feature minimizes the traffic required to check if a VPN peer is available or unavailable (dead). See “Dead peer detection” on page 1421.

4 Select *OK*.

NAT traversal

Network Address Translation (NAT) is a way to convert private IP addresses to publicly routable Internet addresses and vise versa. When an IP packet passes through a NAT device, the source or destination address in the IP header is modified. FortiGate units support NAT version 1 (encapsulate on port 500 with non-IKE marker), version 3 (encapsulate on port 4500 with non-ESP marker), and compatible versions.

NAT cannot be performed on IPsec packets in ESP tunnel mode because the packets do not contain a port number. As a result, the packets cannot be demultiplexed. To work around this, the FortiGate unit provides a way to protect IPsec packet headers from NAT modifications. When the Nat-traversal option is enabled, outbound encrypted packets are wrapped inside a UDP IP header that contains a port number. This extra encapsulation allows NAT devices to change the port number without modifying the IPsec packet directly.

To provide the extra layer of encapsulation on IPsec packets, the Nat-traversal option must be enabled whenever a NAT device exists between two FortiGate VPN peers or a FortiGate unit and a dialup client such as FortiClient. On the receiving end, the FortiGate unit or FortiClient removes the extra layer of encapsulation before decrypting the packet.

NAT keepalive frequency

When a NAT device performs network address translation on a flow of packets, the NAT device determines how long the new address will remain valid if the flow of traffic stops (for example, the connected VPN peer may be idle). The device may reclaim and reuse a NAT address when a connection remains idle for too long.

To work around this, when you enable NAT traversal specify how often the FortiGate unit sends periodic keepalive packets through the NAT device in order to ensure that the NAT address mapping does not change during the lifetime of a session. To be effetive, the keepalive interval msut be smaller than the session lifetime value used by the NAT device.

The keepalive packet is a 138-byte ISAKMP exchange.

Dead peer detection

Sometimes, due to routing issues or other difficulties, the communication link between a FortiGate unit and a VPN peer or client may go down—packets could be lost if the connection is left to time out on its own. The FortiGate unit provides a mechanism called Dead Peer Detection (DPD), sometimes referred to as gateway detection or ping server, to prevent this situation and reestablish IKE negotiations automatically before a connection times out: the active phase 1 security associations are caught and renegotiated (rekeyed) before the phase 1 encryption key expires.

By default, DPD sends probe messages every five seconds by default (see `dpd-retryinterval` in the *FortiGate CLI Reference*). If you are experiencing high network traffic, you can experiment with increasing the ping interval. However longer intervals will require more traffic to detect dead peers which will result in more traffic.

In the web-based manager, the Dead Peer Detection option can be enabled when you define advanced phase 1 options. The `config vpn ipsec phase1` CLI command supports additional options for specifying a retry count and a retry interval.

For more information about these commands and the related `config router gwdetect` CLI command, see the *FortiGate CLI Reference*.

For example, enter the following CLI commands to configure dead peer detection on the existing IPsec Phase1 configuration called `test` to use 15 second intervals and to wait for 3 missed attempts before declaring the peer dead and taking action.

```
config vpn ipsec phase1
  edit test
    set dpd enable
    set dpd-retryinveral 15
    set dpd-retrycount 3
    next
end
```

Using XAuth authentication

Extended authentication (XAuth) increases security by requiring the remote dialup client user to authenticate in a separate exchange at the end of phase 1. XAuth draws on existing FortiGate user group definitions and uses established authentication mechanisms such as PAP, CHAP, RADIUS and LDAP to authenticate dialup clients. You can configure a FortiGate unit to function either as an XAuth server or an XAuth client.

If the server or client is attempting a connection using XAuth and the other end is not using XAuth, the failed connection attempts that are logged will not specify XAuth as the reason.

This section includes:

- Using the FortiGate unit as an XAuth server
- Using the FortiGate unit as an XAuth client

Using the FortiGate unit as an XAuth server

A FortiGate unit can act as an XAuth server for dialup clients. When the phase 1 negotiation completes, the FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.

If the user records on the RADIUS server have suitably configured Framed-IP-Address fields, you can assign client virtual IP addresses by XAuth instead of from a DHCP address range. See "Assigning VIPs by RADIUS user group" on page 1487.

The authentication protocol to use for XAuth depends on the capabilities of the authentication server and the XAuth client:

- Select PAP whenever possible.
- You must select PAP for all implementations of LDAP and some implementations of Microsoft RADIUS.
- Select AUTO when the authentication server supports CHAP but the XAuth client does not. The FortiGate unit will use PAP to communicate with the XAuth client and CHAP to communicate with the authentication server.

To authenticate a dialup user group using XAuth settings

Before you begin, create user accounts and user groups to identify the dialup clients that need to access the network behind the FortiGate dialup server. If password protection will be provided through an external RADIUS or LDAP server, you must configure the FortiGate dialup server to forward authentication requests to the authentication server. For information about these topics, see the *FortiGate User Authentication Guide*.

1. At the FortiGate dialup server, go to *VPN* > *IPsec* > *Auto Key (IKE)*.
2. In the list, select the *Edit* icon of a phase 1 configuration to edit its parameters for a particular remote gateway.
3. Select *Advanced*.
4. Under *XAuth*, select *Enable as Server*.

5 The *Server Type* setting determines the type of encryption method to use between the XAuth client, the FortiGate unit and the authentication server. Select one of the following options:
   - *PAP*—Password Authentication Protocol.
   - *CHAP*— Challenge-Handshake Authentication Protocol.
   - *AUTO*—Use PAP between the XAuth client and the FortiGate unit, and CHAP between the FortiGate unit and the authentication server.
6 From the *User Group* list, select the user group that needs to access the private network behind the FortiGate unit. The group must be added to the FortiGate configuration before it can be selected here.
7 Select *OK*.

Using the FortiGate unit as an XAuth client

If the FortiGate unit acts as a dialup client, the remote peer, acting as an XAuth server, might require a user name and password. You can configure the FortiGate unit as an XAuth client, with its own user name and password, which it provides when challenged.

To configure the FortiGate dialup client as an XAuth client

1 At the FortiGate dialup client, go to *VPN* > *IPsec* > *Auto Key (IKE)*.
2 In the list, select a phase 1 configuration and select *Edit*.
3 Select *Advanced*.
4 Under *XAuth*, select *Enable as Client*.
5 In the *Username* field, type the FortiGate PAP, CHAP, RADIUS, or LDAP user name that the FortiGate XAuth server will compare to its records when the FortiGate XAuth client attempts to connect.
6 In the *Password* field, type the password to associate with the user name.
7 Select *OK*.

Phase 2 parameters

This section describes the phase 2 parameters that are required to establish communication through a VPN.

The following topics are included in this section:

- Basic phase 2 settings
- Advanced phase 2 settings
- Configure the phase 2 parameters

Basic phase 2 settings

After IPsec VPN phase 1 negotiations complete successfully, phase 2 negotiation begins. Phase 2 parameters define the algorithms that the FortiGate unit can use to encrypt and transfer data for the remainder of the session. The basic phase 2 settings associate IPsec phase 2 parameters with a phase 1 configuration.

When defining phase 2 parameters, you can choose any set of phase 1 parameters to set up a secure connection and authenticate the remote peer.

For more information on phase 2 settings in the web-based manager, see “Phase 2 configuration” on page 1399

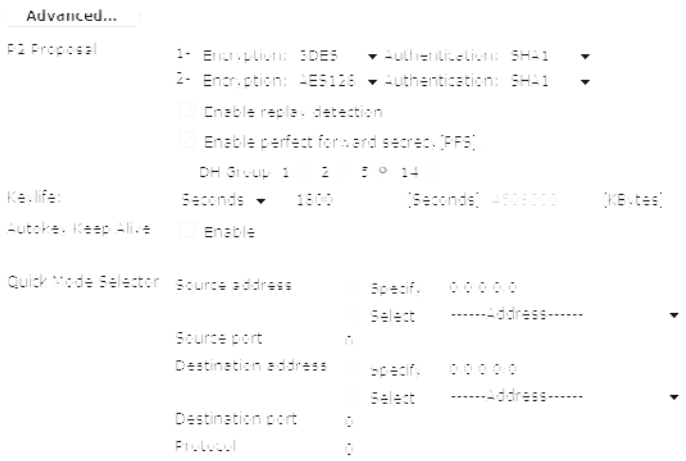
The information and procedures in this section do not apply to VPN peers that perform negotiations using manual keys. Refer to “Manual-key configurations” on page 1551 instead.

Advanced phase 2 settings

The following additional advanced phase 2 settings are available to enhance the operation of the tunnel:

- P2 Proposals
- Replay detection
- Perfect forward secrecy (PFS)(
- Keylife
- Quick mode selectors

Figure 126: Advanced phase 2 settings



P2 Proposals

In phase 2, the VPN peer or client and the FortiGate unit exchange keys again to establish a secure communication channel. The P2 Proposal parameters select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). The keys are generated automatically using a Diffie-Hellman algorithm.

Replay detection

IPsec tunnels can be vulnerable to replay attacks. Replay detection enables the FortiGate unit to check all IPsec packets to see if they have been received before. If any encrypted packets arrive out of order, the FortiGate unit discards them.

Perfect forward secrecy (PFS)(

By default, phase 2 keys are derived from the session key created in phase 1. Perfect forward secrecy forces a new Diffie-Hellman exchange when the tunnel starts and whenever the phase 2 keylife expires, causing a new key to be generated each time. This exchange ensures that the keys created in phase 2 are unrelated to the phase 1 keys or any other keys generated automatically in phase 2.

Keylife

The Keylife setting sets a limit on the length of time that a phase 2 key can be used. The default units are seconds. Alternatively, you can set a limit on the number of kilobytes (KB) of processed data, or both. If you select both, the key expires when either the time has passed or the number of KB have been processed. When the phase 2 key expires, a new key is generated without interrupting service.

Auto-negotiate

By default, the phase 2 security association (SA) is not negotiated until a peer attempts to send data. The triggering packet and some subsequent packets are dropped until the SA is established. Applications normally resend this data, so there is no loss, but there might be a noticeable delay in response to the user.

Automatically establishing the SA can also be important for a dialup peer. This ensures that the VPN tunnel is available for peers at the server end to initiate traffic to the dialup peer. Otherwise, the VPN tunnel does not exist until the dialup peer initiates traffic.

When enabled, auto-negotiate initiates the phase 2 SA negotiation automatically, repeating every five seconds until the SA is established.

The auto-negotiate feature is available only through the Command Line Interface (CLI). Use the following commands to enable it.

```
config vpn ipsec phase2
  edit <phase2_name>
    set auto-negotiate enable
  end
```

If the tunnel goes down, the auto-negotiate feature will attempt to re-establish it. However, the Autokey Keep Alive feature is a better method to ensure your VPN remains up.

Autokey Keep Alive

The phase 2 SA has a fixed duration. If there is traffic on the VPN as the SA nears expiry, a new SA is negotiated and the VPN switches to the new SA without interruption. If there is no traffic, the SA expires and the VPN tunnel goes down. A new SA will not be generated until there is traffic.

The Autokey Keep Alive option ensures that a new SA is negotiated even if there is no traffic so that the VPN tunnel stays up.

DHCP-IPsec

Select this option if the FortiGate unit assigns VIP addresses to FortiClient dialup clients through a DHCP server or relay. This option is available only if the Remote Gateway in the phase 1 configuration is set to Dialup User and it works only on policy-based VPNs.

With the DHCP-IPsec option, the FortiGate dialup server acts as a proxy for FortiClient dialup clients that have VIP addresses on the subnet of the private network behind the FortiGate unit. In this case, the FortiGate dialup server acts as a proxy on the local private network for the FortiClient dialup client. When a host on the network behind the dialup server issues an ARP request that corresponds to the device MAC address of the FortiClient host (when a remote server sends an ARP to the local FortiClient dialup client), the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel.

This feature prevents the VIP address assigned to the FortiClient dialup client from causing possible arp broadcast problems—the normal and VIP addresses can confuse some network switches by two addresses having the same MAC address.

Quick mode selectors

Quick Mode selectors determine which IP addresses can perform IKE negotiations to establish a tunnel. By only allowing authorized IP addresses access to the VPN tunnel, the network is more secure.

The default settings are as broad as possible: any IP address or configured address group, using any protocol, on any port. This enables configurations in which multiple subnets at each end of the tunnel can communicate, limited only by the security policies at each end.

When configuring Quick Mode selector *Source Address* and *Destination address*, valid options include IPv4 and IPv6 single addresses, IPv4 firewall address or group name, IPv4 range, IPv6 range, IPv4 subnet, or IPv6 subnet. For more information on IPv6 IPsec VPN, see “Overview of IPv6 IPsec support” on page 1555.

There are some configurations that require specific selectors:

- the VPN peer is a third-party device that uses specific phase2 selectors
- the FortiGate unit connects as a dialup client to another FortiGate unit, in which case you must specify a source IP address, IP address range or subnet

With FortiOS VPNs, your network has multiple layers of security, with quick mode selectors being an important line of defence.

- Routes guide traffic from one IP address to another.
- Phase 1 and phase 2 connection settings ensure there is a valid remote end point for the VPN tunnel that agrees on the encryption and parameters.
- Quick mode selectors allow IKE negotiations only for allowed peers.
- Security policies control which IP addresses can connect to the VPN.
- Security policies also control what protocols are allowed over the VPN along with any bandwidth limiting.

Configure the phase 2 parameters

Follow this procedure to create an IPsec phase 2 definition.

If you are creating a hub-and-spoke configuration or an Internet-browsing configuration, you may have already started defining some of the required phase 2 parameters. If so, edit the existing definition to complete the configuration.

Specifying the phase 2 parameters

1. Go to *VPN* > *IPsec* > *Auto Key (IKE)*.
2. Select *Create Phase 2*.
3. Include appropriate entries as follows:

Name	Enter a name to identify the phase 2 configuration.
Phase 1	Select the phase 1 configuration that describes how remote peers or dialup clients will be authenticated on this tunnel, and how the connection to the remote peer or dialup client will be secured.

4. Select *Advanced*.
5. Include appropriate entries as follows:

P2 Proposal	Select the encryption and authentication algorithms that will be used to change data into encrypted code. Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define. It is invalid to set both *Encryption* and *Authentication* to null.

Encryption	You can select any of the following symmetric-key algorithms: **NULL** — Do not use an encryption algorithm. **DES** — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. **3DES** — Triple-DES, in which plain text is encrypted three times by three keys. **AES128** — A 128-bit block algorithm that uses a 128-bit key. **AES192** — A 128-bit block algorithm that uses a 192-bit key. **AES256** — A 128-bit block algorithm that uses a 256-bit key.
Authentication	You can select either of the following message digests to check the authenticity of messages during an encrypted session: • **NULL** — Do not use a message digest. • **MD5** — Message Digest 5, the hash algorithm developed by RSA Data Security. • **SHA1** — Secure Hash Algorithm 1, which produces a 160-bit message digest. To specify one combination only, set the *Encryption* and *Authentication* options of the second combination to NULL. To specify a third combination, use the *Add* button beside the fields for the second combination.
Enable replay detection	Optionally enable or disable replay detection. Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.
Enable perfect forward secrecy (PFS)	Enable or disable PFS. Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.
DH Group	Select one Diffie-Hellman group (1, 2, 5, or 14). The remote peer or dialup client must be configured to use the same group.
Keylife	Select the method for determining when the phase 2 key expires: *Seconds*, *KBytes*, or *Both*. If you select *Both*, the key expires when either the time has passed or the number of KB have been processed. The range is from 120 to 172800 seconds, or from 5120 to 2147483648 KB.
Autokey Keep Alive	Enable the option if you want the tunnel to remain active when no data is being processed.
DHCP-IPsec	Select *Enable* if the FortiGate unit acts as a dialup server and FortiGate DHCP server or relay will be used to assign VIP addresses to FortiClient dialup clients. The DHCP server or relay parameters must be configured separately. If the FortiGate unit acts as a dialup server and the FortiClient dialup client VIP addresses match the network behind the dialup server, select *Enable* to cause the FortiGate unit to act as a proxy for the dialup clients. This is available only for phase 2 configurations associated with a dialup phase 1 configuration. It works only on policy-based VPNs.

Quick Mode Selector	Optionally specify the source and destination IP addresses to be used as selectors for IKE negotiations. If the FortiGate unit is a dialup server, keep the default value 0.0.0.0/0 unless you need to circumvent problems caused by ambiguous IP addresses between one or more of the private networks making up the VPN. You can specify a single host IP address, an IP address range, or a network address. You may optionally specify source and destination port numbers and/or a protocol number. If you are editing an existing phase 2 configuration, the *Source address* and *Destination address* fields are unavailable if the tunnel has been configured to use firewall addresses as selectors. This option exists only in the CLI. See the `dst-addr-type`, `dst-name`, `src-addr-type` and `src-name` keywords for the `vpn ipsec phase2` command in the *FortiGate CLI Reference*.
Source address	If the FortiGate unit is a dialup server, type the source IP address that corresponds to the local sender(s) or network behind the local VPN peer (for example, `172.16.5.0/24` or `172.16.5.0/255.255.255.0` for a subnet, or `172.16.5.1/32` or `172.16.5.1/255.255.255.255` for a server or host, or `192.168.10.[80-100]` or `192.168.10.80-192.168.10.100` for an address range). A value of `0.0.0.0/0` means all IP addresses behind the local VPN peer. If the FortiGate unit is a dialup client, source address must refer to the private network behind the FortiGate dialup client.
Source port	Type the port number that the local VPN peer uses to transport traffic related to the specified service (protocol number). The range is 0 to 65535. To specify all ports, type `0`.
Destination address	Type the destination IP address that corresponds to the recipient(s) or network behind the remote VPN peer (for example, `192.168.20.0/24` for a subnet, or `172.16.5.1/32` for a server or host, or `192.168.10.[80-100]` for an address range). A value of `0.0.0.0/0` means all IP addresses behind the remote VPN peer.
Destination port	Type the port number that the remote VPN peer uses to transport traffic related to the specified service (protocol number). The range is 0 to 65535. To specify all ports, type `0`.
Protocol	Type the IP protocol number of the service. The range is `1` to `255`. To specify all services, type `0`.

6 Select *OK*.

Defining VPN security policies

This section explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN, and how to define appropriate security policies.

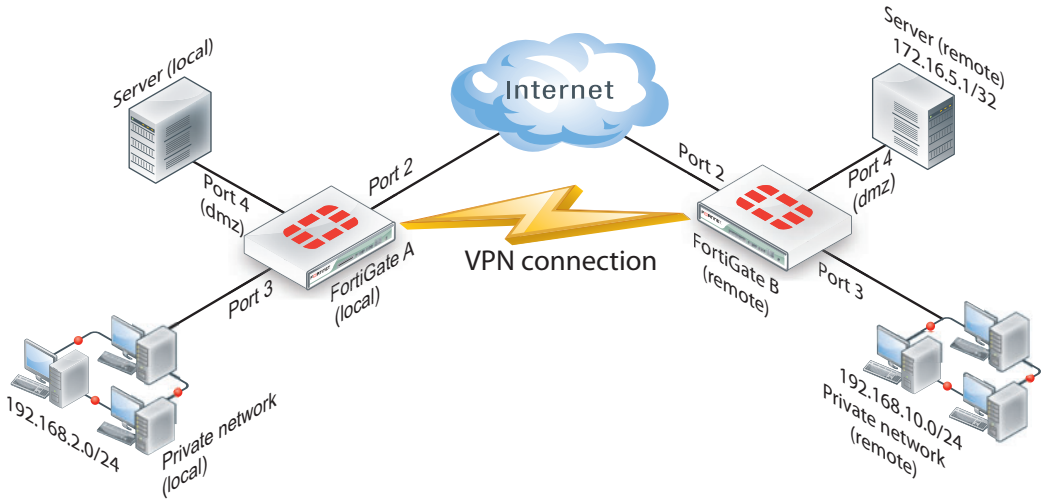
The following topics are included in this section:

Defining policy addresses

A VPN tunnel has two end points. These end points may be VPN peers such as two FortiGate gateways. Encrypted packets are transmitted between the end points. At each end of the VPN tunnel, a VPN peer intercepts encrypted packets, decrypts the packets, and forwards the decrypted IP packets to the intended destination.

You need to define firewall addresses for the private networks behind each peer. You will use these addresses as the source or destination address depending on the security policy.

Figure 127: Example topology for the following policies



In general:

- In a gateway-to-gateway, hub-and-spoke, dynamic DNS, redundant-tunnel, or transparent configuration, you need to define a policy address for the private IP address of the network behind the remote VPN peer (for example, `192.168.10.0/255.255.255.0` or `192.168.10.0/24`).
- In a peer-to-peer configuration, you need to define a policy address for the private IP address of a server or host behind the remote VPN peer (for example, `172.16.5.1/255.255.255.255` or `172.16.5.1/32` or `172.16.5.1`).

For a FortiGate dialup server in a dialup-client or Internet-browsing configuration:

- If you are not using VIP addresses, or if the FortiGate dialup server assigns VIP addresses to FortiClient dialup clients through FortiGate DHCP relay, select the predefined destination address “all” in the security policy to refer to the dialup clients.
- If you assign VIP addresses to FortiClient dialup clients manually, you need to define a policy address for the VIP address assigned to the dialup client (for example, `10.254.254.1/32`), or a subnet address from which the VIP addresses are assigned (for example, `10.254.254.0/24` or `10.254.254.0/255.255.255.0`).
- For a FortiGate dialup client in a dialup-client or Internet-browsing configuration, you need to define a policy address for the private IP address of a host, server, or network behind the FortiGate dialup server.

To define a security IP address

1 Go to *Firewall Objects> Address > Address* and select *Create New*.

2 In the *Address Name* field, type a descriptive name that represents the network, server(s), or host(s).

3 In *Type*, select *Subnet / IP Range*.

4 In the *Subnet/IP Range* field, type the corresponding IP address and subnet mask.

For a subnet you could use the format `172.16.5.0/24` or its equivalent `172.16.5.0/255.255.255.0`. For a server or host it would likely be `172.16.5.1/32`. Alternately you can use an IP address range such as `192.168.10.[80-100]` or `192.168.10.80-192.168.10.100`.

5 Select *OK*.

Defining VPN security policies

Security policies allow IP traffic to pass between interfaces on a FortiGate unit. You can limit communication to particular traffic by specifying source address and destination addresses. Then only traffic from those addresses will be allowed.

Policy-based and route-based VPNs require different security policies.

- A policy-based VPN requires an IPsec security policy. You specify the interface to the private network, the interface to the remote peer and the VPN tunnel. A single policy can enable traffic inbound, outbound, or in both directions.
- A route-based VPN requires an Accept security policy for each direction. As source and destination interfaces, you specify the interface to the private network and the virtual IPsec interface (phase 1 configuration) of the VPN. The IPsec interface is the destination interface for the outbound policy and the source interface for the inbound policy. One security policy must be configured for each direction of each VPN interface.

There are examples of security policies for both policy-based and route-based VPNs throughout this guide. See “Route-based or policy-based VPN” on page 1471.

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won’t be able to retrieve a lease from the FortiGate’s (IPSec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

Defining an IPsec security policy for a policy-based VPN

An IPsec security policy enables the transmission and reception of encrypted packets, specifies the permitted direction of VPN traffic, and selects the VPN tunnel. In most cases, a single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel.

Allow outbound and allow inbound

In addition to these operations, security policies specify which IP addresses can initiate a tunnel. When the *Allow outbound* option is selected, traffic from the local private network initiates the tunnel. When the *Allow inbound* option is selected, traffic from a dialup client or computers on the remote network initiates the tunnel. Both can be enabled at the same time for bi-directional initiation of the tunnel.

Outbound and inbound NAT

When a FortiGate unit operates in NAT mode, you can also enable inbound or outbound NAT. Outbound NAT may be performed on outbound encrypted packets, or on IP packets before they are sent through the tunnel. Inbound NAT is performed on IP packets emerging from the tunnel. By default, these options are not selected in security policies.

- When used in conjunction with the `natip` CLI attribute (see the “config firewall” chapter of the *FortiGate CLI Reference*), outbound NAT enables you to change the source addresses of IP packets before they go into the tunnel. This feature is often used to resolve ambiguous routing when two or more of the private networks making up a VPN have the same or overlapping IP addresses. .

When inbound NAT is enabled, inbound encrypted packets are intercepted and decrypted, and the source IP addresses of the decrypted packets are translated into the IP address of the FortiGate interface to the local private network before they are routed to the private network. If the computers on the local private network can communicate only with devices on the local private network (that is, the FortiGate interface to the private network is not the default gateway) and the remote client (or remote private network) does not have an IP address in the same network address space as the local private network, enable inbound NAT.

Source and destination addresses

Most security policies control outbound IP traffic. A VPN outbound policy usually has a source address originating on the private network behind the local FortiGate unit, and a destination address belonging to a dialup VPN client or a network behind the remote VPN peer. The source address that you choose for the security policy identifies from where outbound cleartext IP packets may originate, and also defines the local IP address or addresses that a remote server or client will be allowed to access through the VPN tunnel. The destination address that you choose identifies where IP packets must be forwarded after they are decrypted at the far end of the tunnel, and determines the IP address or addresses that the local network will be able to access at the far end of the tunnel.

Enabling other policy features

You can fine-tune a policy for services such as HTTP, FTP, and POP3; enable logging, traffic shaping, antivirus protection, web filtering, email filtering, file transfer, and email services throughout the VPN; and optionally allow connections according to a predefined schedule.

As an option, differentiated services (diffserv or DSCP) can be enabled in the security policy through CLI commands. For more information on this feature, see FortiOS Handbook Traffic Shaping chapter or the “firewall” chapter of the *FortiGate CLI Reference*.

When a remote server or client attempts to connect to the private network behind a FortiGate gateway, the security policy intercepts the connection attempt and starts the VPN tunnel. The FortiGate unit uses the remote gateway specified in its phase 1 tunnel configuration to reply to the remote peer. When the remote peer receives a reply, it checks its own security policy, including the tunnel configuration, to determine which communications are permitted. As long as one or more services are allowed through the VPN tunnel, the two peers begin to negotiate the tunnel. To follow this negotiation in the web-based manager, go to *VPN* > *Monitor* > *IPsec Monitor*. There you will find a list of the VPN tunnels, their status, and the data flow both incoming and outgoing.

Before you begin

Before you define the IPsec policy, you must:

- Define the IP source and destination addresses. See “Defining policy addresses” on page 1431.
- Specify the phase 1 authentication parameters. See “Auto Key phase 1 parameters” on page 1407.
- Specify the phase 2 parameters. See “Phase 2 parameters” on page 1425.

To define an IPsec security policy

1 Go to *Policy* > *Policy* > *Policy* and select *Create New*.

2 Include the settings as follows:

Source Interface/Zone	Select the local interface to the internal (private) network.
Source Address Name	Select the name that corresponds to the local network, server(s), or host(s) from which IP packets may originate.
Destination Interface/Zone	Select the local interface to the external (public) network.
Destination Address Name	Select the name that corresponds to the remote network, server(s), or host(s) to which IP packets may be delivered.
Schedule	Keep the default setting (always) unless changes are needed to meet specific requirements.
Service	Keep the default setting (ANY) unless changes are needed to meet your specific requirements.
Action	Select *IPSEC*.

VPN Tunnel	Select the name of the phase 1 tunnel configuration to which this policy will apply.
Allow Inbound	Select if traffic from the remote network will be allowed to initiate the tunnel.
Allow Outbound	Select if traffic from the local network will be allowed to initiate the tunnel.
Inbound NAT	Select if you want to translate the source IP addresses of inbound decrypted packets into the IP address of the FortiGate interface to the local private network.
Outbound NAT	Select in combination with a `natip` CLI value to translate the source addresses of outbound cleartext packets into the IP address that you specify. Do not select Outbound NAT unless you specify a `natip` value through the CLI. When a `natip` value is specified, the source addresses of outbound IP packets are replaced before the packets are sent through the tunnel. For more information, see the “firewall” chapter of the *FortiGate CLI Reference*.

3 You may enable UTM features, and/or event logging, or select advanced settings to authenticate a user group, or shape traffic. For more information, see the *Firewall* chapter of *The Handbook*.

4 Select *OK*.

5 Place the policy in the policy list above any other policies having similar source and destination addresses.

Defining multiple IPsec policies for the same tunnel

You must define at least one IPsec policy for each VPN tunnel. If the same remote server or client requires access to more than one network behind a local FortiGate unit, the FortiGate unit must be configured with an IPsec policy for each network. Multiple policies may be required to configure redundant connections to a remote destination or control access to different services at different times.

To ensure a secure connection, the FortiGate unit must evaluate IPSEC policies before ACCEPT and DENY security policies. Because the FortiGate unit reads policies starting at the top of the list, you must move all IPsec policies to the top of the list. When you define multiple IPsec policies for the same tunnel, you must reorder the IPsec policies that apply to the tunnel so that specific constraints can be evaluated before general constraints.

Adding multiple IPsec policies for the same VPN tunnel can cause conflicts if the policies specify similar source and destination addresses but have different settings for the same service. When policies overlap in this manner, the system may apply the wrong IPsec policy or the tunnel may fail.

For example, if you create two equivalent IPsec policies for two different tunnels, it does not matter which one comes first in the list of IPsec policies—the system will select the correct policy based on the specified source and destination addresses. If you create two different IPsec policies for the same tunnel (that is, the two policies treat traffic differently depending on the nature of the connection request), you might have to reorder the IPsec

policies to ensure that the system selects the correct IPsec policy. Reordering is especially important when the source and destination addresses in both policies are similar (for example, if one policy specifies a subset of the IP addresses in another policy). In this case, place the IPsec policy having the most specific constraints at the top of the list so that it can be evaluated first.

Defining security policies for a route-based VPN

When you define a route-based VPN, you create a virtual IPsec interface on the physical interface that connects to the remote peer. You create ordinary Accept security policies to enable traffic between the IPsec interface and the interface that connects to the private network. This makes configuration simpler than for policy-based VPNs, which require IPsec security policies.

To define security policies for a route-based VPN

1 Define an ACCEPT security policy to permit communications between the local private network and the private network behind the remote peer. Enter these settings in particular:

Source Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select the address name that you defined for the private network behind this FortiGate unit.
Destination Interface/Zone	Select the IPsec Interface you configured.
Destination Address Name	Select the address name that you defined for the private network behind the remote peer.
Action	Select ACCEPT.
NAT	Disable.

2 To permit the remote client to initiate communication, you need to define a security policy for communication in that direction. Enter these settings in particular:

Source Interface/Zone	Select the IPsec Interface you configured.
Source Address Name	Select the address name that you defined for the private network behind the remote peer.
Destination Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address Name	Select the address name that you defined for the private network behind this FortiGate unit.
Action	Select *ACCEPT*.
NAT	Disable.

Gateway-to-gateway configurations

This section explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN.

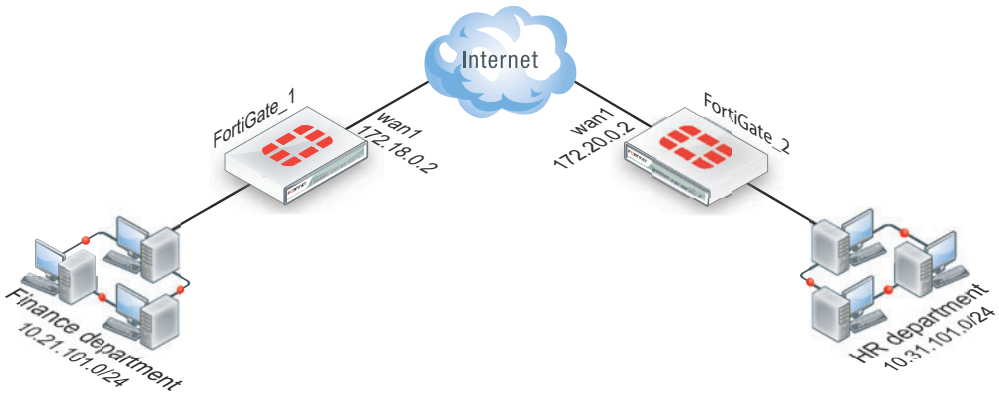
The following topics are included in this section:

- Configuration overview
- General configuration steps
- Configuring the two VPN peers
- How to work with overlapping subnets
- Testing

Configuration overview

In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Figure 128: Example gateway-to-gateway configuration

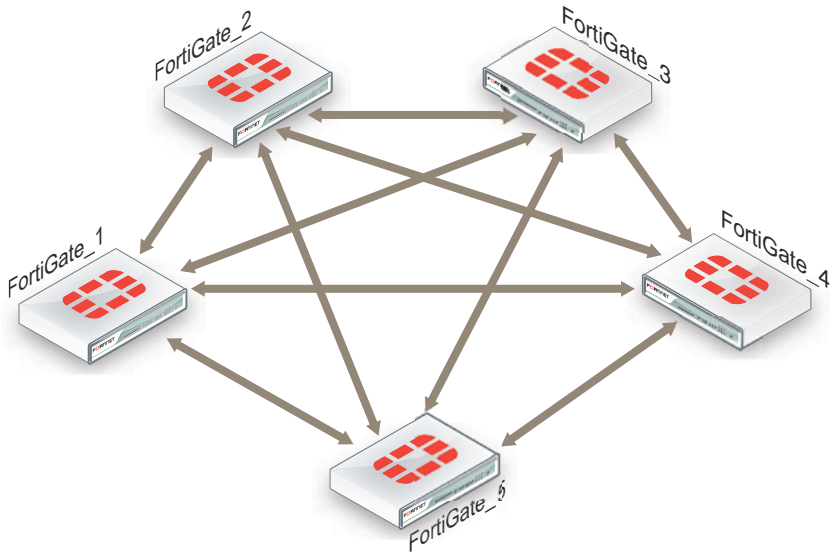


In some cases, computers on the private network behind one VPN peer may (by co-incidence) have IP addresses that are already used by computers on the network behind the other VPN peer. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent. To resolve issues related to ambiguous routing, see "How to work with overlapping subnets" on page 1444.

In other cases, computers on the private network behind one VPN peer may obtain IP addresses from a local DHCP server. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and/or IP-address overlap issues may arise. For a discussion of the related issues, see "FortiGate dialup-client configurations" on page 1501.

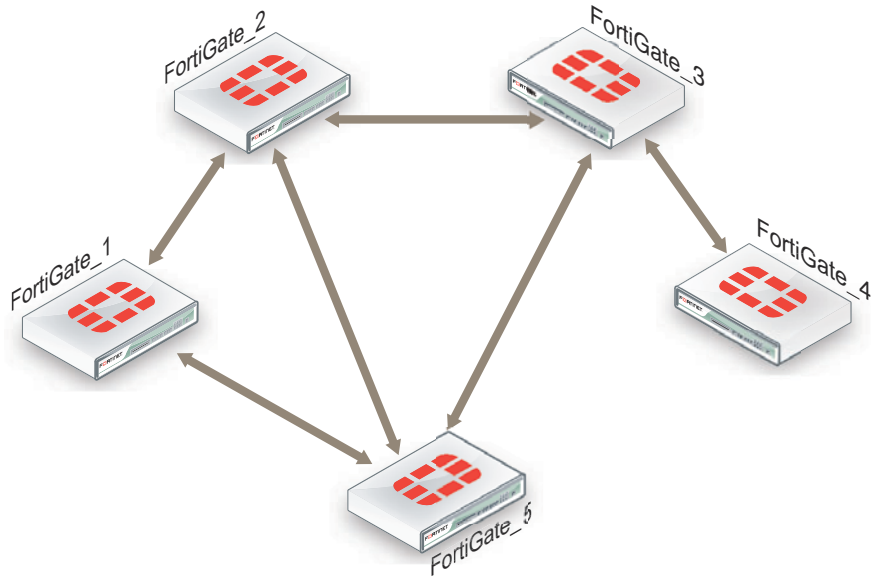
You can set up a fully meshed or partially meshed configuration (see Figure 129 and Figure 130).

Figure 129: Fully meshed configuration



In a fully meshed network, all VPN peers are connected to each other, with one hop between peers. This topology is the most fault-tolerant: if one peer goes down, the rest of the network is not affected. This topology is difficult to scale because it requires connections between all peers. In addition, unnecessary communication can occur between peers. Best practices dictates a hub-and-spoke configuration instead (see "Hub-and-spoke configurations" on page 1453).

Figure 130: Partially meshed configuration



A partially meshed network is similar to a fully meshed network, but instead of having tunnels between all peers, tunnels are only configured between peers that communicate with each other regularly.

General configuration steps

The FortiGate units at both ends of the tunnel must be operating in NAT mode and have static public IP addresses.

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec phase 1 parameters to establish a secure connection and authenticate that VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec phase 2 parameters and applies the IPsec security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed by both FortiGate units:

- Define the phase 1 parameters that the FortiGate unit needs to authenticate the remote peer and establish a secure connection.
- Define the phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with the remote peer.
- Create security policies to control the permitted services and permitted direction of traffic between the IP source and destination addresses.

Configuring the two VPN peers

Configure the VPN peers as follows. Each step is required, but these are general steps. For more detailed information on each step follow the cross references. See “Auto Key phase 1 parameters” on page 1407.

All steps are required. Cross references point to required information that is repeated. No steps are optional.

Configuring Phase 1 and Phase 2 for both peers

This procedure applies to both peers. Repeat the procedure on each FortiGate unit, using the correct IP address for each. You may wish to vary the Phase 1 names but this is optional. Otherwise all steps are the same for each peer.

The phase 1 configuration defines the parameters that FortiGate_1 will use to authenticate FortiGate_2 and establish a secure connection. For the purposes of this example, a preshared key will be used to authenticate FortiGate_2. The same preshared key must be specified at both FortiGate units.

Before you define the phase 1 parameters, you need to:

- Reserve a name for the remote gateway.
- Obtain the IP address of the public interface to the remote peer.
- Reserve a unique value for the preshared key.

The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must have a minimum of 16 randomly chosen alphanumeric characters.

At the local FortiGate unit, define the phase 1 configuration needed to establish a secure connection with the remote peer. See “Phase 1 configuration” on page 1394.

To create phase 1 to establish a secure connection with the remote peer

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 1*.

3 Enter the following information, and select *OK*.

Name	Enter `peer_1`. A name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select *Static IP Address*.
IP Address	Enter 172.20.0.2 when configuring FortiGate_1. Enter 172.18.0.2 when configuring FortiGate_2. The IP address of the remote peer public interface.
Local Interface	Select wan1. The FortiGate unit's public interface. This interface cannot be a loopback interface.
Enable IPsec Interface Mode	Select *Advanced* to see this setting. Enable *IPsec Interface Mode* to have the FortiGate unit create a virtual IPsec interface for a route-based VPN. Disable this option to create a policy-based VPN. For more information, see "Comparing policy-based or route-based VPNs" on page 1390. After you select *OK* to create the phase 1 configuration, you cannot change this setting.

The basic phase 2 settings associate IPsec phase 2 parameters with the phase 1 configuration and specify the remote end point of the VPN tunnel. Before you define the phase 2 parameters, you need to reserve a name for the tunnel. See "Phase 2 configuration" on page 1399.

To configure phase 2 settings

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 2*.

3 Enter the following information, and select OK.

Name	Enter `peer_1_p2`. A name to identify this phase 2 configuration.
Phase 1	Select `peer_1`. The name of the phase 1 configuration.

Creating security policies

Security policies control all IP traffic passing between a source address and a destination address.

An IPsec security policy is needed to allow the transmission of encrypted packets, specify the permitted direction of VPN traffic, and select the VPN tunnel that will be subject to the policy. A single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel.

Before you define security policies, you must first specify the IP source and destination addresses. In a gateway-to-gateway configuration:

- The IP source address corresponds to the private network behind the local FortiGate unit.
- The IP destination address refers to the private network behind the remote VPN peer.

When you are creating security policies, choose one of either route-based or policy-based methods and follow it for both VPN peers. DO NOT configure both route-based and policy-based policies on the same FortiGate unit for the same VPN tunnel.

The configuration of FortiGate_2 is similar to that of FortiGate_1. You must:

- Define the phase 1 parameters that FortiGate_2 needs to authenticate FortiGate_1 and establish a secure connection.
- Define the phase 2 parameters that FortiGate_2 needs to create a VPN tunnel with FortiGate_1.
- Create the security policy and define the scope of permitted services between the IP source and destination addresses.

When creating security policies it is good practice to include a comment describing what the policy does.

When creating security policies you need to be

- Creating firewall addresses
- Creating route-based VPN security policies
- Configuring a default route for VPN interface

or

- Creating firewall addresses
- Creating policy-based VPN security policy

Creating firewall addresses

Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks.

To define the IP address of the network behind FortiGate_1

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information, and select *OK*:

Address Name	Enter `Finance_network` A meaningful address name that describes the network behind FortiGate_1.
Subnet/IP Range	Enter `10.21.101.0/24`. The IP address of the private network behind FortiGate_1.

To specify the address of the network behind FortiGate_2

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information, and select *OK*:

Address Name	Enter `HR_network`.
Subnet/IP Range	Enter the IP address of the private network behind FortiGate_2 (for example, `10.31.101.0/24`).

Creating route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

To create route-based VPN security policies

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New.*

3 Enter the following information, and select *OK*.

Source Interface/Zone	Select internal The interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select *Finance_network* when configuring FortiGate_1. Select *HR_network* when configuring FortiGate_2. The address name that for the private network behind this FortiGate unit.
Destination Interface/Zone	Select *peer_1*. The VPN Tunnel (IPsec Interface) you configured earlier.
Destination Address Name	Select *HR_network* when configuring FortiGate_1. Select *Finance_network* when configuring FortiGate_2. The address name that you defined for the private network behind the remote peer.
Action	Select *ACCEPT*.
NAT	Disable.
Comment	Allow Internal to remote VPN network traffic

4 Configure any additional features such as UTM or traffic shaping you may want. (optional).

5 Select *Create New* to create another policy for the other direction.

6 Enter the following information, and select *OK*.

Source Interface/Zone	Select *peer_1*. The VPN Tunnel (IPsec Interface) you configured.
Source Address Name	Select *HR_network* when configuring FortiGate_1. Select *Finance_Network* when configuring FortiGate_2. The address name defined for the private network behind the remote peer.
Destination Interface/Zone	Select internal The interface that connects to the private network behind this FortiGate unit.
Destination Address Name	Select *Finance_Network* when configuring FortiGate_1. Select *HR_network* when configuring FortiGate_2. The address name defined for the private network behind this FortiGate unit.
Action	Select *ACCEPT*.
NAT	Disable.
Comment	Allow remote VPN network traffic to Internal.

7 Configure any additional features such as UTM or traffic shaping you may want. (optional).

Configuring a default route for VPN interface

All network traffic must have a static route to direct its traffic to the proper destination. Without a route, traffic will not flow even if the security policies are configured properly.

You may need to create a static route entry for both directions of VPN traffic if your security policies allow bi-directional tunnel initiation.

To configure the route for a route-based VPN

1 On FortiGate_2, go to *Router* > *Static* > *Static Route*.

2 Select *Create New*, enter the following information, and then select *OK*:

Destination IP / Mask	10.21.101.0/24
Device	FGT2_to_FGT1_Tunnel
Gateway	Leave as default: 0.0.0.0.
Distance	Leave this at its default. If there are other routes on this FortiGate unit, you may need to set the distance on this route so the VPN traffic will use it as the default route. However, this normally happens by default because this route is typically a better match than the generic default route.

Creating policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

Source Interface/Zone	Select internal. The interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select *Finance_network* when configuring FortiGate_1. Select *HR_network* when configuring FortiGate_2. The address name defined for the private network behind this FortiGate unit.
Destination Interface/Zone	Select wan1. The FortiGate unit's public interface.
Destination Address Name	Select *HR_network* when configuring FortiGate_1. Select *Finance_network* when configuring FortiGate_2. The address name that you defined in Step for the private network behind the remote peer.
Action	Select *IPSEC*.
VPN Tunnel	Select *peer_1*. The name of the phase 1 configuration that you created earlier. Select *Allow inbound* to enable traffic from the remote network to initiate the tunnel. Select *Allow outbound* to enable traffic from the local network to initiate the tunnel.
Comment	Bidirectional policy-based VPN policy

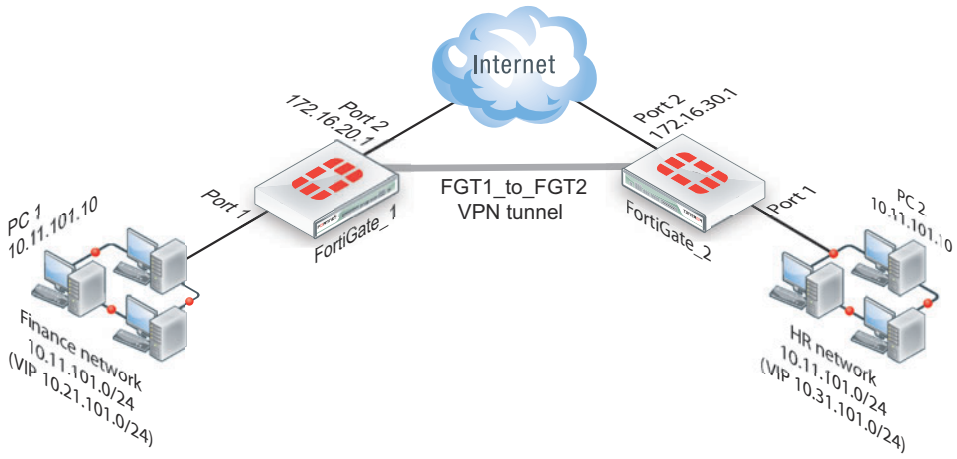
Place VPN policies in the policy list above any other policies having similar source and destination addresses.

How to work with overlapping subnets

A site-to-site VPN configuration sometimes has the problem that the private subnet addresses at each end are the same. You can resolve this problem by remapping the private addresses using virtual IP addresses (VIP).

VIPs allow computers on those overlapping private subnets to each have another set of IP addresses that can be used without confusion. The FortiGate unit maps the VIP addresses to the original addresses. This means if PC1 starts a session with PC2 at 10.31.101.10, FortiGate_2 directs that session to 10.11.101.10 — the actual IP address of PC2. Figure 131 shows this — Finance network VIP is 10.21.101.0/24 and the HR network is 10.31.101.0/24.

Figure 131: Overlapped subnets example



Solution for route-based VPN

You need to:

- Configure IPsec Phase 1 and Phase 2 as you usually would for a route-based VPN. In this example, the resulting IPsec interface is named `FGT1_to_FGT2`.
- Configure virtual IP (VIP) mapping:
  - the 10.21.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate_1
  - the 10.31.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate_2
- Configure an outgoing security policy with ordinary source NAT on both FortiGates.
- Configure an incoming security policy with the VIP as the destination on both FortiGates.
- Configure a route to the remote private network over the IPsec interface on both FortiGates.

To configure VIP mapping on both FortiGates

1 Go to *Firewall Objects* > *Virtual IP* > *Virtual IP*.

2 Select *Create New*, enter the following information, and select *OK*:

Name	Enter a name, for example, `my_vip`.
External Interface	Select `FGT1_to_FGT2`. The IPsec interface.
Type	Static NAT
External IP Address/Range	For the external IP address field enter: • `10.21.101.1` when configuring FortiGate_1, or • `10.31.101.1` when configuring FortiGate_2.

Mapped IP Address/Range	For the Mapped IP Address enter `10.11.101.1`. For the Range enter `10.11.101.254`.
Port Forwarding	Disable

To configure the outbound security policy on both FortiGates

Repeat this procedure on both FortiGate_1 and FortiGate_2.

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*.

3 Enter the following information, and select *OK*:

Source Interface/Zone	Select Port 1.
Source Address Name	Select all.
Destination Interface/Zone	Select `FGT1_to_FGT2`. The IPsec interface.
Destination Address Name	Select all.
Schedule	As required.
Service	As required.
Action	ACCEPT
NAT	Enable

To configure the inbound security policy on both FortiGates

Repeat this procedure on both FortiGate_1 and FortiGate_2.

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information, and then select *OK*:

Source Interface/Zone	Select `FGT1_to_FGT2`.
Source Address Name	Select all.
Destination Interface/Zone	Select Port 1.
Destination Address Name	Select `my-vip`.
Schedule	As required.
Service	As required.
Action	ACCEPT
NAT	Disable

To configure the static route for both FortiGates

Repeat this procedure on both FortiGate_1 and FortiGate_2.

1 Go to *Router* > *Static* > *Static Route*.

2 Select *Create New*, enter the following information, and then select *OK*:

Destination IP / Mask	`Enter 10.31.101.0/24` when configuring FortiGate_1 `Enter 10.21.101.0/24` when configuring FortiGate_2
Device	Select `FGT1_to_FGT2`.
Gateway	Leave as default: 0.0.0.0.
Distance	Leave at default. If you have advanced routing on your network, you may have to change this value.

If you do not add a static route for the VPN tunnel, no traffic will be sent or received.

Solution for policy-based VPN

As with the route-based solution, users contact hosts at the other end of the VPN using an alternate subnet address. PC1 communicates with PC2 using IP address 10.31.101.10, and PC2 communicates with PC1 using IP address 10.21.101.10.

In this solution however, outbound NAT is used to translate the source address of packets from the 10.11.101.0/24 network to the alternate subnet address that hosts at the other end of the VPN use to reply. Inbound packets from the remote end have their destination addresses translated back to the 10.11.101.0/24 network.

For example, PC1 uses the destination address 10.31.101.10 to contact PC2. Outbound NAT on FortiGate_1 translates the PC1 source address to 10.21.101.10. At the FortiGate_2 end of the tunnel, the outbound NAT configuration translates the destination address to the actual PC2 address of 10.11.101.10. Similarly, PC2 replies to PC1 using destination address 10.21.101.10, with the PC2 source address translated to 10.31.101.10. PC1 and PC2 can communicate over the VPN even though they both have the same IP address.

You need to:

- Configure IPsec Phase 1 as you usually would for a policy-based VPN.
- Configure IPsec Phase 2 with the `use-natip disable` CLI option.
- Define a firewall address for the local private network, 10.11.101.0/24.
- Define a firewall address for the remote private network:
  - define a firewall address for 10.31.101.0/24 on FortiGate_1
  - define a firewall address for 10.21.101.0/24 on FortiGate_2
- Configure an outgoing IPsec security policy with outbound NAT to map 10.11.101.0/24 source addresses:
  - to the 10.21.101.0/24 network on FortiGate_1
  - to the 10.31.101.0/24 network on FortiGate_2

To configure IPsec Phase 2 - CLI

```
config vpn ipsec phase2
  edit "FGT1_FGT2_p2"
    set keepalive enable
    set pfs enable
    set phase1name FGT1_to_FGT2
    set proposal 3des-sha1 3des-md5
    set replay enable
    set use-natip disable
  end
```

In this example, your phase 1 definition is named FGT1_to_FGT2. `use-natip` is set to `disable`, so you can specify the source selector using the `src-addr-type`, `src-start-ip` / `src-end-ip` or `src-subnet` keywords. This example leaves these keywords at their default values, which specify the subnet `0.0.0.0/0`.

The `pfs` keyword ensures that perfect forward secrecy (PFS) is used. This ensures that each Phase 2 key created is unrelated to any other keys in use.

To define the local private network firewall address

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New* and enter the following information:

Address Name	Enter `vpn-local`. A meaningful name for the local private network
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	Any

To define the remote private network firewall address

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*.

3 Enter the following information, and select *OK*:

Address Name	Enter `vpn-remote`. A meaningful name for the remote private network.
Type	Subnet / IP Range
Subnet / IP Range	`10.31.101.0 255.255.255.0` on FortiGate_1 `10.21.101.0 255.255.255.0` on FortiGate_2
Interface	Any

To configure the IPsec security policy

In the CLI on FortiGate_1, enter the commands:

```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "vpn-local"
    set dstaddr "vpn-remote"
    set action ipsec
    set schedule "always"
    set service "ANY"
    set inbound enable
    set outbound enable
    set vpntunnel "FGT1_to_FGT2"
    set natoutbound enable
    set natip 10.31.101.0 255.255.255.0
end
```

Optionally, you can set everything except `natip` in the web-based manager and then use the CLI to set `natip`.

Enter the same commands on FortiGate_2, but set natip be `10.21.101.0 255.255.255.0`.

Testing

The best testing is to look at the packets both as the VPN tunnel is negotiated, and when the tunnel is up.

To determine what the other end of the VPN tunnel is proposing

1. Start a terminal program such as puTTY and set it to log all output.

   When necessary refer to the logs to locate information when output is verbose.
2. Logon to the FortiGate unit using a super_admin account.
3. Enter the following CLI commands.
4. Display all the possible IKE error types and the number of times they have occurred:

   ```
   diag vpn ike errors
   ```
5. Check for existing debug sessions:

   ```
   diag debug info
   ```

   If a debug session is running, to halt it enter:

   ```
   diag debug disable
   ```
6. Confirm your proposal settings:

   ```
   diag vpn ike config list
   ```
7. If your proposal settings do not match what you expect, make a change to it and save it to force an update in memory. If that fixes the problem, stop here.
8. List the current vpn filter:

   ```
   diag vpn ike filter
   ```

9 If all fields are set to any, there are no filters set and all VPN ike packets will be displayed in the debug output. If your system has only a few VPNs, skip setting the filter.

If your system has many VPN connections this will result in very verbose output and make it very difficult to locate the correct connection attempt.

10 Set the VPN filter to display only information from the destination IP address for example 10.10.10.10:

```
diag vpn ike log-filter dst-addr4 10.10.10.10
```

To add more filter options, enter them one per line as above. Other filter options are displayed in Table 89.

Table 89: Filter options for diag vpn ike filter

clear	erase the current filter
dst-addr6	the IPv6 destination address range to filter by
dst-port	the destination port range to filter by
interface	interface that IKE connection is negotiated over
list	display the current filter
name	the phase1 name to filter by
negate	negate the specified filter parameter
src-addr4	the IPv4 source address range to filter by
src-addr6	the IPv6 source address range to filter by
src-port	the source port range to filter by
vd	index of virtual domain. 0 matches all

11 Start debugging:

```
diag debug app ike 255
diag debug enable
```

12 Have the remote end attempt a VPN connection.

If the remote end attempts the connection they become the initiator. This situation makes it easier to debug VPN tunnels because then you have the remote information and all of your local information. by initiate the connection, you will not see the other end's information.

13 If possible go to the web-based manager on your FortiGate unit, go to the VPN monitor and try to bring the tunnel up.

14 Stop the debug output:

```
diag debug disable
```

15 Go back through the output to determine what proposal information the initiator is using, and how it is different from your VPN P1 proposal settings.

Things to look for in the debug output of attempted VPN connections are shown below.

Table 90: Important terms to look for in VPN debug output

`initiator`	Starts the VPN attempt, in the above procedure that is the remote end
`responder`	Answers the initiator's request

Table 90: Important terms to look for in VPN debug output

`local ID`	In aggressive mode, this is not encrypted
`error no SA proposal chosen`	There was no proposal match — there was no encryption-authentication pair in common, usually occurs after a long list of proposal attempts
`R U THERE and` `R U THERE ack`	dead peer detection (dpd), also known as dead gateway detection — after three failed attempts to contact the remote end it will be declared dead, no farther attempts will be made to contact it
`negotiation result`	lists the proposal settings that were agreed on
`SA_life_soft and SA_life_hard`	negotiating a new key, and the key life
`R U THERE`	If you see this, it means Phase 1 was successful
`tunnel up`	the negotiation was successful, the VPN tunnel is operational

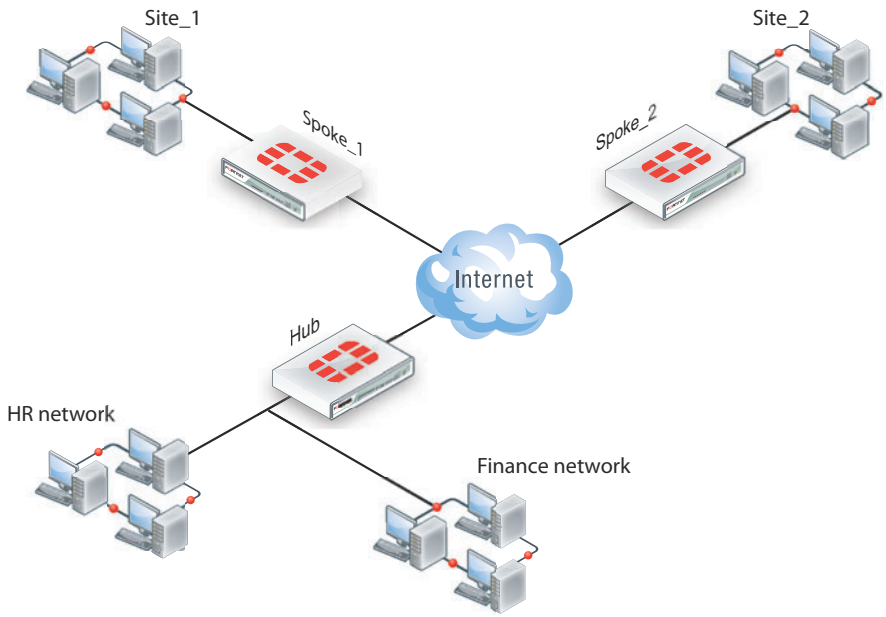
Hub-and-spoke configurations

This section describes how to set up hub-and-spoke IPsec VPNs. The following topics are included in this section:

Configuration overview

In a hub-and-spoke configuration, VPN connections radiate from a central FortiGate unit (the hub) to a number of remote peers (the spokes). Traffic can pass between private networks behind the hub and private networks behind the remote peers. Traffic can also pass between remote peer private networks through the hub.

Figure 132: Example hub-and-spoke configuration



The actual implementation varies in complexity depending on

- whether the spokes are statically or dynamically addressed
- the addressing scheme of the protected subnets
- how peers are authenticated

This guide discusses the issues involved in configuring a hub-and-spoke VPN and provides some basic configuration examples.

Hub-and-spoke infrastructure requirements

- The FortiGate hub must be operating in NAT mode and have a static public IP address.
- Spokes may have static IP addresses, dynamic IP addresses (see “FortiGate dialup-client configurations” on page 1501), or static domain names and dynamic IP addresses (see “Dynamic DNS configuration” on page 1469).

Spoke gateway addressing

The public IP address of the spoke is the VPN remote gateway as seen from the hub. Statically addressed spokes each require a separate VPN phase 1 configuration on the hub. When there are many spokes, this becomes rather cumbersome.

Using dynamic addressing for spokes simplifies the VPN configuration because then the hub requires only a single phase 1 configuration with “dialup user” as the remote gateway. You can use this configuration even if the remote peers have static IP addresses. A remote peer can establish a VPN connection regardless of its IP address if its traffic selectors match and it can authenticate to the hub. See “Dynamic spokes configuration example” on page 1463 for an example of this configuration.

Protected networks addressing

The addresses of the protected networks are needed to configure destination selectors and sometimes for security policies and static routes. The larger the number of spokes, the more addresses there are to manage. You can

- assign spoke subnets as part of a larger subnet, usually on a new network

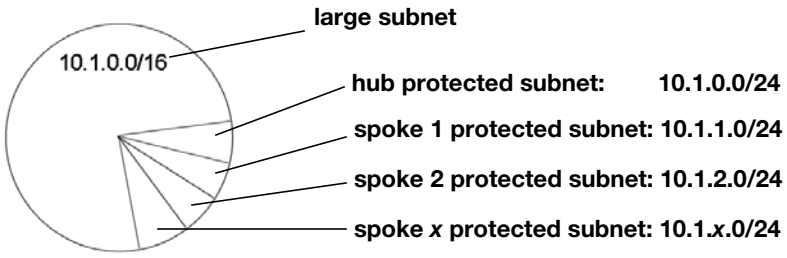
or

- create address groups that contain all of the needed addresses

Using aggregated subnets

If you are creating a new network, where subnet IP addresses are not already assigned, you can simplify the VPN configuration by assigning spoke subnets that are part of a large subnet.

Figure 133: Aggregated subnets



All spokes use the large subnet address, 10.1.0.0/16 for example, as

- the IPsec destination selector
- the destination of the security policy from the private subnet to the VPN (required for policy-based VPN, optional for route-based VPN)
- the destination of the static route to the VPN (route-based)

Each spoke uses the address of its own protected subnet as the IPsec source selector and as the source address in its VPN security policy. The remote gateway is the public IP address of the hub FortiGate unit.

Using an address group

If you want to create a hub-and-spoke VPN between existing private networks, the subnet addressing usually does not fit the aggregated subnet model discussed earlier. All of the spokes and the hub will need to include the addresses of all the protected networks in their configuration.

On FortiGate units, you can define a named firewall address for each of the remote protected networks and add these addresses to a firewall address group. For a policy-based VPN, you can then use this address group as the destination of the VPN security policy.

For a route-based VPN, the destination of the VPN security policy can be set to All. You need to specify appropriate routes for each of the remote subnets.

Authentication

Authentication is by a common preshared key or by certificates. For simplicity, the examples in this chapter assume that all spokes use the same preshared key.

Configure the hub

At the FortiGate unit that acts as the hub, you need to

- configure the VPN to each spoke
- configure communication between spokes

You configure communication between spokes differently for a policy-based VPN than for a route-based VPN. For a policy-based VPN, you configure a VPN concentrator. For a route-based VPN, you must either define security policies or group the IPsec interfaces into a zone

Define the hub-spoke VPNs

Perform these steps at the FortiGate unit that will act as the hub. Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

To configure the VPN hub

1 At the hub, define the phase 1 configuration for each spoke. See "Auto Key phase 1 parameters" on page 1407. Enter these settings in particular:

Name	Enter a name to identify the VPN in phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	The remote gateway is the other end of the VPN tunnel. There are three options: **Static IP Address —** Enter the spoke's public *IP Address*. You will need to create a phase 1 configuration for each spoke. Either the hub or the spoke can establish the VPN connection. **Dialup User** — No additional information is needed. The hub accepts connections from peers with appropriate encryption and authentication settings. Only one phase 1 configuration is needed for multiple dialup spokes. Only the spoke can establish the VPN tunnel. **Dynamic DNS** — If the spoke subscribes to a dynamic DNS service, enter the spoke's *Dynamic DNS* domain name. Either the hub or the spoke can establish the VPN connection. For more information, see "Dynamic DNS configuration" on page 1469.
Local Interface	Select the FortiGate interface that connects to the remote gateway. This is usually the FortiGate unit's public interface. This interface cannot be a loopback interface.
Enable IPsec Interface Mode	You must select Advanced to see this setting. If *IPsec Interface Mode* is enabled, the FortiGate unit creates a virtual IPsec interface for a route-based VPN. Disable this option if you want to create a policy-based VPN. For more information, see "Comparing policy-based or route-based VPNs" on page 1390. After you select *OK* to create the phase 1 configuration, you cannot change this setting.

2 Define the phase 2 parameters needed to create a VPN tunnel with each spoke. See "Phase 2 parameters" on page 1425. Enter these settings in particular:

Name	Enter a name to identify this spoke phase 2 configuration.
Phase 1	Select the name of the phase 1 configuration that you defined for this spoke.

Define the hub-spoke security policies

1 Define a name for the address of the private network behind the hub. For more information, see "Defining policy addresses" on page 1431.

2 Define names for the addresses or address ranges of the private networks behind the spokes. For more information, see "Defining policy addresses" on page 1431.

3 Define the VPN concentrator. See "To define the VPN concentrator" on page 1458.

4 Define security policies to permit communication between the hub and the spokes. For more information, see "Defining VPN security policies" on page 1432.

Route-based VPN security policies

Define ACCEPT security policies to permit communications between the hub and the spoke. You need one policy for each direction. Enter these settings in particular:

Source Interface/Zone	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
Source Address Name	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
Destination Interface/Zone	Select the hub's interface to the internal (private) network.
Destination Address Name	Select the source address that you defined in Step 1.
Action	Select *ACCEPT*.
NAT	Enable.

Source Interface/Zone	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate units.
Source Address Name	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
Destination Interface/Zone	Select the source address that you defined in Step 1.
Destination Address Name	Select the hub's interface to the internal (private) network.
Action	Select *ACCEPT*.
NAT	Enable.

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the hub and the spoke. Enter these settings in particular:

Source Interface/Zone	Select the hub's interface to the internal (private) network.
Source Address Name	Select the source address that you defined in Step 1.
Destination Interface/Zone	Select the hub's public network interface.
Destination Address Name	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
Action	IPSEC
VPN Tunnel	Select the name of the phase 1 configuration that you created for the spoke in Step 1. Select *Allow inbound* to enable traffic from the remote network to initiate the tunnel. Select *Allow outbound* to enable traffic from the local network to initiate the tunnel.

5 In the policy list, arrange the policies in the following order:
- IPsec policies that control traffic between the hub and the spokes first
- the default security policy last

Configuring communication between spokes (policy-based VPN)

For a policy-based hub-and-spoke VPN, you define a concentrator to enable communication between the spokes.

To define the VPN concentrator

1 At the hub, go to *VPN* > *IPSEC* > *Concentrator* and select *Create New*.
2 In the *Concentrator Name* field, type a name to identify the concentrator.
3 From the *Available Tunnels* list, select a VPN tunnel and then select the right-pointing arrow.

To remove tunnels from the VPN concentrator, select the tunnel in the *Members* list and select the left-pointing arrow.

4 Repeat Step 3 until all of the tunnels associated with the spokes are included in the concentrator.
5 Select *OK*.

Configuring communication between spokes (route-based VPN)

For a route-based hub-and-spoke VPN, there are several ways you can enable communication between the spokes:

- put all of the IPsec interfaces into a zone and enable intra-zone traffic. This eliminates the need for any security policy for the VPN, but you cannot apply UTM features to scan the traffic for security threats.
- put all of the IPsec interfaces into a zone and create a single zone-to-zone security policy
- create a security policy for each pair of spokes that are allowed to communicate with each other. The number of policies required increases rapidly as the number of spokes increases.

Using a zone as a concentrator

A simple way to provide communication among all of the spokes is to create a zone and allow intra-zone communication. You cannot apply UTM features using this method.

1 Go to *System* > *Network* > *Interface.*
2 Select the down-arrow on the *Create New* button and select *Zone*.
3 In the *Zone Name* field, enter a name, such as `Our_VPN_zone`.
4 Clear *Block intra-zone traffic*.
5 In the *Interface Members* list, select the IPsec interfaces that are part of your VPN.
6 Select *OK*.

Using a zone with a policy as a concentrator

If you put all of the hub IPsec interfaces involved in the VPN into a zone, you can enable communication among all of the spokes and apply UTM features with just one security policy.

To create a zone for the VPN

1 Go to *System* > *Network* > *Interface.*
2 Select the down-arrow on the *Create New* button and select *Zone*.
3 In the *Zone Name* field, enter a name, such as `Our_VPN_zone`.
4 Select *Block intra-zone traffic*.
5 In the *Interface Members* list, select the IPsec interfaces that are part of your VPN.
6 Select *OK*.

To create a security policy for the zone

1 Go to *Policy* > *Policy* > *Policy*. Select *Create New* and enter the settings:

Source Interface/Zone	Select the zone you created for your VPN.
Source Address Name	Select *All*.
Destination Interface/Zone	Select the zone you created for your VPN.
Destination Address Name	Select *All*.
Action	Select *ACCEPT*.
NAT	Enable.
UTM	If you want to apply UTM features to this traffic, select the appropriate profiles.

2 Select *OK*.

Using security policies as a concentrator

To enable communication between two spokes, you need to define an ACCEPT security policy for them. To allow either spoke to initiate communication, you must create a policy for each direction. This procedure describes a security policy for communication from Spoke 1 to Spoke 2. Others are similar.

1 Define names for the addresses or address ranges of the private networks behind each spoke. For more information, see “Defining policy addresses” on page 1431.
2 Go to *Policy* > *Policy* > *Policy*. Select *Create New* and enter the settings:

Source Interface/Zone	Select the IPsec interface that connects to Spoke 1.
Source Address Name	Select the address of the private network behind Spoke 1.
Destination Interface/Zone	Select the IPsec interface that connects to Spoke 2.
Destination Address Name	Select the address of the private network behind Spoke 2.
Action	Select *ACCEPT*.

NAT	Enable.
UTM	If you want to apply UTM features to this traffic, select the appropriate profiles.

3 Select *OK*.

Configure the spokes

Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

Perform these steps at each FortiGate unit that will act as a spoke.

To create the phase 1 and phase_2 configurations

1 At the spoke, define the phase 1 parameters that the spoke will use to establish a secure connection with the hub. See "Auto Key phase 1 parameters" on page 1407. Enter these settings:

Remote Gateway	Select *Static IP Address*.
IP Address	Type the IP address of the interface that connects to the hub.
Enable IPsec Interface Mode	Enable if you are creating a route-based VPN. Clear if you are creating a policy-based VPN.

2 Create the phase 2 tunnel definition. See "Phase 2 parameters" on page 1425. Select the set of phase 1 parameters that you defined for the hub. You can select the name of the hub from the *Static IP Address* part of the list.

Configuring security policies for hub-to-spoke communication

1 Create an address for this spoke. See "Defining policy addresses" on page 1431. Enter the IP address and netmask of the private network behind the spoke.

2 Create an address to represent the hub. See "Defining policy addresses" on page 1431. Enter the IP address and netmask of the private network behind the hub.

3 Define the security policy to enable communication with the hub.

Route-based VPN security policy

Define two security policies to permit communications to and from the hub. Enter these settings:

Source Interface/Zone	Select the virtual IPsec interface you created.
Source Address Name	Select the hub address you defined in Step 1.
Destination Interface/Zone	Select the spoke's interface to the internal (private) network.
Destination Address Name	Select the spoke addresses you defined in Step 2.
Action	Select ACCEPT
NAT	Enable

Source Interface/Zone	Select the spoke's interface to the internal (private) network.
Source Address Name	Select the spoke address you defined in Step 1.
Destination Interface/Zone	Select the virtual IPsec interface you created.
Destination Address Name	Select the hub destination addresses you defined in Step 2.
Action	Select ACCEPT
NAT	Enable

Policy-based VPN security policy

Define an IPsec security policy to permit communications with the hub. See "Defining VPN security policies" on page 1432. Enter these settings in particular:

Source Interface/Zone	Select the spoke's interface to the internal (private) network.
Source Address Name	Select the spoke address you defined in Step 1.
Destination Interface/Zone	Select the spoke's interface to the external (public) network.
Destination Address Name	Select the hub address you defined in Step 2.
Action	Select IPSEC
VPN Tunnel	Select the name of the phase 1 configuration you defined. Select Allow inbound to enable traffic from the remote network to initiate the tunnel. Select Allow outbound to enable traffic from the local network to initiate the tunnel.

Configuring security policies for spoke-to-spoke communication

Each spoke requires security policies to enable communication with the other spokes. Instead of creating separate security policies for each spoke, you can create an address group that contains the addresses of the networks behind the other spokes. The security policy then applies to all of the spokes in the group.

1 Define destination addresses to represent the networks behind each of the other spokes. Add these addresses to an address group. For more information, see "Configuring Address Groups" section in the "Firewall Address" chapter of the *FortiGate Administration Guide*.

2 Define the security policy to enable communication between this spoke and the spokes in the address group you created.

Policy-based VPN security policy

Define an IPsec security policy to permit communications with the other spokes. See "Defining VPN security policies" on page 1432. Enter these settings in particular:

Route-based VPN security policy

Define two security policies to permit communications to and from the other spokes. Enter these settings in particular:

Source Interface/Zone	Select the virtual IPsec interface you created.
Source Address Name	Select the spoke address group you defined in Step 1.
Destination Interface/Zone	Select the spoke's interface to the internal (private) network.
Destination Address Name	Select this spoke's address name.
Action	Select *ACCEPT*
NAT	Enable

Source Interface/Zone	Select the spoke's interface to the internal (private) network.
Source Address Name	Select this spoke's address name.
Destination Interface/Zone	Select the virtual IPsec interface you created.
Destination Address Name	Select the spoke address group you defined in Step 1.
Action	Select *ACCEPT*
NAT	Enable

Policy-based VPN security policy

Source Interface/Zone	Select this spoke's internal (private) network interface.
Source Address Name	Select this spoke's source address.
Destination Interface/Zone	Select the spoke's interface to the external (public) network.
Destination Address Name	Select the spoke address group you defined in Step 1.

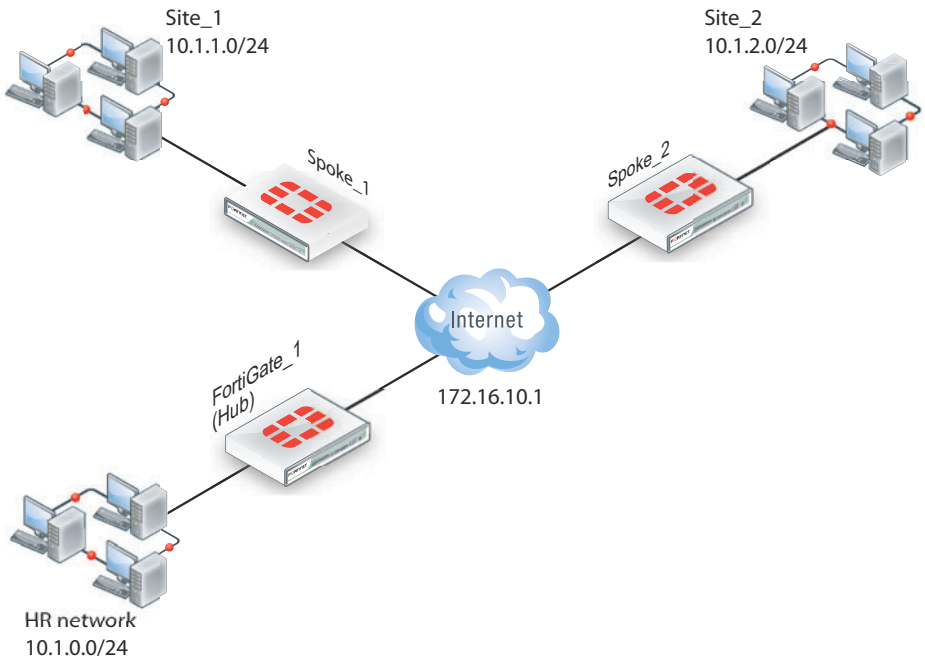
Action	Select *IPSEC*
VPN Tunnel	Select the name of the phase 1 configuration you defined. Select *Allow inbound* to enable traffic from the remote network to initiate the tunnel. Select *Allow outbound* to enable traffic from the local network to initiate the tunnel.

1 Place this policy or policies in the policy list above any other policies having similar source and destination addresses.

Dynamic spokes configuration example

This example demonstrates how to set up a basic route-based hub-and-spoke IPsec VPN that uses preshared keys to authenticate VPN peers.

Figure 134: Example hub-and-spoke configuration



In the example configuration, the protected networks 10.1.0.0/24, 10.1.1.0/24 and 10.1.2.0/24 are all part of the larger subnet 10.1.0.0/16. The steps for setting up the example hub-and-spoke configuration create a VPN among Site 1, Site 2, and the HR Network.

The spokes are dialup. Their addresses are not part of the configuration on the hub, so only one spoke definition is required no matter the number of spokes. For simplicity, only two spokes are shown.

Configure the hub (FortiGate_1)

The phase 1 configuration defines the parameters that FortiGate_1 will use to authenticate spokes and establish secure connections.

For the purposes of this example, one preshared key will be used to authenticate all of the spokes. Each key must contain at least 6 printable characters and best practices dictates that it only be known by network administrators. For optimum protection against currently known attacks, each key must consist of a minimum of 16 randomly chosen alphanumeric characters.

Define the IPsec configuration

To define the phase 1 parameters

1 At FortiGate_1, go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Define the phase 1 parameters that the hub will use to establish a secure connection to the spokes. Select *Create Phase 1*, enter the following information, and select *OK*:

Name	Type a name (for example, `toSpokes`).
Remote Gateway	Dialup user
Local Interface	External
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID

The basic phase 2 settings associate IPsec phase 2 parameters with the phase 1 configuration and specify the remote end points of the VPN tunnels.

To define the phase 2 parameters

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Create a phase 2 tunnel definition for the spokes. Select *Create Phase 2*, enter the following information, and select *OK*:

Name	Enter a name for the phase 2 definition (for example, `toSpokes_ph2`).
Phase 1	Select the Phase 1 configuration that you defined previously (for example, `toSpokes`).

Define the security policies

security policies control all IP traffic passing between a source address and a destination address. For a route-based VPN, the policies are simpler than for a policy-based VPN. Instead of an IPSEC policy, you use an ACCEPT policy with the virtual IPsec interface as the external interface.

Before you define security policies, you must first define firewall addresses to use in those policies. You need addresses for:

- the HR network behind FortiGate_1
- the aggregate subnet address for the protected networks

To define the IP address of the HR network behind FortiGate_1

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information, and select *OK*:

Address Name	Enter an address name (for example, `HR_Network`).
Subnet/IP Range	Enter the IP address of the HR network behind FortiGate_1 (for example, `10.1.0.0/24`).

To specify the IP address the aggregate protected subnet

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information, and select *OK*:

Address Name	Enter an address name (for example, `Spoke_net`).
Subnet/IP Range	Enter the IP address of the aggregate protected network, `10.1.0.0/16`

To define the security policy for traffic from the hub to the spokes

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Select the interface to the HR network, *port 1*.
Address Name	`HR_Network`
Destination Interface/Zone	Select the virtual IPsec interface that connects to the spokes, `toSpokes`
Address Name	`Spoke_net`
Schedule	As required.
Service	As required.
Action	ACCEPT

3 Place the policy in the policy list above any other policies having similar source and destination addresses.

Configure communication between spokes

Spokes communicate with each other through the hub. You need to configure the hub to allow this communication. An easy way to do this is to create a zone containing the virtual IPsec interfaces even if there is only one, and create a zone-to-zone security policy.

To create a zone for the VPN

1 Go to *System* > *Network* > *Interface.*

2 Select the down-arrow on the *Create New* button and select *Zone*.

3 In the *Zone Name* field, enter a name, such as `Our_VPN_zone`.

4 Select *Block intra-zone traffic*.

You could enable intra-zone traffic and then you would not need to create a security policy. But, you would not be able to apply UTM features.

5 In *Interface Members*, select the virtual IPsec interface, `toSpokes`.

6 Select *OK*.

To create a security policy for the zone

1 Go to *Policy* > *Policy* > *Policy*. Select *Create New* and enter these settings:

Source Interface/Zone	Select `Our_VPN_zone`.
Source Address Name	Select *All*.
Destination Interface/Zone	Select `Our_VPN_zone`.
Destination Address Name	Select *All*.
Action	Select *ACCEPT*.
NAT	Enable.
UTM	Select the appropriate UTM profiles.

2 Select *OK*.

Configure the spokes

In this example, all spokes have nearly identical configuration, requiring the following:

- phase 1 authentication parameters to initiate a connection with the hub
- phase 2 tunnel creation parameters to establish a VPN tunnel with the hub
- a source address that represents the network behind the spoke. This is the only part of the configuration that is different for each spoke.
- a destination address that represents the aggregate protected network
- a security policy to enable communications between the spoke and the aggregate protected network

Define the IPsec configuration

At each spoke, create the following configuration.

To define the Phase 1 parameters

1 At the spoke, go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	Type a name, for example, `toHub`.
Remote Gateway	Static IP Address
IP Address	`172.16.10.1`
Local Interface	Port2
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. The value must be identical to the preshared key that you specified previously in the FortiGate_1 configuration.
Peer Options	Accept any peer ID
Enable IPsec Interface Mode	Select *Advanced* to see this option. Enable the option to create a route-based VPN.

To define the Phase 2 parameters

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 2*, enter the following information, and select *OK*:

Name		Enter a name for the tunnel, for example, `toHub_ph2`.
Phase 1		Select the name of the phase 1 configuration that you defined previously, for example, `toHub`.
Advanced		Select to show the following *Quick Mode Selector* settings.
	Source	Enter the address of the protected network at this spoke. For spoke_1, this is `10.1.1.0/24`. For spoke_2, this is `10.1.2.0/24`.
	Destination	Enter the aggregate protected subnet address, `10.1.0.0/16`.

Define the security policies

You need to define firewall addresses for the spokes and the aggregate protected network and then create a security policy to enable communication between them.

To define the IP address of the network behind the spoke

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information, and select *OK*:

Address Name	Enter an address name, for example `LocalNet`.
Subnet/IP Range	Enter the IP address of the private network behind the spoke. For spoke_1, this is `10.1.1.0/24`. For spoke_2, this is `10.1.2.0/24`.

To specify the IP address of the aggregate protected network

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information, and select *OK*:

Address Name	Enter an address nam, for example, `Spoke_net`.
Subnet/IP Range	Enter the IP address of the aggregate protected network, `10.1.0.0/16`.

To define the security policy

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Select the virtual IPsec interface, `toHub`.
Address Name	Select the aggregate protected network address `Spoke_net`
Destination Interface/Zone	Select the interface to the internal (private) network, `port1`.

Address Name	Select the address for this spoke's protected network `LocalNet`
Schedule	As required.
Service	As required.
Action	ACCEPT

3 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Select the interface to the internal private network, `port1`.
Address Name	Select the address for this spoke's protected network, `LocalNet`
Destination Interface/Zone	Select the virtual IPsec interface, `toHub`.
Address Name	Select the aggregate protected network address, `Spoke_net`
Schedule	As required.
Service	As required.
Action	ACCEPT

4 Place these policies in the policy list above any other policies having similar source and destination addresses.

Dynamic DNS configuration

This section describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a domain name and a dynamic IP address.

The following topics are included in this section:

Dynamic DNS over VPN concepts

A typical computer has a static IP address and one or more DNS servers to resolve fully qualified domain names (FQDN) into IP addresses. A domain name assigned to this computer is resolved by any DNS server having an entry for the domain name and its static IP address. The IP address never changes or changes only rarely so the DNS server can reliably say it has the correct address for that domain all the time.

Dynamic DNS (DDNS)

It is different when a computer has a dynamic IP address, such as an IP address assigned dynamically by a DHCP server, and a domain name. Computers that want to contact this computer do not know what its current IP address is. To solve this problem there are dynamic DNS servers. These are public servers that store a DNS entry for your computer that includes its current IP address and associated domain name. These entries are kept up to date by your computer sending its current IP address to the dynamic DNS (DDNS) server to ensure its entry is always up to date. When other computers want to contact your domain, their DNS gets your IP address from your DDNS server. To use DDNS servers, you must subscribe to them and usually pay for their services.

When configuring DDNS on your FortiGate unit, go to *System* > *Network* > *DNS* and enable *Use DDNS*. Then select the interface with the dynamic connection, which DDNS server you have an account with, your domain name, and account information. If your DDNS server is not on the list, there is a generic option where you can provide your DDNS server information.

Routing

When an interface has some form of changing IP address (DDNS, PPPoE, or DHCP assigned address), routing needs special attention. The standard static route cannot handle the changing IP address. The solution is to use the dynamic-gateway command in the CLI. Say for example you already have four static routes, and you have a PPPoE connection over the wan2 interface and you want to use that as your default route.

The route is configured on the dynamic address VPN peer trying to access the static address FortiGate unit.

To configure dynamic gateway routing - CLI

```
config router static
  edit 5
    set dst 0.0.0.0 0.0.0.0
    set dynamic-gateway enable
    set device wan2
  next
end
```

handbook chapter

Dynamic DNS over VPN

IPsec VPN expects an IP address for each end of the VPN tunnel. All configuration and communication with that tunnel depends on the IP addresses as reference points. However, when the interface the tunnel is on has DDNS enabled there is no set IP address. The remote end of the VPN tunnel now needs another way to reference your end of the VPN tunnel. This is accomplished using Local ID.

A FortiGate unit that has a domain name and a dynamic IP address can initiate VPN connections anytime—the remote peer can reply to the local FortiGate unit using the source IP address that was sent in the packet header because it is current. Without doing a DNS lookup first, the remote peer runs the risk of the dynamic IP changing before it attempts to connect. To avoid this, the remote peer must perform a DNS lookup for the domain name of to be sure of the dynamic IP address before initiating the connection.

Remote Gateway

When configuring the Phase 1 entry for a VPN tunnel, the Remote Gateway determines the addressing method the remote end of the tunnel uses as one of Static IP Address, Dialup User, or Dynamic DNS. There are different fields for each option.

When you select the Dynamic DNS VPN type there is a related field called Dynamic DNS. The Dynamic DNS field is asking for the FQDN of the remote end of the tunnel. It uses this information to look up the IP address of the remote end of the tunnel through the DDNS server associated with that domain name.

Local ID (peer ID)

The Local ID or peer ID can be used to uniquely identify one end of a VPN tunnel. This enables a more secure connection. Also if you have multiple VPN tunnels negotiating, this ensures the proper remote and local ends connect. When you configure it on your end, it is your Local ID. When the remote end connects to you, they see it as your peer ID.

If you are debugging a VPN connection, the Local ID is part of the VPN negotiations. You can use it to help troubleshoot connection problems.

To configure your Local ID

1. Go to *VPN* > *IPsec* > *Auto Key (IKE*).
2. Select *Create New Phase 1* or edit an existing Phase 1 entry.
3. Select *Advanced*.
4. In the *P1 Proposal* section, enter your Local ID.
5. Select *OK*.

The default configuration is to accept all local IDs (peer IDs). If you have the Local ID set, the remote end of the tunnel must be configured to accept your Local ID.

To accept a specific Peer ID

1 Go to *VPN* > *IPsec* > *Auto Key (IKE*).
2 Select *Create New Phase 1.*
3 Select *Aggressive mode*.
4 For *Peer Options*, select *Accept this peer ID*. This option becomes visible only when Aggressive mode is selected.
5 Enter the string the other end of the tunnel used for its Local ID.
6 Configure the rest of the Phase 1 entry as required.
7 Select *OK*.

Route-based or policy-based VPN

VPN over dynamic DNS can be configured with either route-based or policy-based VPN settings. Both are valid, but have differences in configuration. Choose the best method based on your requirements. For more information on route-based and policy-based, see "Types of VPNs" on page 1389.

Route-based VPN configuration requires two security policies to be configured (one for each direction of traffic) to permit traffic over the VPN virtual interface, and you must also add a static route entry for that VPN interface or the VPN traffic will not reach its destination. See "Creating branch_2 route-based security policies" on page 1475 and "Creating branch_1 route-based security policies" on page 1480.

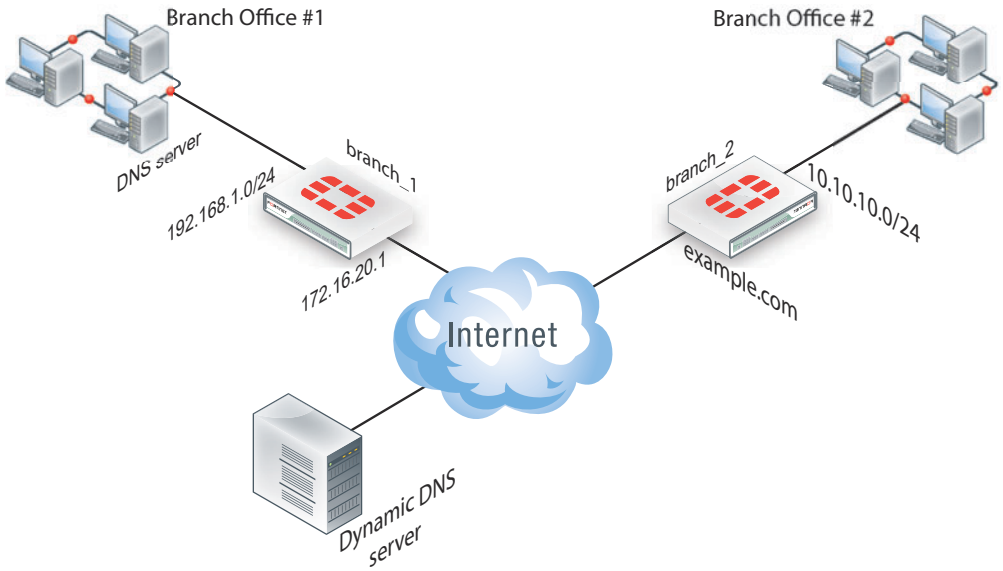
Policy-based VPN configuration uses more complex and often more IPsec security policies, but does not require a static route entry. It has the benefit of being able to configure multiple policies for handling multiple protocols in different ways, such as more scanning of less secure protocols or guaranteeing a minimum bandwidth for protocols such as VoIP. See "Creating branch_2 policy-based security policies" on page 1477 and "Creating branch_1 policy-based security policies" on page 1481

Dynamic DNS topology

In this scenario, two branch offices each have a FortiGate unit and are connected in a gateway-to-gateway VPN configuration. One FortiGate unit has a domain name (example.com) with a dynamic IP address. See `branch_2` in Figure 135.

Whenever the `branch_2` unit connects to the Internet (and possibly also at predefined intervals set by the ISP), the ISP may assign a different IP address to the FortiGate unit. The unit has its domain name registered with a dynamic DNS service. The `branch_2` unit checks in with the DDNS server on a regular basis, and that server provides the DNS information for the domain name, updating the IP address from time to time. Remote peers have to locate the `branch_2` FortiGate unit through a DNS lookup each time to ensure the address they get is current and correct.

Figure 135: Example dynamic DNS configuration



When a remote peer (such as the `branch_1` FortiGate unit in Figure 135) initiates a connection to `example.com`, the local DNS server looks up and returns the IP address that matches the domain name `example.com`. The remote peer uses the retrieved IP address to establish a VPN connection with the `branch_2` FortiGate unit.

Assumptions

- You have administrator access to both FortiGate units.
- Both FortiGate units have interfaces named wan1 and internal. (If not, you can use the alias feature to assign these labels as “nicknames” to other interfaces to follow this example.)
- Both FortiGate units have the most recent firmware installed, have been configured for their networks, and are currently passing normal network traffic.
- The `branch_2` FortiGate unit has its `wan1` interface defined as a dynamic DNS interface with the domain name of *example.com*.
- A basic gateway-to-gateway configuration is in place (see “Gateway-to-gateway configurations” on page 1437) except one of the FortiGate units has a static domain name and a dynamic IP address instead of a static IP address.
- The FortiGate unit with the domain name is subscribed to one of the supported dynamic DNS services. Contact one of the services to set up an account. For more information and instructions about how to configure the FortiGate unit to push its dynamic IP address to a dynamic DNS server, see the System Administration handbook chapter.

General configuration steps

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec phase 1 parameters to establish a secure connection and authenticate the VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec phase 2 parameters and applies the security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

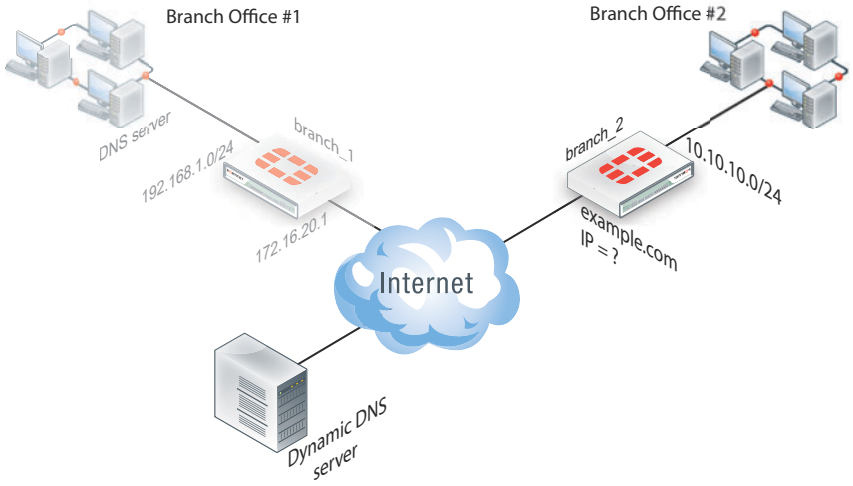
To support these functions, the following general configuration steps must be performed:

- Configure the branch_2 FortiGate unit with the dynamic IP address. This unit uses a Local ID string instead of an IP address to identify itself to the remote peer. See "Configure the dynamically-addressed VPN peer" on page 1473.
  - Configuring branch_2 VPN tunnel settings
  - Configuring branch_2 security policies
- Configure the fixed-address VPN peer. To initiate a VPN tunnel with the dynamically-addressed peer, this unit must first retrieve the IP address for the domain from the dynamic DNS service. See "Configure the fixed-address VPN peer" on page 1478.
  - Configuring branch_1 VPN tunnel settings
  - Configuring branch_1 security policies

Configure the dynamically-addressed VPN peer

It is assumed that this FortiGate unit (`branch_2`) has already had its public facing interface, for example the `wan1`, configured with the proper dynamic DNS configuration.

Figure 136: Configure branch_2, the dynamic address side



Configuring the dynamically-addressed VPN peer includes:

- Configuring branch_2 VPN tunnel settings
- Configuring branch_2 security policies

Configuring branch_2 VPN tunnel settings

Define the phase 1 parameters needed to establish a secure connection with the remote peer. See "Auto Key phase 1 parameters" on page 1407. During this procedure you need to choose if you will be using route-based or policy-based VPNs.

To configure branch_2 VPN tunnel settings

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create New Phase 1*.

3 Enter the following information and select *OK*.

Name	Enter `branch_2`, a name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies, and the VPN monitor.
Remote Gateway	Select *Static IP Address*. The remote peer this FortiGate is connecting to has a static IP public address. If the remote interface is PPPoE do not select *Retrieve default gateway from server*.
IP Address	Enter 172.16.20.1 The IP address of the public interface to the remote peer.
Mode	Select *Aggressive*.
Advanced	
Enable IPsec Interface Mode	Enable for a route-based VPN and when configuring policies, go to "Creating branch_2 route-based security policies" on page 1475. Disable for a policy-based VPN and when configuring policies, go to "Creating branch_2 policy-based security policies" on page 1477. If enabled, default settings are used.
Local ID	Enter `example.com` A character string used by the `branch_2` FortiGate unit to identify itself to the remote peer. This value must be identical to the value in the *Accept this peer ID* field of the phase 1 remote gateway configuration on the branch_1 remote peer. See "Configuring branch_1 VPN tunnel settings" on page 1478.

4 Select *Create Phase 2*.

Define the phase 2 parameters needed to create a VPN tunnel with the remote peer. For details on phase 2, see "Phase 2 parameters" on page 1425.

5 Enter the following information and select *OK*.

Name	Enter `branch_2_phase2`. A name to identify this phase 2 configuration.
Phase 1	Select `branch_2`. The name of the phase 1 configuration that you defined earlier.

Configuring branch_2 security policies

Define security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see "Defining VPN security policies" on page 1432.

After defining the two address ranges, select one of "Creating branch_2 route-based security policies" on page 1475 or "Creating branch_2 policy-based security policies" on page 1477 to configure the appropriate VPN policies.

Define address ranges for branch_2 security policies

Define VPN connection names for the address ranges of the private networks. These addresses are used in the security policies that permit communication between the networks. For more information, see "Defining policy addresses" on page 1431.

Define an address name for the IP address and netmask of the private network behind the local FortiGate unit.

To define branch_2 address ranges

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*.

3 Enter the following information, and select *OK*.

Address Name	Enter `branch_2_internal`. Enter a meaningful name.
Type	Subnet/IP Range.
Subnet / IP Range	10.10.10.0/24 Include the netmask or specify a specific range.
Interface	internal The interface that will be handling the traffic from the internal network.

Define an address name for the IP address and netmask of the private network behind the remote peer.

4 Select *Create New*.

5 Enter the following information, and select *OK*.

Address Name	Enter `branch_1_internal`. A meaningful name for the private network at the remote end of the VPN tunnel.
Type	Subnet/IP Range.
Subnet / IP Range	192.168.1.0/24 Include the netmask. Optionally you can specify a range.
Interface	any The interface that will be handling the remote VPN traffic on this FortiGate unit. If you are unsure, or multiple interfaces may be handling this traffic use `any`.

Creating branch_2 route-based security policies

Define ACCEPT security policies to permit communication between the branch_2 and branch_1 private networks.

Once the route-based policy is configured a routing entry must be configured to route traffic over the VPN interface.

To create route-based security policies

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*.

Define a policy to permit the branch_2 local FortiGate unit to initiate a VPN session with the branch_1 VPN peer.

3 Enter the following information, and select *OK*.

Source Interface/Zone	Select internal. The interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select `branch_2_internal`. Select the address name for the private network behind this FortiGate unit.
Destination Interface/Zone	Select `branch_2`. The VPN Tunnel (IPsec Interface).
Destination Address Name	Select `branch_1_internal` The address name the private network behind the remote peer.
Action	Select *ACCEPT*. Accept VPN traffic on this interface pair in this direction.
NAT	Disable.
Comment	route-based: Initiate a branch_2 to branch_1 VPN tunnel

4 Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.

Define a policy to permit the branch_1 remote VPN peer to initiate VPN sessions.

5 Enter the following information, and select *OK*.

Source Interface/Zone	Select `branch_2`. The VPN Tunnel (IPsec Interface).
Source Address Name	Select `branch_1_internal`. The address name for the private network behind the remote peer.
Destination Interface/Zone	Select internal. The interface connecting the private network behind this FortiGate unit.
Destination Address Name	Select `branch_2_internal`. The address name for the private network behind this FortiGate unit.
Action	Select *ACCEPT*.
NAT	Disable.
Comment	route-based: Initiate a branch_1 to branch_2 internal VPN tunnel.

6 Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.

7 Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

To create routing entry for VPN interface - CLI

```
config router static
  edit 5
    set dst 0.0.0.0 0.0.0.0
    set dynamic-dateway enable
    set device wan1
  next
end
```

This routing entry must be added in the CLI because the dynamic-gateway option is not available in the web-based manager.

Creating branch_2 policy-based security policies

Define an IPsec policy to permit VPN sessions between the private networks.

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*.

Define an IPsec policy to permit the VPN sessions between the local branch_2 unit and the remote branch_1 unit.

3 Enter the following information, and select *OK*.

Source Interface/Zone	Select internal. The interface connecting the private network behind this FortiGate unit.
Source Address Name	Select `branch_2_internal`. The address name for the private network behind this local FortiGate unit.
Destination Interface/Zone	Select wan1. The FortiGate unit's public interface.
Destination Address Name	Select `branch_1_internal`. The address name for the private network behind branch_1, the remote peer.
Action	Select *IPSEC*.
VPN Tunnel	Select branch_2 The name of the phase 1 tunnel.
Allow Inbound **Allow Outbound**	Select both *Allow inbound* and *Allow outbound* to enable traffic from either direction to initiate the tunnel. If you have problems connecting, try enabling NAT.
Comment	policy-based: allows traffic in either direction to initiate the VPN tunnel.

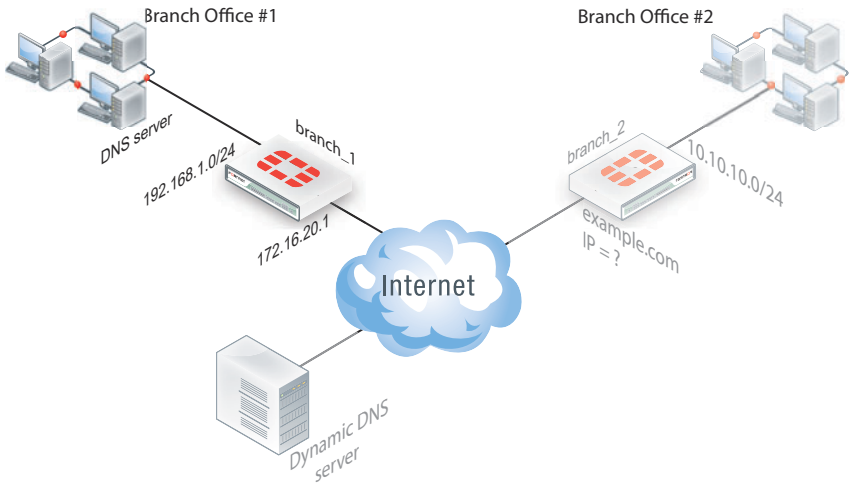
4 Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.

5 Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

Configure the fixed-address VPN peer

The fixed-address VPN peer, branch_1, needs to retrieve the IP address from the dynamic DNS service to initiate communication with the dynamically-addressed peer, branch_2. It also depends on the peer ID (local ID) to initiate the VPN tunnel with branch_2.

Figure 137: Configure branch_1, the fixed address side



Configuring the fixed-address VPN peer includes:

- Configuring branch_1 VPN tunnel settings
- Configuring branch_1 security policies

Configuring branch_1 VPN tunnel settings

Define the phase 1 parameters needed to establish a secure connection with the remote peer. For more information, see “Auto Key phase 1 parameters” on page 1407.

To configure branch_1 phase 1 VPN settings

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create New Phase 1*.

3 Enter the following information and select *OK*.

Name	Enter `branch_1`. A name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select *Dynamic DNS*. The remote peer this FortiGate is connecting to has a dynamic IP address.

Dynamic DNS	Type the fully qualified domain name of the remote peer (for example, `example.com`).
Interface	Enter wan1. The public facing interface on the fixed-address FortiGate unit. This interface cannot be a loopback interface.
Mode	Select *Aggressive*.
Peer Options	Select *Accept this peer ID*, and enter `example.com`. This option only appears when the mode is set to Aggressive. The identifier of the FortiGate unit with the dynamic address.
Advanced	
Enable IPsec Interface Mode	Enable for a route-based VPN and when configuring policies, go to "Creating branch_1 route-based security policies" on page 1480. Disable for a policy-based VPN and when configuring policies, go to "Creating branch_1 policy-based security policies" on page 1481. If Interface mode is enabled, default settings are used.

4 Define the phase 2 parameters needed to create a VPN tunnel with the remote peer. See "Phase 2 parameters" on page 1425. Enter these settings in particular:

Name	Enter `branch_1_p2`. A name to identify this phase 2 configuration.
Phase 1	Select `branch_1`. The name of the phase 1 configuration that you defined for the remote peer. You can select the name of the remote gateway from the Dynamic DNS part of the list.

Configuring branch_1 security policies

The `branch_1` FortiGate unit has a fixed IP address and will be connecting to the `branch_2` FortiGate unit that has a dynamic IP address and a domain name of `example.com`.

Remember if you are using route-based security policies that you must add a route for the VPN traffic.

Defining address ranges for branch_1 security policies

As with `branch_2` previously, `branch_1` needs address ranges defined as well. See "Defining policy addresses" on page 1431.

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*.

3 Enter the following information, and select *OK*.

Address Name	Enter `branch_2_internal`. A meaningful name for the private network behind the `branch_2` FortiGate unit.
Type	Subnet/IP Range.

Subnet / IP Range	10.10.10.0/24 Include the netmask or specify a specific range.
Interface	internal This is the interface on this FortiGate unit that will be handling with this traffic.

4 Define an address name for the IP address and netmask of the private network behind the remote peer.

5 Select *Create New*.

6 Enter the following information, and select *OK*.

Address Name	Enter `branch_1_internal`. A meaningful name for the private network behind the `branch_1` peer.
Type	Subnet/IP Range.
Subnet / IP Range	192.168.1.0/24 Include the netmask or specify a specific range.
Interface	any The interface on this FortiGate unit that will be handling with this traffic. If you are unsure, or multiple interfaces may be handling this traffic use `any`.

Creating branch_1 route-based security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses. See "Defining VPN security policies" on page 1432.

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*.

3 Enter the following information, and select *OK*.

Source Interface/Zone	Select internal. The interface that connects to the private network behind the `branch_1` FortiGate unit.
Source Address Name	Select `branch_1_internal`. The address name that you defined for the private network behind this FortiGate unit.
Destination Interface/Zone	Select `branch_1`. The VPN Tunnel (IPsec Interface) you configured earlier.
Destination Address Name	Select `branch_2_internal`. The address name that you defined for the private network behind the `branch_2` peer.
Action	Select *ACCEPT*.
NAT	Disable
Comments	Internal -> branch22

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

4 Select *Create New*.

5 Enter the following information, and select *OK*.

Source Interface/Zone	Select `branch_1` The VPN Tunnel (IPsec Interface) you configured earlier.
Source Address Name	Select `branch_2_internal`. The address name that you defined for the private network behind the `branch_2` remote peer.
Destination Interface/Zone	Select internal. The interface that connects to the private network behind this FortiGate unit.
Destination Address Name	Select `branch_1_internal`. The address name that you defined for the private network behind this FortiGate unit.
Action	Select *ACCEPT*.
NAT	Disable
Comments	branch_2 -> Internal

Creating branch_1 policy-based security policies

A policy-based security policy allows you the flexibility to allow inbound or outbound traffic or both through this single policy.

This policy-based IPsec VPN security policy allows both inbound and outbound traffic

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*.

3 Enter the following information, and select *OK*.

Source Interface/Zone	Select `internal`. The interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select `branch_1_internal`. The address name that you defined for the private network behind this FortiGate unit.
Destination Interface/Zone	Select `wan1`. The FortiGate unit's public interface.
Destination Address Name	Select `branch_2_internal`. The address name that you defined for the private network behind the remote peer.

Action	Select *IPSEC*.
VPN Tunnel	Select `branch_1`. The name of the phase 1 configuration that you created earlier. Select *Allow inbound* to enable traffic from the remote network to initiate the tunnel. Select *Allow outbound* to enable traffic from the local network to initiate the tunnel.

4 Place this security policy in the policy list above any other policies having similar source and destination addresses.

Testing

Once both ends are configured, you can test the VPN tunnel.

To test the VPN initiated by branch_2

1 On branch_2, go to *VPN* > *Monitor* > *IPsec Monitor*.

All IPsec VPN tunnels will be listed on this page, no matter if they are connected or disconnected.

2 Select the tunnel listed for branch_2, and select the status column for that entry.

The status will say *Bring Up* and remote port, incoming and outgoing data will all be zero. This indicates an inactive tunnel. When you select *Bring Up*, the FortiGate will try to set up a VPN session over this tunnel. If it is successful, Bring Up will change to Active, and the arrow icon will change to a green up arrow icon.

3 If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting:

To test the VPN initiated by branch_1

1 On branch_1, go to *VPN* > *Monitor* > *IPsec Monitor*.

2 Select the tunnel listed for branch_1, and select the status column.

The difference between branch_2 and branch_1 at this point is that the tunnel entry for branch-1 will not have a remote gateway IP address. It will be resolved when the VPN tunnel is started.

3 If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting.

Some troubleshooting ideas include:

- If there was no entry for the tunnel on the monitor page, check the Auto Key (IKE) page to verify the phase 1 and phase 2 entries exist.
- Check the security policy or policies, and ensure there is an outgoing policy as a minimum.
- Check that you entered a local ID in the phase 1 configuration, and that branch_1 has the same local ID.
- Ensure the local DNS server has an up-to-date DNS entry for exmaple.com.

For more information on VPN troubleshooting and testing, see “VPN troubleshooting tips” on page 1609.

FortiClient dialup-client configurations

The FortiClient Endpoint Security application is an IPsec VPN client with antivirus, antispam and firewall capabilities. This section explains how to configure dialup VPN connections between a FortiGate unit and one or more FortiClient Endpoint Security applications.

FortiClient users are usually mobile or remote users who need to connect to a private network behind a FortiGate unit. For example, the users might be employees who connect to the office network while traveling or from their homes.

For greatest ease of use, the FortiClient application can download the VPN settings from the FortiGate unit to configure itself automatically. This section covers both automatic and manual configuration.

The FortiClient configurations in this guide do not apply to the FortiClient Consumer Edition, which does not include the IPsec VPN feature.

The following topics are included in this section:

Configuration overview

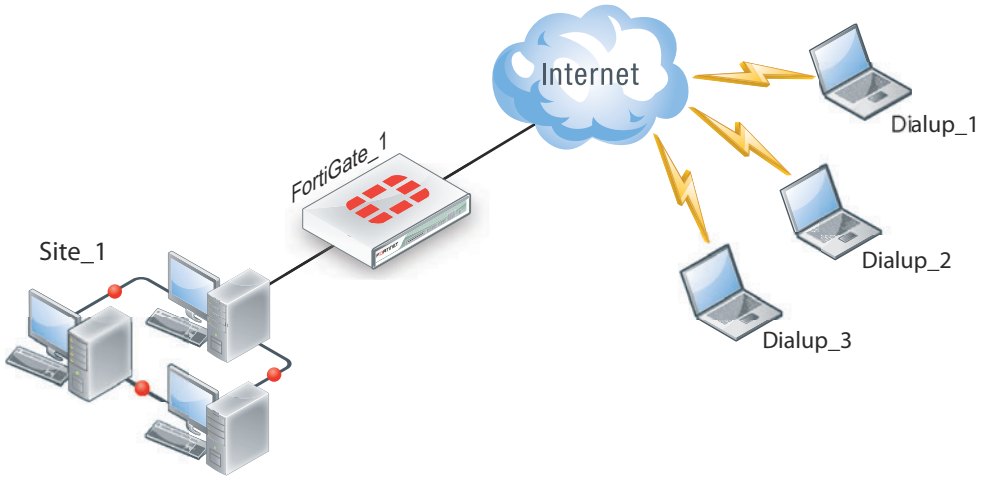
Dialup users typically obtain dynamic IP addresses from an ISP through Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE). Then, the FortiClient Endpoint Security application initiates a connection to a FortiGate dialup server.

By default the FortiClient dialup client has the same IP address as the host PC on which it runs. If the host connects directly to the Internet, this is a public IP address. If the host is behind a NAT device, such as a router, the IP address is a private IP address. The NAT device must be NAT traversal (NAT-T) compatible to pass encrypted packets (see "NAT traversal" on page 1420). The FortiClient application also can be configured to use a virtual IP address (VIP). For the duration of the connection, the FortiClient application and the FortiGate unit both use the VIP address as the IP address of the FortiClient dialup client.

For a faster and easier method of configuring a FortiGate - to - FortiClient VPN, see "One button FortiGate - to - FortiClient Phase1 VPN" on page 1485.

The FortiClient application sends its encrypted packets to the VPN remote gateway, which is usually the public interface of the FortiGate unit. It also uses this interface to download VPN settings from the FortiGate unit. See “Automatic configuration of FortiClient dialup clients” on page 1484.

Figure 138: Example FortiClient dialup-client configuration



Peer identification

The FortiClient application can establish an IPsec tunnel with a FortiGate unit configured to act as a dialup server. When the FortiGate unit acts as a dialup server, it does not identify the client using the phase 1 remote gateway address. The IPsec tunnel is established if authentication is successful and the IPsec security policy associated with the tunnel permits access. There are several different ways to authenticate dialup clients and restrict access to private networks based on client credentials. For more information, see “Authenticating remote peers and clients” on page 1412.

Automatic configuration of FortiClient dialup clients

The FortiClient application can obtain its VPN settings from the FortiGate VPN server. FortiClient users need to know only the FortiGate VPN server IP address and their user name and password on the FortiGate unit.

The FortiGate unit listens for VPN policy requests from clients on TCP port 8900. When the dialup client connects:

- The client initiates a Secure Sockets Layer (SSL) connection to the FortiGate unit.
- The FortiGate unit requests a user name and password from the FortiClient user. Using these credentials, it authenticates the client and determines which VPN policy applies to the client.
- Provided that authentication is successful, the FortiGate unit downloads a VPN policy to the client over the SSL connection. The information includes IPsec phase 1 and phase 2 settings, and the IP addresses of the private networks that the client is authorized to access.
- The client uses the VPN policy settings to establish an IPsec phase 1 connection and phase 2 tunnel with the FortiGate unit.

One button FortiGate - to - FortiClient Phase1 VPN

On the FortiOS VPN IKE page there is a button to create a Phase1 portion of a VPN tunnel between the FortiGate and FortiClient. Very little information is required for this configuration. No encryption or authentication method is required. This feature is ideal for setting up quick VPN connections with basic settings.

This one button is only compatible with FortiClient 4.3 and higher. Earlier versions of FortiClient need to create IKE Phase-1 object separately, similar to earlier versions of FortiOS.

On the Phase 1 screen (*VPN > IPsec > Phase 1*) is a button called *Create a FortiClient VPN.* This button asks a few basic VPN configuration related questions. Once all the information is added, click *Create Now*. This will create a new dial-up IPsec-interface mode tunnel. Phase 1 and Phase 2 will be added using the default ike settings.

The following Settings will be used when creating a one-button FortiClient VPN Phase1 object:

- Remote Gateway: Dialup User
- Mode: Aggressive
- Enable IPSec Interface Mode
- Default setting for P1 and P2 Proposal
- XAUTH Enable as Server (Auto)
- IKE mode-config will be enabled
- Peer Option set to "Accept any peer ID"
- Rest of the setting use the current defaults (Default value needs to be the same on FCT side)

Once the one button Phase1 is complete, you must create a default Phase2 configuration. This only requires a name for the Phase2 object, and select the one-button Phase1 name.

How the FortiGate unit determines which settings to apply

The FortiGate unit follows these steps to determine the configuration information to send to the FortiClient application:

1. Check the virtual domain associated with the connection to determine which VPN policies might apply.
2. Select the VPN policy that matches the dialup client's user group and determine which tunnel (phase 1 configuration) is involved.
3. Check all IPsec security policies that use the specified tunnel to determine which private networks the dialup clients may access.
4. Retrieve the rest of the VPN policy information from the existing IPsec phase 1 and phase 2 parameters in the dialup-client configuration.

Using virtual IP addresses

When the FortiClient host PC is located behind a NAT device, unintended IP address overlap issues may arise between the private networks at the two ends of the tunnel. For example, the client's host might receive a private IP address from a DHCP server on its network that by co-incidence is the same as a private IP address on the network behind the FortiGate unit. A conflict will occur in the host's routing table and the FortiClient Endpoint Security application will be unable to send traffic through the tunnel. Configuring virtual IP (VIP) addresses for FortiClient applications prevents this problem.

Using VIPs ensures that client IP addresses are in a predictable range. You can then define security policies that allow access only to that source address range. If you do not use VIPs, the security policies must allow all source addresses because you cannot predict the IP address for a remote mobile user.

The FortiClient application must not have the same IP address as any host on the private network behind the FortiGate unit or any other connected FortiClient application. You can ensure this by reserving a range of IP addresses on the private network for FortiClient users. Or, you can assign FortiClient VIPs from an uncommonly used subnet such as 10.254.254.0/24 or 192.168.254.0/24.

You can reserve a VIP address for a particular client according to its device MAC address and type of connection. The DHCP server then always assigns the reserved VIP address to the client. For more information about this feature, see the "dhcp reserved-address" section in the "system" chapter of the *FortiGate CLI Reference*.

On the host computer, you can find out the VIP address that the FortiClient Endpoint Security application is using. For example,
On Windows, type `ipconfig /all` at the Windows Command Prompt.
On Linux or Mac OS X, type `ifconfig` in a terminal window.
The output will also show the IP address that has been assigned to the host Network Interface Card (NIC).

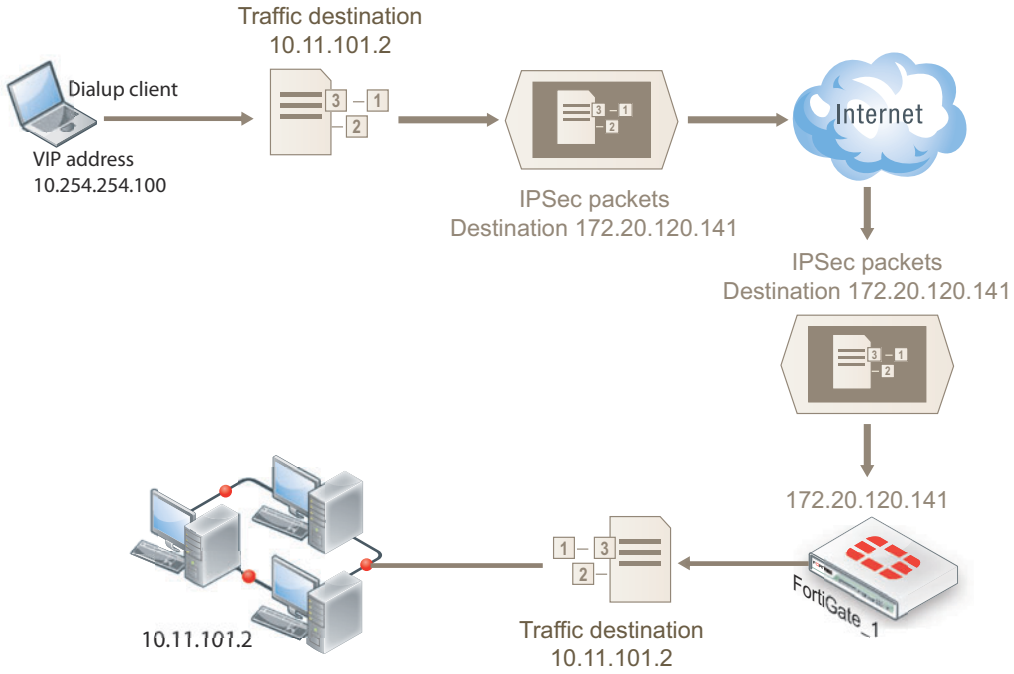
It is best to assign VIPs using DHCP over IPsec. The FortiGate dialup server can act as a DHCP server or relay requests to an external DHCP server. You can also configure VIPs manually on FortiClient applications, but it is more difficult to ensure that all clients use unique addresses.

If you assign a VIP on the private network behind the FortiGate unit and enable DHCP-IPsec (a phase 2 advanced option), the FortiGate unit acts as a proxy on the local private network for the FortiClient dialup client. Whenever a host on the network behind the dialup server issues an ARP request for the device MAC address of the FortiClient host, the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel. For more information, see "DHCP-IPsec" on page 1427.

FortiGate units fully support RFC 3456. The FortiGate DHCP over IPsec feature can be enabled to allocate VIP addresses to FortiClient dialup clients using a FortiGate DHCP server.

Figure 139 shows an example of a FortiClient-to-FortiGate VPN where the FortiClient application is assigned a VIP on an uncommonly used subnet. The diagram also shows that while the destination for the information in the encrypted packets is the private network behind the FortiGate unit, the destination of the IPsec packets themselves is the public interface of the FortiGate unit that acts as the end of the VPN tunnel.

Figure 139: IP address assignments in a FortiClient dialup-client configuration



Assigning VIPs by RADIUS user group

If you use XAuth authentication, you can assign users the virtual IP address stored in the Framed-IP-Address field of their record on the RADIUS server. (See RFC 2865 and RFC 2866 for more information about RADIUS fields.) To do this:

- Set the DHCP server *IP Assignment Mode* to *User-group defined method*. This is an Advanced setting. See "To configure a DHCP server on the FortiGate unit" on page 1491.
- Create a new firewall user group and add the RADIUS server to it.
- In your phase 1 settings, configure the FortiGate unit as an XAuth server and select from *User Group* the new user group that you created. For more information, see "Using the FortiGate unit as an XAuth server" on page 1422.
- Configure the FortiClient application to use XAuth. See "Adding XAuth authentication" on page 1494.

FortiClient dialup-client infrastructure requirements

- To support policy-based VPNs, the FortiGate dialup server may operate in either NAT mode or transparent mode. NAT mode is required if you want to create a route-based VPN.
- If the FortiClient dialup clients will be configured to obtain VIP addresses through FortiGate DHCP relay, a DHCP server must be available on the network behind the FortiGate unit and the DHCP server must have a direct route to the FortiGate unit.

- If the FortiGate interface to the private network is not the default gateway, the private network behind the FortiGate unit must be configured to route IP traffic destined for dialup clients back (through an appropriate gateway) to the FortiGate interface to the private network. As an alternative, you can configure the IPsec security policy on the FortiGate unit to perform inbound NAT on IP packets. Inbound NAT translates the source addresses of inbound decrypted packets into the IP address of the FortiGate interface to the local private network.

FortiClient-to-FortiGate VPN configuration steps

Configuring dialup client capability for FortiClient dialup clients involves the following general configuration steps:

1. If you will be using VIP addresses to identify dialup clients, determine which VIP addresses to use. As a precaution, consider using VIP addresses that are not commonly used.
2. Configure the FortiGate unit to act as a dialup server. See "Configure the FortiGate unit" on page 1488.
3. If the dialup clients will be configured to obtain VIP addresses through DHCP over IPsec, configure the FortiGate unit to act as a DHCP server or to relay DHCP requests to an external DHCP server.
4. Configure the dialup clients. See "Configure the FortiClient Endpoint Security application" on page 1493.

When a FortiGate unit has been configured to accept connections from FortiClient dialup-clients, you can optionally arrange to have an IPsec VPN configuration downloaded to FortiClient dialup clients automatically. For more information, see "Configuring the FortiGate unit as a VPN policy server" on page 1491.

Configure the FortiGate unit

Configuring the FortiGate unit to establish VPN connections with FortiClient Endpoint Security users involves the following steps:

1. configure the VPN settings
2. if the dialup clients use automatic configuration, configure the FortiGate unit as a VPN policy server
3. if the dialup clients obtain VIP addresses by DHCP over IPsec, configure an IPsec DHCP server or relay

The procedures in this section cover basic setup of policy-based and route-based VPNs compatible with FortiClient Endpoint Security. A route-based VPN is simpler to configure.

Configuring FortiGate unit VPN settings

To configure FortiGate unit VPN settings to support FortiClient users, you need to:

- configure the FortiGate Phase 1 VPN settings
- configure the FortiGate Phase 2 VPN settings

- add the security policy

1 At the local FortiGate unit, define the phase 1 configuration needed to establish a secure connection with the FortiClient peer. See “Auto Key phase 1 parameters” on page 1407. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select *Dialup User*.
Local Interface	Select the interface through which clients connect to the FortiGate unit.
Mode	Select *Main (ID Protection)*.
Authentication Method	Select *Pre-shared Key*.
Pre-shared Key	Enter the pre-shared key. This must be the same preshared key provided to the FortiClient users.
Peer option	Select *Accept any peer ID*.
Enable IPsec Interface Mode	You must select *Advanced* to see this setting. If *IPsec Interface Mode* is enabled, the FortiGate unit creates a virtual IPsec interface for a route-based VPN.

2 Define the phase 2 parameters needed to create a VPN tunnel with the FortiClient peer. See “Phase 2 parameters” on page 1425. Enter these settings in particular:

Name	Enter a name to identify this phase 2 configuration.
Phase 1	Select the name of the phase 1 configuration that you defined.
Advanced	Select to configure the following optional setting.
DHCP-IPsec	Select if you provide virtual IP addresses to clients using DHCP.

3 Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks. For more information, see “Defining policy addresses” on page 1431.

Enter these settings in particular:

- Define an address name for the individual address or the subnet address that the dialup users access through the VPN.
- If FortiClient users are assigned VIP addresses, define an address name for the subnet to which these VIPs belong.

4 Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see “Defining VPN security policies” on page 1432.

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won’t be able to retrieve a lease from the FortiGate’s (IPSec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

Route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses. Enter these settings in particular:

Source Interface/Zone	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
Source Address Name	Select *All*.
Destination Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address Name	Select *All*.
Action	Select *ACCEPT*.
NAT	Disable.

If you want to allow hosts on the private network to initiate communications with the FortiClient users after the tunnel is established, you need to define a security policy for communication in that direction. Enter these settings in particular:

Source Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select *All*.
Destination Interface/Zone	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
Destination Address Name	Select *All*.
Action	Select *ACCEPT*.
NAT	Disable.

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses. Enter these settings in particular:

Source Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select the address name that you defined in Step 3 for the private network behind this FortiGate unit.
Destination Interface/Zone	Select the FortiGate unit's public interface.
Destination Address Name	If FortiClient users are assigned VIPs, select the address name that you defined in Step 3 for the VIP subnet. Otherwise, select All.
Action	Select *IPSEC*.
VPN Tunnel	Select the name of the phase 1 configuration that you created in Step 1. Select *Allow inbound* to enable traffic from the remote network to initiate the tunnel. Select *Allow outbound* if you want to allow hosts on the private network to initiate communications with the FortiClient users after the tunnel is established.

Place VPN policies in the policy list above any other policies having similar source and destination addresses.

Configuring the FortiGate unit as a VPN policy server

When a FortiClient application set to automatic configuration connects to the FortiGate unit, the FortiGate unit requests a user name and password. If the user supplies valid credentials, the FortiGate unit downloads the VPN settings to the FortiClient application.

You must do the following to configure the FortiGate unit to work as a VPN policy server for FortiClient automatic configuration:

1 Create user accounts for FortiClient users.

2 Create a user group for FortiClient users and the user accounts that you created in step 1.

3 Connect to the FortiGate unit CLI and configure VPN policy distribution as follows:

```
config vpn ipsec forticlient
  edit <policy_name>
    set phase2name <tunnel_name>
    set usergroupname <group_name>
    set status enable
  end
```

`<tunnel_name>` must be the Name you specified in the step 2 of "Configure the FortiGate unit" on page 1488. `<group_name>` must be the name of the user group your created for FortiClient users.

Configuring DHCP service on the FortiGate unit

If the FortiClient dialup clients are configured to obtain a VIP address using DHCP, configure the FortiGate dialup server to either:

- relay DHCP requests to a DHCP server behind the FortiGate unit (see "To configure DHCP relay on the FortiGate unit" below).
- act as a DHCP server (see "To configure a DHCP server on the FortiGate unit" on page 1491).

To configure DHCP relay on the FortiGate unit

1 Go to *System* > *Network* > *DHCP Server* and select *Create New*.

2 In *Interface Name*, select the interface that connects to the Internet (for example, external or wan1).

3 In *Mode*, select *Relay*.

4 In *Type* select *IPsec*.

5 In the *DHCP Server IP* field, type the IP address of the DHCP server.

6 Select *OK*.

7 If a router is installed between the FortiGate unit and the DHCP server, define a static route to the DHCP server.

To configure a DHCP server on the FortiGate unit

1 Go to *System* > *DHCP Server* and select *Create New*.

2 In *Interface Name*, select the interface that connects to the Internet (for example, external or wan1).

3 In *Mode*, select *Server*.

4 Select *Enable*.

5 Enter the following information and select *OK*:

Type	IPsec
IP Range	Enter the range of VIP addresses that the DHCP server can dynamically assign to dialup clients when they connect. As a precaution, do not assign VIP addresses that match the private network behind the FortiGate unit. If you need to exclude specific IP addresses from the range, you can define an exclusion range (see Advanced... below). ***Note:*** If you will use a RADIUS server to assign VIP addresses, these fields are not needed.
Network Mask	Enter the network mask of the IP addresses that you specified in the IP Range fields (for example, `255.255.255.0` for a class C network).
Default Gateway	Enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
DNS Service	Select *Use System DNS Setting*. If you want to use a different DNS server for VPN clients, select *Specify* and enter an IP address in *DNS Server 0*.
Advanced...	Select *Advanced* to configure any of the following options.
Domain	If you want the FortiGate unit to assign a domain name to dialup clients when they connect, enter the registered domain name.
Lease Time	Specify a lease time: • Select *Unlimited* to allow the dialup client to use the assigned IP address for an unlimited amount of time (that is, until the client disconnects). • Enter the amount of time (in days, hours, and minutes) that the dialup client may use the assigned IP address, after which the dialup client must request new settings from the DHCP server. The range is from 5 minutes to 100 days.
IP Assignment Mode	*Server IP Range* — assign addresses from *IP Range* (default) *User-group defined method* — assign addresses from user's record on RADIUS server. See "Assigning VIPs by RADIUS user group" on page 1487.
WINS Server 0 **WINS Server 1**	Optionally, enter the IP addresses of one or two Windows Internet Service (WINS) servers that dialup clients can access after the tunnel has been established.
Options	Optionally, you can send up to three DHCP options to the dialup client. Select *Options* and enter the option code in the *Code* field, and if applicable, type any associated data in the *Options* field. For more information, see RFC 2132.
Exclude Ranges	To specify any VIP addresses that must be excluded from the VIP address range, select *Exclude Ranges*, select the + button and then type the starting and ending IP addresses. You can add multiple ranges to exclude.

Configure the FortiClient Endpoint Security application

The following procedure explains how to configure the FortiClient Endpoint Security application to communicate with a remote FortiGate dialup server using the VIP address that you specify manually.

Configuring FortiClient to work with VPN policy distribution

If the remote FortiGate gateway is configured as a VPN policy server, you can configure the FortiClient software to download the VPN settings from the FortiGate gateway.

For VPNs with automatic configuration, only preshared keys are supported. Certificates are not supported.

To add a VPN with automatic configuration on the FortiClient PC

1 Go to *VPN* > *Connections*.
2 Select *Advanced* and then select *Add*.
3 In the *New Connection* dialog box, enter a connection name.
4 For *Configuration*, select *Automatic*.
5 For *Policy Server*, enter the IP address or FQDN of the FortiGate gateway.
6 Select *OK*.

Configuring FortiClient manually

This procedure explains how to configure the FortiClient application manually using the default IKE and IPsec settings. For more information, refer to the FortiClient Endpoint Security User Guide.

This procedure includes instructions for configuring a virtual IP for the FortiClient application, either manually or using DHCP over IPsec.

To create a FortiClient VPN configuration

1 Go to *VPN* > *Connections*.
2 Select *Advanced* and then select *Add*.
3 Enter the following information:

Connection Name	Enter a descriptive name for the connection.
Configuration	Select *Manual*
Remote Gateway	Enter the IP address or the fully qualified domain name (FQDN) of the remote gateway.
Remote Network	Enter the IP address and netmask of the network behind the FortiGate unit.
Authentication Method	Select *Pre-shared Key*.
Pre-shared Key	Enter the pre-shared key.

4 Follow the remaining steps only if you want to configure a VIP. Otherwise, select *OK*.
5 Select *Advanced*.
6 Enable *Acquire a virtual IP address* and then select the adjacent *Config* button.

7 Enter the following information and select *OK*.

Options	Select one of these options:
DHCP	Obtain virtual IP address from the FortiGate unit using DHCP over IPsec.
Manually Set	Assign the virtual IP address manually using the settings in the *Manual VIP* section.
Manual VIP	These settings are available only if you select *Manually Set* in the *Options* section.
IP	Enter the IP address that the FortiClient dialup client uses. This address must not conflict with any IP address at either end of the VPN tunnel.
Subnet Mask	Enter the subnet for the private network.
DNS Server **WINS Server**	Optionally, enter the addresses of the DNS and WINS servers that the FortiClient user can access through the VPN.

8 Select *OK* twice to close the dialog boxes.

9 Repeat this procedure for each FortiClient dialup client.

Adding XAuth authentication

Extended Authentication (XAuth) increases security by requiring additional user authentication in a separate exchange at the end of the VPN phase 1 negotiation. The FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.

Implementation of XAuth requires configuration at both the FortiGate unit and the FortiClient application. For information about configuring a FortiGate unit as an XAuth server, see "Using the FortiGate unit as an XAuth server" on page 1422. The following procedure explains how to configure the FortiClient application.

XAuth is not compatible with IKE version 2.

To configure the FortiClient Endpoint Security application

In the FortiClient Endpoint Security application, make the following changes to the VPN configuration to enable XAuth authentication to the FortiGate unit.

1 Go to *VPN* > *Connections*, select the VPN connection you want to modify.

2 Select *Advanced* > *Edit* > *Advanced*.

3 Select the *eXtended Authentication* check box and then select the *Config* button to the right of it.

4 In the *Extended Authentication (XAuth)* dialog box, select one of the 2 following choices:

- To always prompt for username and password, select *Prompt to login*.

  This is the default.
- To never prompt for username and password, clear the *Prompt to login* check box and fill in the *User Name* and *Password* fields.

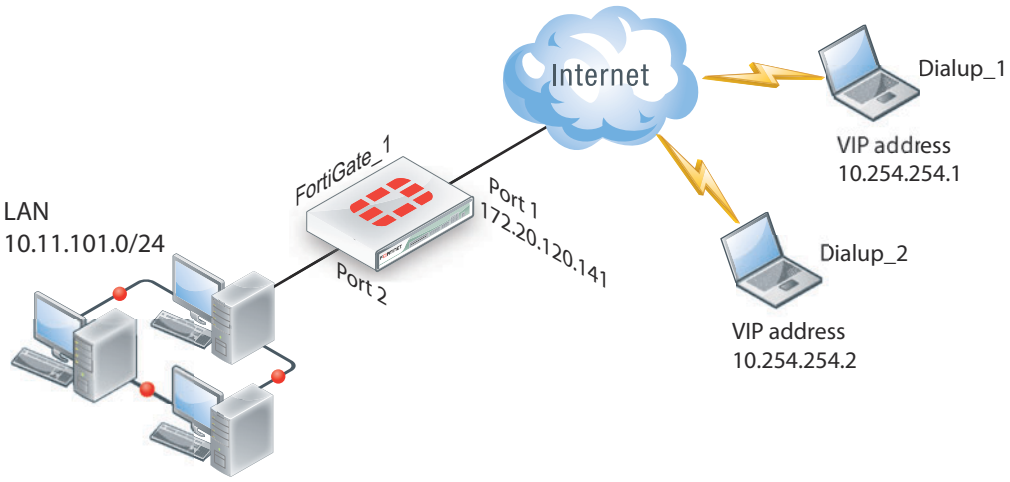
  The FortiClient Endpoint Security application will use these values and automatically responds to the XAuth challenge.

5 Select *OK* to close all dialog boxes.

FortiClient dialup-client configuration example

This example demonstrates how to set up a FortiClient dialup-client IPsec VPN that uses preshared keys for authentication purposes. In the example configuration, the DHCP over IPsec feature is enabled in the FortiClient Endpoint Security application so that the FortiClient Endpoint Security application can acquire a VIP address through the FortiGate DHCP server. Both route-based and policy-based solutions are covered.

Figure 140: Example FortiClient dialup-client configuration



In the example configuration:

- VIP addresses that are not commonly used (in this case, 10.254.254.0/24) are assigned to the FortiClient dialup clients using a DHCP server.
- The dialup clients are have access to the LAN behind FortiGate_1.
- The other network devices are assigned IP addresses as shown in Figure 140.

Configuring FortiGate_1

When a FortiGate unit receives a connection request from a dialup client, it uses IPsec phase 1 parameters to establish a secure connection and authenticate the client. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec phase 2 parameters and applies the IPsec security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed at the FortiGate unit:

- Define the phase 1 parameters that the FortiGate unit needs to authenticate the dialup clients and establish a secure connection. See "To define the phase 1 parameters" on page 1496.
- Define the phase 2 parameters that the FortiGate unit needs to create a VPN tunnel and enable all dialup clients having VIP addresses on the 10.254.254.0/24 network to connect using the same tunnel definition. See "To define the phase 2 parameters" on page 1496.
- Create security policy to control the permitted services and permitted direction of traffic between the IP source address and the dialup clients. See "To define the firewall addresses" on page 1496.
- Configure the FortiGate unit to service DHCP requests from dialup clients. See "To configure a DHCP server on the FortiGate unit" on page 1498.

To define the phase 1 parameters

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	todialups
Remote Gateway	Dialup User
Local Interface	Port 1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	hardtoguess
Peer Options	Accept any peer ID
Advanced	Select
Enable IPsec Interface Mode	Enable for route-based VPN. Disable for policy-based VPN.

To define the phase 2 parameters

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*and select *Create Phase 2*.

2 Select *Advanced*, enter the following information, and select *OK*:

Name	td_2
Phase 1	todialups
Advanced	DHCP-IPsec

To define the firewall addresses

1 Go to *Firewall Objects* > *Address* > *Address*.

2 Select *Create New*, enter the following information, and select *OK*:

Address Name	internal_net
Subnet/IP Range	10.11.101.0/24
Interface	Port 2

3 Select *Create New*, enter the following information, and select *OK*:

Address Name	dialups
Subnet/IP Range	10.254.254.[1-10]
Interface	Route-based VPN: todialups Policy-based VPN: Any

The security policies for route-based and policy-based VPNs are described in separate sections below.

To define security policies - route-based VPN

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	todialups
Source Address Name	dialups
Destination Interface/Zone	Port 2
Destination Address Name	internal_net
Schedule	As required.
Service	As required.
Action	ACCEPT
NAT	Disable

3 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Port 2
Source Address Name	internal_net
Destination Interface/Zone	todialups
Destination Address Name	dialups
Schedule	As required.
Service	As required.
Action	ACCEPT
NAT	Disable

4 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Port 2
Source Address Name	internal_net
Destination Interface/Zone	todialups
Destination Address Name	all
Schedule	As required.
Service	DHCP

Action	ACCEPT
NAT	Disable

5 Place these policies in the policy list above any other policies having similar source and destination addresses.

The policy in step 4 is required for DHCP to function properly for policy-based VPNs. You can omit this policy if you change the *Destination Address Name* to `all` in the step before. Route-based policies are not affected by this.

To define the security policy - policy-based VPN

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Port 2
Source Address Name	internal_net
Destination Interface/Zone	Port 1
Destination Address Name	dialups
Schedule	As required.
Service	As required.
Action	IPSEC
VPN Tunnel	todialups.
Allow Inbound	Enable
Allow Outbound	Enable if you want to allow hosts on the private network behind the FortiGate unit to initiate communications with the FortiClient users after the tunnel is established.
Inbound NAT	Disable
Outbound NAT	Disable

3 Place the policy in the policy list above any other policies having similar source and destination addresses.

To configure a DHCP server on the FortiGate unit

1 Go to *System* > *DHCP Server* and select *Create New*.

2 Enter the following information and select *OK*:

Interface Name	Route-based VPN: select virtual IPsec interface. For example, todialups. Policy-based VPN: select the public interface. For example, Port 1.
Mode	Server
Type	IPSEC.
IP Range	10.254.254.1 - 10.254.254.10

Network Mask	255.255.255.0
Default Gateway	172.20.120.2

Configuring the FortiClient Endpoint Security application

The following procedure explains how to configure the FortiClient Endpoint Security application to connect to FortiGate_1 and broadcast a DHCP request. The dialup client uses the VIP address acquired through FortiGate DHCP relay as its IP source address for the duration of the connection.

To configure FortiClient

1 At the remote host, start FortiClient.

2 Go to *VPN* > *Connections* and select *Advanced* > *Add*.

3 Enter the following settings:

Connection Name	Office
VPN Type	Manual IPsec
Remote Gateway	172.20.120.141
Remote Network	10.11.101.0 / 255.255.255.0
Authentication Method	Preshared Key
Preshared Key	hardtoguess

4 Select *Advanced*.

5 In the *Advanced Settings* dialog box, select *Acquire virtual IP address* and then select *Config*.

6 Verify that the *Dynamic Host Configuration Protocol (DHCP) over IPsec* option is selected, and then select *OK*.

7 Select *OK* twice to close the dialog boxes.

8 Exit FortiClient and repeat this procedure at all other remote hosts.

FortiGate dialup-client configurations

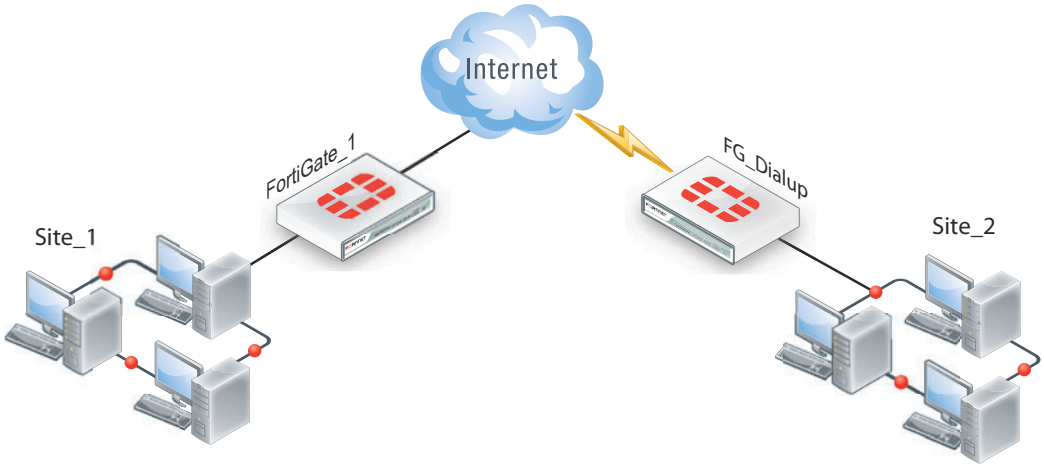
This section explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit having a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

The following topics are included in this section:

Configuration overview

A dialup client can be a FortiGate unit—the FortiGate dialup client typically obtains a dynamic IP address from an ISP through the Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE) before initiating a connection to a FortiGate dialup server.

Figure 141: Example FortiGate dialup-client configuration



In a dialup-client configuration, the FortiGate dialup server does not rely on a phase 1 remote gateway address to establish an IPsec VPN connection with dialup clients. As long as authentication is successful and the IPsec security policy associated with the tunnel permits access, the tunnel is established.

Several different ways to authenticate dialup clients and restrict access to private networks based on client credentials are available. To authenticate FortiGate dialup clients and help to distinguish them from FortiClient dialup clients when multiple clients will be connecting to the VPN through the same tunnel, best practices dictate that you assign a unique identifier (local ID or peer ID) to each FortiGate dialup client. For more information, see "Authenticating remote peers and clients" on page 1412.

Whenever you add a unique identifier (local ID) to a FortiGate dialup client for identification purposes, you must select Aggressive mode on the FortiGate dialup server and also specify the identifier as a peer ID on the FortiGate dialup server. For more information, see "Enabling VPN access with user accounts and pre-shared keys" on page 1415.

Users behind the FortiGate dialup server cannot initiate the tunnel because the FortiGate dialup client does not have a static IP address. After the tunnel is initiated by users behind the FortiGate dialup client, traffic from the private network behind the FortiGate dialup server can be sent to the private network behind the FortiGate dialup client.

Encrypted packets from the FortiGate dialup client are addressed to the public interface of the dialup server. Encrypted packets from the dialup server are addressed either to the public IP address of the FortiGate dialup client (if the dialup client connects to the Internet directly), or if the FortiGate dialup client is behind a NAT device, encrypted packets from the dialup server are addressed to the public IP address of the NAT device.

If a router with NAT capabilities is in front of the FortiGate dialup client, the router must be NAT-T compatible for encrypted traffic to pass through the NAT device. For more information, see "NAT traversal" on page 1420.

When the FortiGate dialup server decrypts a packet from the FortiGate dialup client, the source address in the IP header may be one of the following values, depending on the configuration of the network at the far end of the tunnel:

- If the FortiGate dialup client connects to the Internet directly, the source address will be the private IP address of a host or server on the network behind the FortiGate dialup client.
- If the FortiGate dialup client is behind a NAT device, the source address will be the public IP address of the NAT device.

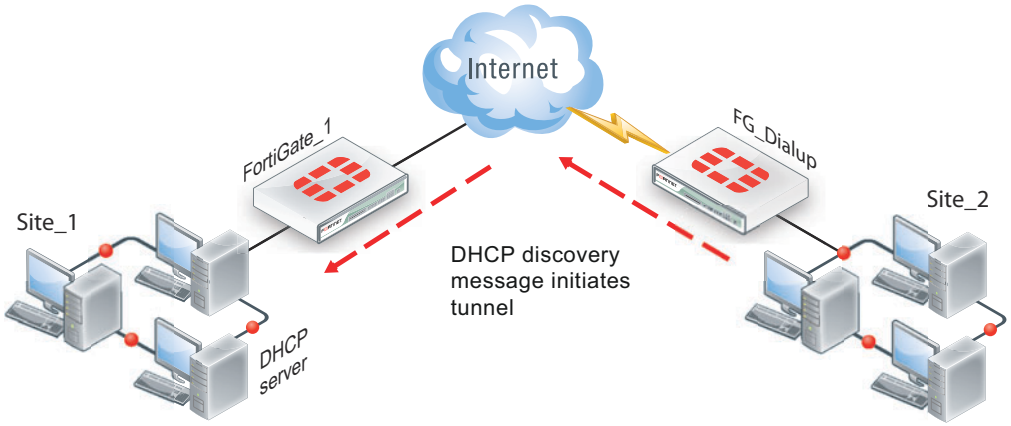
In some cases, computers on the private network behind the FortiGate dialup client may (by co-incidence) have IP addresses that are already used by computers on the network behind the FortiGate dialup server. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent.

In many cases, computers on the private network behind the FortiGate dialup client will most likely obtain IP addresses from a local DHCP server behind the FortiGate dialup client. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and IP-address overlap issues may arise.

To avoid these issues, you can configure FortiGate DHCP relay on the dialup client instead of using a DHCP server on the network behind the dialup client. The FortiGate dialup client can be configured to relay DHCP requests from the local private network to a DHCP server that resides on the network behind the FortiGate dialup server (see Figure 142 on page 1503). You configure the FortiGate dialup client to pass traffic from the local private network to the remote network by enabling FortiGate DHCP relay on the FortiGate dialup client interface that is connected to the local private network.

Afterward, when a computer on the network behind the dialup client broadcasts a DHCP request, the dialup client relays the message through the tunnel to the remote DHCP server. The remote DHCP server responds with a private IP address for the computer. To avoid ambiguous routing and network overlap issues, the IP addresses assigned to computers behind the dialup client cannot match the network address space used by the private network behind the FortiGate dialup server.

Figure 142: Preventing network overlap in a FortiGate dialup-client configuration



When the DHCP server resides on the private network behind the FortiGate dialup server, the IP destination address specified in the IPsec security policy on the FortiGate dialup client must refer to that network.

You must add a static route to the DHCP server FortiGate unit if it is not directly connected to the private network behind the FortiGate dialup server—its IP address does not match the IP address of the private network. Also, the destination address in the IPsec security policy on the FortiGate dialup client must refer to the DHCP server address. The DHCP server must be configured to assign a range of IP addresses different from the DHCP server's local network, and also different from the private network addresses behind the FortiGate dialup server. See “Routing” on page 1469.

FortiGate dialup-client infrastructure requirements

The requirements are:

- The FortiGate dialup server must have a static public IP address.
- NAT mode is required if you want to create a route-based VPN.
- The FortiGate dialup server may operate in either NAT mode or transparent mode to support a policy-based VPN.

- Computers on the private network behind the FortiGate dialup client can obtain IP addresses either from a DHCP server behind the FortiGate dialup client, or a DHCP server behind the FortiGate dialup server.
  - If the DHCP server resides on the network behind the dialup client, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup server.
  - If the DHCP server resides on the network behind the FortiGate dialup server, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup client.

FortiGate dialup-client configuration steps

The procedures in this section assume that computers on the private network behind the FortiGate dialup client obtain IP addresses from a local DHCP server. The assigned IP addresses do not match the private network behind the FortiGate dialup server.

In situations where IP-address overlap between the local and remote private networks is likely to occur, FortiGate DHCP relay can be configured on the FortiGate dialup client to relay DHCP requests to a DHCP server behind the FortiGate dialup server. For more information, see “To configure DHCP relay on the FortiGate unit” on page 1491.

Configuring dialup client capability for FortiGate dialup clients involves the following general configuration steps:

- Determine which IP addresses to assign to the private network behind the FortiGate dialup client, and add the IP addresses to the DHCP server behind the FortiGate dialup client. Refer to the software supplier’s documentation to configure the DHCP server.
- Configure the FortiGate dialup server. See “Configure the server to accept FortiGate dialup-client connections” on page 1504.
- Configure the FortiGate dialup client. See “Configure the FortiGate dialup client” on page 1506.

Configure the server to accept FortiGate dialup-client connections

Before you begin, optionally reserve a unique identifier (peer ID) for the FortiGate dialup client. The dialup client will supply this value to the FortiGate dialup server for authentication purposes during the IPsec phase 1 exchange. In addition, the value will enable you to distinguish FortiGate dialup-client connections from FortiClient dialup-client connections. The same value must be specified on the dialup server and on the dialup client.

1 At the FortiGate dialup server, define the phase 1 parameters needed to authenticate the FortiGate dialup client and establish a secure connection. See “Auto Key phase 1 parameters” on page 1407. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel. This name appears in phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select *Dialup User*.
Local Interface	Select the interface through which clients connect to the FortiGate unit.

Mode	If you will be assigning an ID to the FortiGate dialup client, select *Aggressive*.
Peer Options	If you will be assigning an ID to the FortiGate dialup client, select *Accept this peer ID* and type the identifier that you reserved for the FortiGate dialup client into the adjacent field.
Enable IPsec Interface Mode	You must select *Advanced* to see this setting. If *IPsec Interface Mode* is enabled, the FortiGate unit creates a virtual IPsec interface for a route-based VPN. Disable this option if you want to create a policy-based VPN. After you select *OK* to create the phase 1 configuration, you cannot change this setting.

2 Define the phase 2 parameters needed to create a VPN tunnel with the FortiGate dialup client. See "Phase 2 parameters" on page 1425. Enter these settings in particular:

Name	Enter a name to identify this phase 2 configuration.
Phase 1	Select the name of the phase 1 configuration that you defined.

3 Define names for the addresses or address ranges of the private networks that the VPN links. See "Defining policy addresses" on page 1431. Enter these settings in particular:

- Define an address name for the server, host, or network behind the FortiGate dialup server.
- Define an address name for the private network behind the FortiGate dialup client.

4 Define the security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see "Defining VPN security policies" on page 1432.

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind the FortiGate dialup client and the private network behind this FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

Enter these settings in particular:

Source Interface/Zone	Select the VPN tunnel (IPsec interface) created in Step 1.
Source Address Name	Select *All*.
Destination Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address Name	Select *All*.
Action	Select *ACCEPT*.
NAT	Disable

Policy-based VPN security policy

Define an IPsec security policy. Enter these settings in particular:

Source Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select the address name that you defined in Step 3 for the private network behind this FortiGate unit.
Destination Interface/Zone	Select the FortiGate unit's public interface.
Destination Address Name	Select the address name that you defined in Step 3.
Action	Select *IPSEC*.
VPN Tunnel	Select the name of the phase 1 configuration that you created in Step 1. Select *Allow inbound* to enable traffic from the remote network to initiate the tunnel. Clear *Allow outbound* to prevent traffic from the local network from initiating the tunnel after the tunnel has been established.

1 Place the policy in the policy list above any other policies having similar source and destination addresses.

2 If configuring a route-based policy, configure a default route for VPN traffic on this interface.

Configure the FortiGate dialup client

Configure the FortiGate dialup client as follows:

1 At the FortiGate dialup client, define the phase 1 parameters needed to authenticate the dialup server and establish a secure connection. See "Auto Key phase 1 parameters" on page 1407. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel.
Remote Gateway	Select *Static IP Address*.
IP Address	Type the IP address of the dialup server's public interface.
Local Interface	Select the interface that connects to the public network.
Mode	The FortiGate dialup client has a dynamic IP address, select *Aggressive*.
Advanced	Select to view the following options.
Local ID	If you defined a peer ID for the dialup client in the FortiGate dialup server configuration, enter the identifier of the dialup client. The value must be identical to the peer ID that you specified previously in the FortiGate dialup server configuration.

Enable IPsec Interface Mode	If *IPsec Interface Mode* is enabled, the FortiGate unit creates a virtual IPsec interface for a route-based VPN. Disable this option if you want to create a policy-based VPN. After you select *OK* to create the phase 1 configuration, you cannot change this setting.

2 Define the phase 2 parameters needed to create a VPN tunnel with the dialup server. See "Phase 2 parameters" on page 1425. Enter these settings in particular:

Name	Enter a name to identify this phase 2 configuration.
Phase 1	Select the set of phase 1 parameters that you defined in step 1.

3 Define names for the addresses or address ranges of the private networks that the VPN links. See "Defining policy addresses" on page 1431. Enter these settings in particular:

- Define an address name for the server, host, or network behind the FortiGate dialup server.
- Define an address name for the private network behind the FortiGate dialup client.

4 Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see "Defining VPN security policies" on page 1432.

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind this FortiGate dialup client and the private network behind the FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy. Enter these settings in particular:

Source Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select *All*.
Destination Interface/Zone	Select the VPN tunnel (IPsec interface) created in Step 1.
Destination Address Name	Select *All*.
Action	Select *ACCEPT*.
NAT	Disable

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses. Enter these settings in particular:

Source Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Source Address Name	Select the address name that you defined in Step 3 for the private network behind this FortiGate unit.
Destination Interface/Zone	Select the FortiGate unit's public interface.

Destination Address Name	Select the address name that you defined in Step 3 for the private network behind the dialup server.
Action	Select *IPSEC*.
VPN Tunnel	Select the name of the phase 1 configuration that you created in Step 1. Clear *Allow inbound* to prevent traffic from the remote network from initiating the tunnel after the tunnel has been established. Select *Allow outbound* to enable traffic from the local network to initiate the tunnel.

Place the policy in the policy list above any other policies having similar source and destination addresses.

Supporting IKE Mode config clients

IKE Mode Config is an alternative to DHCP over IPsec. A FortiGate unit can be configured as either an IKE Mode Config server or client. This chapter contains the following sections:

Automatic configuration overview

VPN configuration for remote clients is simpler if it is automated. Several protocols support automatic configuration:

- The Fortinet FortiClient Endpoint Security application can completely configure a VPN connection with a suitably configured FortiGate unit given only the FortiGate unit's address. This protocol is exclusive to Fortinet. For more information, see the "FortiClient dialup-client configurations" chapter.
- DHCP over IPsec can assign an IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms.
- IKE Mode Config can configure host IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms. Several network equipment vendors support IKE Mode Config, which is described in the ISAKMP Configuration Method document *draft-dukes-ike-mode-cfg-02.txt*.

This chapter describes how to configure a FortiGate unit as either an IKE Mode Config server or client.

IKE Mode Config overview

Dialup VPN clients connect to a FortiGate unit that acts as a VPN server, providing the client the necessary configuration information to establish a VPN tunnel. The configuration information typically includes a virtual IP address, netmask, and DNS server address.

IKE Mode Config is available only for VPNs that are route-based, also known as interface-based. A FortiGate unit can function as either an IKE Configuration Method server or client. IKE Mode Config is configurable only in the CLI.

Configuring IKE Mode Config

IKE Mode Config is configured with the CLI command `vpn ipsec phase1-interface`. The `mode-cfg` variable enables IKE Mode Config. The `type` field determines whether you are creating an IKE Mode Config server or a client. Setting `type` to `dynamic` creates a server configuration, otherwise the configuration is a client.

Configuring an IKE Mode Config client

If the FortiGate unit will connect as a dialup client to a remote gateway that supports IKE Mode Config, the relevant `vpn ipsec phase1-interface` variables are as follows:

Variable	Description
`ike-version 1`	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is not compatible with IKE v2.
`mode-cfg enable`	Enable IKE Mode Config.
`type {ddns | static}`	If you set `type` to `dynamic`, an IKE Mode Config server is created.
`assign-ip {enable | disable}`	Enable to request an IP address from the server.
`interface <interface_name>`	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
`proposal <encryption_combination>`	This is a regular IPsec VPN field that determines the encryption and authentication settings that the client will accept. For more information, see "Defining IKE negotiation parameters" on page 1417.
`mode-cfg-ip-version {4|6}`	Select if the Method client receives an IPv4 or IPv6 IP address. The default is `4`. the `ip-version` setting matches this variable's value.
`ip-version <4 | 6>`	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set `ip-version` to `6` to create a VPN with IPv6 addressing.

Configuring an IKE Mode Config server

If the FortiGate unit will accept connection requests from dialup clients that support IKE Mode Config, the following `vpn ipsec phase1-interface` settings are required before any other configuration is attempted:

Variable	Description
`ike-version 1`	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is not compatible with IKE v2.
`mode-cfg enable`	Enable IKE Mode Config.
`type dynamic`	Any other setting creates an IKE Mode Config client.

Variable	Description
`interface <interface_name>`	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
`proposal <encryption_combination>`	This is a regular IPsec VPN field that determines the encryption and authentication settings that the server will accept. For more information, see "Defining IKE negotiation parameters" on page 1417.
`ip-version <4 | 6>`	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set `ip-version` to `6` to create a VPN with IPv6 addressing.

After you have enabled the basic configuration, you can configure:

- IP address assignment for clients
- DNS and WINS server assignment

IP address assignment

Usually you will want to assign IP addresses to clients. The simplest method is to assign addresses from a specific range, similar to a DHCP server.

If your clients are authenticated by a RADIUS server, you can obtain the user's IP address assignment from the Framed-IP-Address attribute. The user must be authenticated using XAuth.

To assign IP addresses from an address range

If your VPN uses IPv4 addresses,

```
config vpn ipsec phase1-interface
  edit vpn1
    set mode-cfg-ipversion 4
    set assign-ip enable
    set assign-ip-type ip
    set assign-ip-from range
    set ipv4-start-ip <range_start>
    set ipv4-end-ip <range_end>
    set ipv4-netmask <netmask>
  end
```

If your VPN uses IPv6 addresses,

```
config vpn ipsec phase1-interface
  edit vpn1
    set mode-cfg-ipversion 6
    set assign-ip enable
    set assign-ip-type ip
    set assign-ip-from range
    set ipv6-start-ip <range_start>
    set ipv6-end-ip <range_end>
  end
```

To assign IP addresses from a RADIUS server

The users must be authenticated by a RADIUS server and assigned to the FortiGate user group `<grpname>`. Since the IP address will not be static, `type` is set to dynamic, and `mode-cfg` is enabled. This is IKE Configuration Method so that compatible clients can configure themselves with settings that the FortiGate unit provides.

```
config vpn ipsec phase1-interface
  edit vpn1
  set type dynamic
    set mode-cfg enable
    set assign-ip enable
    set assign-ip-from usrgrp
    set xauthtype auto
    set authusrgrp <grpname>
  end
```

Example: FortiGate unit as IKE Mode Config server

In this example, the FortiGate unit assigns IKE Mode Config clients addresses in the range of 10.11.101.160 through 10.11.101.180. DNS and WINS server addresses are also provided. The public interface of the FortiGate unit is Port 1.

The `ipv4-split-include` variable specifies a firewall address that represents the networks to which the clients will have access. This destination IP address information is sent to the clients.

Only the CLI fields required for IKE Mode Config are shown here. For detailed information about these variables, see the *FortiGate CLI Reference*.

```
config vpn ipsec phase1-interface
  edit vpn1
    set ip-version 4
    set type dynamic
    set interface port1
    set proposal 3des-sha1 aes128-sha1
    set mode-cfg enable
    set mode-cfg-ipversion 4
    set assign-ip enable
    set assign-ip-type ip
    set assign-ip-from range
    set ipv4-start-ip 10.11.101.160
    set ipv4-end-ip 10.11.101.180
    set ipv4-netmask 255.255.255.0
    set dns-server1 10.11.101.199
    set dns-server2 66.11.168.195
    set wins-server1 10.11.101.191
    set domain example
    set ipv4-split-include OfficeLAN
  end
```

Example: FortiGate unit as IKE Mode Config client

In this example, the FortiGate unit connects to a VPN gateway with a static IP address that can be reached through Port 1. Only the port, gateway and proposal information needs to be configured. All other configuration information will come from the IKE Mode Config server.

```
config vpn ipsec phase1-interface
  edit vpn1
    set ip-version 4
    set type static
    set remote-gw <gw_address>
    set interface port 1
    set proposal 3des-sha1 aes128-sha1
    set mode-cfg enable
    set mode-cfg-ipversion 4
    set assign-ip enable
  end
```

Internet-browsing configuration

This section explains how to support secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

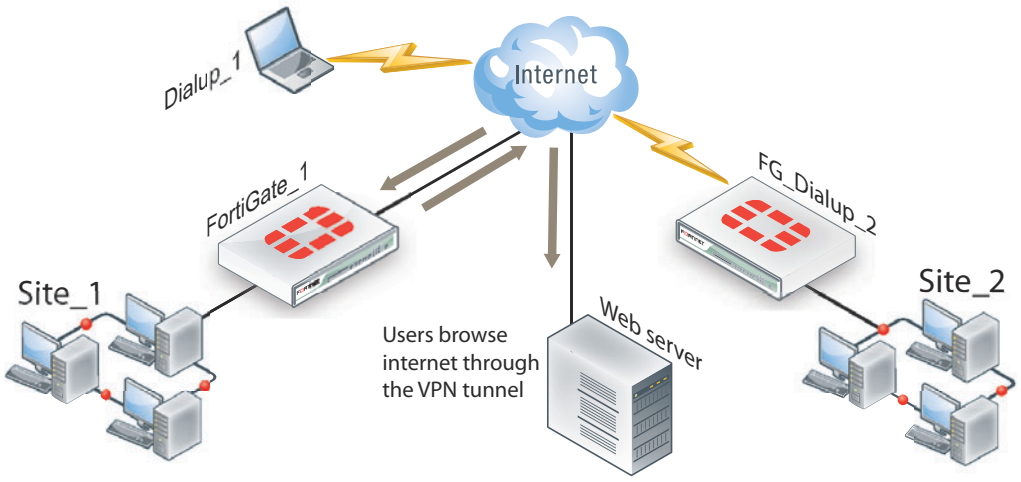
The following topics are included in this section:

Configuration overview

A VPN provides secure access to a private network behind the FortiGate unit. You can also enable VPN clients to access the Internet securely. The FortiGate unit inspects and processes all traffic between the VPN clients and hosts on the Internet according to the Internet browsing policy. This is accomplished even though the same FortiGate interface is used for both encrypted VPN client traffic and unencrypted Internet traffic.

In Figure 143, FortiGate_1 enables secure Internet browsing for FortiClient Endpoint Security users such as Dialup_1 and users on the Site_2 network behind FortiGate_2, which could be a VPN peer or a dialup client.

Figure 143: Example Internet-browsing configuration



You can adapt any of the following configurations to provide secure Internet browsing:

- a gateway-to-gateway configuration (see “Gateway-to-gateway configurations” on page 1437)
- a FortiClient dialup-client configuration (see “FortiClient dialup-client configurations” on page 1483)

- a FortiGate dialup-client configuration (see "FortiGate dialup-client configurations" on page 1501)

The procedures in this section assume that one of these configurations is in place, and that it is operating properly.

To create an internet-browsing configuration based on an existing gateway-to-gateway configuration, you must edit the gateway-to-gateway configuration as follows:

- On the FortiGate unit that will provide Internet access, create an Internet browsing security policy. See "Creating an Internet browsing security policy", below.
- Configure the remote peer or client to route all traffic through the VPN tunnel. You can do this on a FortiGate unit or on a FortiClient Endpoint Security application. See "Routing all remote traffic through the VPN tunnel" on page 1517.

Creating an Internet browsing security policy

On the FortiGate unit that acts as a VPN server and will provide secure access to the Internet, you must create an Internet browsing security policy. This policy differs depending on whether your gateway-to-gateway configuration is policy-based or route-based.

To create an Internet browsing policy - policy-based VPN

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information and then select *OK*:

Source Interface	The interface to which the VPN tunnel is bound.
Source Address Name	All
Destination Interface	The interface to which the VPN tunnel is bound.
Destination Address Name	The internal range of address of the remote spoke site.
Schedule	As required.
Service	As required.
Action	IPSEC
VPN Tunnel	Select the tunnel that provides access to the private network behind the FortiGate unit.
UTM	Select the UTM feature profiles that you want to apply to Internet access.
Allow Inbound	Enable
Allow Outbound	Enable
Inbound NAT	Enable

To create an Internet browsing policy - route-based VPN

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information and then select *OK*:

Source Interface	The IPsec VPN interface.
Source Address Name	All
Destination Interface	The interface that connects to the Internet. The virtual IPsec interface is configured on this physical interface.
Destination Address Name	All
Schedule	As required.
Service	As required.
Action	ACCEPT
NAT	Enable
UTM	Select the UTM features that you want to apply to Internet access.

The VPN clients must be configured to route all Internet traffic through the VPN tunnel.

Routing all remote traffic through the VPN tunnel

To make use of the Internet browsing configuration on the VPN server, the VPN peer or client must route all traffic through the VPN tunnel. Usually, only the traffic destined for the private network behind the FortiGate VPN server is sent through the tunnel.

The remote end of the VPN can be a FortiGate unit that acts as a peer in a gateway-to-gateway configuration or a FortiClient Endpoint Security application that protects an individual client such as a notebook PC.

- To configure a remote peer FortiGate unit for Internet browsing via VPN, see "Configuring a FortiGate remote peer to support Internet browsing".
- To configure a FortiClient Endpoint Security application for Internet browsing via VPN, see "Configuring a FortiClient application to support Internet browsing" on page 1518.

These procedures assume that your VPN connection to the protected private network is working and that you have configured the FortiGate VPN server for Internet browsing as described in "Creating an Internet browsing security policy" on page 1516.

Configuring a FortiGate remote peer to support Internet browsing

The configuration changes to send all traffic through the VPN differ for policy-based and route-based VPNs.

To route all traffic through a policy-based VPN

1 At the FortiGate dialup client, go to *Policy* > *Policy* > Policy.

2 Select the IPsec security policy and then select *Edit*.

3 From the *Destination Address* list, select *all*.

4 Select *OK*.

All packets are routed through the VPN tunnel, not just packets destined for the protected private network.

To route all traffic through a route-based VPN

1 At the FortiGate dialup client, go to *Router* > *Static* > *Static Route*.

2 Select the default route (destination IP 0.0.0.0) and then select *Edit*. If there is no default route, select *Create New*. Enter the following information and select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	Select the IPsec virtual interface.
Distance	Leave at default.

All packets are routed through the VPN tunnel, not just packets destined for the protected private network.

Configuring a FortiClient application to support Internet browsing

By default, the FortiClient application configures the PC so that traffic destined for the remote protected network passes through the VPN tunnel but all other traffic is sent to the default gateway. You need to modify the FortiClient settings so that it configures the PC to route all outbound traffic through the VPN.

To route all traffic through VPN - FortiClient application

1 At the remote host, start FortiClient.

2 Go to *VPN* > *Connections*.

3 Select the definition that connects FortiClient to the FortiGate dialup server.

4 Select *Advanced* and then select *Edit*.

5 In the *Edit Connection* dialog box, select *Advanced*.

6 In the *Remote Network* group, select *Add*.

7 In the *IP* and *Subnet Mask* fields, type `0.0.0.0/0.0.0.0` and select *OK*.

The address is added to the *Remote Network* list. The first destination IP address in the list establishes a VPN tunnel. The second destination address (`0.0.0.0/0.0.0.0` in this case) forces all other traffic through the VPN tunnel.

8 Select *OK*.

Redundant VPN configurations

This section discusses the options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches.

The following topics are included in this section:

Configuration overview

A FortiGate unit with two interfaces connected to the Internet can be configured to support redundant VPNs to the same remote peer. If the primary connection fails, the FortiGate unit can establish a VPN using the other connection.

Redundant tunnels do not support Tunnel Mode or Manual Keys. You must use Interface Mode.

A fully-redundant configuration requires redundant connections to the Internet on both peers. Figure 144 on page 1520 shows an example of this. This is useful to create a reliable connection between two FortiGate units with static IP addresses.

When only one peer has redundant connections, the configuration is partially-redundant. For an example of this, see "Partially-redundant route-based VPN example" on page 1534. This is useful to provide reliable service from a FortiGate unit with static IP addresses that accepts connections from dialup IPsec VPN clients.

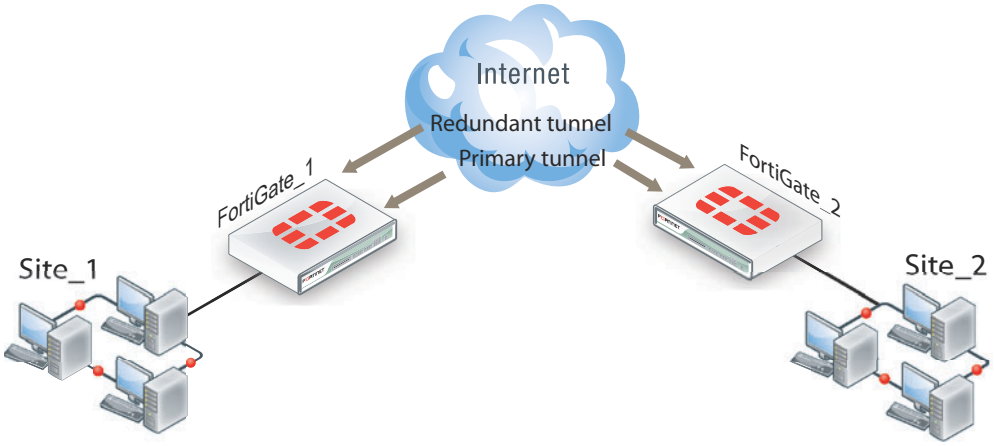
In a fully-redundant VPN configuration with two interfaces on each peer, four distinct paths are possible for VPN traffic from end to end. Each interface on a peer can communicate with both interfaces on the other peer. This ensures that a VPN will be available as long as each peer has one working connection to the Internet.

You configure a VPN and an entry in the routing table for each of the four paths. All of these VPNs are ready to carry data. You set different routing distances for each route and only the shortest distance route is used. If this route fails, the route with the next shortest distance is used.

The redundant configurations described in this chapter use route-based VPNs, otherwise known as virtual IPsec interfaces. This means that the FortiGate unit must operate in NAT mode. You must use auto-keying. A VPN that is created using manual keys (see "Manual-key configurations" on page 1551) cannot be included in a redundant-tunnel configuration.

The configuration described here assumes that your redundant VPNs are essentially equal in cost and capability. When the original VPN returns to service, traffic continues to use the replacement VPN until the replacement VPN fails. If your redundant VPN uses more expensive facilities, you want to use it only as a backup while the main VPN is down. For information on how to do this, see “Creating a backup IPsec interface” on page 1541.

Figure 144: Example redundant-tunnel configuration



A VPN that is created using manual keys (see “Manual-key configurations” on page 1551) cannot be included in a redundant-tunnel configuration.

General configuration steps

A redundant configuration at each VPN peer includes:

- one phase 1 configuration (virtual IPsec interface) for each path between the two peers. In a fully-meshed redundant configuration, each network interface on one peer can communicate with each network interface on the remote peer. If both peers have two public interfaces, this means that each peer has four paths, for example.
- one phase 2 definition for each phase 1 configuration
- one static route for each IPsec interface, with different distance values to prioritize the routes
- two Accept security policies per IPsec interface, one for each direction of traffic
- dead peer detection enabled in each phase 1 definition

The procedures in this section assume that two separate interfaces to the Internet are available on each VPN peer.

Configure the VPN peers - route-based VPN

VPN peers are configured using Interface Mode for redundant tunnels.

Configure each VPN peer as follows:

1 Ensure that the interfaces used in the VPN have static IP addresses.

2 Create a phase 1 configuration for each of the paths between the peers. Enable IPsec Interface mode so that this creates a virtual IPsec interface. Enable dead peer detection so that one of the other paths is activated if this path fails.

Enter these settings in particular:

Path 1

Remote Gateway	Select *Static IP Address*.
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Enable IPsec Interface Mode	Enable
Dead Peer Detection	Enable

Other settings as required by VPN.

Path 2

Remote Gateway	Select *Static IP Address*.
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Enable IPsec Interface Mode	Enable
Dead Peer Detection	Enable

Other settings as required by VPN.

Path 3

Remote Gateway	Select *Static IP Address*.
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Enable IPsec Interface Mode	Enable
Dead Peer Detection	Enable

Other settings as required by VPN.

Path 4

Remote Gateway	Select Static *IP Address*.
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Enable IPsec Interface Mode	Enable
Dead Peer Detection	Enable

Other settings as required by VPN.

For more information, see "Auto Key phase 1 parameters" on page 1407.

3 Create a phase 2 definition for each path. See "Phase 2 parameters" on page 1425. Enter these settings in particular:

Phase 1	Select the phase 1 configuration (virtual IPsec interface) that you defined for this path. You can select the name from the Static IP Address part of the list.

4 Create a route for each path to the other peer. If there are two ports on each peer, there are four possible paths between the peer devices.

Destination IP/Mask	The IP address and netmask of the private network behind the remote peer.
Device	One of the virtual IPsec interfaces on the local peer.
Distance	For each path, enter a different value to prioritize the paths.

5 Define the security policy for the local primary interface. See "Defining VPN security policies" on page 1432. You need to create two policies for each path to enable communication in both directions. Enter these settings in particular:

Source Interface/Zone	Select the local interface to the internal (private) network
Source Address Name	All
Destination Interface/Zone	Select one of the virtual IPsec interfaces you created in Step 2.
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

Source Interface/Zone	Select one of the virtual IPsec interfaces you created in Step 2.
Source Address Name	All
Destination Interface/Zone	Select the local interface to the internal (private) network.
Destination Address Name	All

Schedule	Always
Service	Any
Action	ACCEPT

6 Place the policy in the policy list above any other policies having similar source and destination addresses.

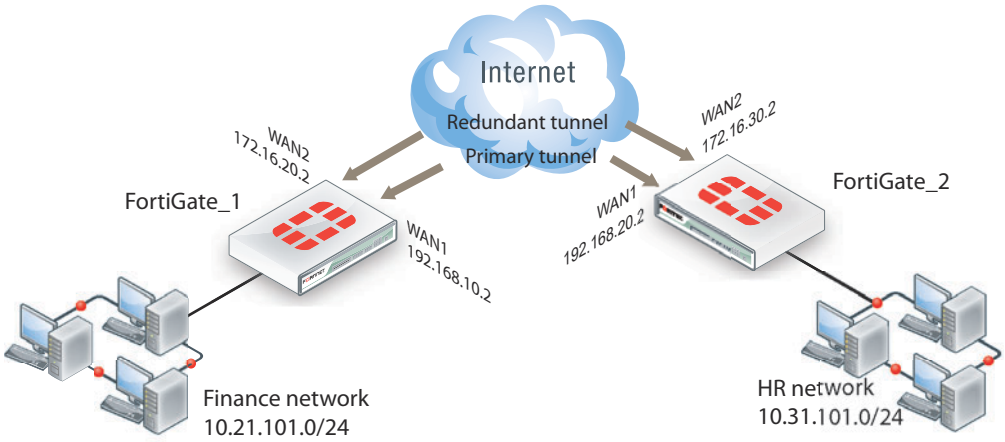
7 Repeat this procedure at the remote FortiGate unit.

Redundant route-based VPN configuration example

This example demonstrates a fully redundant site-to-site VPN configuration using route-based VPNs. At each site, the FortiGate unit has two interfaces connected to the Internet through different ISPs. This means that there are four possible paths for communication between the two units. In this example, these paths, listed in descending priority, are:

- FortiGate_1 WAN 1 to FortiGate_2 WAN 1
- FortiGate_1 WAN 1 to FortiGate_2 WAN 2
- FortiGate_1 WAN 2 to FortiGate_2 WAN 1
- FortiGate_1 WAN 2 to FortiGate_2 WAN 2

Figure 145: Example redundant route-based VPN configuration



For each path, VPN configuration, security policies and routing are defined. By specifying a different routing distance for each path, the paths are prioritized. A VPN tunnel is established on each path, but only the highest priority one is used. If the highest priority path goes down, the traffic is automatically routed over the next highest priority path. You could use dynamic routing, but to keep this example simple, static routing is used.

Configuring FortiGate_1

You must

- configure the interfaces involved in the VPN
- define the phase 1 configuration for each of the four possible paths, creating a virtual IPsec interface for each one
- define the phase 2 configuration for each of the four possible paths
- configure routes for the four IPsec interfaces, assigning the appropriate priorities

- configure incoming and outgoing security policies between the internal interface and each of the virtual IPsec interfaces

To configure the network interfaces

1 Go to *System* > *Network* > *Interface*.

2 Select the the Internal interface and select *Edit*.

3 Enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	10.21.101.0/255.255.255.0

4 Select the WAN1 interface and select *Edit*, enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	192.168.10.2/255.255.255.0

5 Select the WAN2 interface and select *Edit*, enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	172.16.20.2/255.255.255.0

To configure the IPsec interfaces (phase 1 configurations)

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	Site_1_A
Remote Gateway	Static IP Address
IP Address	192.168.20.2
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

3 Select Create Phase 1, enter the following information, and select OK:

Name	Site_1_B
Remote Gateway	Static IP Address

IP Address	172.16.30.2
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

4 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	Site_1_C
Remote Gateway	Static IP Address
IP Address	192.168.20.2
Local Interface	WAN2
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

5 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	Site_1_D
Remote Gateway	Static IP Address
IP Address	172.16.30.2
Local Interface	WAN2
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

To define the phase 2 configurations for the four VPNs

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_A.
Phase 1	Site_1_A

3 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_B.
Phase 1	Site_1_B

4 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_C.
Phase 1	Site_1_C

5 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_D.
Phase 1	Site_1_D

To configure routes

1 Go to *Router* > *Static* > *Static Route*.

2 Select *Create New*, enter the following default gateway information and then select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	WAN1
Gateway	192.168.10.1
Distance	10

3 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.31.101.0/255.255.255.0
Device	Site_1_A
Distance	1

4 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.31.101.0/255.255.255.0
Device	Site_1_B
Distance	2

5 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.31.101.0/255.255.255.0
Device	Site_1_C
Distance	3

6 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.31.101.0/255.255.255.0
Device	Site_1_D
Distance	4

To configure security policies

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information, and then select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_1_A
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

3 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Site_1_A
Source Address Name	All
Destination Interface/Zone	Internal
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

4 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_1_B
Destination Address Name	All
Schedule	Always

Service	Any
Action	ACCEPT

5 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Site_1_B
Source Address Name	All
Destination Interface/Zone	Internal
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

6 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_1_C
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

7 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Site_1_C
Source Address Name	All
Destination Interface/Zone	Internal
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

8 Select *Create New*, enter the following information, and select *OK*:

Configuring FortiGate_2

The configuration for FortiGate_2 is very similar that of FortiGate_1. You must

- configure the interfaces involved in the VPN
- define the phase 1 configuration for each of the four possible paths, creating a virtual IPsec interface for each one
- define the phase 2 configuration for each of the four possible paths
- configure routes for the four IPsec interfaces, assigning the appropriate priorities
- configure incoming and outgoing security policies between the internal interface and each of the virtual IPsec interfaces

To configure the network interfaces

1 Go to *System* > *Network* > *Interface*.

2 Select the Internal interface and then select *Edit*. Enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	`10.31.101.0/255.255.255.0`

3 Select the WAN1 interface and then select *Edit*. Enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	`192.168.20.2/255.255.255.0`

4 Select the WAN2 interface and then select *Edit*. Enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	`172.16.30.2/255.255.255.0`

To configure the IPsec interfaces (phase 1 configurations)

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	`Site_2_A`
Remote Gateway	Static IP Address
IP Address	`192.168.10.2`
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

3 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	`Site_2_B`
Remote Gateway	Static IP Address
IP Address	`172.16.20.2`
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

4 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	`Site_2_C`
Remote Gateway	Static IP Address
IP Address	`192.168.10.2`
Local Interface	WAN2
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	

Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

5 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	Site_2_D
Remote Gateway	Static IP Address
IP Address	172.16.20.2
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

To define the phase 2 configurations for the four VPNs

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_A.
Phase 1	Site_2_A

3 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_B.
Phase 1	Site_2_B

4 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_C.
Phase 1	Site_2_C

5 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_D.
Phase 1	Site_2_D

To configure routes

1 Go to *Router* > *Static* > *Static Route*.

2 Select *Create New*, enter the following default gateway information and then select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	WAN1
Gateway	192.168.10.1
Distance	10

3 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_A
Distance	1

4 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_B
Distance	2

5 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_C
Distance	3

6 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_D
Distance	4

To configure security policies

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_2_A

Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

3 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Site_2_A
Source Address Name	All
Destination Interface/Zone	Internal
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

4 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_2_B
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

5 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Site_2_B
Source Address Name	All
Destination Interface/Zone	Internal
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

6 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_2_C

Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

7 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Site_2_C
Source Address Name	All
Destination Interface/Zone	Internal
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

8 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_2_D
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

9 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Site_2_D
Source Address Name	All
Destination Interface/Zone	Internal
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

Partially-redundant route-based VPN example

This example demonstrates how to set up a partially redundant IPsec VPN between a local FortiGate unit and a remote VPN peer that receives a dynamic IP address from an ISP before it connects to the FortiGate unit. For more information about FortiGate dialup-client configurations, see “FortiGate dialup-client configurations” on page 1501.

When a FortiGate unit has more than one interface to the Internet (see FortiGate_1 in Figure 146), you can configure redundant routes—if the primary connection fails, the FortiGate unit can establish a VPN using the redundant connection.

In this case, FortiGate_2 has only one connection to the Internet. If the link to the ISP were to go down, the connection to FortiGate_1 would be lost, and the tunnel would be taken down. The tunnel is said to be partially redundant because FortiGate_2 does not support a redundant connection.

In the configuration example:

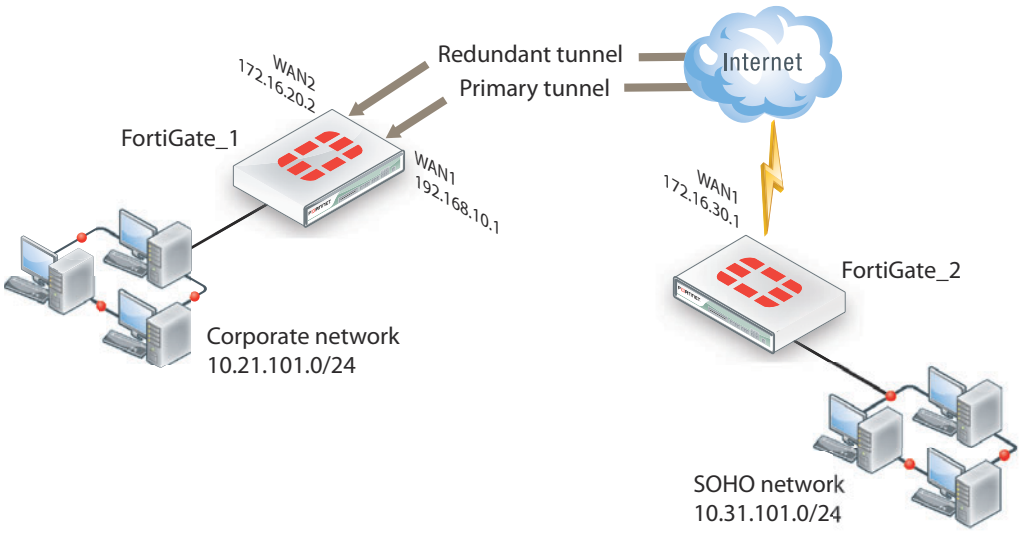
- Both FortiGate units operate in NAT mode.
- Two separate interfaces to the Internet (192.168.10.2 and 172.16.20.2) are available on FortiGate_1. Each interface has a static public IP address.
- FortiGate_2 has a single connection to the Internet and obtains a dynamic public IP address (for example, 172.16.30.1) when it connects to the Internet.
- FortiGate_2 forwards IP packets from the SOHO network (10.31.101.0/24) to the corporate network (10.21.101.0/24) behind FortiGate_1 through a partially redundant IPsec VPN. Encrypted packets from FortiGate_2 are addressed to the public interface of FortiGate_1. Encrypted packets from FortiGate_1 are addressed to the public IP address of FortiGate_2.

There are two possible paths for communication between the two units. In this example, these paths, listed in descending priority, are:

- FortiGate_1 WAN 1 to FortiGate_2 WAN 1
- FortiGate_1 WAN 2 to FortiGate_2 WAN 1

For each path, VPN configuration, security policies and routing are defined. By specifying a different routing distance for each path, the paths are prioritized. A VPN tunnel is established on each path, but only the highest priority one is used. If the highest priority path goes down, the traffic is automatically routed over the next highest priority path. You could use dynamic routing, but to keep this example simple, static routing is used.

Figure 146: Example partially redundant route-based configuration



Configuring FortiGate_1

You must

- configure the interfaces involved in the VPN
- define the phase 1 configuration for each of the two possible paths, creating a virtual IPsec interface for each one
- define the phase 2 configuration for each of the two possible paths
- configure incoming and outgoing security policies between the internal interface and each of the virtual IPsec interfaces

To configure the network interfaces

1 Go to *System* > *Network* > *Interface*.

2 Select the Internal interface and select *Edit*. Enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	`10.21.101.2/255.255.255.0`

3 Select the WAN1 interface and select *Edit*. Enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	`192.168.10.2/255.255.255.0`

4 Select the WAN2 interface and select *Edit*. Enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	`172.16.20.2/255.255.255.0`

To configure the IPsec interfaces (phase 1 configurations)

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	`Site_1_A`
Remote Gateway	Dialup User
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	

Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

3 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	Site_1_B
Remote Gateway	Dialup User
Local Interface	WAN2
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

To define the phase 2 configurations for the two VPNs

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_A.
Phase 1	Site_1_A

3 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_B.
Phase 1	Site_1_B

To configure routes

1 Go to *Router* > *Static* > *Static Route*.

2 Select *Create New*, enter the following default gateway information and then select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	WAN1
Gateway	192.168.10.1
Distance	10

To configure security policies

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_1_A
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

3 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_1_B
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

Configuring FortiGate_2

The configuration for FortiGate_2 is similar to that of FortiGate_1. You must

- configure the interface involved in the VPN
- define the phase 1 configuration for the primary and redundant paths, creating a virtual IPsec interface for each one
- define the phase 2 configurations for the primary and redundant paths, defining the internal network as the source address so that FortiGate_1 can automatically configure routing
- configure the routes for the two IPsec interfaces, assigning the appropriate priorities
- configure security policies between the internal interface and each of the virtual IPsec interfaces

To configure the network interfaces

1 Go to *System* > *Network* > *Interface*.

2 Select the Internal interface and select *Edit*. Enter the following information and then select *OK*:

Addressing mode	Manual
IP/Netmask	`10.31.101.2/255.255.255.0`

3 Select the WAN1 interface and select *Edit*. Enter the following information and then select *OK*:

Addressing mode	DHCP

To configure the two IPsec interfaces (phase 1 configurations)

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	`Site_2_A`
Remote Gateway	Static IP Address
IP Address	`192.168.10.2`
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

3 Select *Create Phase 1*, enter the following information, and select *OK*:

Name	`Site_2_B`
Remote Gateway	Static IP Address
IP Address	`172.16.20.2`
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Accept any peer ID
Advanced	
Enable IPsec Interface Mode	Select
Dead Peer Detection	Select

To define the phase 2 configurations for the two VPNs

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_A.
Phase 1	Site_2_A
Advanced	
Source Address	10.31.101.0/24

3 Select *Create Phase 2*, enter the following information and select *OK*:

Name	Route_B.
Phase 1	Site_2_B
Advanced	
Source Address	10.31.101.0/24

To configure routes

1 Go to *Router* > *Static* > *Static Route*.

2 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_A
Distance	1

3 Select *Create New*, enter the following information and then select *OK*:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_B
Distance	2

To configure security policies

1 Go to *Policy* > *Policy* > *Policy*.

2 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_2_A
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

3 Select *Create New*, enter the following information, and select *OK*:

Source Interface/Zone	Internal
Source Address Name	All
Destination Interface/Zone	Site_2_B
Destination Address Name	All
Schedule	Always
Service	Any
Action	ACCEPT

Creating a backup IPsec interface

You can configure a route-based VPN that acts as a backup facility to another VPN. It is used only while your main VPN is out of service. This is desirable when the redundant VPN uses a more expensive facility.

You can configure a backup IPsec interface only in the CLI. The backup feature works only on interfaces with static addresses that have dead peer detection enabled. The monitor-phase1 option creates a backup VPN for the specified phase 1 configuration.

In the following example, backup_vpn is a backup for main_vpn.

```
config vpn ipsec phase1-interface
  edit main_vpn
    set dpd on
    set interface port1
    set nattraversal enable
    set psksecret "hard-to-guess"
    set remote-gw 192.168.10.8
    set type static
  end
  edit backup_vpn
    set dpd on
    set interface port2
    set monitor-phase1 main_vpn
    set nattraversal enable
    set psksecret "hard-to-guess"
    set remote-gw 192.168.10.8
    set type static
  end
```

Transparent mode VPNs

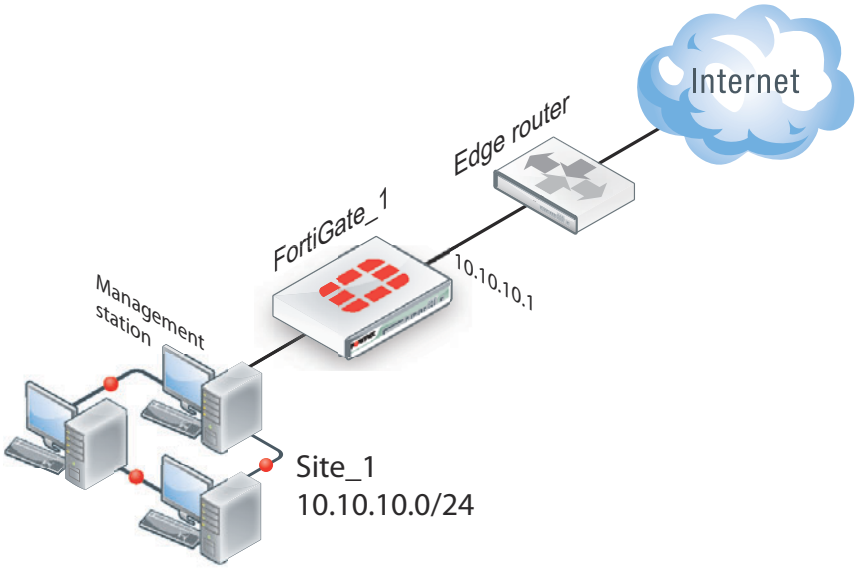
This section describes transparent VPN configurations, in which two FortiGate units create a VPN tunnel between two separate private networks transparently.

The following topics are included in this section:

Configuration overview

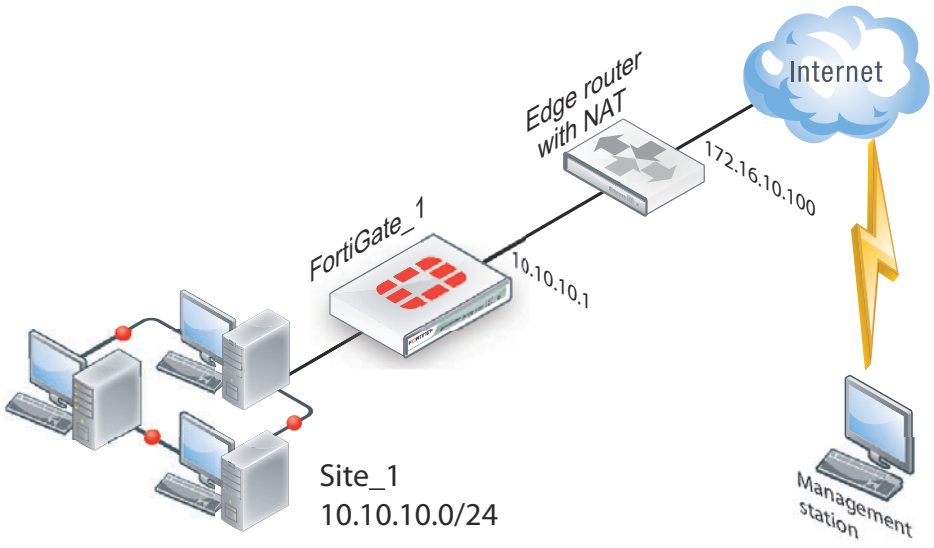
In transparent mode, all interfaces of the FortiGate unit except the management interface (which by default is assigned IP address 10.10.10.1/255.255.255.0) are invisible at the network layer. Typically, when a FortiGate unit runs in transparent mode, different network segments are connected to the FortiGate interfaces. Figure 147 shows the management station on the same subnet. The management station can connect to the FortiGate unit directly through the web-based manager.

Figure 147: Management station on internal network



An edge router typically provides a public connection to the Internet and one interface of the FortiGate unit is connected to the router. If the FortiGate unit is managed from an external address (see Figure 148 on page 1544), the router must translate (NAT) a routable address to direct management traffic to the FortiGate management interface.

Figure 148: Management station on external network



In a transparent VPN configuration, two FortiGate units create a VPN tunnel between two separate private networks transparently. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Both FortiGate units may be running in transparent mode, or one could be running in transparent mode and the other running in NAT mode. If the remote peer is running in NAT mode, it must have a static public IP address.

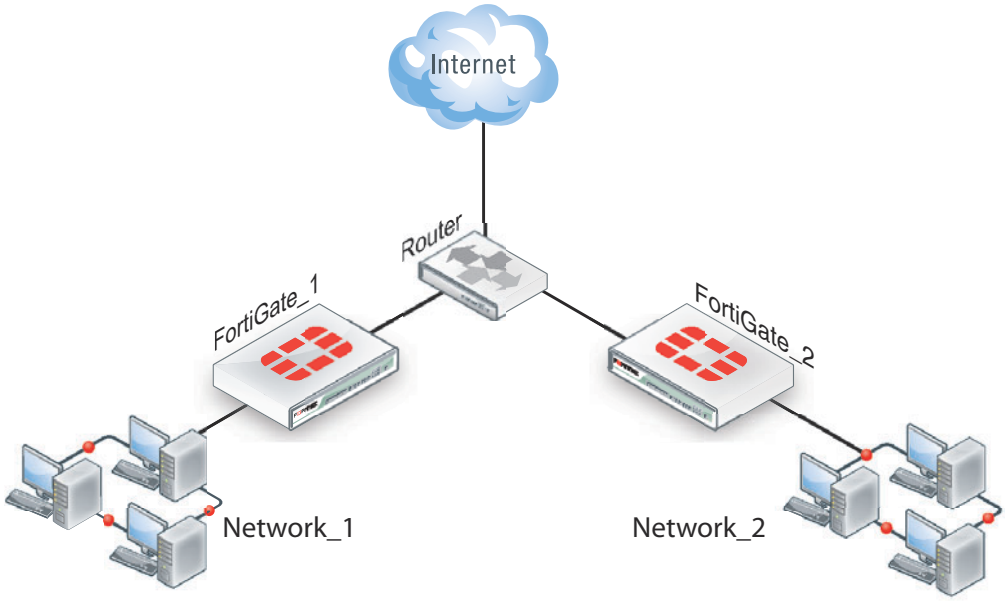
VPNs between two FortiGate units running in transparent mode do not support inbound/outbound NAT (supported through CLI commands) within the tunnel. In addition, a FortiGate unit running in transparent mode cannot be used in a hub-and-spoke configuration.

Encrypted packets from the remote VPN peer are addressed to the management interface of the local FortiGate unit. If the local FortiGate unit can reach the VPN peer locally, a static route to the VPN peer must be added to the routing table on the local FortiGate unit. If the VPN peer connects through the Internet, encrypted packets from the local FortiGate unit must be routed to the edge router instead. For information about how to add a static route to the FortiGate routing table, see the *Advanced Routing* .

In the example configuration shown in Figure 148, Network Address Translation (NAT) is enabled on the router. When an encrypted packet from the remote VPN peer arrives at the router through the Internet, the router performs inbound NAT and forwards the packet to the FortiGate unit. Refer to the software supplier's documentation to configure the router.

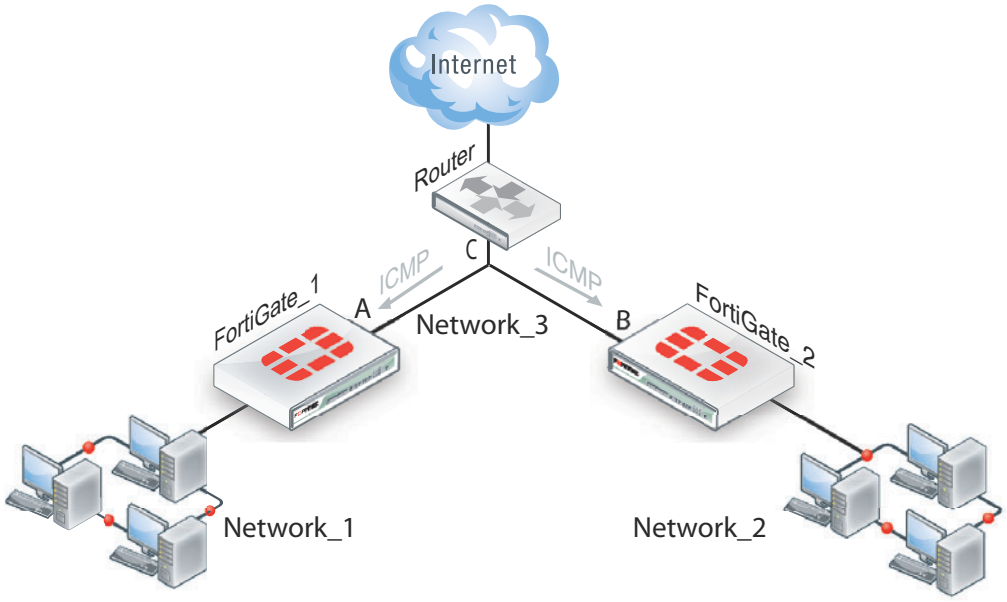
If you want to configure a VPN between two FortiGate units running in transparent mode, each unit must have an independent connection to a router that acts as a gateway to the Internet, and both units must be on separate networks that have a different address space. When the two networks linked by the VPN tunnel have different address spaces (see Figure 149 on page 1545), at least one router must separate the two FortiGate units, unless the packets can be redirected using ICMP (see Figure 150 on page 1545).

Figure 149: Link between two FortiGate units in transparent mode



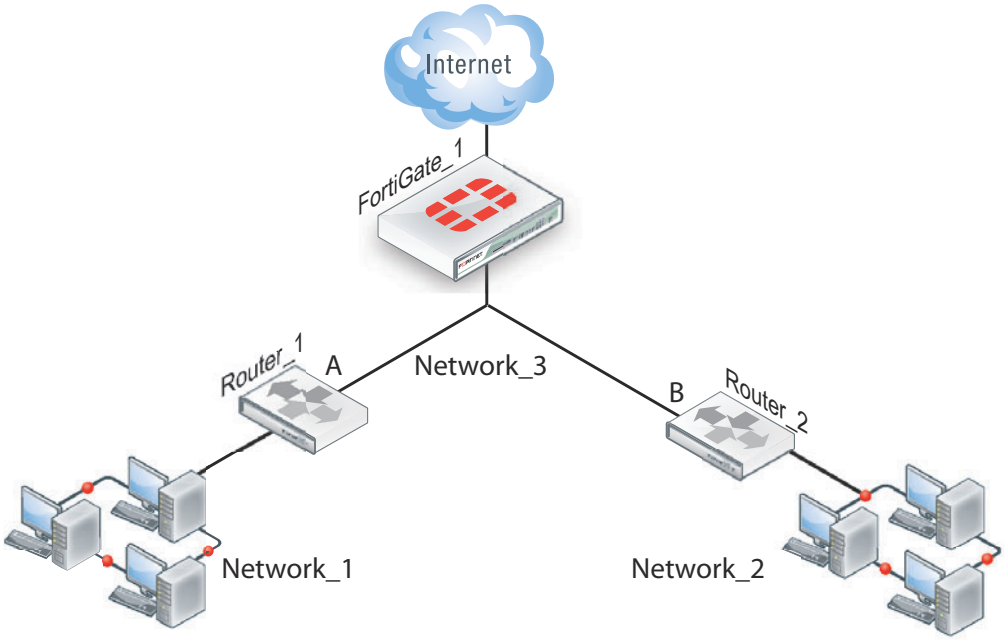
In Figure 150, interface C behind the router is the default gateway for both FortiGate units. Packets that cannot be delivered on Network_1 are routed to interface C by default. Similarly, packets that cannot be delivered on Network_2 are routed to interface C. In this case, the router must be configured to redirect packets destined for Network_1 to interface A and redirect packets destined for Network_2 to interface B.

Figure 150: ICMP redirecting packets to two FortiGate units in transparent mode



If there are additional routers behind the FortiGate unit (see Figure 151 on page 1546) and the destination IP address of an inbound packet is on a network behind one of those routers, the FortiGate routing table must include routes to those networks. For example, in Figure 151, the FortiGate unit must be configured with static routes to interfaces A and B in order to forward packets to Network_1 and Network_2 respectively.

Figure 151: Destinations on remote networks behind internal routers



Transparent VPN infrastructure requirements

- The local FortiGate unit must be operating in transparent mode.
- The management IP address of the local FortiGate unit specifies the local VPN gateway. The management IP address is considered a static IP address for the local VPN peer.
- If the local FortiGate unit is managed through the Internet, or if the VPN peer connects through the Internet, the edge router must be configured to perform inbound NAT and forward management traffic and/or encrypted packets to the FortiGate unit.
- If the remote peer is operating in NAT mode, it must have a static public IP address.

A FortiGate unit operating in transparent mode requires the following basic configuration to operate as a node on the IP network:

- The unit must have sufficient routing information to reach the management station.
- For any traffic to reach external destinations, a default static route to an edge router that forwards packets to the Internet must be present in the FortiGate routing table.
- When all of the destinations are located on the external network, the FortiGate unit may route packets using a single default static route. If the network topology is more complex, one or more static routes in addition to the default static route may be required in the FortiGate routing table.

Only policy-based VPN configurations are possible in transparent mode.

Before you begin

An IPsec VPN definition links a gateway with a tunnel and an IPsec policy. If your network topology includes more than one virtual domain, you must choose components that were created in the same virtual domain. Therefore, before you define a transparent VPN configuration, choose an appropriate virtual domain in which to create the required interfaces, security policies, and VPN components. For more information, see the *Virtual Domains* chapter of *The Handbook*.

Configure the VPN peers

1 The local VPN peer need to operate in transparent mode.

To determine if your FortiGate unit is in transparent mode, go to *System* > *Dashboard* > *Status* to *the System Information* widget. Select *[change].* Select transparent for the Operation Mode— two new fields will appear to enter the *Management IP/Netmask*, and the *Default Gateway*.

In transparent mode, the FortiGate unit is invisible to the network. All of its interfaces are on the same subnet and share the same IP address. You only have to configure a management IP address so that you can make configuration changes.

The remote VPN peer may operate in NAT mode or transparent mode.

2 At the local FortiGate unit, define the phase 1 parameters needed to establish a secure connection with the remote peer. See “Auto Key phase 1 parameters” on page 1407. Select *Advanced* and enter these settings in particular:

Remote Gateway	Select Static IP Address.
IP Address	Type the IP address of the public interface to the remote peer. If the remote peer is a FortiGate unit running in transparent mode, type the IP address of the remote management interface.
Advanced	Select Nat-traversal, and type a value into the Keepalive Frequency field. These settings protect the headers of encrypted packets from being altered by external NAT devices and ensure that NAT address mappings do not change while the VPN tunnel is open. For more information, see “NAT traversal” on page 1420 and “NAT keepalive frequency” on page 1421.

3 Define the phase 2 parameters needed to create a VPN tunnel with the remote peer. See “Phase 2 parameters” on page 1425.

Phase 1	Select the set of phase 1 parameters that you defined for the remote peer. The name of the remote peer can be selected from the Static IP Address list.

4 Define the source and destination addresses of the IP packets that are to be transported through the VPN tunnel. See "Defining policy addresses" on page 1431. Enter these settings in particular:

- For the originating address (source address), enter the IP address and netmask of the private network behind the local peer network. for the management interface, for example, `10.10.10.0/24`. This address needs to be a range to allow traffic from your network through the tunnel. Optionally select `any` for this address.
- For the remote address (destination address), enter the IP address and netmask of the private network behind the remote peer (for example, `192.168.10.0/24`). If the remote peer is a FortiGate unit running in transparent mode, enter the IP address of the remote management interface instead.

5 Define an IPsec security policy to permit communications between the source and destination addresses. See "Defining VPN security policies" on page 1432. Enter these settings in particular:

Source Interface/Zone	Select the local interface to the internal (private) network.
Source Address Name	Select the source address that you defined in Step 4.
Destination Interface/Zone	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Destination Address Name	Select the destination address that you defined in Step 4.
Action	IPSEC
VPN Tunnel	Select the name of the phase 2 tunnel configuration that you created in Step 3. Select *Allow inbound* to enable traffic from the remote network to initiate the tunnel. Select *Allow outbound* to enable traffic from the local network to initiate the tunnel.

6 Place the policy in the policy list above any other policies having similar source and destination addresses.

7 Define another IPsec security policy to permit communications between the source and destination addresses in the opposite direction. This security policy and the previous one form a bi-directional policy pair. See "Defining VPN security policies" on page 1432. Enter these settings in particular:

Source Interface/Zone	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Source Address Name	Select the destination address that you defined in Step 4.
Destination Interface/Zone	Select the local interface to the internal (private) network.
Destination Address Name	Select the source address that you defined in Step 4.

Action	IPSEC
VPN Tunnel	Select the name of the phase 2 tunnel configuration that you created in Step 3. Select *Allow inbound* to enable traffic from the remote network to initiate the tunnel. Select *Allow outbound* to enable traffic from the local network to initiate the tunnel.

8 Repeat this procedure at the remote FortiGate unit to create bidirectional security policies. Use the local interface and address information local to the remote FortiGate unit.

For more information on transparent mode, see the System Administration handbook chapter.

Manual-key configurations

This section explains how to manually define cryptographic keys to establish an IPsec VPN, either policy-based or route-based.

For more information on web-based manual key configuration, see "Manual Key" on page 1403.

The following topics are included in this section:

Configuration overview

You manual define cryptographic keys where prior knowledge of the encryption and/or authentication key is required (that is, one of the VPN peers requires a specific IPsec encryption and/or authentication key). In this case, you do not specify IPsec phase 1 and phase 2 parameters; you define manual keys by going to *VPN* > *IPsec* > *Manual Key*.

If one VPN peer uses specific authentication and encryption keys to establish a tunnel, both VPN peers must be configured to use the same encryption and authentication algorithms and keys.

It may not be safe or practical to define manual keys because network administrators must be trusted to keep the keys confidential, and propagating changes to remote VPN peers in a secure manner may be difficult.

It is essential that both VPN peers be configured with matching encryption and authentication algorithms, matching authentication and encryption keys, and complementary Security Parameter Index (SPI) settings.

You can define either the encryption or the authentication as NULL (disabled), but not both.

Each SPI identifies a Security Association (SA). The value is placed in ESP datagrams to link the datagrams to the SA. When an ESP datagram is received, the recipient refers to the SPI to determine which SA applies to the datagram. An SPI must be specified manually for each SA. Because an SA applies to communication in one direction only, you must specify two SPIs per configuration (a local SPI and a remote SPI) to cover bidirectional communications between two VPN peers.

If you are not familiar with the security policies, SAs, selectors, and SA databases for your particular installation, do not attempt the following procedure without qualified assistance.

Specify the manual keys for creating a tunnel

Specify the manual keys for creating a tunnel as follows:

1 Go to *VPN* > *IPsec* > *Manual Key* and select *Create New*.

2 Include appropriate entries as follows:

Name	Type a name for the VPN tunnel.
Local SPI	Type a hexadecimal number (up to 8 characters, 0-9, a-f) that represents the SA that handles outbound traffic on the local FortiGate unit. The valid range is from `0x100` to `0xffffffff`. This value must match the *Remote SPI* value in the manual key configuration at the remote peer.
Remote SPI	Type a hexadecimal number (up to 8 characters, 0-9, a-f) that represents the SA that handles inbound traffic on the local FortiGate unit. The valid range is from `0x100` to `0xffffffff`. This value must match the *Local SPI* value in the manual key configuration at the remote peer.
Remote Gateway	Type the IP address of the public interface to the remote peer. The address identifies the recipient of ESP datagrams.
Local Interface	Select the name of the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound. The FortiGate unit obtains the IP address of the interface from *System* > *Network* > *Interface* settings. This is available in NAT mode only.
Encryption Algorithm	Select one of the following symmetric-key encryption algorithms: • **DES —** Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. • **3DES** — Triple-DES, in which plain text is encrypted three times by three keys. • **AES128** — A 128-bit block algorithm that uses a 128-bit key. • **AES192** — A 128-bit block algorithm that uses a 192-bit key. • **AES256** — A 128-bit block algorithm that uses a 256-bit key.
Encryption Key	If you selected: • DES, type a 16-character hexadecimal number (0-9, a-f). • 3DES, type a 48-character hexadecimal number (0-9, a-f) separated into three segments of 16 characters. • AES128, type a 32-character hexadecimal number (0-9, a-f) separated into two segments of 16 characters. • AES192, type a 48-character hexadecimal number (0-9, a-f) separated into three segments of 16 characters. • AES256, type a 64-character hexadecimal number (0-9, a-f) separated into four segments of 16 characters.
Authentication Algorithm	Select one of the following message digests: • **MD5** — Message Digest 5 algorithm, which produces a 128-bit message digest. • **SHA1** — Secure Hash Algorithm 1, which produces a 160-bit message digest.

Authentication Key	If you selected: • MD5, type a 32-character hexadecimal number (0-9, a-f) separated into two segments of 16 characters. • SHA1, type 40-character hexadecimal number (0-9, a-f) separated into one segment of 16 characters and a second segment of 24 characters.
IPsec Interface Mode	Select to create a route-based VPN. A virtual IPsec interface is created on the Local Interface that you selected. This option is available only in NAT mode.

3 Select *OK*.

IPv6 IPsec VPNs

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality. To access IPv6 functionality through the web-based manager, go to *System Admin* > *Settings* and enable *IPv6* in the section, *Display Options on GUI*.

The following topics are included in this section:

Overview of IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support. FortiOS 4.0 MR3 is Pv6 Ready Logo Program Phase 2 certified.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported. This is because FortiOS 3.0 does not support IPv6 DNS.
- You cannot use RSA certificates in which the common name (cn) is a domain name that resolves to an IPv6 address. This is because FortiOS 3.0 does not support IPv6 DNS.
- DHCP over IPsec is not supported, because FortiOS 3.0 does not support IPv6 DHCP.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

Certificates

On a VPN with IPv6 phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN: phase 1 settings, phase 2 settings, security policies and routing.

To access IPv6 functionality through the web-based manager, go to *System Admin* > *Settings* and enable *IPv6* in the section, *Display Options on GUI*.

Phase 1 configuration

In the web-based manager, you define the Phase 1 as IPv6 in the Advanced settings. Enable the IPv6 Version check box. You can then enter an IPv6 address for the remote gateway.

In the CLI, you define an IPsec phase 1 configuration as IPv6 by setting `ip-version` to `6`. Its default value is `4`. Then, the `local-gw` and `remote-gw` keywords are hidden and the corresponding `local-gw6` and `remote-gw6` keywords are available. The values for `local-gw6` and `remote-gw6` must be IPv6 addresses. For example:

```
config vpn ipsec phase1-interface
  edit tunnel6
    set ip-version 6
    set remote-gw6 0:123:4567::1234
    set interface port3
    set proposal 3des-md5
  end
```

Phase 2 configuration

To create an IPv6 IPsec phase 2 configuration in the web-based manager, you need to define IPv6 selectors in the Advanced settings. Change the default “0.0.0.0/0” address for Source address and Destination address to the IPv6 value “::/0”. If needed, enter specific IPv6 addresses, address ranges or subnet addresses in these fields.

In the CLI, set `src-addr-type` and `dst-addr-type` to `ip6`, `range6` or `subnet6` to specify IPv6 selectors. By default, zero selectors are entered, “::/0” for the `subnet6` address type, for example. The simplest IPv6 phase 2 configuration looks like this:

```
config vpn ipsec phase2-interface
  edit tunnel6_p2
    set phase1name tunnel6
    set proposal 3des-md5
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
```

Security policies

To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network’s port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6.

Routing

Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them. You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. You also need a route to the remote protected network via the IPsec interface.

To create a static route in the web-based manager, go to *Router* > *Static* > *Static Route*. Select the drop-down arrow on the Create New button and select IPv6 Route. Enter the information and select OK. In the CLI, use the `router static6` command. For example, where the remote network is fec0:0000:0000:0004::/64 and the IPsec interface is `toB`:

```
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toB
    set dst fec0:0000:0000:0004::/64
  next
end
```

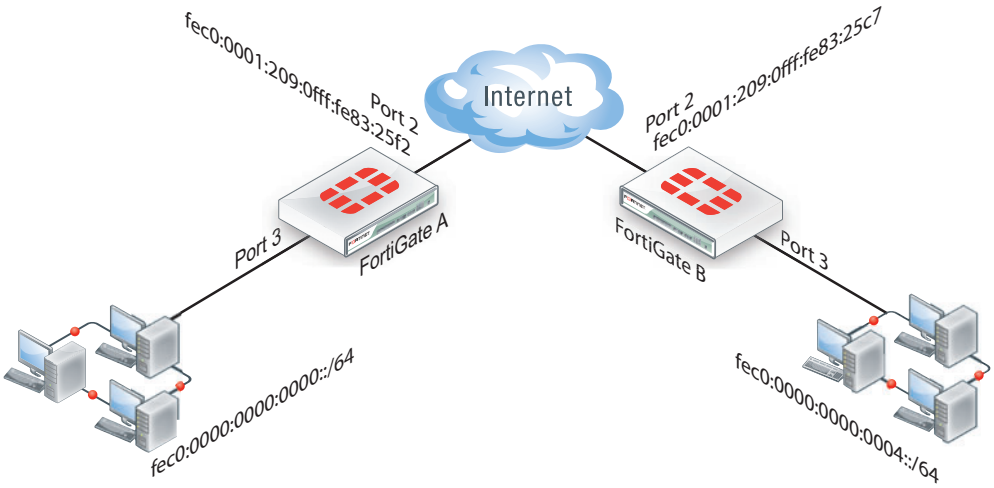
If the VPN is IPV4 over IPv6, the route to the remote protected network is an IPv4 route. If the VPN is IPv6 over IPv4, the route to the remote VPN gateway is an IPv4 route.

Site-to-site IPv6 over IPv6 VPN example

In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

To access IPv6 functionality through the web-based manager, go to *System Admin* > *Settings* and enable *IPv6* in the section, *Display Options on GUI*.

Figure 152: Example IPv6-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
  next
```

```
    edit port3
      config ipv6
        set ip6-address fec0::0000:209:0fff:fe83:25f3/64
      end
    next
  end
```

Configure FortiGate A IPsec settings

The phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to `6` and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toB
    set dstintf port3
```

```
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toB
    set dst fec0:0000:0000:0004::/64
  end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

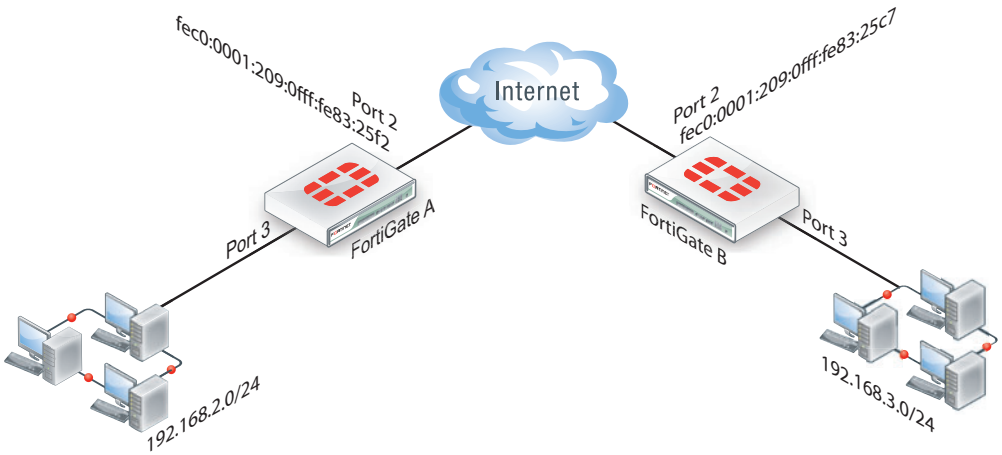
```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0003:209:0fff:fe83:25c7/64
    end
  next
  edit port3
    config ipv6
      set ip6-address fec0::0004:209:0fff:fe83:2569/64
    end
  end
config vpn ipsec phase1-interface
  edit toA
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
```

```
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toA
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toA
    set dstintf port3
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  end
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toA
    set dst fec0:0000:0000:0000::/64
  end
```

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

Figure 153: Example IPv4-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f2/64
    end
  next
  edit port3
    set 192.168.2.1/24
  end
```

Configure FortiGate A IPsec settings

The phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The phase 2 configuration is the same as you would use for an IPv4 VPN. By default, phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
  end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toB
    set dstintf port3
    set srcaddr all
    set dstaddr all
```

```
    set action accept
    set service ANY
    set schedule always
  end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toB
    set dst 192.168.3.0/24
  end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

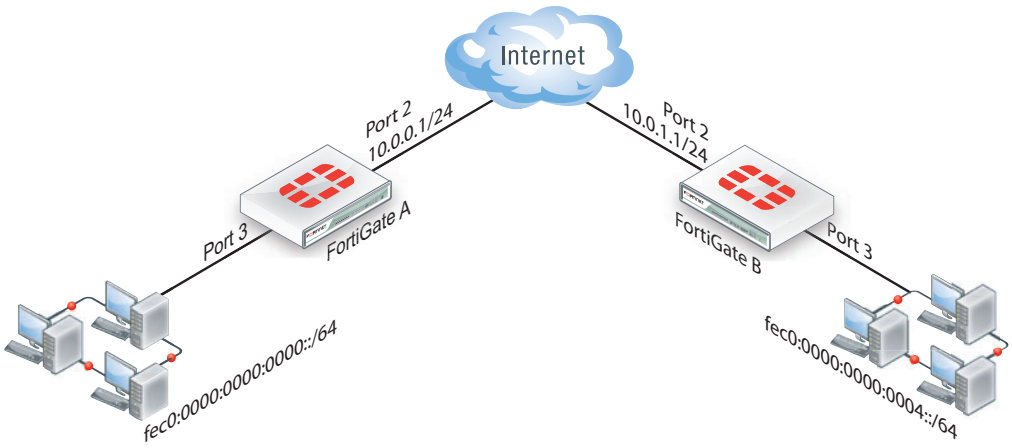
```
config system interface
  edit port2
    config ipv6
      set ip6-address fec0::0003:fe83:25c7/64
    end
  next
  edit port3
    set 192.168.3.1/24
  end
config vpn ipsec phase1-interface
  edit toA
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
  end
```

```
config firewall policy
  edit 1
    set srcintf port3
    set dstintf toA
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toA
    set dstintf port3
    set srcaddr all
    set dstaddr all
    set action accept
    set service ANY
    set schedule always
  end
config router static6
  edit 1
    set device port2
    set dst 0::/0
  next
  edit 2
    set device toA
    set dst 192.168.2.0/24
  end
```

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

Figure 154: Example IPv6-over-IPv4 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
  edit port2
    set 10.0.0.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0001:209:0fff:fe83:25f3/64
    end
```

Configure FortiGate A IPsec settings

The phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
  edit toB
    set interface port2
    set remote-gw 10.0.1.1
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

The phase 2 configuration uses IPv6 selectors. By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
```

Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toB
    set dstintf port3
    set srcaddr all6
    set dstaddr all6
```

```
    set action accept
    set service ANY
    set schedule always
  end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on port2.

```
config router static6
  edit 1
    set device toB
    set dst fec0:0000:0000:0004::/64
  end
config router static
  edit 1
    set device port2
    set dst 0.0.0.0/0
    set gateway 10.0.0.254
  end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
  edit port2
    set 10.0.1.1/24
  next
  edit port3
    config ipv6
      set ip6-address fec0::0004:209:0fff:fe83:2569/64
    end
config vpn ipsec phase1-interface
  edit toA
    set interface port2
    set remote-gw 10.0.0.1
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
config vpn ipsec phase2-interface
  edit toA2
    set phase1name toA
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
```

```
    set dst-addr-type subnet6
  end
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toA
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toA
    set dstintf port3
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  end
config router static6
  edit 1
    set device toA
    set dst fec0:0000:0000:0000::/64
  end
config router static
  edit 1
    set device port2
    set gateway 10.0.1.254
  end
```

L2TP and IPsec (Microsoft VPN)

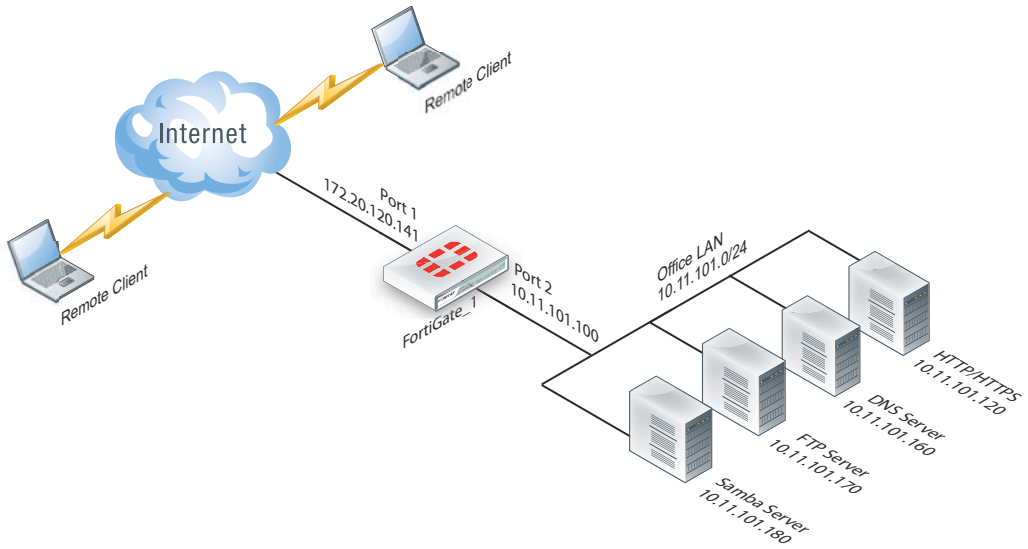
This section describes how to set up a VPN that is compatible with the Microsoft Windows native VPN, which is Layer 2 Tunneling Protocol (L2TP) with IPsec encryption.

The following topics are included in this section:

Overview

The topology of a VPN for Microsoft Windows dialup clients is very similar to the topology for FortiClient Endpoint Security clients.

Figure 155: Example FortiGate VPN configuration with Microsoft clients



For users, the difference is that instead of installing and using the FortiClient application, they configure a network connection using the software built into the Microsoft Windows operating system. Starting in FortiOS 4.0 MR2, you can configure a FortiGate unit to work with unmodified Microsoft VPN client software.

Layer 2 Tunneling Protocol (L2TP)

L2TP is a tunneling protocol published in 1999 that is used with VPNs, as the name suggests. Microsoft Windows operating system has a built-in L2TP client starting since Windows 2000. Mac OS X 10.3 system and higher also have a built-in client.

L2TP provides no encryption and used UDP port 1701. IPsec is used to secure L2TP packets. The initiator of the L2TP tunnel is called the L2TP Access Concentrator (LAC).

L2TP and IPSec is supported for native Windows XP, Windows Vista and Mac OSX native VPN clients. However, in Mac OSX (OSX 10.6.3, including patch releases) the L2TP feature does not work properly on the Mac OS side.

Assumptions

The following assumptions have been made for this example:

- L2TP protocol traffic is allowed through network firewalls (TCP and UDP port 1701)
- User has Microsoft Windows 2000 or higher — a Windows version that supports L2TP

Configuring the FortiGate unit

To configure the FortiGate unit, you need to:

- configure LT2P users and firewall user group;
- configure the L2TP VPN, including the IP address range it assigns to clients;
- configure an IPsec VPN with encryption and authentication settings that match the Microsoft VPN client;
- configure security policies.

Configuring LT2P users and firewall user group

Remote users must be authenticated before they can request services and/or access network resources through the VPN. The authentication process can use a password defined on the FortiGate unit or an established external authentication mechanism such as RADIUS or LDAP.

Creating user accounts

You need to create user accounts and then add these users to a firewall user group to be used for L2TP authentication. The Microsoft VPN client can automatically send the user's Window network logon credentials. You might want to use these for their L2TP user name and password.

To create a user account - web-based manager

1. Go to *User* > *User* > *User* and select *Create New*.
2. Enter the *User Name*.
3. Do one of the following:
   - Select Password and enter the user's assigned password.
   - Select *LDAP*, *RADIUS*, or *TACACS+* and select the authentication server from the list. The authentication server must be already configured on the FortiGate unit.
4. Select *OK*.

To create a user account - CLI

To create a user account called `user1` with the password `123_user`, you would enter:

```
config user local
  edit user1
    set type password
    set passwd "123_user"
    set status enable
  end
```

Creating a user group

When clients connect using the L2TP-over-IPsec VPN, the FortiGate unit checks their credentials against the user group you specify for L2TP authentication. You need to create a firewall user group to use for this purpose.

To create a user group - web-based manager

1 Go to *User* > *User Group* > *User Group*, select *Create New*, and enter the following information:

Name	Type or edit the user group name (for example, `L2TP_group`).
Type	Select *Firewall*.
Available Users/Groups	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that can be added to the user group. To add a member to this list, select the name and then select the right arrow button.
Members	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that belong to the user group. To remove a member, select the name and then select the left arrow button.

2 Select *OK*.

To create a user group - CLI

To create the user group L2TP_group and add members User_1, User_2, and User_3, you would enter:

```
config user group
  edit L2TP_group
    set group-type firewall
    set member User_1 User_2 User_3
  end
```

Configuring L2TP

You can only configure L2TP settings in the CLI. As well as enabling L2TP, you set the range of IP address values that are assigned to L2TP clients and specify the user group that can access the VPN. For example, to allow access to users in the L2TP_group and assign them addresses in the range 192.168.0.50 to 192.168.0.59, you would enter

```
config vpn l2tp
  set sip 192.168.0.50
  set eip 192.168.0.59
  set status enable
  set usrgrp "L2TP_group"
end
```

One of the security policies for the L2TP over IPsec VPN uses the client address range, so you need also need to create a firewall address for that range. For example,

```
config firewall address
  edit L2TPclients
    set type iprange
    set end-ip 192.168.6.88
    set start-ip 192.168.6.85
end
```

Alternatively, you could define this range in the web-based manager.

Configuring IPsec

The Microsoft VPN client uses IPsec for encryption. The configuration needed on the FortiGate unit is the same as for any other IPsec VPN with the following exceptions.

- Transport mode is used instead of tunnel mode.
- The encryption and authentication proposals must be compatible with the Microsoft client.

L2TP over IPsec is supported on the FortiGate unit using policy-based, not route-based configurations.

Configuring phase 1 - web-based manager

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)* and select *Create Phase 1*.

2 Enter the following information and then select *OK*.

Name	Enter a name for this VPN, dialup_p1 for example.
Remote Gateway	*Dialup User*
Local Interface	Select the network interface that connects to the Internet. For example, port1.
Mode	*Main (ID protection)*
Authentication Method	*Preshared Key*
Pre-shared Key	Enter the preshared key. This key must also be entered in the Microsoft VPN client.
Advanced	Select *Advanced* to enter the following information.
Enable IPsec Interface Mode	This must ***not*** be selected.
P1 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
DH Group	*2*
NAT Traversal	Enable
Dead Peer Detection	Enable

Configuring phase 1 - CLI

To create a phase 1 configuration called dialup_p1 on a FortiGate unit that has port1 connected to the Internet, you would enter:

```
config vpn ipsec phase1
  edit dialup_p1
    set type dynamic
    set interface port1
    set mode main
    set psksecret ********
    set proposal aes256-md5 3des-sha1 aes192-sha1
    set dhgrp 2
    set nattraversal enable
    set dpd enable
  end
```

Configuring phase 2 - web-based manager

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)* and select *Create Phase 2*.

2 Enter the following information and then select *OK*.

Name	Enter a name for this phase 2 configuration.
Phase 1	Select the name of the phase 1 configuration.
Advanced	Select *Advanced* to enter the following information.
P2 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
Enable replay detection	Enable
Enable perfect forward secrecy (PFS)	Disable
Keylife	3600 seconds

3 Make this a transport-mode VPN. You must use the CLI to do this. If your phase 2 name is dialup_p2, you would enter:

```
config vpn ipsec phase2
  edit dialup_p2
    set encapsulation transport-mode
  end
```

Configuring phase 2 - CLI

To configure a phase 2 to work with your phase_1 configuration, you would enter:

```
config vpn ipsec phase2
  edit dialup_p2
    set phase1name dialup_p1
    set proposal aes256-md5 3des-sha1 aes192-sha1
    set replay enable
    set pfs disable
    set keylifeseconds 3600
    set encapsulation transport-mode
  end
```

Configuring security policies

The security policies required for L2TP over IPsec VPN are:

- an IPSEC policy, as you would create for any policy-based IPsec VPN
- a regular ACCEPT policy to allow traffic from the L2TP clients to access the protected network

Configuring the IPSEC security policy - web-based manager

1 Go to *Policy* > *Policy* > *Policy* and select *Create New*.

2 Enter the following information and then select OK:

Source Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	*all*
Destination Interface/Zone	Select the FortiGate unit's public interface.
Destination Address	*all*
Action	*IPSEC*
VPN Tunnel	Select the name of the phase 1 configuration that you created. For example, dialup_p1. See "Configuring IPsec" on page 1570.
Allow inbound	Enable
Allow outbound	Enable
UTM	Optional settings for UTM features.

Configuring the IPSEC security policy - CLI

If your VPN tunnel (phase 1) is called dialup_p1, your protected network is on port2, and your public interface is port1, you would enter:

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action ipsec
    set schedule always
    set service ANY
    set inbound enable
    set outbound enable
    set vpntunnel dialup_p1
  end
```

Configuring the ACCEPT security policy - web-based manager

1 Go to *Policy* > *Policy* > *Policy* and select *Create New*.

2 Enter the following information and then select *OK*:

Source Interface/Zone	Select the FortiGate unit's public interface.
Source Address	Select the firewall address that you defined for the L2TP clients.
Destination Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	*all*
Action	*ACCEPT*
UTM	Optionally, select UTM feature profiles.

Configuring the ACCEPT security policy - CLI

If your public interface is port1, your protected network is on port2, and L2TPclients is the address range that L2TP clients use, you would enter:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr L2TPclients
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  end
```

Configuring the Windows PC

Configuration of the Windows PC for a VPN connection to the FortiGate unit consists of the following:

- In Network Connections, configure a Virtual Private Network connection to the FortiGate unit.
- Ensure that the IPSEC service is running.
- Ensure that IPsec has not been disabled for the VPN client. It may have been disabled to make the Microsoft VPN compatible with an earlier version of FortiOS.

The instructions in this section are based on Windows XP SP3. Other versions of Windows may vary slightly.

To configure the network connection

1 Open *Network Connections*.

This is available through the Control Panel.

2 Double-click *New Connection Wizard* and *Select Next*.

3 Select *Connect to the network at my workplace*.

4 Select *Next*.

5 Select *Virtual Private Network connection* and then select *Next*.
6 In the *Company Name* field, enter a name for the connection and then select *Next*.
7 Select *Do not dial the initial connection* and then select *Next*.
8 Enter the public IP address or FQDN of the FortiGate unit and then select *Next*.
9 Optionally, select *Add a shortcut to this connection to my desktop*.
10 Select *Finish*.

The *Connect* dialog opens on the desktop.

11 Select *Properties* and then select the *Security* tab.
12 Select IPSec Settings.
13 Select *Use pre-shared key for authentication*, enter the preshared key that you configured for your VPN, and select *OK*.
14 Select OK.

To check that the IPSEC service is running

1 Open *Administrative Tools*.

This is available through the Control Panel.

2 Double-click *Services*.
3 Look for IPSEC Services. Confirm that the *Startup Type* is *Automatic* and *Status* is set to *Started*. If needed, double-click *IPSEC Services* to change these settings.

To check that IPsec has not been disabled

1 Select *Start* > *Run*.
2 Enter regedit and select OK.
3 Find the Registry key HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RasMan\Parameters
4 If there is a ProhibitIPSec value, it must be set to 0.

Troubleshooting

This section describes some checks and tools you can use to resolve issues with L2TP-over-IPsec VPNs.

This section includes:

- Quick checks
- Mac OS X and L2TP
- Setting up logging
- Understanding the log messages
- Using the FortiGate unit debug commands

Quick checks

The table below is a list of common L2TP over IPsec VPN problems and the possible solutions.

Problem	What to check
IPsec tunnel does not come up.	Check the logs to determine whether the failure is in Phase 1 or Phase 2. Check the settings, including encapsulation setting, which must be transport-mode. Check the user password. Confirm that the user is a member of the user group assigned to L2TP. On the Windows PC, check that the IPsec service is running and has not been disabled. See "Configuring the Windows PC" on page 1573.
Tunnel connects, but there is no communication.	Did you create an ACCEPT security policy from the public network to the protected network for the L2TP clients? See "Configuring security policies" on page 1572.

Mac OS X and L2TP

FortiOS allows L2TP connections with empty AVP host names and therefore Mac OS X L2TP connections can connect to the FortiGate.

Prior to FortiOS 4.0 MR3, FortiOS refused L2TP connections with empty AVP host names in compliance with RFC 2661 and RFC 3931.

Setting up logging

L2TP logging must be enabled to record L2TP events. Alert email can be configured to report L2TP errors.

To configure FortiGate logging for L2TP over IPsec

1 Go to *Log&Report* > *Log Config* > *Log Setting*.
2 Select *Event Log*.
3 Select the *L2TP/PPTP/PPPoE service event* and *IPsec negotiation event* check boxes.
4 Select *Apply*.

To configure FortiGate logging level

1 Go to *Log&Report* > *Log Config* > *Log Setting*.
2 Select the *Local Logging & Archiving* check box.
3 Set *Minimum log level* to *Information*.
4 Select *Apply*.

To view FortiGate logs

1 Go to *Log&Report* > *Log & Archive Access* > *Event Log*.

2 Select the storage location if required.

3 After each attempt to start the L2TP over IPsec VPN, select *Refresh* to view any logged events.

Understanding the log messages

Successful startup of an L2TP over IPsec VPN follows a well-defined sequence. If you compare your logs to the sequence shown in Table 91, you will be able to determine at what stage your configuration is failing.

Table 91: Sequence of log messages for L2TP over IPsec VPN connection startup

	ID	Sub Type	Action	Message
1	37127	ipsec	negotiate	progress IPsec phase 1
2	37127	ipsec	negotiate	progress IPsec phase 1
3	37127	ipsec	negotiate	progress IPsec phase 1
4	37127	ipsec	negotiate	progress IPsec phase 1
5	37129	ipsec	negotiate	progress IPsec phase 2
6	37133	ipsec	install_sa	install IPsec SA
7	37139	ipsec	phase2-up	IPsec phase 2 status change
8	37138	ipsec	tunnel-up	IPsec connection status change
9	37129	ipsec	negotiate	progress IPsec phase 2
10	37122	ipsec	negotiate	negotiate IPsec phase 2
11	31008	ppp	connect	Client 172.20.120.151 control connection started (id 743), assigned ip 192.168.6.85
12	29013	ppp		
13	29002	ppp	auth_success	User 'user1' using l2tp with authentication protocol MSCHAP_V2, succeeded
14	31101	ppp	tunnel-up	L2TP tunnel established

This table lists messages in top down chronological order. In the web-based manager log viewer, you need to read the messages from the bottom up. The newest message appears at the top of that list.

In Table 91, messages 1 through 4 show the IKE phase 1 negotiation stages that result in the creation of the Security Association (SA) shown in message 6. Phase 2 negotiation in messages 5, 9, 10 produce the tunnel-up condition reported in message 8.

With IPsec communication established, the L2TP connection is established (message 11), the pppd daemon starts (message 12), the user is authenticated (message 13), and the L2TP tunnel is now ready to use.

Using the FortiGate unit debug commands

To view debug output for IKE and L2TP

1 Start an SSH or Telnet session to your FortiGate unit.

2 Enter the following CLI commands

```
diagnose debug application ike -1
diagnose debug application l2tp -1
diagnose debug enable
```

3 Attempt to use the VPN and note the debug output in the SSH or Telnet session.

4 Enter the following command to reset debug settings to default:

```
diagnose debug reset
```

To use the packet sniffer

1 Start an SSH or Telnet session to your FortiGate unit.

2 Enter the following CLI command

```
diagnose sniffer packet any icmp 4
```

3 Attempt to use the VPN and note the debug output.

4 Enter `Ctrl-C` to end sniffer operation.

Typical L2TP over IPsec session startup log entries - raw format

GRE over IPsec (Cisco VPN) configurations

This section describes how to configure a FortiGate VPN that is compatible with Cisco-style VPNs that use GRE in an IPsec tunnel.

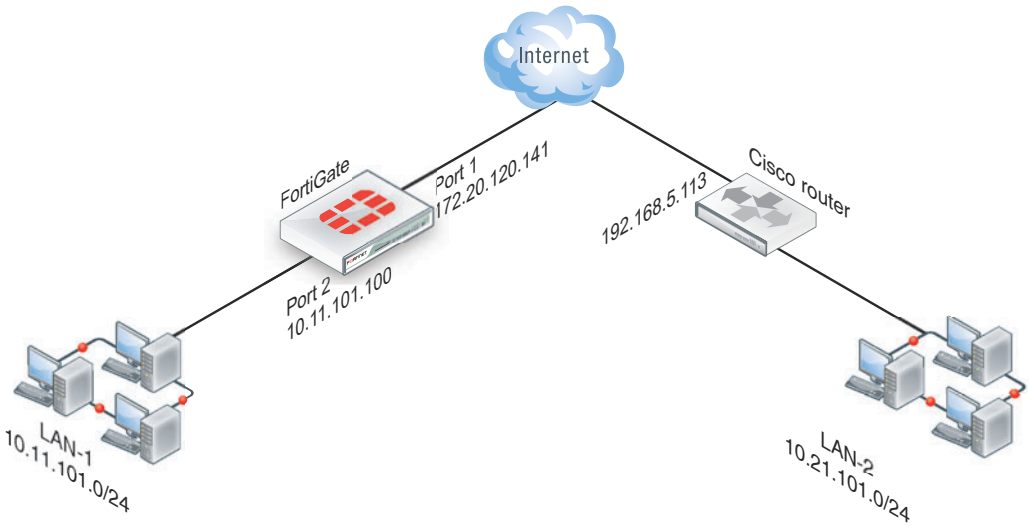
The following topics are included in this section:

Overview

Cisco products that include VPN support often use Generic Routing Encapsulation (GRE) protocol tunnel over IPsec encryption. This chapter describes how to configure a FortiGate unit to work with this type of Cisco VPN.

Cisco VPNs can use either transport mode or tunnel mode IPsec. Before FortiOS 4.0 MR2, the FortiGate unit was compatible only with tunnel mode IPsec.

Figure 156: Example FortiGate to Cisco GRE-over-IPsec VPN



In this example, users on LAN-1 are provided access to LAN-2.

Configuring the FortiGate unit

There are several steps to the GRE-over-IPsec configuration:

- Enable overlapping subnets. This is needed because the IPsec and GRE tunnels will use the same addresses.
- Configure a route-based IPsec VPN on the external interface.
- Configure a GRE tunnel on the virtual IPsec interface. Set its local gateway and remote gateway addresses to match the local and remote gateways of the IPsec tunnel.
- Configure security policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Configure security policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.
- Configure a static route to direct traffic destined for the network behind the Cisco router into the GRE-over-IPsec tunnel.

Enabling overlapping subnets

By default, each FortiGate unit network interface must be on a separate network. The configuration described in this chapter assigns an IPsec tunnel end point and the external interface to the same network. Enable subnet overlap as follows:

```
config system settings
  set allow-subnet-overlap enable
end
```

Configuring the IPsec VPN

A route-based VPN is required. It must use encryption and authentication algorithms compatible with the Cisco equipment to which it connects. In this chapter, preshared key authentication is shown.

To configure the IPsec VPN - web-based manager

1 Define the phase 1 configuration needed to establish a secure connection with the remote Cisco device. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel, tocisco for example. This is the name of the virtual IPsec interface. It appears in phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select *Static IP Address*.
IP Address	Enter the IP address of the Cisco device public interface. For example, 192.168.5.113
Local Interface	Select the FortiGate unit's public interface. For example, 172.20.120.141
Mode	Select *Main (ID Protection)*.
Authentication Method	*Preshared Key*
Pre-shared Key	Enter the preshared key. It must match the preshared key on the Cisco device.
Advanced	Select the Advanced button to see the following settings.

Enable IPsec Interface Mode	Enable.
P1 Proposal	*3DES-MD5* At least one proposal must match the settings on the Cisco unit.

For more information about these settings, see "Auto Key phase 1 parameters" on page 1407.

2 Define the phase 2 parameters needed to create a VPN tunnel with the remote peer. For compatibility with the Cisco router, Quick Mode Selectors must be entered, which includes specifying protocol 47, the GRE protocol. Enter these settings in particular:

Name	Enter a name to identify this phase 2 configuration.
Phase 1	Select the name of the phase 1 configuration that you defined in Step 1.
Advanced	Select *Advanced* to view the following fields.
P2 Proposal	*3DES-MD5* At least one proposal must match the settings on the Cisco unit.
Quick Mode Selector	
Source Address	Enter the GRE local tunnel end IP address. For example 172.20.120.141
Source Port	0
Destination Address	Enter the GRE remote tunnel end IP address. For example 192.168.5.113
Destination Port	0
Protocol	47

For more information about these settings, see "Phase 2 parameters" on page 1425.

3 If the Cisco device is configured to use transport mode IPsec, you need to use transport mode on the FortiGate VPN. You can configure this only in the CLI. In your phase 2 configuration, set `encapsulation` to `transport-mode` (default is `tunnel-mode`) as follows:

```
config vpn phase2-interface
  edit to_cisco_p2
    set encapsulation transport-mode
  end
```

To configure the IPsec VPN - CLI

```
config vpn ipsec phase1-interface
  edit tocisco
    set interface port1
    set proposal 3des-sha1 aes128-sha1
    set remote-gw 192.168.5.113
    set psksecret xxxxxxxxxxxxxxx
  end
config vpn ipsec phase2-interface
  edit tocisco_p2
    set phase1name "tocisco"
    set proposal 3des-md5
    set encapsulation tunnel-mode      // if tunnel mode
```

```
    set encapsulation transport-mode  // if transport mode
    set protocol 47
    set src-addr-type ip
    set dst-start-ip 192.168.5.113
    set src-start-ip 172.20.120.141
  end
```

Adding IPsec tunnel end addresses

The Cisco configuration requires an address for its end of the IPsec tunnel. The addresses are set to match the GRE gateway addresses. Use the CLI to set the addresses, like this:

```
config system interface
  edit tocisco
    set ip 172.20.120.141 255.255.255.255
    set remote-ip 192.168.5.113
  end
```

Configuring the GRE tunnel

The GRE tunnel runs between the virtual IPsec public interface on the FortiGate unit and the Cisco router. You must use the CLI to configure a GRE tunnel. In the example, you would enter:

```
config system gre-tunnel
  edit gre1
    set interface tocisco
    set local-gw 172.20.120.141
    set remote-gw 192.168.5.113
end
```

`interface` is the virtual IPsec interface, `local-gw` is the FortiGate unit public IP address, and `remote-gw` is the remote Cisco device public IP address

Adding GRE tunnel end addresses

You will also need to add tunnel end addresses. The Cisco router configuration requires an address for its end of the GRE tunnel. Using the CLI, enter tunnel end addresses that are not used elsewhere on the FortiGate unit, like this:

```
config system interface
  edit gre1
    set ip 10.0.1.1 255.255.255.255
    set remote-ip 10.0.1.2
  end
```

Configuring security policies

Two sets of security policies are required:

- policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.

To configure security policies - web-based manager

1 Define an ACCEPT security policy to permit communications between the protected network and the GRE tunnel:

Source Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Source Address Name	*All*
Destination Interface/Zone	Select the GRE tunnel virtual interface you configured.
Destination Address Name	*All*
Action	*ACCEPT*
NAT	Disable

2 To permit the remote client to initiate communication, you need to define a security policy for communication in that direction:

Source Interface/Zone	Select the GRE tunnel virtual interface you configured.
Source Address Name	*All*
Destination Interface/Zone	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address Name	*All*
Action	*ACCEPT*.
NAT	Disable

3 Define a pair of ACCEPT security policies to permit traffic to flow between the GRE virtual interface and the IPsec virtual interface:

Source Interface/Zone	Select the GRE virtual interface. See “Configuring the GRE tunnel” on page 1582.
Source Address Name	*All*
Destination Interface/Zone	Select the virtual IPsec interface you created. See “Configuring the IPsec VPN” on page 1580.
Destination Address Name	*All*
Action	*ACCEPT*.
NAT	Disable

Source Interface/Zone	Select the virtual IPsec interface you created. See “Configuring the IPsec VPN” on page 1580.
Source Address Name	*All*

Destination Interface/Zone	Select the GRE virtual interface. See "Configuring the GRE tunnel" on page 1582.
Destination Address Name	*All*
Action	Select *ACCEPT*.
NAT	Disable.

To configure security policies - CLI

```
config firewall policy
  edit 1                    // LAN to GRE tunnel
    set srcintf port2
    set dstintf gre1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 2                    // GRE tunnel to LAN
    set srcintf gre1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 3                    // GRE tunnel to IPsec interface
    set srcintf "gre1"
    set dstintf "tocisco"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
  next
  edit 4                    // IPsec interface to GRE tunnel
    set srcintf "tocisco"
    set dstintf "gre1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
  end
```

Configuring routing

Traffic destined for the network behind the Cisco router must be routed to the GRE tunnel. To do this, create a static route as follows:

Destination IP/Mask	Enter the IP address and netmask for the network behind the Cisco router. For example 10.21.101.0 255.255.255.0
Device	Select the GRE virtual interface.
Distance	Leave setting at default value.

In the CLI, using the example values, you would enter

```
config router static
  edit 0
    set device gre1
    set dst 10.21.101.0 255.255.255.0
  end
```

Configuring the Cisco router

Using Cisco IOS, you would configure the Cisco router as follows, using the addresses from the example:

```
config ter
crypto ipsec transform-set myset esp-3des esp-md5-hmac
no mode
exit
no ip access-list extended tunnel
ip access-list extended tunnel
permit gre host 192.168.5.113 host 172.20.120.141
exit
interface Tunnel1
ip address 10.0.1.2 255.255.255.0
tunnel source 192.168.5.113
tunnel destination 172.20.120.141
!
ip route 10.11.101.0 255.255.255.0 Tunnel1
end
clea crypto sa
clea crypto isakmp
```

For transport mode, change `no mode` to `mode transport`.

This is only the portion of the Cisco router configuration that applies to the GRE-over-IPsec tunnel. For more information, refer to the Cisco documentation.

Troubleshooting

This section describes some checks and tools you can use to resolve issues with the GRE-over-IPsec VPN.

Quick checks

Here is a list of common problems and what to verify.

Problem	What to check
No communication with remote network.	Use the `execute ping` command to ping the Cisco device public interface. Use the FortiGate VPN Monitor page to see whether the IPsec tunnel is up or can be brought up.
IPsec tunnel does not come up.	Check the logs to determine whether the failure is in Phase 1 or Phase 2. Check that the encryption and authentication settings match those on the Cisco device. Check the encapsulation setting: tunnel-mode or transport-mode. Both devices must use the same mode.
Tunnel connects, but there is no communication.	Check the security policies. See "Configuring security policies" on page 1582. Check routing. See "Configuring routing" on page 1585.

Setting up logging

To configure FortiGate logging for IPsec

1 Go to *Log&Report* > *Log Config* > *Log Setting*.
2 Select the *Event Logging*.
3 Select *IPsec negotiation event*.
4 Select *Apply*.

To configure FortiGate logging level

1 Go to *Log&Report* > *Log Config* > *Log Setting*.
2 Select *Local Logging & Archiving*.
3 Set *Minimum log level* to *Information*.
4 Optionally, enable and configure disk logging.
5 Select *Apply*.

To view FortiGate logs

1 Go to *Log & Report* > *Log & Archive Access* > *Event Log*.
2 Select the log storage type.
3 Select *Refresh* to view any logged events.

Understanding the log messages

Successful startup of an IPsec VPN follows a well-defined sequence. If you compare your logs to the sequence shown in Table 92, you will be able to determine at what stage your configuration is failing.

Table 92: Typical sequence of log messages for IPsec VPN connection startup

	ID	Sub Type	Action	Message
1	37127	ipsec	negotiate	progress IPsec phase 1
2	37127	ipsec	negotiate	progress IPsec phase 1
3	37127	ipsec	negotiate	progress IPsec phase 1
4	37127	ipsec	negotiate	progress IPsec phase 1
5	37129	ipsec	negotiate	progress IPsec phase 2
6	37133	ipsec	install_sa	install IPsec SA
7	37139	ipsec	phase2-up	IPsec phase 2 status change
8	37138	ipsec	tunnel-up	IPsec connection status change

This table lists messages in top down chronological order. In the web-based manager log viewer, you need to read the messages from the bottom up. The newest message appears at the top of that list.

Using diagnostic commands

There are some diagnostic commands that can provide useful information.

When using diagnostic commands, it is best practice that you connect to the CLI using a terminal program, such as puTTY, that allows you to save output to a file. This will allow you to review the data later on at your own speed without worry about missed data as the diag output scrolls by.

To use the packet sniffer

1 Enter the following CLI command:

```
diag sniff packet any icmp 4
```

2 Ping an address on the network behind the FortiGate unit from the network behind the Cisco router.

The output will show packets coming in from the GRE interface going out of the interface that connects to the protected network (LAN) and vice versa. For example:

```
114.124303 gre1 in 10.0.1.2 -> 10.11.101.10: icmp: echo request
114.124367 port2 out 10.0.1.2 -> 10.11.101.10: icmp: echo request
114.124466 port2 in 10.11.101.10 -> 10.0.1.2: icmp: echo reply
114.124476 gre1 out 10.11.101.10 -> 10.0.1.2: icmp: echo reply
```

3 Enter CTRL-C to stop the sniffer.

To view debug output for IKE

1 Enter the following CLI commands

```
diagnose debug application ike -1
diagnose debug enable
```

2 Attempt to use the VPN or set up the VPN tunnel and note the debug output.

3 Enter CTRL-C to stop the debug output.

4 Enter the following command to reset debug settings to default:

```
diagnose debug reset
```

Protecting OSPF with IPsec

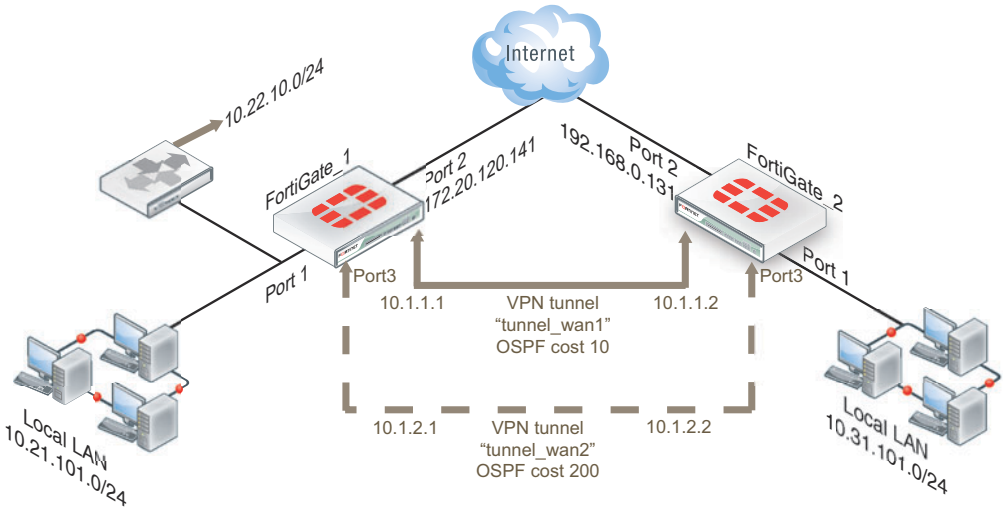
For enhanced security, OSPF dynamic routing can be carried over IPsec VPN links.

The following topics are included in this section:

Overview

This chapter shows an example of OSPF routing conducted over an IPsec tunnel between two FortiGate units. The network shown in Figure 157 is a single OSPF area. FortiGate_1 is an Area border router that advertises a static route to 10.22.10.0/24 in OSPF. FortiGate_2 advertises its local LAN as an OSPF internal route.

Figure 157: OSPF over an IPsec VPN tunnel



The section "OSPF over IPsec configuration" describes the configuration with only one IPsec VPN tunnel, tunnel_wan1. Then, the section "Creating a redundant configuration" on page 1595 describes how you can add a second tunnel to provide a redundant backup path. This is shown in Figure 157 as VPN tunnel "tunnel_wan2".

Only the parts of the configuration concerned with creating the IPsec tunnel and integrating it into the OSPF network are described. It is assumed that security policies are already in place to allow traffic to flow between the interfaces on each FortiGate unit.

OSPF over IPsec configuration

There are several steps to the OSPF-over-IPsec configuration:

- Configure a route-based IPsec VPN on an external interface. It will connect to a corresponding interface on the other FortiGate unit. Define the two tunnel-end addresses.
- Configure a static route to the other FortiGate unit.
- Configure the tunnel network as part of the OSPF network and define the virtual IPsec interface as an OSPF interface.

This section describes the configuration with only one VPN, tunnel_wan1. The other VPN is added in the section "Creating a redundant configuration" on page 1595.

Configuring the IPsec VPN

A route-based VPN is required. In this chapter, preshared key authentication is shown. Certificate authentication is also possible. Both FortiGate units need this configuration.

To configure Phase 1

1 Define the phase 1 configuration needed to establish a secure connection with the other FortiGate unit. For more information, see "Auto Key phase 1 parameters" on page 1407. Enter these settings in particular

Name	Enter a name to identify the VPN tunnel, tunnel_wan1 for example. This becomes the name of the virtual IPsec interface.
Remote Gateway	Select *Static IP Address*.
IP Address	Enter the IP address of the other FortiGate unit's public (Port 2) interface.
Local Interface	Select this FortiGate unit's public (Port 2) interface.
Mode	Select *Main (ID Protection)*.
Authentication Method	*Preshared Key*
Pre-shared Key	Enter the preshared key. It must match the preshared key on the other FortiGate unit.
Advanced	Select *Advanced*.
Enable IPsec Interface Mode	Enable

To assign the tunnel end IP addresses

1 Go to *System* > *Network* > *Interface,* select the virtual IPsec interface that you just created on Port 2 and select *Edit*.

2 In the *IP* and *Remote IP* fields, enter the following tunnel end addresses:

	FortiGate_1	**FortiGate_2**
IP	10.1.1.1	10.1.1.2
Remote_IP	10.1.1.2	10.1.1.1

These addresses are from a network that is not used for anything else.

To configure Phase 2

1 Define the phase 2 parameters needed to create a VPN tunnel with the remote peer. For more information, see "Phase 2 parameters" on page 1425. Enter these settings in particular:

Name	Enter a name to identify this phase 2 configuration, twan1_p2, for example.
Phase 1	Select the name of the phase 1 configuration that you defined in Step 1, tunnel_wan1 for example.

Configuring static routing

You need to define the route for traffic leaving the external interface. Go to *Router* > *Static* > *Static Route*, select *Create New*, and enter the following information.

Destination IP/Mask	Leave as 0.0.0.0 0.0.0.0.
Device	Select the external interface.
Gateway	Enter the IP address of the next hop router.
Distance	Leave setting at default value.

Configuring OSPF

This section does not attempt to explain OSPF router configuration. It focusses on the integration of the IPsec tunnel into the OSPF network. This is accomplished by assigning the tunnel as an OSPF interface, creating an OSPF route to the other FortiGate unit.

This configuration uses loopback interfaces to ease OSPF troubleshooting. The OSPF router ID is set to the loopback interface address.The loopback interface ensures the router is always up. Even though technically the router ID doesn't have to match a valid IP address on the FortiGate unit, having an IP that matches the router ID makes troubleshooting a lot easier.

The two FortiGate units have slightly different configurations. FortiGate_1 is an AS border router that advertises its static default route. FortiGate_2 advertises its local LAN as an OSPF internal route.

Setting the router ID for each FortiGate unit to the lowest possible value is useful if you want the FortiGate units to be the designated router (DR) for their respective ASes. This is the router that broadcasts the updates for the AS.

Leaving the IP address on the OSPF interface at 0.0.0.0 indicates that all potential routes will be advertised, and it will not be limited to any specific subnet. For example if this IP address was 10.1.0.0, then only routes that match that subnet will be advertised through this interface in OSPF.

FortiGate_1 OSPF configuration

When configuring FortiGate_1 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

To create the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.1, you would enter:

```
config system interface
  edit lback1
    set vdom root
    set ip 10.0.0.1 255.255.255.255
    set type loopback
  end
```

The loopback addresses and corresponding router IDs on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

To configure OSPF area, networks, and interfaces - web-based manager

1 On FortiGate_1, go to *Router* > *Dynamic* > *OSPF* and enter the following information to define the router, area, and interface information.

Router ID	Enter 10.0.0.1. Select *Apply* before entering the remaining information.
Advanced Options	
Redistribute	Select the *Connected* and *Static* check boxes. Use their default metric values.
Areas	Select *Create New*, enter the *Area* and *Type* and then select *OK*.
Area	0.0.0.0
Type	Regular
Interfaces	
Name	Enter a name for the OSPF interface, ospf_wan1 for example.
Interface	Select the virtual IPsec interface, tunnel_wan1.
IP	0.0.0.0

2 For *Networks*, select *Create New*.

3 Enter the following information.

IP/Netmask	10.1.1.0/255.255.255.0.
Area	0.0.0.0

4 For *Networks*, select *Create New*.

5 Enter the following information:

IP/Netmask	10.0.0.1/255.255.255.255
Area	0.0.0.0

6 Select *Apply*.

To configure OSPF area and interfaces - CLI

Your loopback interface is 10.0.0.1, your tunnel ends are on the 10.1.1.0/24 network, and your virtual IPsec interface is named `tunnel_wan1`. Enter the following CLI commands:

```
config router ospf
  set router-id 10.0.0.1
  config area
    edit 0.0.0.0
  end
  config network
    edit 4
      set prefix 10.1.1.0 255.255.255.0
    next
    edit 2
      set prefix 10.0.0.1 255.255.255.255
    end
  config ospf-interface
    edit ospf_wan1
      set cost 10
      set interface tunnel_wan1
      set network-type point-to-point
    end
  config redistribute connected
    set status enable
  end
  config redistribute static
    set status enable
  end
end
```

FortiGate_2 OSPF configuration

When configuring FortiGate_2 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

Configuring FortiGate_2 differs from FortiGate_1 in that three interfaces are defined instead of two. The third interface is the local LAN that will be advertised into OSPF.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

To create the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.2, you would enter:

```
config system interface
  edit lback1
    set vdom root
    set ip 10.0.0.2 255.255.255.255
    set type loopback
  end
```

The loopback addresses on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

To configure OSPF area and interfaces - web-based manager

1 On FortiGate_2, go to *Router* > *Dynamic* > *OSPF*.

2 For *Router ID*, enter 10.0.0.2.

Router ID	10.0.0.2
Areas	Select *Create New*, enter the *Area* and *Type* and then select *OK*.
Area	0.0.0.0
Type	Regular
Interfaces	
Name	Enter a name for the OSPF interface, ospf_wan1 for example.
Interface	Select the virtual IPsec interface, tunnel_wan1
IP	0.0.0.0

3 For *Networks*, select *Create New*.

4 Enter the following information for the loopback interface:

IP/Netmask	10.0.0.2/255.255.255.255
Area	0.0.0.0

5 For *Networks*, select *Create New*.

6 Enter the following information for the tunnel interface:

IP/Netmask	10.1.1.0/255.255.255.0
Area	0.0.0.0

7 For *Networks*, select *Create New*.

8 Enter the following information for the local LAN interface:

IP/Netmask	10.31.101.0/255.255.255.0
Area	0.0.0.0

9 Select *Apply*.

To configure OSPF area and interfaces - CLI

If for example, your loopback interface is 10.0.0.2, your tunnel ends are on the 10.1.1.0/24 network, your local LAN is 10.31.101.0/24, and your virtual IPsec interface is named tunnel_wan1, you would enter:

```
config router ospf
  set router-id 10.0.0.2
  config area
    edit 0.0.0.0
  end
  config network
    edit 1
      set prefix 10.1.1.0 255.255.255.0
    next
    edit 2
      set prefix 10.31.101.0 255.255.255.0
```

```
    next
    edit 2
      set prefix 10.0.0.2 255.255.255.255
    end
  config ospf-interface
    edit ospf_wan1
      set interface tunnel_wan1
      set network-type point-to-point
    end
end
```

Creating a redundant configuration

You can improve the reliability of the OSPF over IPsec configuration described in the previous section by adding a second IPsec tunnel to use if the default one goes down. Redundancy in this case is not controlled by the IPsec VPN configuration but by the OSPF routing protocol.

To do this you:

- Create a second route-based IPsec tunnel on a different interface and define tunnel end addresses for it.
- Add the tunnel network as part of the OSPF network and define the virtual IPsec interface as an additional OSPF interface.
- Set the OSPF cost for the added OSPF interface to be significantly higher than the cost of the default route.

Adding the second IPsec tunnel

The configuration is the same as in "Configuring the IPsec VPN" on page 1590, but the interface and addresses will be different. Ideally, the network interface you use is connected to a different Internet service provider for added redundancy.

When adding the second tunnel to the OSPF network, choose another unused subnet for the tunnel ends, 10.1.2.1 and 10.1.2.2 for example.

Adding the OSPF interface

OSPF uses the metric called cost when determining the best route, with lower costs being preferred. Up to now in this example, only the default cost of 10 has been used. Cost can be set only in the CLI.

The new IPsec tunnel will have its OSPF cost set higher than that of the default tunnel to ensure that it is only used if the first tunnel goes down. The new tunnel could be set to a cost of 200 compared to the default cost is 10. Such a large difference in cost will ensure this new tunnel will only be used as a last resort.

If the new tunnel is called tunnel_wan2, you would enter the following on both FortiGate units:

```
config router ospf
  config ospf-interface
    edit ospf_wan2
      set cost 200
      set interface tunnel_wan2
      set network-type point-to-point
    end
  end
```

Hardware offloading and acceleration

FortiGate units incorporate proprietary FortiASIC NP2 network processors that can provide accelerated processing for IPsec VPN traffic. This section describes how to configure offloading and acceleration.

The following topics are included in this section:

Overview

Fortinet's NP2 network processors contain features to improve IPsec tunnel performance. For example, network processors can encrypt and decrypt packets, offloading cryptographic work from the FortiGate unit's main processing resources.

On FortiGate units with the appropriate hardware, you can configure offloading of both IPsec sessions and HMAC checking.

IPsec session offloading requirements

Sessions must be fast path ready. Fast path ready session requirements are:

- Layer 2 type/length must be 0x0800 (IEEE 802.1q VLAN specification is supported); link aggregation between any network interfaces sharing the same network processor(s) may be used (IEEE 802.3ad specification is supported)
- Layer 3 protocol must be IPv4
- Layer 4 protocol must be UDP, TCP or ICMP
- Layer 3 / Layer 4 header or content modification must not require a session helper (for example, SNAT, DNAT, andTTL reduction are supported, but application layer content modification is not supported)
- FortiGate unit security policy must not require antivirus or IPS inspection, although hardware accelerated anomaly checks are acceptable.
- The session must not use an aggregated link or require QoS, including rate limits and bandwidth guarantees (NP1 processor only).
- Ingress and egress network interfaces are both attached to the same network processor(s)
- In Phase I configuration, Local Gateway IP must be specified as an IP address of a network interface attached to a network processor

- In Phase II configuration:
  - encryption algorithm must be DES, 3DES, AES-128, AES-192, AES-256, or null (for NP1 processor, only 3DES is supported)
  - authentication must be MD5, SHA1, or null (for NP1 processor, only MD5 is supported)
  - if replay detection is enabled, encryption and decryption options must be enabled in the CLI (see "IPsec encryption offloading", below)

  If the IPsec session meets the above requirements, the FortiGate unit sends the IPsec security association (SA) and configured processing actions to the network processors.

Packet offloading requirements

In addition to the session requirements, the packets themselves must meet fast-path requirements:

- Incoming packets must not be fragmented.
- Outgoing packets must be 385 bytes or larger after any fragmentation. This means the configured MTU (Maximum Transmission Unit) for the network processors' interfaces must have an MTU of 385 bytes or larger.

If packet offloading requirements are not met, an individual packet will use the FortiGate unit main processing resources, regardless of whether other packets in the session are offloaded to the specialized network processors.

IPsec encryption offloading

Network processing unit (NPU) settings configure offloading behavior for IPsec VPNs. Configured behavior applies to all network processors contained by the FortiGate unit itself or any installed AMC modules.

If replay detection is not enabled (IPsec Phase 2 settings), encryption is always offloaded.

To enable offloading of encryption even when replay detection is enabled

```
config system npu
  set enc-offload-antireplay enable
end
```

To enable offloading of decryption even when replay detection is enabled

```
config system npu
  set dec-offload-antireplay enable
end
```

HMAC check offloading

The Hash-based Message Authentication Code (HMAC) check can also be offloaded to hardware. SHA-256, SHA-384, or SHA-512 cannot be off-loaded to hardware, and must be processed using only software resources.

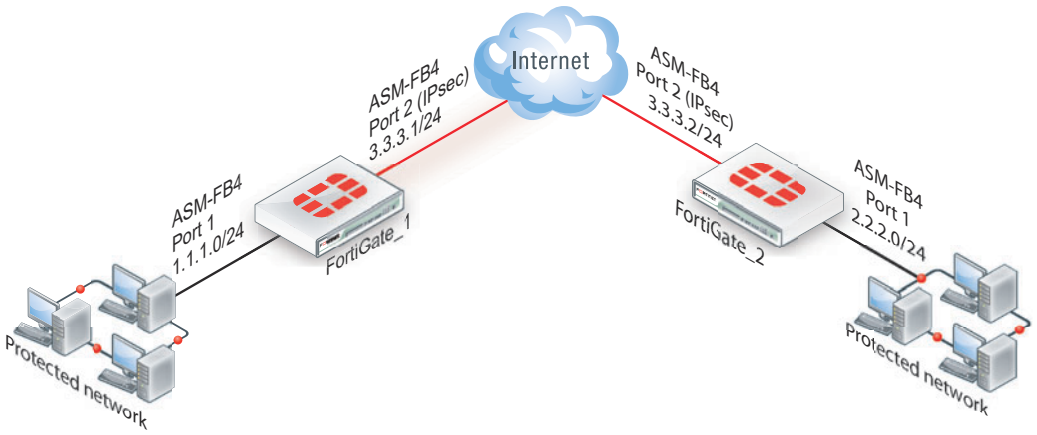
To enable HMAC check offloading

```
configure system global
  set ipsec-hmac-offload (enable|disable)
end
```

IPsec offloading configuration examples

The following examples configure two FortiASIC NP2 accelerated VPNs, one route-based, the other policy based. In both cases, the network topology is as shown in Figure 158.

Figure 158: Hardware accelerated IPsec VPN topology



Accelerated route-based VPN configuration

This example uses the accelerated ports on FortiGate-ASM-FB4 modules in each FortiGate unit. These accelerated ports on the modules are paired interfaces that have their own network processor (NPU) to offload work from the FortiGate unit CPU. Beyond this fact, the example is normal VPN example.

Configuring the FortiGate units require the same basic steps:

- Configure VPN Phase 1
- Configure VPN Phase 2
- Create security policies to allow traffic to flow
- Create a static route to allow traffic to flow

When both FortiGates are have the VPN tunnel configured, test to ensure it is working properly.

To configure FortiGate_1

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)* and select *Create Phase 1*.

2 Configure Phase 1 settings (name FGT_1_IPsec), plus

- Select *Advanced*.
- Select *Enable IPsec Interface Mode*.
- In *Local Gateway IP*, select *Specify* and enter the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1's FortiGate-ASM-FB4 module on port 2.

3 Select *OK*.

4 Select *Create Phase 2* and configure Phase 2 settings, including

- Select *Enable replay detection*.
- set `enc-offload-antireplay` to `enable` using the `config system npu` CLI command.

5 Go to *Policy* > *Policy* > *Policy*.

6 Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 2 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.

7 Go to *Router* > *Static* > *Static Route*.

8 Configure a static route to route traffic destined for FortiGate_2's protected network to the virtual IPsec interface, FGT_1_IPsec.

To add the static route from the CLI:

```
config router static
  edit 2
    set device "FGT_1_IPsec"
    set dst 2.2.2.0 255.255.255.0
  end
```

To configure FortiGate_2

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)* and select *Create Phase 1*.

2 Configure Phase 1 settings (name FGT_2_IPsec), plus

- Select *Advanced*.
- Select *Enable IPsec Interface Mode*.
- In *Local Gateway IP*, select *Specify* and enter the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2's FortiGate-ASM-FB4 module on port 2.

3 Select *OK*.

4 Select *Create Phase 2* and configure Phase 2 settings, including

- Select *Enable replay detection*.
- set `enc-offload-antireplay` to `enable` using the `config system npu` CLI command.

5 Go to *Policy* > *Policy* > *Policy*.

6 Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 2 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.

7 Go to *Router* > *Static* > *Static Route*.

8 Configure a static route to route traffic destined for FortiGate_1's protected network to the virtual IPsec interface, FGT_2_IPsec.

To add the static route from the CLI:

```
config router static
  edit 2
    set device "FGT_2_IPsec"
    set dst 1.1.1.0 255.255.255.0
  end
```

To test the VPN

1 Activate the IPsec tunnel by sending traffic between the two protected networks.

2 To verify tunnel activation, go to *VPN* > *Monitor* > *IPsec Monitor*.

Accelerated policy-based VPN configuration

To configure FortiGate_1

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)* and select *Create Phase 1*.

2 ConfigurePhase 1 settings (name FGT_1_IPsec), plus

- Select *Advanced*.
- Ensure that the *Enable IPsec Interface Mode* check box is not selected.
- In *Local Gateway IP*, select *Specify* and enter the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1's FortiGate-ASM-FB4 module on port 2.

3 Select *OK*.

4 Select*Create Phase 2* and configure Phase 2 settings, including

- Select *Enable replay detection*.
- set `enc-offload-antireplay` to `enable` using the `config system npu` CLI command.

5 Go to *Policy* > *Policy* > *Policy*.

6 Configure an IPSEC policy to apply the Phase 1 IPsec tunnel you configured in step 2 to traffic between FortiGate-ASM-FB4 module ports 1 and 2.

7 Go to *Router* > *Static* > *Static Route*.

8 Configure a static route to route traffic destined for FortiGate_2's protected network to FortiGate_2's VPN gateway, 3.3.3.2, through the FortiGate-ASM-FB4 module's port 2 (device).

To add the static route from the CLI:

```
config router static
  edit 0
    set device "AMC-SW1/2"
    set dst 2.2.2.0 255.255.255.0
    set gateway 3.3.3.1
  end
```

To configure FortiGate_2

1 Go to *VPN* > *IPsec* > *Auto Key (IKE)* and select *Create Phase 1*.

2 Configure Phase 1 settings (name FGT_2_IPsec), plus

- Select *Advanced*.
- Select *Enable IPsec Interface Mode*.
- In *Local Gateway IP*, select *Specify* and enter the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2's FortiGate-ASM-FB4 module on port 2.

3 Select *OK*.

4 Select *Create Phase 2* and configure Phase 2 settings, including

- Select *Enable replay detection*.
- set `enc-offload-antireplay` to `enable` using the `config system npu` CLI command.

5 Go to *Policy* > *Policy* > *Policy*.

6 Configure an IPSEC policy to apply the Phase 1 IPsec tunnel you configured in step 2 to traffic between FortiGate-ASM-FB4 module ports 1 and 2.

7 Go to *Router* > *Static* > *Static Route*.

8 Configure a static route to route traffic destined for FortiGate_1's protected network to FortiGate_2's VPN gateway, 3.3.3.2, through the FortiGate-ASM-FB4 module's port 2 (device).

To add the static route from the CLI:

```
config router static
  edit 0
    set device "AMC-SW1/2"
    set dst 1.1.1.0 255.255.255.0
    set gateway 3.3.3.2
  end
```

To test the VPN

1 Activate the IPsec tunnel by sending traffic between the two protected networks.

2 To verify tunnel activation, go to *VPN* > *Monitor* > *IPsec Monitor*.

Monitoring and troubleshooting

This section provides some general maintenance and monitoring procedures for VPNs.

The following topics are included in this section:

Monitoring VPN connections

You can use the monitor to view activity on IPsec VPN tunnels and to start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels. See "IPsec Monitor" on page 1405.

Monitoring connections to remote peers

The list of tunnels provides information about VPN connections to remote peers that have static IP addresses or domain names. You can use this list to view status and IP addressing information for each tunnel configuration. You can also start and stop individual tunnels from the list.

To view the list of static-IP and dynamic-DNS tunnels go to*VPN* > *Monitor* > *IPsec Monitor*.

Monitoring dialup IPsec connections

The list of dialup tunnels provides information about the status of tunnels that have been established for dialup clients. The list displays the IP addresses of dialup clients and the names of all active tunnels. The number of tunnels shown in the list can change as dialup clients connect and disconnect.

To view the list of dialup tunnels go to *VPN* > *Monitor* > *IPsec Monitor*.

If you take down an active tunnel while a dialup client such as FortiClient is still connected, FortiClient will continue to show the tunnel connected and idle. The dialup client must disconnect before another tunnel can be initiated.

The list of dialup tunnels displays the following statistics:

- The Name column displays the name of the tunnel.
- The meaning of the value in the Remote gateway column changes, depending on the configuration of the network at the far end:

    - When a FortiClient dialup client establishes a tunnel, the Remote gateway column displays either the public IP address and UDP port of the remote host device (on which the FortiClient Endpoint Security application is installed), or if a NAT device exists in front of the remote host, the Remote gateway column displays the public IP address and UDP port of the remote host.
    - When a FortiGate dialup client establishes a tunnel, the Remote gateway column displays the public IP address and UDP port of the FortiGate dialup client.
- The Username column displays the peer ID, certificate name, or XAuth user name of the dialup client (if a peer ID, certificate name, or XAuth user name was assigned to the dialup client for authentication purposes).
- The Timeout column displays the time before the next key exchange. The time is calculated by subtracting the time elapsed since the last key exchange from the keylife.
- The Proxy ID Source column displays the IP addresses of the hosts, servers, or private networks behind the FortiGate unit. A network range may be displayed if the source address in the security encryption policy was expressed as a range of IP addresses.
- The meaning of the value in the Proxy ID Destination column changes, depending on the configuration of the network at the far end:
    - When a FortiClient dialup client establishes a tunnel:
        - If VIP addresses are not used and the remote host connects to the Internet directly, the Proxy ID Destination field displays the public IP address of the Network Interface Card (NIC) in the remote host.
        - If VIP addresses are not used and the remote host is behind a NAT device, the Proxy ID Destination field displays the private IP address of the NIC in the remote host.
        - If VIP addresses were configured (manually or through FortiGate DHCP relay), the Proxy ID Destination field displays either the VIP address belonging to a FortiClient dialup client, or a subnet address from which VIP addresses were assigned.
    - When a FortiGate dialup client establishes a tunnel, the Proxy ID Destination field displays the IP address of the remote private network.

Testing VPN connections

A VPN connection has multiple stages that can be confirmed to ensure the connection is working properly. It is easiest to see if the final stage is successful first since if it is successful the other stages will be working properly. Otherwise, you will need to work back through the stages to see where the problem is located.

- Testing VPN connection
- Troubleshooting VPN connections

Testing VPN connection

When a VPN connection is properly established, traffic will flow from one end to the other as if both ends were physically in the same place. If you can determine the connection is working properly then any problems are likely problems with your applications.

If the connection is not working properly, you can move on to "Troubleshooting VPN connections" on page 1605 to determine the exact problem.

LAN interface connection

To confirm whether a VPN connection over LAN interfaces has been configured correctly, issue a ping or traceroute command on the network behind the FortiGate unit to test the connection to a computer on the remote network. If the connection is properly configured, a VPN tunnel will be established automatically when the first data packet destined for the remote network is intercepted by the FortiGate unit.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel. You can confirm this by going to *VPN* > *Monitor* > *IPsec Monitor* where you will be able to see your connection. A green arrow means the tunnel is up and currently processing traffic. A red arrow means the tunnel is not processing traffic, and this VPN connection has a problem.

If the connection has problems, see "Troubleshooting VPN connections" on page 1605.

Dialup connection

A dialup VPN connection has additional steps. To confirm that a VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The VPN tunnel initializes when the dialup client attempts to connect.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel, or dialup client. As with the LAN connection, confirm the VPN tunnel is established by checking *VPN* > *Monitor* > *IPsec Monitor*.

If the connection has problems, see Troubleshooting.

Troubleshooting VPN connections

If you have determined that your VPN connection is not working properly through "Testing VPN connection" on page 1604, the next step is to verify that you have a phase2 connection.

If traffic is not passing through the FortiGate unit as you expect, ensure the traffic does not contain IPcomp packets (IP protocol 108, RFC 3173). FortiGate units do not allow IPcomp packets, they compress packet payload, preventing it from being scanned.

Testing phase 1 and 2 connections is a bit more difficult than testing the working VPN. This is because they require diagnose CLI commands. These commands are typically used by Fortinet customer support to discover more information about your FortiGate unit and its current configuration.

Before you start troubleshooting you need to:

- configure FortiGate units on both ends for interface VPN
- record the information in your VPN phase 1 and phase 2 configurations - for our example here the remote IP address is 10.101.101.101.101 and the names of the phases are Phase1 and Phase2
- install a telnet or SSH client such as putty that allows logging of output
- ensure that the admin interface supports your chosen connection protocol so you can connect to your FortiGate unit admin interface.
- For this example, default values were used unless stated otherwise.

To get diagnose information for the VPN connection - CLI

1 Log into the CLI as admin with the output being logged to a file.

2 Stop any diag debug sessions that are currently running with the CLI command

```
diag debug disable
```

3 Clear any existing log-filters by running

```
diag debug log-filter clear
```

4 Set the log-filter to the IP address of the remote computer (10.11.101.10). This filters out all VPN connections except ones to the IP address we are concerned with. The command is

```
diag debug log-filter dst-addr4 10.11.101.10.
```

5 Set up the commands to output the VPN handshaking. The commands are:

```
diag debug app ike 255
diag debug enable
```

6 Have the remote FortiGate initiate the VPN connection in the web-based manager by going to *VPN* > *Monitor* and selecting *Bring up*.

This makes the remote FortiGate the initiator and the local FortiGate becomes the responder. Establishing the connection in this manner means the local FortiGate will have its configuration information as well as the information the remote computer sends. Having both sets of information locally makes it easier to troubleshoot your VPN connection.

7 Watch the screen for output, and after roughly 15 seconds enter the following CLI command to stop the output.

```
diag debug disable
```

8 If needed, save the log file of this output to a file on your local computer.

Saving the output to a file can make it easier to search for a particular phrase, or save the output for future comparison with different output.

To troubleshoot a phase1 VPN connection

Using the output from "To get diagnose information for the VPN connection - CLI" on page 1606, search for the word `proposal` in the output. It may occur once indicating a successful connection, or it will occur two or more times for an unsuccessful connection — there will be one proposal listed for each end of the tunnel and each possible combination in their settings. For example if 10.11.101.10 selected both DH Group 1 and 5, that would be at least 2 proposals set.

A successful negotiation proposal will look similar to

- XXX insert output sample here XXX

Note the phrases "`initiator: main mode is sending 1st message...`" and "" which show you the handshake between the ends of the tunnel is in progress. Initiator shows the remote unit is sending the first message.

In the proposal you will see the Diffie-Hellman Group (DH Group) listed as OAKLEY and vn=<a number>. This is normal.

Logging VPN events

You can configure the FortiGate unit to log VPN events. For IPsec VPNs, phase 1 and phase 2 authentication and encryption events are logged. For information about how to interpret log messages, see the *FortiGate Log Message Reference*.

To log VPN events

1 Go to *Log&Report* > *Log Config* > *Log Setting*.

2 Enable the storage of log messages to one or more of the following locations:

- a FortiLog unit
- the FortiGate system memory
- a remote computer running a syslog server

If available on your FortiGate unit, you can enable the storage of log messages to a system hard disk. In addition, as an alternative to the options listed above, you may choose to forward log messages to a remote computer running a WebTrends firewall reporting server. For more information about enabling either of these options through CLI commands, see the "log" chapter of the *FortiGate CLI Reference.*

3 If the options are concealed, select the blue arrow beside each option to reveal and configure associated settings.

4 If logs will be written to system memory, from the Log Level list, select Information. For more information, see the *Logging and Reporting* chapter of *The Handbook*.

5 Select *Apply*.

To filter VPN events

1 Go to *Log&Report* > *Log Config* > *Log Setting*.

2 Verify that the *IPsec negotiation event* option is selected.

3 Select *Apply*.

To view event logs

1 Go to *Log&Report* > *Log & Archive Access* > *Event Log*.

2 If the option is available from the *Type* list, select the log file from disk or memory.

Entries similar to the following indicate that a tunnel has been established. The following log messages concern a VPN tunnel called `vpn_test` on port2 interface in the root VDOM. Pay attention to the `status` and `msg` values.

```

cookies=3896343ae575f210/0a7ba199149e31e9 action=negotiate
status=negotiate_error msg="Negotiate SA Error: probable pre-
shared secret mismatch"
```

For more information about how to interpret error log messages, see the *FortiGate Log Message Reference*.

VPN troubleshooting tips

More in-depth VPN troubleshooting can be found in the *Troubleshooting handbook chapter*.

The VPN proposal is not connecting

One side may attempt to initiate the VPN tunnel unsuccessful. There are a number of potential reasons for this problem.

Attempting hardware offloading beyond SHA1

If you are trying to off-load VPN processing to a network processing unit (NPU), remember that only SHA1 authentication is supported. For high levels of authentication such as SHA256, SHA384, and SHA512 hardware offloading is not an option — all VPN processing must be done in software.

Check Phase 1 proposal settings

Ensure that both sides have at least one Phase 1 proposal in common. Otherwise they will not connect. If there are many proposals in the list, this will slow down the negotiating of Phase 1. If its too slow, the connection may timeout before completing. If this happens, try removing some of the unused proposals.

Ensure you are not using a loopback for the local VPN interface

The Local Interface field in Phase 1 VPN configuration cannot not be configured to point to a loopback interface, or the IPSec tunnel will not be established.

Check your routing

If routing is not properly configured with an entry for the remote end of the VPN tunnel, traffic will not flow properly. You may need static routes on both ends of the tunnel. If routing is the problem, the proposal will likely setup properly but no traffic will flow.

Try enabling XAuth

If one end of an attempted VPN tunnel is using XAuth and the other end is not, the connection attempt will fail. The log messages for the attempted connection will not mention XAuth is the reason, but when connections are failing it is a good idea to ensure both ends have the same XAuth settings. If you do not know the other end's settings enable or disable XAuth on your end to see if that is the problem.

General troubleshooting tips

Most connection failures are due to a configuration mismatch between the FortiGate unit and the remote peer. In general, begin troubleshooting an IPsec VPN connection failure as follows:

1. Ping the remote network or client to verify whether the connection is up. See "Testing VPN connections" on page 1604.
2. Traceroute the remote network or client. If DNS is working, you can use domain names. Otherwise use IP addresses.
3. Check the routing behind the dialup client. Routing problems may be affecting DHCP. If this appears to be the case, configure a DHCP relay service to enable DHCP requests to be relayed to a DHCP server on or behind the FortiGate server.
4. Verify the configuration of the FortiGate unit and the remote peer. Check the following IPsec parameters:

- The mode setting for ID protection (main or aggressive) on both VPN peers must be identical.
- The authentication method (preshared keys or certificates) used by the client must be supported on the FortiGate unit and configured properly.
- If preshared keys are being used for authentication purposes, both VPN peers must have identical preshared keys.
- The remote client must have at least one set of phase 1 encryption, authentication, and Diffie-Hellman settings that match corresponding settings on the FortiGate unit.
- Both VPN peers must have the same NAT traversal setting (enabled or disabled).
- The remote client must have at least one set of phase 2 encryption and authentication algorithm settings that match the corresponding settings on the FortiGate unit.
- If you are using manual keys to establish a tunnel, the *Remote SPI* setting on the FortiGate unit must be identical to the *Local SPI* setting on the remote peer, and vise versa.

5 To correct the problem, see the following table.

Table 93: VPN trouble-shooting tips

Configuration problem	Correction
Mode settings do not match.	Select complementary mode settings. See “Choosing main mode or aggressive mode” on page 1408.
Peer ID or certificate name of the remote peer or dialup client is not recognized by FortiGate VPN server.	Check Phase 1 configuration. Depending on the Remote Gateway and Authentication Method settings, you have a choice of options to authenticate FortiGate dialup clients or VPN peers by ID or certificate name (see “Authenticating remote peers and clients” on page 1412). If you are configuring authentication parameters for FortiClient dialup clients, refer to the Authenticating FortiClient Dialup Clients Technical Note.
Preshared keys do not match.	Reenter the preshared key. See “Authenticating remote peers and clients” on page 1412.
Phase 1 or phase 2 key exchange proposals are mismatched.	Make sure that both VPN peers have at least one set of proposals in common for each phase. See “Defining IKE negotiation parameters” on page 1417 and “Configure the phase 2 parameters” on page 1428.
NAT traversal settings are mismatched.	Select or clear both options as required. See “NAT traversal” on page 1420 and “NAT keepalive frequency” on page 1421.
SPI settings for manual key tunnels are mismatched.	Enter complementary SPI settings. See “Manual-key configurations” on page 1551.

A word about NAT devices

When a device with NAT capabilities is located between two VPN peers or a VPN peer and a dialup client, that device must be NAT traversal (NAT-T) compatible for encrypted traffic to pass through the NAT device. For more information, see “NAT traversal” on page 1420.

Chapter 9 SSL VPN

- Introduction to SSL VPN provides useful general information about VPN and SSL, how the FortiGate unit implements them, and gives guidance on how to choose between SSL and IPsec.
- Basic Configuration explains how to configure the FortiGate unit and the web portal. Along with these configuration details, this chapter also explains how to grant unique access permissions, configure the SSL virtual interface (`ssl.root`), and describes the SSL VPN OS Patch Check feature that allows a client with a specific OS patch to access SSL VPN services.
- The SSL VPN client provides an overview of the FortiClient software required for tunnel mode, where to obtain the software, install it and the configuration information required for remote users to connect to the internal network.
- Setup examples explores several configuration scenarios with step-by-step instructions. While the information provided is enough to set up the described SSL VPN configurations, these scenarios are not the only possible SSL VPN setups.

Introduction to SSL VPN

Over the past several years, as organizations have grown and become more complex, secure remote access to network resources has become critical for day-to-day operations. In addition, businesses are expected to provide clients with efficient, convenient services including knowledge bases and customer portals. Employees travelling across the country or around the world require timely and comprehensive access to network resources. As a result of the growing need for providing remote/mobile clients with easy, cost-effective and secure access to a multitude of resources, the concept of a Virtual Private Network was developed.

SSL VPNs establish connectivity using SSL, which functions at Levels 4 - 5 (Transport and Session). Information is encapsulated at Levels 6 - 7 (Presentation and Application), and SSL VPNs communicate at the highest levels in the OSI model. SSL is not strictly a Virtual Private Network (VPN) technology allows clients to connect to remote networks in a secure way. A VPN is a secure logical network created from physically separate networks. VPNs use encryption and other security methods to ensure that only authorized users can access the network. VPNs also ensure that the data transmitted between computers cannot be intercepted by unauthorized users. When data is encoded and transmitted over the Internet, the data is said to be sent through a “VPN tunnel”. A VPN tunnel is a non-application oriented tunnel that allows the users and networks to exchange a wide range of traffic regardless of application or protocol.

The advantages of a VPN over an actual physical private network are two-fold. Rather than utilizing expensive leased lines or other infrastructure, you use the relatively inexpensive, high-bandwidth Internet. Perhaps more important though is the universal availability of the Internet - in most areas, access to the Internet is readily obtainable without any special arrangements or long wait times.

SSL (Secure Sockets Layer) as HTTPS is supported by most web browsers for exchanging sensitive information securely between a web server and a client. SSL establishes an encrypted link, ensuring that all data passed between the web server and the browser remains private and secure. SSL protection is initiated automatically when a user (client) connects to a web server that is SSL-enabled. Once the successful connection is established, the browser encrypts all the information before it leaves the computer. When the information reaches its destination, it is decrypted using a secret (private) key. Any data sent back is first encrypted, and is decrypted when it reaches the client.

SSL VPN modes of operation

When a remote client connects to the FortiGate unit, the FortiGate unit authenticates the user based on user name, password, and authentication domain. A successful login determines the access rights of remote users according to user group. The user group settings specify whether the connection will operate in web-only mode or tunnel mode.

Web-only mode

Web-only mode provides remote users with a fast and efficient way to access server applications from any thin client computer equipped with a web browser. Web-only mode offers true clientless network access using any web browser that has built-in SSL encryption and the Sun Java runtime environment.

Support for SSL VPN web-only mode is built into the FortiOS operating system. The feature comprises of an SSL daemon running on the FortiGate unit, and a web portal, which provides users with access to network services and resources including HTTP/HTTPS, telnet, FTP, SMB/CIFS, VNC, RDP and SSH.

In web-only mode, the FortiGate unit acts as a secure HTTP/HTTPS gateway and authenticates remote users as members of a user group. After successful authentication, the FortiGate unit redirects the web browser to the web portal home page and the user can access the server applications behind the FortiGate unit.

When the FortiGate unit provides services in web-only mode, a secure connection between the remote client and the FortiGate unit is established through the SSL VPN security in the FortiGate unit and the SSL security in the web browser. After the connection has been established, the FortiGate unit provides access to selected services and network resources through a web portal.

FortiGate SSL VPN web portals have a 1- or 2-column page layout and portal functionality is provided through small applets called widgets. Widget windows can be moved or minimized. The controls within each widget depend on its function. There are predefined web portals and the administrator can create additional portals.

Configuring the FortiGate unit involves selecting the appropriate web portal configuration in the user group settings. These configuration settings determine which server applications can be accessed. SSL encryption is used to ensure traffic confidentiality.

For information about client operating system and browser requirements, see the Release Notes for your FortiGate firmware.

Tunnel mode

Tunnel mode offers remote users the freedom to connect to the internal network using the traditional means of web-based access from laptop computers, as well as from airport kiosks, hotel business centers, and Internet cafés. If the applications on the client computers used by your user community vary greatly, you can deploy a dedicated SSL VPN client to any remote client through its web browser. The SSL VPN client encrypts all traffic from the remote client computer and sends it to the FortiGate unit through an SSL VPN tunnel over the HTTPS link between the web browser and the FortiGate unit. Another option is split tunneling, which ensures that only the traffic for the private network is sent to the SSL VPN gateway. Internet traffic is sent through the usual unencrypted route. This conserves bandwidth and alleviates bottlenecks.

In tunnel mode, remote clients connect to the FortiGate unit and the web portal login page using Microsoft Internet Explorer, Mozilla Foundation/Firefox, Mac OS, or Linux. The FortiGate unit acts as a secure HTTP/HTTPS gateway and authenticates remote users as members of a user group. After successful authentication, the FortiGate unit redirects the web browser to the web portal home page dictated by the user group settings. If the user does not have the SSL VPN client installed, they will be prompted to download the SSL VPN client (an ActiveX or Java plugin) and install it using controls provided through the web portal. SSL VPN tunnel mode can also be initiated from a standalone application on Windows, Mac OS, and Linux.

When the user initiates a VPN connection with the FortiGate unit through the SSL VPN client, the FortiGate unit establishes a tunnel with the client and assigns the client a virtual IP address from a range of reserved addresses. The client uses the assigned IP address as its source address for the duration of the connection. After the tunnel has been established, the user can access the network behind the FortiGate unit.

Configuring the FortiGate unit to establish a tunnel with remote clients involves enabling the feature through SSL VPN configuration settings and selecting the appropriate web portal configuration for tunnel-mode access in the user group settings. The security policy and protection profiles on the FortiGate unit ensure that inbound traffic is screened and processed securely

The user account used to install the SSL VPN client on the remote computer must have administrator privileges.

If you are using Windows Vista, you must disable UAC (User Account Control) before installing the SSL VPN tunnel client. This UAC setting must be disabled before the SSL VPN tunnel client is installed. IE7 in Windows Vista runs in Protected Mode by default. To install SSL VPN client ActiveX, you need to launch IE7 by using 'Run as administrator' (right-click the IE7 icon and select 'Run as administrator').

For information about client operating system requirements, see the Release Notes for your FortiGate firmware.

For information on configuring tunnel mode, see “Tunnel mode settings” on page 1625.

Port forwarding mode

While tunnel mode provides a Layer 3 tunnel that users can run any application over it, the user needs to install the tunnel client, and have the required administrative rights to do so. In some situations, this may not be desirable, yet the simple web mode does not provide enough flexibility for application support. For example, using an email client that needs to communicate with a POP3 server. The port forward mode, or proxy mode, provides this middle ground between web mode and tunnel mode.

SSL VPN port forwarding listens on local ports on the user’s computer. When it receives data from a client application, the port forward module encrypts and sends the data to the FortiGate unit, which then forwards the traffic to the application server.

The port forward module is implemented with a Java applet, which is downloaded and runs on the user’s computer. The applet provides the up-to-date status information such as addressing and bytes sent and received.

On the user end, the user logs into the FortiGate SSL VPN portal, and selects a port forward bookmark configured for a specific application. The bookmark defines the server address and port as well as which port to listen to on the user’s computer.

The user must configure the application on the PC to point to the local proxy instead of the application server. For information on this configuration change, see the application documentation.

This mode only supports client/server applications that are using a static TCP port. It will not support client/server applications using dynamic ports or traffic over UDP.

For information on configuring a port forward tunnel, see “Port forward tunnel” on page 1628.

Application support

With Citrix application servers, the server downloads an ICA configuration file to the user's PC. The client application uses this information to connect to the Citrix server. The FortiGate unit will read this file and append a SOCKS entry to set the SOCKS proxy to localhost. The Citrix client will then be able to connect to the SSL VPN port forward module to provide the connection. When configuring the port forwarding module, an selection is available for Citrix servers.

For Windows Remote Desktop Connections, when selecting the RDP option, the tunnel will launch the RDP client and connect to the local loopback address after the port forward module has been initiated.

SSL VPN and IPv6

FortiOS supports SSL VPN using IPv6 addressing using IPv6 configurations for security policies and addressing including:

- Policy matching for IPv6 addresses
- Support for DNS resolving in SSL VPN
- Support IPv6 for ping
- FTP applications
- SMB
- Support IPV6 for all the java applets (Telnet, VNC, RDP and so on)

Traveling and security

Because SSL VPN provides a means for "on-the-go" users to dial in to the network while away from the office, you need to ensure that wherever and however they choose to dial in is secure, and not potentially compromising the corporate network.

When setting up the portal, you can include two options to ensure corporate data is safe; a host check for antivirus software, and a cache cleaner.

Host check

You can enable a host integrity checker to scan the remote client. The integrity checker probes the remote client computer to verify that it is safe before access is granted. Security attributes recorded on the client computer (for example, in the Windows registry, in specific files, or held in memory due to running processes) are examined and uploaded to the FortiGate unit.

For more information, see "Host Check" on page 1640.

Cache cleaning

You can enable a cache cleaner to remove any sensitive data that would otherwise remain on the remote computer after the session ends. For example, all cache entries, browser history, cookies, encrypted information related to user authentication, and any temporary data generated during the session are removed from the remote computer. If the client's browser cannot install and run the cache cleaner, the user is not allowed to access the SSL-VPN portal.

For more information, see "Cache cleaning" on page 1616.

Basic Configuration

Configuring SSL VPN involves a number of configurations within FortiOS that you need to complete to make it all come together. This chapter describes the components required, and how and where to configure them to set up the FortiGate unit as an SSL VPN server. The configurations and steps are high level, to show you the procedures needed, and where in FortiOS they are located. For real-world examples, see the chapter, "Setup examples" on page 1655.

There are three or four key steps to configuring an SSL VPN tunnel. The first three in the points below are mandatory, while the other is optional. This chapter will outline these four key steps, as well as additional configuration you can do for tighter security and monitoring.

The key steps are:

- Create user accounts and user groups for the remote clients.
  ("User accounts and groups" on page 1617)
- Create a web portal to define user access to network resources.
  ("Configuring SSL VPN web portals" on page 1620)
- Configure the security policies.
  ("Configuring security policies" on page 1631)
- For tunnel-mode operation, add routing to ensure that client tunnel-mode packets reach the SSL VPN interface.
  ("Routing in tunnel mode" on page 1638)
- Setup logging of SSL VPN activities.
  ("SSL VPN logs" on page 1647)

User accounts and groups

The first step for an SSL VPN tunnel is to add the users and user groups that will access the tunnel. You may already have users defined for other authentication-based security policies. These users and groups are identified when creating the security policy when defining the authentication rules.

The user group is associated with the web portal that the user sees after logging in. If you have multiple portals, you will need multiple user groups. You can use one policy for multiple groups, or multiple policies to handle differences between the groups such as access to different services, or different schedules.

To create a user account

- in the web-based manager, go to *User* > *User*, and select *Create New*.
- in the CLI, use the commands in `config user local`.

All users accessing the SSL tunnel must be in a firewall user group. As part of configuring the user group, you select the SSL VPN web portal that the members of the group access after authentication.

To create user groups

- in the web-based manager, go to *User* > *User Group* > *User Group* and select *Create New*.
- in the CLI, use the commands in `config user group`.

Authentication

Remote users must be authenticated before they can request services and/or access network resources through the web portal. The authentication process can use a password defined on the FortiGate unit or optionally use established external authentication mechanisms such as RADIUS or LDAP.

To authenticate users, you can use a plain text password on the FortiGate unit (Local domain), forward authentication requests to an external RADIUS, LDAP or TACACS+ server, or utilize PKI certificates.

For information about how to create RADIUS, LDAP, TACACS+ or PKI user accounts and certificates, see the *User Authentication* chapter of *The Handbook*.

FortiOS supports LDAP password renewal notification and updates through SSL VPN. Configuration is enabled using the CLI commands:

```
config user ldap
  edit <username>
    set password-expiry-warning enable
    set password-renewal enable
end
```

For more information, see the *User Authentication* chapter of *The Handbook*.

IP addresses for users

After the FortiGate unit authenticates a request for a tunnel-mode connection, the FortiGate unit assigns the SSL VPN client an IP address for the session. The address is assigned from an address range (IP Pool) which is a firewall address that defines an IP address range.

Take care to prevent overlapping IP addresses. Do not assign to clients any IP addresses that are already in use on the private network. As a precaution, consider assigning IP addresses from a network that is not commonly used (for example, 10.254.254.0/24).

To set tunnel-mode client IP address range - web-based manager

1. Go to *Firewall Objects* > *Address* > *Address* and select *Create New*.
2. Enter an *Address Name*, for example, `SSL_VPN_tunnel_range`.
3. In the *Subnet/IP Range* field, enter the starting and ending IP addresses that you want to assign to SSL VPN clients, for example `10.254.254.[80-100]`.
4. In *Interface*, select *Any*.
5. Select *OK*.

To set tunnel-mode client IP address range - CLI

If your SSL VPN tunnel range is for example 10.254.254.80 - 10.254.254.100, you could enter

```
config firewall address
  edit SSL_tunnel_users
    set type iprange
    set end-ip 10.254.254.100
    set start-ip 10.254.254.80
  end
end
```

You can select the tunnel-mode IP Pools in two places:

- The *VPN* > *SSL* > *Config* page *IP Pools* setting applies to all web portals that do not specify their own IP Pools.
- The web portal Tunnel Mode widget *IP Pools* setting, if used, applies only to the web portal and overrides the setting in *VPN* > *SSL* > *Config*. See "Tunnel mode settings" on page 1625.

Authentication of remote users

When remote users connect to the SSL VPN tunnel, they must perform authentication before being able to use the internal network resources. This can be as simple as assigning users with their own passwords, connecting to an LDAP server or using more secure options. FortiOS provides a number of options for authentication as well as security option for those connected users.

The web portal can include bookmarks to connect to internal network resources. A web (HTTP/HTTPS) bookmark can include login credentials so that the FortiGate unit automatically logs the user into the web site. This means that the user logs into the SSL VPN and then does not have to enter any more credentials to visit preconfigured web sites.

Both the administrator and the end user can configure bookmarks, including SSO bookmarks. To add bookmarks as a web portal user, see "The Bookmarks widget" on page 1628.

Setting the client authentication timeout

The client authentication timeout controls how long an authenticated user will remain connected. When this time expires, the system forces the remote client to authenticate again. As with the idle timeout, a shorter period of time is more secure. The default value is 28800 seconds (8 hours). You can only modify this timeout value in the CLI.

For example, to change the authentication timeout to 18 000 seconds, enter the following commands:

```
config vpn ssl settings
  set auth-timeout 18000
end
```

Strong authentication with security certificates

The FortiGate unit supports strong (two-factor) authentication through X.509 security certificates (version 1 or 3). The FortiGate unit can require clients to authenticate using a certificate. Similarly, the client can require the FortiGate unit to authenticate using a certificate.

For information about obtaining and installing certificates, see the *User Authentication* chapter of *The Handbook*.

You can select the *Require Client Certificate* option in *SSL VPN settings* so that clients must authenticate using certificates. The client browser must have a local certificate installed, and the FortiGate unit must have the corresponding CA certificate installed.

When the remote client initiates a connection, the FortiGate unit prompts the client browser for its client-side certificate as part of the authentication process.

To require client authentication by security certificates - web-based manager

1 Go to *VPN* > *SSL* > *Config*.
2 Select *Require Client Certificate*.
3 Select *Apply*.

To require client authentication by security certificates - CLI

```
config vpn ssl settings
  set reqclientcert enable
end
```

If your SSL VPN clients require strong authentication, the FortiGate unit must offer a CA certificate that the client browser has installed.

In the FortiGate unit SSL VPN settings, you can select which certificate the FortiGate offers to authenticate itself. By default, the FortiGate unit offers its factory installed (self-signed) certificate from Fortinet to remote clients when they connect.

To enable FortiGate unit authentication by certificate - web-based manager

1 Go to *VPN* > *SSL* > *Config*.
2 From the *Server Certificate* list, select the certificate that the FortiGate unit uses to identify itself to SSL VPN clients.
3 Select *Apply*.

To enable FortiGate unit authentication by certificate - CLI

For example, to use the `example_cert` certificate

```
config vpn ssl settings
  set servercert example_cert
end
```

Configuring SSL VPN web portals

The SSL VPN portal enables remote users to access internal network resources through a secure channel using a web browser. FortiGate administrators can configure log in privileges for system users and which network resources are available to the users.

This step in the configuration of the SSL VPN tunnel sets up the infrastructure; the addressing, encryption, certificates needed to make the initial connection to the FortiGate unit. This step also is where you set up what the remote user sees when the connection is successful. The portal view defines what resources are available to the remote users and what functionality they have on the network.

SSL connection configuration

To configure the basic SSL VPN settings for encryption and log in options, go to *VPN* > *SSL* > *Config.*

IP Pools	Select *Edit* to select the range or subnet firewall addresses that represent IP address ranges reserved for tunnel-mode SSL VPN clients. The IP Pool that you select will be the one created in the previous steps.
Server Certificate	Select the signed server certificate to use for authentication. If you leave the default setting (Self-Signed), the FortiGate unit offers its factory installed certificate from Fortinet, to remote clients when they connect.
Require Client Certificate	Select to use group certificates for authenticating remote clients. When the remote client initiates a connection, the FortiGate unit prompts the client for its client-side certificate as part of the authentication process. For information on using PKI to provide client certificate authentication, see the *User Authentication Guide*.
Encryption Key Algorithm	Select the algorithm for creating a secure SSL connection between the remote client web browser and the FortiGate unit. This will depend on what the web browser of the client can support. The FortiGate unit supports a range of cryptographic cipher suites to match the capabilities of various web browsers. The web browser and the FortiGate unit negotiate a cipher suite before any information is transmitted over the SSL link.
Idle Timeout	Type the period of time (in seconds) that the connection can remain idle before the user must log in again. The range is from 10 to 28800 seconds. Setting the value to 0 will disable the idle connection timeout. This setting applies to the SSL VPN session. The interface does not time out when web application sessions or tunnels are up.
Login Port	Enter the port number for HTTPS access.
Advanced (DNS and WINS Servers)	Enter up to two DNS servers and/r two WINS servers to be provided for the use of clients.

Portal configuration

The portal configuration determines what the remote user sees when they log in to the portal. Both the system administrator and the user have the ability to customize the SSL VPN portal.

There are three pre-defined default web portal configurations available:

- *full-access*
- *tunnel-access*
- *web-access*

To view the portals settings page, go to *VPN* > *SSL* > *Portal*.

Portal Settings page	
Edit Settings window	Provides general, virtual desktop and security control settings for the SSL VPN Service portal page. This window appears when you select *Settings*. This window also appears when you select *Create New*.
Settings	Select to edit the settings for the SSL VPN web portal.
Add Widget	Select to add a new widget to the page.
Widgets	The widgets that will appear on the SSL VPN Service page. By default when starting a new portal, all four of the widgets available for the portal appear on the screen. You can add widgets from the Add Widgets drop-down list.

Portal settings

The portal settings determine what SSL VPN users see when they log in to the FortiGate unit. Both the FortiGate administrator and the SSL VPN user have the ability to customize the web portal settings.

Portal settings are configured by going to *VPN* > *SSL* > *Portal* and select *Settings*.

General settings

The general settings tab enables you to set up the portal container - what the remote user sees when they log in. It also is the location where you define what applications the remote user can use when connecting. The applications selected affect how you configure the widgets later on. For example, if you do not select the HTTP/HTTPS option, you cannot add bookmarks in the bookmark widget.

Virtual Desktop settings

The virtual desktop options, available for Windows XP and Windows Vista client PCs, are configured to completely isolate the SSL VPN session from the client computer's desktop environment. All data is encrypted, including cached user credentials, browser history, cookies, temporary files, and user files created during the session. When the SSL VPN session ends normally, the files are deleted. If the session ends unexpectedly, any files that may remain will be encrypted.

Virtual desktop requires the Fortinet host check plug in. If the plug in is not present, it is automatically downloaded to the client computer.

Security Control settings

Security control options provide cache cleaning and host checking to the clients of your web portal. Cache cleaning clears information from the client browser cache just before the SSL VPN session ends. The cache cleaner is effective only if the session terminates normally. The cache is not cleaned if the session ends unexpectedly.

Host checking enforces the client's use of antivirus or firewall software. Each client is checked for security software that is recognized by the Windows Security Center. As an alternative, you can create a custom host check that looks for specific security software selected from the Host Check list located at *VPN* > *SSL* > *Host Check*. See "Host Check" on page 1640.

Portal widgets

Portal widgets are sections of information that the user will view when they log in to the portal. By default, all widgets are shown. You can modify or remove widgets as required.

Session Information

The *Session Information* widget displays the login name of the user, the amount of time the user has been logged in and the inbound and outbound traffic statistics.

Bookmarks

Bookmarks are used as links to internal network resources. When a bookmark is selected from a bookmark list, a pop-up window appears with the web page. Telnet, VNC, and RDP require a browser plug-in. FTP and Samba replace the bookmarks page with an HTML file-browser.

A web bookmark can include login credentials to automatically log the SSL VPN user into the web site. When the administrator configures bookmarks, the web site credentials must be the same as the user's SSL VPN credentials. Users configuring their own bookmarks can specify alternative credentials for the web site.

Connection Tool

Use the *Connection Tool* widget to connect to a internal network resource without adding a bookmark to the bookmark list. You select the type of resource and specify the URL or IP address of the host computer.

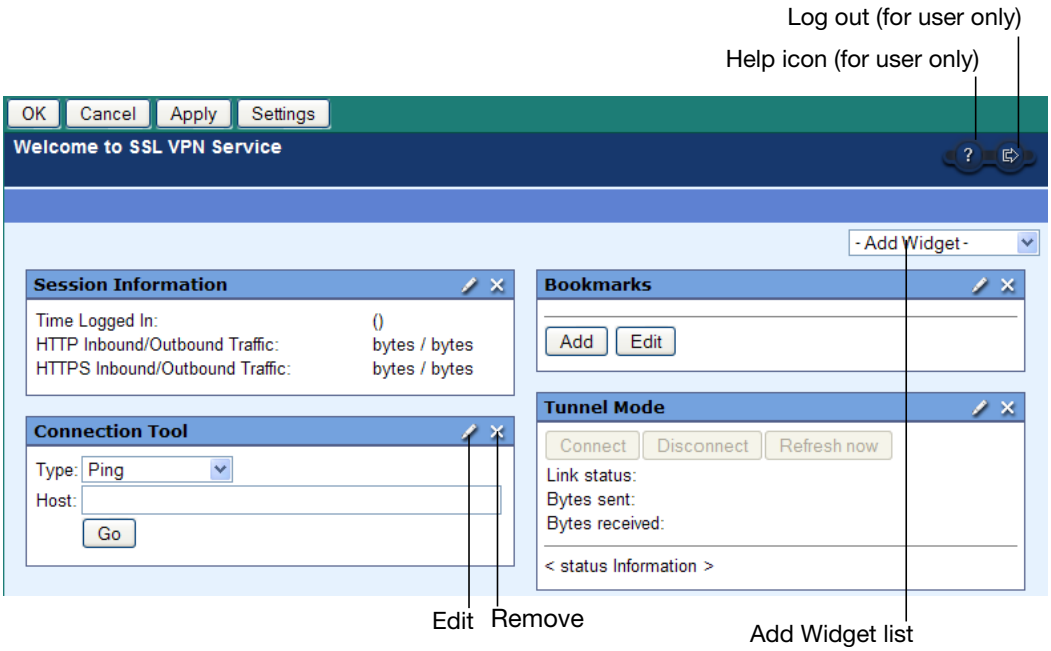
Tunnel Mode

If your web portal provides tunnel mode access, you need to configure the *Tunnel Mode* widget. These settings determine how tunnel mode clients are assigned IP addresses.

Configuring the web portal page layout

You can determine which widgets are displayed on the web portal page and adjust the layout.

Figure 159: Configuring the SSL VPN web portal page



To configure the web portal page - web-based manager

On the web portal page itself, you can make several adjustments to the appearance of the portal:

- Arrange widgets on the page by dragging them by their title bar.
- Add a widget by choosing a widget from the *Add Widget* list.
- Remove a widget by selecting the *Remove* icon in the widget title bar.
- Configure a widget by selecting the *Edit* icon in the widget title bar. For configuration information about each widget type, see the following sections:
  - “Tunnel mode settings” on page 1625
  - “The Session Information widget” on page 1628
  - “The Connection Tool widget” on page 1630
- To modify the color scheme and other basic settings, select the *Settings* button. You can also configure several advanced features. For more information, see
  - “The Connection Tool widget” on page 1630
  - “Configuring cache cleaning” on page 1643
  - “Configuring virtual desktop” on page 1644
  - “Configuring client OS Check” on page 1646 (CLI only)

When you have finished configuring the web portal page, select *Apply* to save the modifications.

To configure the web portal page - CLI

You can also define a portal layout using CLI commands, although due its complexity, is not recommended. Unlike configuring with the web-based manager, a new portal created in the CLI has by default no heading and no widgets. Also, the widgets do not have default names. You must specify all of this information.

For example, to create the portal layout shown in Figure 159 on page 1624, you would enter:

```
config vpn ssl web portal
  set heading "Welcome to SSL VPN Service"
  set page-layout double-column
  set theme blue
  edit myportal
    config widget
      edit 0
        set type info
        set name "Session Information"
        set column one
      next
      edit 0
        set type bookmark
        set name "Bookmarks"
        set column one
      next
      edit 0
        set type tunnel
        set name "Tunnel Mode"
        set column two
      next
      edit 0
        set type tool
        set name "Connection Tool"
        set column two
      end
```

When you use `edit 0`, as in this example, the CLI automatically assigns an unused index value when you exit the edit shell by typing `end`.

Tunnel mode settings

If your web portal provides tunnel mode access, the *Tunnel Mode* widget is included automatically when creating a new portal, with the *Split Tunneling* option enabled. These settings determine how tunnel mode clients are assigned IP addresses.

If this web portal will assign a different range of IP addresses to clients than the IP Pools you specified on the *VPN* > *SSL* > *Config* page, you need to define a firewall address for the IP address range that you want to use. You will then need to specify this address in the Tunnel Mode widget *IP Pools* setting.

If the tunnel mode and session information widgets are the only widgets configured, the user will automatically be logged into the SSL-VPN tunnel.

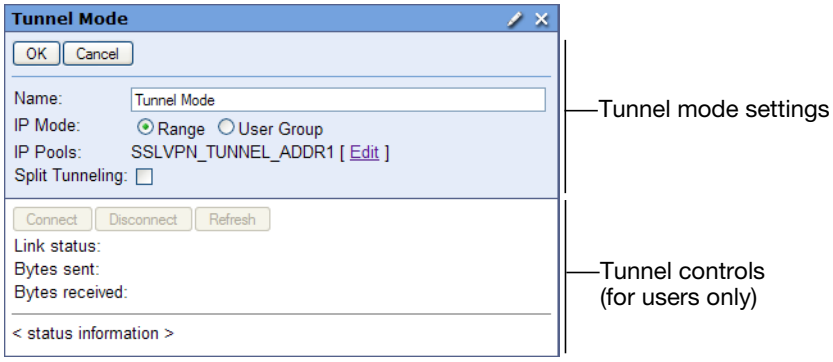
Optionally, you can enable a split tunneling configuration so that the VPN carries only the traffic for the networks behind the FortiGate unit. The user's other traffic follows its normal route.

To configure tunnel mode settings - web-based manager

1 Go to *VPN* > *SSL* > *Portal* and select *Create New*.

2 Select the *Edit* icon in the *Tunnel Mode* widget title bar.

Figure 160: Tunnel Mode widget - edit mode



3 Enter the following information:

Name	Enter a name for the widget.
IP Mode	Select the mode by which the IP address is assigned to the user.
Range	Use the IP address ranges specified by *IP Pools*.
User Group	The user is assigned the IP address specified in the Framed-IP-Address field of the user's record on the RADIUS server. This option is valid only for users authenticated by a RADIUS server.
IP Pools	If you want to specify an IP address range for clients of this portal only, select *Edit*. From the *Available* list, select the appropriate firewall address. You must configure the desired IP address range as a firewall address before you can select it here.
Split Tunneling	Split tunneling is enabled by default. When enabled, only traffic that requires the SSL VPN is sent through the tunnel. Other traffic follows the user's regular routing. When split tunneling is disabled, all of the user's traffic with other networks passes through the tunnel. This does not affect traffic between the user's computer and hosts on the local network. For enhanced security, some administrators prefer to force all traffic through the SSL VPN tunnel, including traffic between the user and the user's local network. To do this, use the CLI tunnel mode settings to enable `exclusive-routing`.

The remaining items in the widget are controls that are available to the user during an SSL VPN session.

4 Select *OK* in the *Tunnel Mode* widget.

5 Select *Apply*.

To configure tunnel mode settings - CLI

To enable tunnel mode operation for portal2 portal users and assign them addresses from the `SSLVPN_TUNNEL_ADDR2` range, you would enter:

```
config vpn ssl web portal
  edit portal2
    config widget
      edit 0
        set type tunnel
        set ip-mode range
        set ip-pools SSLVPN_TUNNEL_ADDR2
      end
  end
```

The preceding example applies to a web portal that does not already have a tunnel mode widget. To modify the settings on an existing tunnel mode widget, you need to determine the widget's number. Enter:

```
config vpn ssl web portal
  edit portal1
    config widget
    show
```

In the output, you will see, for example,

```
      edit 3
        set name "Tunnel Mode"
        set type tunnel
        ...
```

You can now enter `edit 3` and modify the tunnel mode widget's settings.

To force all traffic through the tunnel - CLI

If you disable split tunneling, all of the user's traffic to other networks passes through the SSL VPN tunnel. But, this does not apply to traffic between the user and the user's local network. For enhanced security, some administrators prefer to force all of the user's traffic, including traffic with the local network, to pass through the SSL VPN tunnel. To do this, enable `exclusive-routing` in the tunnel widget settings. For example:

```
config vpn ssl web portal
  edit portal2
    config widget
      edit 0
        set type tunnel
        set ip-mode range
        set ip-pools SSLVPN_TUNNEL_ADDR2
        set split-tunneling disable
        set set exclusive-routing enable
      end
  end
```

Port forward tunnel

Port forwarding provides a method of connecting to application servers without configuring a tunnel mode connection, and requiring the installation of tunnel mode client. Set up the portal as described at “Configuring SSL VPN web portals” on page 1620. To configure the application, create a bookmark with the *Type* of *PortForward*.

Ensure that *Port Forward* is enabled in the *Applications* list of the *General* settings, by selecting the *Settings* button in the portal configuration window.

The Session Information widget

The *Session Information* widget displays the login name of the user, the amount of time the user has been logged in, and the inbound and outbound traffic statistics of HTTP and HTTPS. You can change the widget name.

To edit the session information, in the *Session Information* widget select *Edit* and enter the session name.

To configure Session Information settings - CLI

To change the name of the web-access Session Information widget to “My Session”, you would enter:

```
config vpn ssl web portal
  edit web-access
    config widget
      edit 4
        set name "My Session"
      end
```

The Bookmarks widget

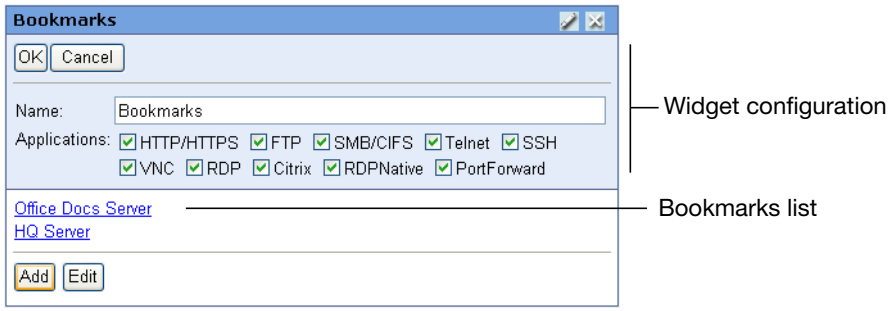
Bookmarks are used as links to specific resources on the network. When a bookmark is selected from a bookmark list, a pop-up window appears with the requested web page. Telnet, VNC, and RDP all pop up a window that requires a browser plug-in. FTP and Samba replace the bookmarks page with an HTML file-browser.

Ensure that *HTTP/HTTPS* is enabled in the *Applications* list of the *General* settings, by selecting the *Settings* button in the portal configuration window.

To configure the Bookmarks widget

1 Go to *VPN* > *SSL* > *Portal*, and select *Create New*.

2 Select the *Edit* icon in the *Bookmarks* widget title bar.



3 Select the *Applications* check boxes for the types of bookmarks that you want to support.

4 To add a bookmark, select *Add*.

5 Enter or edit the following information:

Name	Enter a name for the bookmark.
Type	Select the type of application to which the bookmark links. For example, select HTTP/HTTPS for a web site. Only the application types that you configured in the settings are in the list. You can select Edit in the widget title bar to enable additional application types.
Location	Enter the destination of the bookmark.
Description	Enter a descriptive tooltip for the bookmark.
SSO	A Single Sign-On (SSO) bookmark automatically enters the login credentials for the bookmark destination. Select one of: **Disabled** — This is not an SSO bookmark. **Automatic** — Use the user's SSL VPN credentials for login. **Static** — Use the login credentials defined below.
Single Sign-On settings available when SSO is Static	
Field Name	Enter a required login page field name, "User Name" for example.
Value	Enter the value to enter in the field identified by *Field Name*. If you are an administrator configuring a bookmark for users: Enter `%usrname%` to represent the user's SSL VPN user name. Enter `%passwd%` to represent the user's SSL VPN password.
Add	Enter another *Field Name* / *Value* pair, for the password for example. A new set of *Field Name* / *Value* fields is added.

6 Select *OK*.

7 Select *Apply* at the top of the web portal page to save the changes that you made.

To configure the Bookmarks widget and add/edit bookmarks - CLI

To allow only FTP and web connections on the web-access portal and to configure a bookmark to example.com, you would enter:

```
config vpn ssl web portal
  edit web-access
    config widget
      edit 1
        set type bookmark
        set allow-apps ftp web
        config bookmarks
          edit "example"
            set apptype web
            set description "example bookmark"
            set url "http://example.com"
          end
        end
      end
```

To delete bookmarks - CLI

To delete the bookmark added above, you would enter:

```
config vpn ssl web portal
  edit web-access
    config widget
      edit 1
        config bookmarks
          delete example
        end
      end
    end
```

The Connection Tool widget

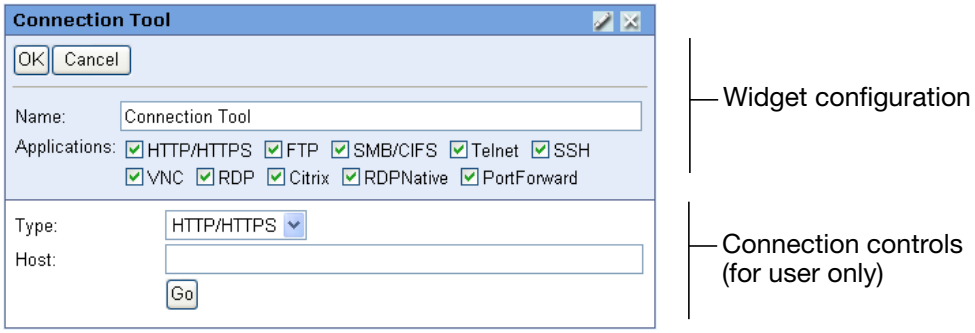
The *Connection Tool* enables a user to connect to resources for which there are no bookmarks.

Ensure that what you want remote users to connect to is enabled in the *Applications* list of the *General* settings, by selecting the *Settings* button in the portal configuration window.

To configure the Connection Tool widget

1 Go to *VPN* > *SSL* > *Portal*, and select *Create New*.

2 Select the *Edit* icon in the *Connection Tool* widget title bar.



3 Enter a new *Name* for the widget.

4 Select the types of *Applications* that the Connection Tool is enabled to access.

5 Select *OK*.

To configure the Connection Tool widget - CLI

To change, for example, the full-access portal Connection Tool widget to allow all application types except Telnet, you would enter:

```
config vpn ssl web portal
  edit full-access
    config widget
      edit 3
        set allow-apps ftp rdp smb ssh vnc web
      end
    end
  end
```

Configuring security policies

You will need at least one SSL VPN security policy. This is an identity-based policy that authenticates users and enables them to access the SSL VPN web portal. The SSL VPN user groups named in the policy determine who can authenticate and which web portal they will use. From the web portal, users can access protected resources or download the SSL VPN tunnel client application.

This section contains the procedures needed to configure security policies for web-only mode operation and tunnel-mode operation. These procedures assume that you have already completed the procedures outlined in "User accounts and groups" on page 1617.

If you will provide tunnel mode access, you will need a second security policy — an ACCEPT tunnel mode policy to permit traffic to flow between the SSL VPN tunnel and the protected networks.

Firewall addresses

Before you can create security policies, you need to define the firewall addresses you will use in those policies. For both web-only and tunnel mode operation, you need to create firewall addresses for all of the destination networks and servers to which the SSL VPN client will be able to connect.

For tunnel mode, you will already have defined firewall addresses for the IP address ranges that the FortiGate unit will assign to SSL VPN clients. See "Windows OS check" on page 1643.

The source address for your SSL VPN security policies will be the predefined "all" address. Both the address and the netmask are `0.0.0.0`. The "all" address is used because VPN clients will be connecting from various addresses, not just one or two known networks. For improved security, if clients will be connecting from one or two known locations you should configure firewall addresses for those locations, instead of using the "all" address.

To create a firewall address, in the web-based manager, go to *Firewall Objects* > *Address* > *Address*, and select *Create New.* Using the CLI, use the commands in `config firewall address`.

Create an SSL VPN security policy

At minimum, you need one SSL VPN security policy to authenticate users and provide access to the protected networks. You will need additional security policies only if you have multiple web portals that provide access to different resources.

The user group is associated with the web portal that the user sees after logging in. If you have multiple portals, you will need multiple user groups. You can use one policy for multiple groups, or multiple policies to handle differences between the groups such as access to different services, or different schedules.

The SSL VPN security policy specifies:

- the source address that corresponds to the IP address of the remote user.
- the destination address that corresponds to the IP address or addresses that remote clients need to access.

  The destination address may correspond to an entire private network, a range of private IP addresses, or the private IP address of a server or host.
- the level of SSL encryption to use and the authentication method.
- which SSL VPN user groups can use the security policy.
- the times (schedule) and types of services that users can access.
- the UTM features and logging that are applied to the connection.

Do not use ALL as the destination address. If you do, you will see the "Destination address of Split Tunneling policy is invalid" error when you enable Split Tunneling.

To create an SSL-VPN security policy - web-based manager

1 Go to *Policy* > *Policy* > *Policy* and select *Create New.*

2 Enter the following information:

Source Interface/Zone	Select the name of the FortiGate network interface to that connects to the Internet.
Source Address	Select *all*.
Destination Interface/Zone	Select the FortiGate network interface that connects to the protected network.

Destination Address	Select the firewall address you created that represents the networks and servers to which the SSL VPN clients will connect. If you want to associate multiple firewall addresses or address groups with the *Destination Interface/Zone*, from *Destination Address*, select the plus symbol. In the dialog box, move the firewall addresses or address groups from the *Available Addresses* section to the *Members* section, then select *OK*.
Action	Select *SSL-VPN*.
SSL Client Certificate Restrictive	Allow access only to holders of a (shared) group certificate. The holders of the group certificate must be members of an SSL VPN user group, and the name of that user group must be present in the Allowed field. See "Strong authentication with security certificates" on page 1619.
Cipher Strength	Select the bit level of SSL encryption. The web browser on the remote client must be capable of matching the level that you select.
Configure SSL-VPN Users	A security policy for an SSL VPN is automatically an identity-based policy.
Add	Add a user group to the policy. The Edit Authentication Rule window opens on top of the security policy. Enter the following information and then select OK. You can select Add again to add more groups.
User Group	Select user groups in the left list and use the right arrow button to move them to the right list.
Service	Select service in the left list and use the right arrow button to move them to the right list. Select the ANY service to allow the user group access to all services.

3 Select *OK*.

Your identity-based policies are listed in the security policy table. The FortiGate unit searches the table from the top down to find a policy to match the client's user group. Using the move icon in each row, you can change the order of the policies in the table to ensure the best policy will be matched first. You can also use the icons to edit or delete policies.

To create an SSL VPN security policy - CLI

To create the security policy by entering the following CLI commands.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr OfficeLAN
    set action ssl-vpn
    set nat enable
    config identity-based-policy
      edit 0
        set groups SSL-VPN
        set schedule always
```

```
        set service ANY
      end
    end
```

Create a tunnel mode security policy

If your SSL VPN will provide tunnel mode operation, you need to create a security policy to enable traffic to pass between the SSL VPN virtual interface and the protected networks. This is in addition to the SSL VPN security policy that you created in the preceding section.

The SSL VPN virtual interface is the FortiGate unit end of the SSL tunnel that connects to the remote client. It is named `ssl.<vdom_name>`. In the root VDOM, for example, it is named `ssl.root`. If VDOMs are not enabled on your FortiGate unit, the SSL VPN virtual interface is also named ssl.root.

To configure the tunnel mode security policy - web-based manager

1 Go to *Policy* > *Policy*> *Policy* and select *Create New*.

2 Enter the following information and select *OK*.

Source Interface/Zone	Select the virtual SSL VPN interface, such as *ssl.root*.
Source Address	Select the firewall address you created that represents the IP address range assigned to SSL VPN clients, such as SSL_VPN_tunnel_users.
Destination Interface/Zone	Select the interface that connects to the protected network.
Destination Address	Select the firewall address that represents the networks and servers the SSL VPN clients will connect to. To select multiple firewall addresses or address groups, select the plus sign next to the drop-down list.
Action	Select *Accept*.
NAT	Select *Enable NAT*

To configure the tunnel mode security policy - CLI

```
config firewall policy
  edit <id>
    set srcintf ssl.root
    set dstintf <dst_interface_name>
    set srcaddr <tunnel_ip_address>
    set dstaddr <protected_network_address_name>
    set schedule always
    set service ANY
    set nat enable
  end
```

This policy enables the SSL VPN client to initiate communication with hosts on the protected network. If you want to enable hosts on the protected network to initiate communication with the SSL VPN client, you should create another Accept policy like the preceding one but with the source and destination settings reversed.

You must also add a static route for tunnel mode operation.

Routing for tunnel mode

If you your SSL VPN operates in tunnel mode, you must add a static route so that replies from the protected network can reach the remote SSL VPN client.

To add the tunnel mode route - web-based manager

1 Go to *Router* > *Static* > *Static Route* and select *Create New*.
2 Enter the *Destination IP/Mask* of the tunnel IP address that you assigned to the users of the web portal.
3 Select the SSL VPN virtual interface for the *Device*.
4 Select *OK*.

To add the tunnel mode route - CLI

If you assigned 10.11.254.0/24 as the tunnel IP range, you would enter:

```
config router static
  edit <id>
    set device ssl.root
    set dst 10.11.254.0/24
    set gateway <gateway_IP>
  end
```

Split tunnel Internet browsing policy

With split tunneling disabled, all of the SSL VPN client's requests are sent through the SSL VPN tunnel. But the tunnel mode security policy provides access only to the protected networks behind the FortiGate unit. Clients will receive no response if they attempt to access Internet resources. You can enable clients to connect to the Internet through the FortiGate unit.

To add an Internet browsing policy

1 Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2 Enter the following information and select *OK*.

Source Interface/Zone	Select the virtual SSL VPN interface, *ssl.root*, for example.
Source Address	Select the firewall address you created that represents the IP address range assigned to SSL VPN clients.
Destination Interface/Zone	Select the FortiGate network interface that connects to the Internet.
Destination Address	Select *all*.
Action	Select *Accept*.
NAT	Enable.
Leave other settings at their default values.	

To configure the Internet browsing security policy - CLI

To enable browsing the Internet through port1, you would enter:

```
config firewall policy
  edit 0
    set srcintf ssl.root
```

```
    set dstintf port1
    set srcaddr SSL_tunne_users
    set dstaddr all
    set schedule always
    set service ANY
    set nat enable
  end
```

Enabling a connection to an IPsec VPN

You might want to provide your SSL VPN clients access to another network, such as a branch office, that is connected by an IPsec VPN. To do this, you need only to add the appropriate security policy. For information about route-based and policy-based IPsec VPNs, see the *IPsec VPN Guide*.

Route-based Connection

To configure interconnection with a route-based IPsec VPN - web-based manager

1 Go to *Policy* > *Policy* > *Policy* and select *Create New*.

2 Enter the following information and select *OK*.

Source Interface/Zone	Select the virtual SSL VPN interface, *ssl.root*, for example.
Source Address	Select the firewall address that represents the IP address range assigned to SSL VPN clients.
Destination Interface/Zone	Select the virtual IPsec interface for your IPsec VPN.
Destination Address	Select the address of the IPsec VPN remote protected subnet.
Action	Select *ACCEPT*.
NAT	Enable.
Leave other settings at their default values.	

To configure interconnection with a route-based IPsec VPN - CLI

If, for example, you want to enable SSL VPN users to connect to the private network (address name OfficeAnet) through the toOfficeA IPsec VPN, you would enter:

```
config firewall policy
  edit 0
    set srcintf ssl.root
    set dstintf toOfficeA
    set srcaddr SSL_tunnel_users
    set dstaddr OfficeAnet
    set action accept
    set nat enable
    set schedule always
    set service ANY
  end
```

Policy-based connection

To configure interconnection with a policy-based IPsec VPN - web-based manager

1 Go to *Policy* > *Policy* > *Policy* and select *Create New*.

2 Enter the following information and select *OK*.

Source Interface/Zone	Select the virtual SSL VPN interface, *ssl.root*, for example.
Source Address	Select the firewall address that represents the IP address range assigned to SSL VPN clients.
Destination Interface/Zone	Select the FortiGate network interface that connects to the Internet.
Destination Address	Select the address of the IPsec VPN remote protected subnet.
Action	Select *IPSEC*.
VPN tunnel	Select the Phase 1 configuration name of your IPsec VPN.
Allow inbound	Enable
Allow outbound	Enable
NAT inbound	Enable
Leave other settings at their default values.	

To configure interconnection with a policy-based IPsec VPN - CLI

If, for example, you want to enable SSL VPN users to connect to the private network (address name OfficeAnet) through the OfficeA IPsec VPN, you would enter:

```
config firewall policy
  edit 0
    set srcintf ssl.root
    set dstintf port1
    set srcaddr SSL_tunnel_users
    set dstaddr OfficeAnet
    set action ipsec
    set schedule always
    set service ANY
    set inbound enable
    set outbound enable
    set natinbound enable
    set vpntunnel toOfficeA
  end
```

In this example, port1 is connected to the Internet.

Additional configuration options

Beyond the basics of setting up the SSL VPN, you can configure a number of other options that can help to ensure your internal network is secure and limit the possibility of attacks and viruses entering the network from an outside source.

Routing in tunnel mode

If are creating a SSL VPN connection in tunnel mode, you need to add a static route so that replies from the protected network can reach the remote SSL VPN client.

To add the tunnel mode route - web-based manager

1. Go to *Router* > *Static* > *Static Route* and select *Create New*.
2. Enter the *Destination IP/Mask* of the tunnel IP address that you assigned to the users of the web portal.
3. Select the SSL VPN virtual interface for the *Device*.
4. 4 Select *OK*.

To add the tunnel mode route - CLI

If you assigned 10.11.254.0/24 as the tunnel IP range, you would enter:

```
config router static
  edit <id>
    set device ssl.root
    set dst 10.11.254.0/24
    set gateway <gateway_IP>
end
```

Changing the port number for web portal connections

You can specify a different TCP port number for users to access the web portal login page through the HTTPS link. By default, the port number is 10443 and users can access the web portal login page using the following default URL:

`https://<FortiGate_IP_address>:10443/remote/login`

where `<FortiGate_IP_address>` is the IP address of the FortiGate interface that accepts connections from remote users.

To change the SSL VPN port - web-based manager

1. If *Current VDOM* appears at the bottom left of the screen, select *Global* from the list of VDOMs.
2. Go to *VPN* > *SSL* > *Config*.
3. Type an unused port number in *SSLVPN Login Port*, and select *Apply*.

To change the SSL VPN port - CLI

This is a global setting. For example, to set the SSL VPN port to 10443, enter:

```
config global
  config system global
    set sslvpn-sport 10443
  end
```

SSL offloading

Configuring SSL offloading that allows or denies client renegotiation, is configured in the CLI. This feature helps to resolve the issues that affect all SSL and TLS servers that support renegotiation, identified by the Common Vulnerabilities and Exposures system in CVE-2009-3555. The IETF is currently working on a TLS protocol change that will permanently resolve the issue. The SSL offloading renegotiation feature is considered a workaround until the IETF permanently resolves the issue.

The CLI command is `ssl-client-renegotiation` and is found in `config firewall vip` command.

Customizing the web portal login page

The default web portal login page shows only the *Name* and *Password* fields and the Login button, centred in the web browser window. You can customize the page with your company name or other information.

The login page is a form of replacement message, in HTML format. You can modify the content to display a customized message. Note that there are specific fields that must remain in the code to ensure the page appears correctly in the user's browser.

Before you begin, copy the default web portal login page text to a separate text file for safe-keeping. Afterward, if needed you can restore the text to the original version.

To configure the SSL VPN login page - web-based manager

1. If you want to edit the global login page and *Current VDOM* appears at the bottom left of the screen, select *Global* from the list of VDOMs.
2. Go to *System* > *Config* > *Replacement Messages*.
3. Expand the *SSL VPN* row and select the *Edit* icon for the *SSL VPN login message*.
4. Edit the HTML text. Note the following content that must remain on the page:
   - The login page must contain a form with `ACTION="%%SSL_ACT%%"` and `METHOD="%%SSL_METHOD%%"`
   - The form must contain the `%%SSL_LOGIN%%` tag to provide the login form.
   - The form must contain the `%%SSL_HIDDEN%%` tag.
5. Select *OK*.

To configure the SSL VPN login page - CLI

Do one of the following:

- If VDOMs are enabled and you want to modify the global login page, enter:

```
config global
config system replacemsg sslvpn sslvpn-login
```

- If you want to modify the login page for a VDOM, enter:

```
config vdom
edit <vdom_name>
  config system replacemsg-group
  edit default
    config sslvpn
      edit sslvpn-login
```

To change the login page content, enter the modified page content as a string. In this example, the page title is changed to "Secure Portal login" and headings are added above the login dialog which say "example.com Secure Portal":

```
    set buffer "<html><head><title>Secure Portal login</title>
       <meta http-equiv="Pragma" content="no-cache"><meta http-
       equiv="cache-control" content="no-cache"> <meta http-
       equiv="cache-control" content="must-revalidate"><link
       href="/sslvpn/css/login.css" rel="stylesheet"
       type="text/css"><script type="text/javascript">if (top &&
       top.location != window.location) top.location =
       top.location;if (window.opener && window.opener.top) {
       window.opener.top.location = window.opener.top.location;
       self.close(); }</script></head><body class="main">
       <center><table width="100%" height="100%" align="center"
       class="container" valign="middle" cellpadding="0"
       cellspacing="0"><tr valign=top><td align=center>
       <h1>example.com</h1><h3>Secure Portal</h3></td></tr><tr
       valign=top><td><form action="%%SSL_ACT%%"
       method="%%SSL_METHOD%%" name="f"><table class="list"
       cellpadding=10 cellspacing=0 align=center width=400
       height=180>%%SSL_LOGIN%%</table>%%SSL_HIDDEN%%</td></tr></
       table></form></center></body><script>document.forms[0].use
       rname.focus();</script></html>"
end
```

Your console application determines how the text wraps. It is easier to edit the code in a separate text editor and then paste the finished code into the `set buffer` command. Be sure to enclose the entire string in quotation (") marks.

Host Check

When you enable AV, FW, or AV-FW host checking in the web portal Security Control settings, each client is checked for security software that is recognized by the Windows Security Center. As an alternative, you can create a custom host check that looks for security software selected from the Host Check list. For more information, see "Portal settings" on page 1622.

The Host Check list includes default entries for many security software products.

To configure host checking, go to *VPN* > *SSL* > *Host Check*. To add to the list, select *Create New*.

Host integrity checking is only possible with client computers running Microsoft Windows platforms.

Host Check Software page	
Name	Enter a name for the host check list.
Type	Select the type of host checking, either AV or FW.
GUID	Enter the Globally Unique IDentifier (GUID) for the host check application, if known. Windows uses GUIDs to identify applications in the Windows Registry. The GUID can be found in the Windows registry in the HKEY_CLASSES_ROOT section.
Version	Enter the software's version.
Create New	Creates a new check item to add to the list below.

Edit	Modifies the settings within the software.
Delete	Removes the check software item from the list on the Host Check Software page. To remove multiple check software items from the list, select the check box for each row to remove, and select *Delete*.
#	The order in which each item is listed.
Target	The type of target that you chose.
Type	The type of check that you chose.
Action	The type of action that you chose.
Host Check Software window	
Type	Select how the FortiGate unit checks for the correct version of the application.
Action	Select one of the following: *Require* – If the item is found, the client meets the check item condition. *Deny* – If the item is found, the client is considered to not meet the check item condition. Use this option if it is necessary to prevent use of a particular security product.
File/Path	Enter the file name and path. This field appears when you select the *Type* of *File*.
Process	Enter the application's executable file name. This field appears when you select the *Type* of *Process*.
Registry	Enter the registry number of the application. This field appears when you select the *Type* of *Registry*.
Version	Enter the application's version.
MD5 Signatures (one per line)	Enter the MD5 signature for application executable file. You can enter more than one but each one needs to be on a separate line. You can use a third-party utility to calculate MD5 signatures or hashes for the file. Entering multiple MD5 signatures helps to match multiple versions of the application.

To configure host checking - CLI

To configure the full-access portal to check for AV and firewall software on client Windows computers, you would enter the following:

```
config vpn ssl web portal
  edit full-access
    set host-check av-fw
  end
```

To configure the full-access portal to perform a custom host check for FortiClient Host Security AV and firewall software, you would enter the following:

```
config vpn ssl web portal
  edit full-access
    set host-check custom
    set host-check-policy FortiClient-AV FortiClient-FW
  end
```

Creating a custom host check list

If you configure a custom host check for your web portal (see "Host Check" on page 1640), you choose security applications from the list on the *VPN* > *SSL* > *Host Check* page. The *Host Check* list includes default entries for many security software products. You can add, remove, or modify entries in this list.

Host integrity checking is only possible with client computers running Microsoft Windows platforms.

To add an entry to the Host Check list - web-based manager

1 Go to *VPN* > *SSL* > *Host Check.*

2 Select *Create New* and enter the following information:

Name	Enter a name of the application. The name does not need to match the actual application name.
Type	Select the type of security application. Can be AV for antivirus or FW for firewall.
GUID	Enter the Globally Unique IDentifier (GUID) for the host check application, if known. Windows uses GUIDs to identify applications in the Windows Registry. The GUID can be found in the Windows registry in the HKEY_CLASSES_ROOT section.
Version	The version of the security application. To get the exact versioning, in Windows right-click on the .EXE file of the application and select *Properties*. Select the *Version* tab.
Create New	If you do not know the GUID, add alternative checks for the application. The security software is considered found only if all checks succeed.
Type	Select how to check for the application: • **File** — Look for a file. This could be the application's executable file or any other file that would confirm the presence of the application. In *File/Path*, enter the full path to the file. Where applicable, you can use environment variables enclosed in percent (%) marks. For example, `%ProgramFiles%\Fortinet\FortiClient\FortiClient.exe` • **Process** — Look for the application as a running process. In *Process,* enter the application's executable file name. • **Registry** — Search for a Windows Registry entry. In *Registry,* enter a registry item, for example `HKLM\SOFTWARE\Fortinet\FortiClient\Misc`

Action	Select one of • **Require** — If the item is found, the client meets the check item condition. • **Deny** — If the item is found, the client is considered to not meet the check item condition. Use this option if it is necessary to prevent use of a particular security product.
MD5 Signatures	If *Type* is *File* or *Process*, enter one or more known MD5 signatures for the application executable file.You can use a third-party utility to calculate MD5 signatures or hashes for any file. You can enter multiple signatures to match multiple versions of the application.

3 Select *OK*.

Windows OS check

The Windows patch check enables you to define the minimum Windows version and patch level allowed when connecting to the SSL VPN portal. When the user attempts to connect to the web portal, FortiOS performs a query on the version of Windows the user has installed. If it does not match the minimum requirement, the connection is denied. The Windows patch check is configured in the CLI.

The following example shows how you would add an OS check to the g1portal web portal. This OS check accepts all Windows XP users and Windows 2000 users running patch level 3.

To specify the acceptable patch level, you set the `latest-patch-level` and the `tolerance`. The lowest acceptable patch level is `latest-patch-level` minus `tolerance`. In this case, `latest-patch-level` is 3 and `tolerance` is 1, so 2 is the lowest acceptable patch level.

```
config vpn ssl web portal
  edit g1portal
    set os-check enable
    config os-check-list windows-2000
      set action check-up-to-date
      set latest-patch-level 3
      set tolerance 1
    end
    config os-check-list windows-xp
      set action allow
    end
  end
```

Configuring cache cleaning

When the SSL VPN session ends, the client browser cache may retain some information. To enhance security, cache cleaning clears this information just before the SSL VPN session ends.

The cache cleaner is effective only if the session terminates normally. The cache is not cleaned if the session ends due to a malfunction, such as a power failure.

To enable cache cleaning - web-based manager

1 Go to *VPN* > *SSL* > *Portal,* select the web portal and then select *Edit*.

2 Select the *Settings* and then select the *Security Control* tab.

3 Select *Clean Cache*.

4 Select *OK* then *Apply*.

To enable cache cleaning - CLI

To enable cache cleaning on the full-access portal, you would enter:

```
config vpn ssl web portal
  edit full-access
    set cache-cleaner enable
  end
```

Cache cleaning requires a browser plug-in. If the user does not have the plug-in, it is automatically downloaded to the client computer.

Configuring virtual desktop

Available for Windows XP, Windows Vista, and Windows 7 client PCs, the virtual desktop feature completely isolates the SSL VPN session from the client computer's desktop environment. All data is encrypted, including cached user credentials, browser history, cookies, temporary files, and user files created during the session. When the SSL VPN session ends normally, the files are deleted. If the session ends due to a malfunction, files might remain, but they are encrypted, so the information is protected.

When the user starts an SSL VPN session which has virtual desktop enabled, the virtual desktop replaces the user's normal desktop. When the virtual desktop exits, the user's normal desktop is restored.

Virtual desktop requires the Fortinet cache cleaner plug in. If the plug in is not present, it is automatically downloaded to the client computer.

To enable virtual desktop - web-based manager

1 Go to *VPN* > *SSL* > *Portal,* select the web portal and then select *Edit*.

2 Select the *Settings* and then select the *Virtual Desktop* tab.

3 Select *Enable Virtual Desktop*.

4 Enable the other options as needed.

5 Optionally, select an Application Control List.

See "Configuring virtual desktop application control".

6 Select *OK*, then select *Apply*.

To enable virtual desktop - CLI

To enable virtual desktop on the full-access portal and apply the application control list List1, for example, you would enter:

```
config vpn ssl web portal
  edit full-access
    set virtual-desktop enable
    set virtual-desktop-app-list List1
  end
```

Configuring virtual desktop application control

You can control which applications users can run on their virtual desktop. To do this, you create an Application Control List of either allowed or blocked applications. When you configure the web portal, you select the list to use.

Configuration is located in *VPN* > *SSL* > *Virtual Desktop Application Control* and select *Create New*.

Virtual Desktop Application Control List page	
Name	Enter a name for the virtual desktop application list.
Allow the applications on the list and block all others	Select to allow the applications on this list.
Block the applications on the list and allow all others	Select to block the applications on the list.
Create New	Creates a new application signature.
Edit	Modifies the settings within the application signature.
Delete	Removes an application signature from the list on the Virtual Desktop Application Control List page. To remove multiple signatures from the list, on the Virtual Desktop Application Control List page, select the check box for the applications and select *Delete*.
Applications	The name of the application.
Application Signatures (window)	
Name	Enter the name of the application.
MD5 Signatures (one per line)	Enter the MD5 signature for application executable file. You can enter more than one but each one requires to be on a separate line. Entering multiple MD5 signatures helps to match multiple versions of the application.

There are two types of application control list:

- allow the listed applications and block all others

or

- block the listed applications and allow all others.

You can create multiple application control lists, but each in web portal you can select only one list to use.

To create an Application Control List - web-based manager

1 Go to *VPN* > *SSL* > *Virtual Desktop Application Control* and select *Create New*.

2 Enter a *Name* for the list.

3 Select one of the following:
   - *Allow the applications on this list and block all others*
   - *Block the applications on this list and allow all others*
4 Select *Add*.
5 Enter a *Name* for the application.

   This can be any name and does not have to match the official name of the application.
6 Enter one or more known *MD5 Signatures* for the application executable file.

   You can use a third-party utility to calculate MD5 signatures or hashes for any file. You can enter multiple signatures to match multiple versions of the application.
7 Select *OK*.
8 Repeat steps 4 through 7 for each additional application.
9 Select *OK*.

To create an Application Control List - CLI

If you want to add BannedApp to List1, a list of blocked applications, you would enter:

```
config vpn ssl web virtual-desktop-app-list
  edit "List1"
    set action block
    config apps
      edit "BannedApp"
        set md5s "06321103A343B04DF9283B80D1E00F6B"
      end
  end
```

Configuring client OS Check

The SSLVPN client OS Check feature can determine if clients are running the Windows 2000, Windows XP, Windows Vista or Windows 7 operating system. You can configure the OS Check to do any of the following:

- allow the client access
- allow the client access only if the operating system has been updated to a specified patch (service pack) version
- deny the client access

The OS Check has no effect on clients running other operating systems.

To configure OS Check - CLI

OS Check is configurable only in the CLI.

```
config vpn ssl web portal
  edit <portal_name>
    set os-check enable
    config os-check-list {windows-2000 | windows-xp
       | windows-vista | windows-7}
      set action {allow | check-up-to-date | deny}
      set latest-patch-level {disable | 0 - 255}
      set tolerance {tolerance_num}
    end
  end
```

Adding WINS and DNS services for clients

You can specify the WINS or DNS servers that are made available to SSL-VPN clients.

DNS servers provide the IP addresses that browsers need to access web sites. For Internet sites, you can specify the DNS server that your FortiGate unit uses. If SSL VPN users will access intranet sites using URLs, you need to provide them access to the intranet's DNS server. You specify a primary and a secondary DNS server.

A WINS server provides IP addresses for named servers in a Windows domain. If SSL VPN users will access a Windows network, you need to provide them access to the domain WINS server. You specify a primary and a secondary WINS server.

To specify WINS and DNS services for clients - web-based manager

1 Go to *VPN* > *SSL* > *Config*.
2 Select the *Expand Arrow* to display the *Advanced* section.
3 Enter the IP addresses of DNS servers in the *DNS Server* fields as needed.
4 Enter the IP addresses of WINS servers in the *WINS Server* fields as needed.
5 Select *Apply*.

To specify WINS and DNS services for clients - CLI

```
config vpn ssl settings
  set dns-server1 <address_ipv4>
  set dns-server2 <address_ipv4>
  set wins-server1 <address_ipv4>
  set wins-server2 <address_ipv4>
end
```

Setting the idle timeout setting

The idle timeout setting controls how long the connection can remain idle before the system forces the remote user to log in again. For security, keep the default value of 300 seconds (5 minutes) or less.

To set the idle timeout - web-based manager

1 Go to *VPN* > *SSL* > *Config*.
2 In the *Idle Timeout* field, enter the timeout value.

   The valid range is from 10 to 28800 seconds.
3 Select *Apply*.

To set the idle timeout - CLI

```
config vpn ssl settings
  set idle-timeout <seconds_int>
end
```

SSL VPN logs

Logging is available for SSP VPN traffic so you can monitor users connected to the FortiGate unit and their activity.

For more information on configuring logs on the FortiGate unit, see the *Logging and Reporting* chapter of *The Handbook*.

To enable logging of SSL VPN events - web-based manager

1 Go to *Log&Report* > *Log Config* > *Log Setting*.

2 Select *Enable*, and then select one or more of the following options:

- SSL VPN user authentication event
- SSL VPN administration event
- SSL VPN session event

3 Select *Apply*.

To enable logging of SSL VPN events - CLI

```
config log {fortianalyzer | memory | syslog} filter
  set event enable
  set sslvpn-log-adm enable
  set sslvpn-log-auth enable
  set sslvpn-log-session enable
end
```

Logging of SSL VPN traffic is configured when you create the security policy, by selecting the *Log Allowed Traffic* option in the web-based manager or using the CLI command `set logtraffic enable` under `config firewall policy`.

Viewing log data

To view the SSL VPN log data, in the web-based manager, go to *Log&Report* > *Log & Archive Access* and select either the *Event Log* or *Traffic Log*.

In event log entries, look for the sub-types “sslvpn-session” and “sslvpn-user”.

In the traffic logs, look for the sub-type “allowed”. For web-mode traffic, the source is the host IP address. For tunnel-mode traffic, the source is the address assigned to the host from the SSL VPN address pool.

For information about how to interpret log messages, see the *FortiGate Log Message Reference*.

Monitoring active SSL VPN sessions

You can go to *User* > *Monitor* to view a list of active SSL VPN sessions. The list displays the user name of the remote user, the IP address of the remote client, and the time the connection was made. You can also see which services are being provided, and delete an active web session from the FortiGate unit.

To monitor SSL VPNs - web-based manager

To view the list of active SSL VPN sessions, go to *VPN* > *SSL* > *Monitor*.

When a tunnel-mode user is connected, the *Description* field displays the IP address that the FortiGate unit assigned to the remote host.

If required, you can end a session/connection by selecting its check box and then selecting the *Delete* icon.

To monitor SSL VPNs - CLI

To list all of the SSL VPN sessions and their index numbers:

```
get vpn ssl monitor
```

To delete tunnel-mode or web-mode sessions:

```
execute vpn sslvpn del-tunnel <index_int>
```

```
execute vpn sslvpn del-web <index_int>
```

Troubleshooting

Here is a list of common SSL VPN problems and the likely solutions.

No response from SSL VPN URL	Check SSL VPN port assignment (default 10443). Verify the SSL VPN security policy.
Error: “The web page cannot be found.”	Check URL: `https://<FortiGate_IP>:<SSLVPN_port>/remote/login`
Tunnel connects, but there is no communication.	Check that there is a static route to direct packets destined for the tunnel users to the SSL VPN interface. See “Routing for tunnel mode” on page 1635.

Tunnel-mode connection shuts down after a few seconds	This issue occurs when there are multiple interfaces connected to the Internet, for example, a dual WAN configuration. Upgrade to the latest firmware then use the following CLI command:
	`config vpn ssl settings`
	`set route-source-interface enable`
	`end`

Error: “Destination address of Split Tunneling policy is invalid.”	The SSL VPN security policy uses the ALL address as its destination. Specify the address of the protected network instead.
When trying to connect using FortiClient the error message “Unable to logon to the server. Your user name or password may not be configured properly for this connection. (-12)” appears. When trying to login to the web portal, login and password are entered and login page will be sent back.	Cookies must be enabled for SSL VPN to function in Web portal or with FortiClient. Access to the web portal or tunnel will fail if Internet Explorer has the privacy Internet Options set to High. If set to High, Internet Explorer will: Block cookies that do not have a compact privacy policy. Block cookies that use personally identifiable information without your explicit consent.

The SSL VPN client

The remote client connects to the SSL VPN tunnel in various ways, depending on the VPN configuration.

- Web mode requires nothing more than a web browser. Microsoft Internet Explorer, Mozilla Firefox, and Apple Safari browsers are supported. For detailed information about supported browsers see the Release Notes for your FortiOS firmware.
- Tunnel mode establishes a connection to the remote protected network that any application can use. This requires FortiClient SSL VPN application that sends and receives data through the SSL VPN tunnel.

  If the client computer runs Microsoft Windows, they can download the tunnel mode client from the web portal Tunnel Mode widget. After installing the client, they can start and stop tunnel operation from the Tunnel Mode widget, or open the tunnel mode client as a standalone application. The tunnel mode client is available on the Start menu at *All Programs* > *FortiClient* > *FortiClient SSL VPN*.

  If the client computer runs Linux or Mac OS X, the user needs to download the tunnel mode client application from the Fortinet Support web site. See the Release Notes for your FortiOS firmware for the specific operating system versions that are supported. On Linux and Mac OS X platforms, tunnel mode operation cannot be initiated from the web portal Tunnel Mode widget. The remote user must use the standalone tunnel client application.
- The virtual desktop application creates a virtual desktop on a user's PC and monitors the data read/write activity of the web browser running inside the virtual desktop. When the application starts, it presents a 'virtual desktop' to the user. The user starts the web browser from within the virtual desktop and connects to the SSL VPN web portal. The browser file/directory operation is redirected to a new location, and the data is encrypted before it is written to the local disk. When the virtual desktop application exits normally, all the data written to the disk is removed. If the session terminates abnormally (power loss, system failure), the data left behind is encrypted and unusable to the user. The next time you start the virtual desktop, the encrypted data is removed.

FortiClient

Remote users can use FortiClient software to initiate an SSL VPN tunnel to connect to the internal network. FortiClient uses local port TCP 1024 to initiate an SSL encrypted connection to the FortiGate unit, on port TCP 10443. When connection using FortiClient, the FortiGate unit authenticates the FortiClient SSL VPN request based on the user group options. The FortiGate unit establishes a tunnel with the client and assigns a virtual IP address to the client PC. Once the tunnel has been established, the user can access the network behind the FortiGate unit.

There are three FortiClient application options available, depending on your requirements:

- FortiClient/FortiClient Premium
- FortiClient Lite (free) - http://download.cnet.com/FortiClient-Lite/3000-2239_4-75532356.html
- Standalone client (free)
- iPhone and iPad app available for free from the iTunes App Store.

For details on configuring FortiClient for SSL VPN, see the FortiClient documentation.

Downloading the SSL VPN tunnel mode client

SSL VPN standalone tunnel client applications are available for Windows, Linux, and Mac OS X systems (see the Release Notes for your FortiOS firmware for the specific versions that are supported). There are separate download files for each operating system.

Windows users can also download the tunnel mode client from an SSL VPN web portal that contains the Tunnel Mode widget.

The most recent version of the SSL VPN standalone client applications can be found at: http://support.fortinet.com/

To download the SSL VPN tunnel client

1. Log in to Fortinet Support at http://support.fortinet.com/.
2. In the Download area, select Firmware Images.
3. Select FortiGate.
4. Select *v4.00* and then select the latest firmware release.
5. Select *SSL VPN Clients*.
6. Select the appropriate client.

   Windows: `SslvpnClient.exe` or `SslvpnClient.msi`

   Linux: `forticlientsslvpn_linux_`<version>`.tar.gz`

   Mac OS X: `forticlientsslvpn_macosx_`<version>`.dmg`

The location of the SSL VPN tunnel client on the Support web site is subject to change. If you have difficulty finding the appropriate file, contact Customer Support.

Tunnel mode client configuration

The FortiClient SSL VPN tunnel client requires basic configuration by the remote user to connect to the SSL VPN tunnel. When distributing the FortiClient software, provide the following information for the remote user to enter once the client software has been started. Once entered, they can select *Connect* to begin a SSL VPN session.

Connection Name	If you have pre-configured the connection settings, select the connection from the list and then select *Connect*. Otherwise, enter the settings in the fields below.
Server Address	Enter the IP address or FQDN of the FortiGate unit that hosts the SSL VPN.
Username	Enter your user name.
Password	Enter the password associated with your user account.
Client Certificate	Use this field if the SSL VPN requires a certificate for authentication. Select the required certificate from the drop-down list. The certificate must be installed in the Internet Explorer certificate store.
Settings...	Select to open the *Settings* dialog and select the *Keep connection alive until manually stopped* check box to prevent tunnel connections from closing due to inactivity.

Uninstalling the tunnel mode client

If you want to remove the tunnel mode client application, follow the instructions for your operating system.

To uninstall from Windows

1. In the *Control Panel*, select *Programs and Features (Add or Remove Programs* in Windows XP).
2. Select *FortiClient SSL VPN* and then *Remove*.

To uninstall from Linux

Remove/delete the folder containing all the SSL VPN client application files.

To uninstall from Mac OS X

In the Applications folder, select `forticlientsslvpn.app` and drag it into the Trash.

Setup examples

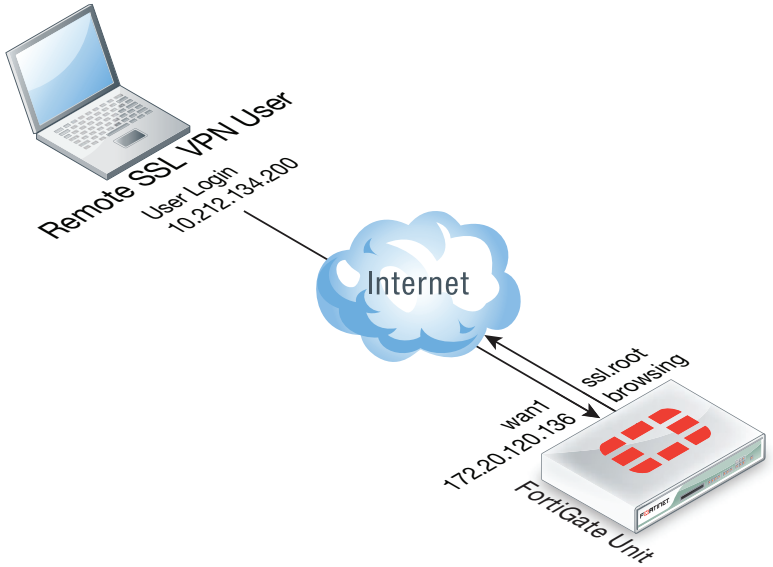
The examples in this chapter demonstrate the basic configurations needed for common connections to the SSL VPN tunnel and portals, applying the steps outlined in the chapter "Basic Configuration" on page 1617.

The example included are:

- Secure internet browsing
- Split Tunnel
- Multiple user groups with different access permissions example

Secure internet browsing

This example sets up an SSL VPN tunnel to provide remote users the ability to access the Internet while travelling, and ensure that they are not subjected to malware and other dangers, by using the corporate firewall to filter all of their Internet traffic. Essentially, the remote user will connect to the corporate FortiGate unit to surf the Internet.



Using SSL VPN and FortiClient SSL VPN software, you create a means to use the corporate FortiGate to browse the web safely.

Creating an SSL VPN IP pool and SSL VPN web portal

1. Go to *VPN* > *SSL* > *Config* and for *IP Pools* select *Edit* and add *SSLVPN_TUNNEL_ADDR1* to the *Selected* table.
2. Create the SSL VPN portal to by going to *VPN* > *SSL* > *Portal* and selecting *tunnel-access*.

3 Select the *Edit* pencil icon for the Tunnel Mode widget and enter the following:

Name	Browsing
IP Mode	User Group
IP Pools	SSLVPN_TUNNEL_ADDR1

4 Select *OK*.

Creating the SSL VPN user and user group

Create the SSL VPN user and add the user to a user group configured for SSL VPN use.

1 Go to *User* > *User* > *User* and select *Create New* to add the user:

User Name	twhite
Password	password

2 Select *OK*.

3 Go to *User* > *User Group* > *User Group* and select *Create New* to add `twhite` to the SSL VPN user group:

Name	Tunnel
Type	Firewall
Allow SSL-VPN Access	tunnel-access

Make sure you select the *Allow SSL VPN Access* option. If not selected, the *Tunnel* user group will not appear in the group list when configuring the authentication security policy.

4 Move *twhite* to the *Members* list.

5 Select *OK*.

Creating a static route for the remote SSL VPN user

Create a static route to direct traffic destined for tunnel users to the SSL VPN tunnel.

1 Go to *Router* > *Static* > *Static* and select *Create New* to add the static route:

Destination IP/Mask	10.212.134.0/255.255.255.0
Device	ssl.root

The *Destination IP/Mask* matches the network address of the remote SSL VPN user.

2 Select *OK*.

Creating security policies

Create an SSL VPN security policy with SSL VPN user authentication to allow SSL VPN traffic to enter the FortiGate unit. Create a normal security policy from ssl.root to wan1 to allow SSL VPN traffic to connect to the Internet.

1 Go to ***Policy > Policy > Policy*** and select ***Create New*** to add the SSL VPN security policy:

Source Interface/Zone	wan1
Source Address	all
Destination Interface/Zone	ssl.root
Destination Address	all
Action	SSL-VPN

2 Select *Configure SSL-VPN Users* and select *Add* to add an authentication rule for the remote user:

Selected User Groups	Tunnel
Selected Services	ANY
Schedule	always

If the *Tunnel* user group does not appear in the *User Group* list, ensure you select the *SSL VPN Access* option when creating the user group. If that option is not selected, the *Tunnel* user group will not appear in the user group list when configuring the authentication security policy.

3 Select *OK*.

4 Select *Create New* to add a security policy that allows remote SSL VPN users to connect to the Internet:

Source Interface/Zone	ssl.root
Source Address	all
Destination Interface/Zone	wan1
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT

5 Select *OK*.

Results

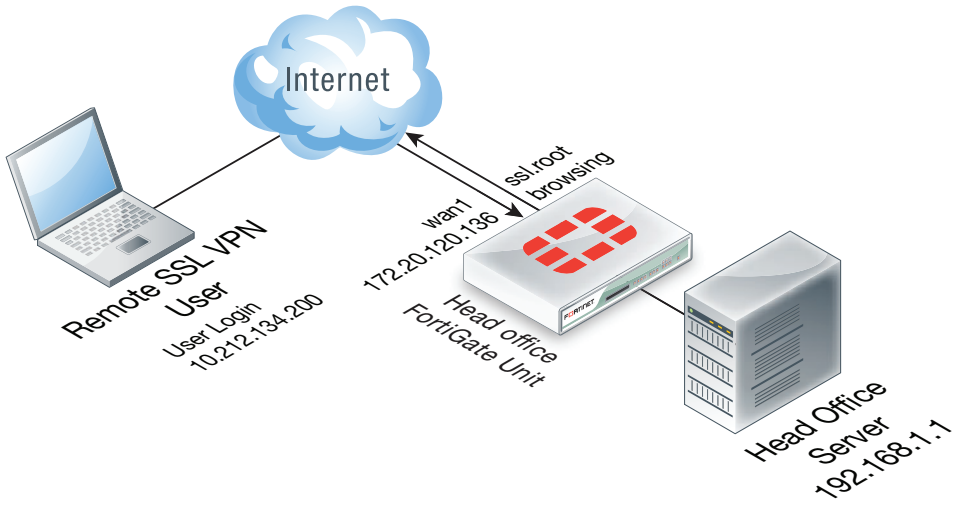
Using FortiClient SSLVPN application, log into the VPN using the address `https://172.20.120.136:10443/` and log in as `twhite`. Once connected, you can browse the Internet.

From the FortiGate web-based manager go to *VPN > Monitor > SSL-VPN Monitor* to view the list of users connected using SSL VPN. The *Subsession* entry indicates the split tunnel which redirects to the Internet.

Split Tunnel

For this example, the remote users are configured to be able to securely access head office internal network servers, and browse the Internet through the head office firewall. This will enable the remote user to use the FortiGate security to connect to the internal network and the web.

This solution describes how to configure FortiGate SSL VPN split tunnelling using the FortiClient SSL VPN software, available from the Fortinet Support site.



Using split tunneling, all communication from remote SSL VPN users to the head office internal network and to the Internet uses an SSL VPN tunnel between the user's PC and the head office FortiGate unit. Connections to the Internet are routed back out the head office FortiGate unit to the Internet. Replies come back into the head office FortiGate unit before being routed back through the SSL VPN tunnel to the remote user.

Creating a firewall address for the head office server

1 Go to *Firewall Objects* > *Address* > *Address* and select *Create New* and add the head office server address:

Address Name	Head office server
Type	Subnet / IP Range
Subnet / IP Range	192.168.1.12
Interface	Internal

2 Select *OK*.

Creating an SSL VPN IP pool and SSL VPN web portal

1 Go to *VPN* > *SSL* > *Config* and for *IP Pools* select *Edit* and add *SSLVPN_TUNNEL_ADDR1* to the *Selected* table.

2 Create the SSL VPN portal to by going to *VPN* > *SSL* > *Portal* and selecting *tunnel-access*.

3 Select the *Edit* pencil icon for the *Tunnel Mode* widget and enter the following:

Name	Connect to head office server
IP Mode	User Group
IP Pools	SSLVPN_TUNNEL_ADDR1
Split Tunneling	Enable

4 Select *OK*.

Creating the SSL VPN user and user group

Create the SSL VPN user and add the user to a user group configured for SSL VPN use.

1 Go to *User* > *User* > *User*, select *Create New* and add the user:

User Name	twhite
Password	password

2 Select *OK*.

3 Go to *User* > *User Group* > *User Group* and select *Create New* to add *twhite* to the SSL VPN user group:

Name	Tunnel
Type	Firewall
Allow SSL-VPN Access	tunnel-access

Make sure you select the *Allow SSL-VPN Access* option. If not selected, the *Tunnel* user group will not appear in the group list when configuring the authentication security policy.

4 Move *twhite* to the *Members* list.

5 Select *OK*.

Creating a static route for the remote SSL VPN user

Create a static route to direct traffic destined for tunnel users to the SSL VPN tunnel.

1 Go to *Router* > *Static* > *Static* and select *Create New* to add the static route:

Destination IP/Mask	10.212.134.0/255.255.255.0
Device	ssl.root

The *Destination IP/Mask* matches the network address of the remote SSL VPN user.

2 Select *OK*.

Creating security policies

Create an SSL VPN security policy with SSL VPN user authentication to allow SSL VPN traffic to enter the FortiGate unit. Create a normal security policy from ssl.root to wan1 to allow SSL VPN traffic to connect to the Internet.

1 Go to *Policy* > *Policy* > *Policy* and select *Create New* to add the SSL VPN security policy:

Source Interface/Zone	wan1
Source Address	all
Destination Interface/Zone	internal
Destination Address	Head office server
Action	SSL-VPN

2 Select *Configure SSL-VPN Users* and select *Add* to add an authentication rule for the remote user:

Selected User Groups	Tunnel
Selected Services	ANY
Schedule	always

If the *Tunnel* user group does not appear in the *User Group* list, ensure you select the *SSL VPN Access* option when creating the user group. If that option is not selected, the *Tunnel* user group will not appear in the user group list when configuring the authentication security policy.

3 Select *OK*.

4 Select *Create New* to add a security policy that allows remote SSL VPN users to connect to the Internet:

Source Interface/Zone	ssl.root
Source Address	all
Destination Interface/Zone	wan1
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT

5 Select *OK*.

Results

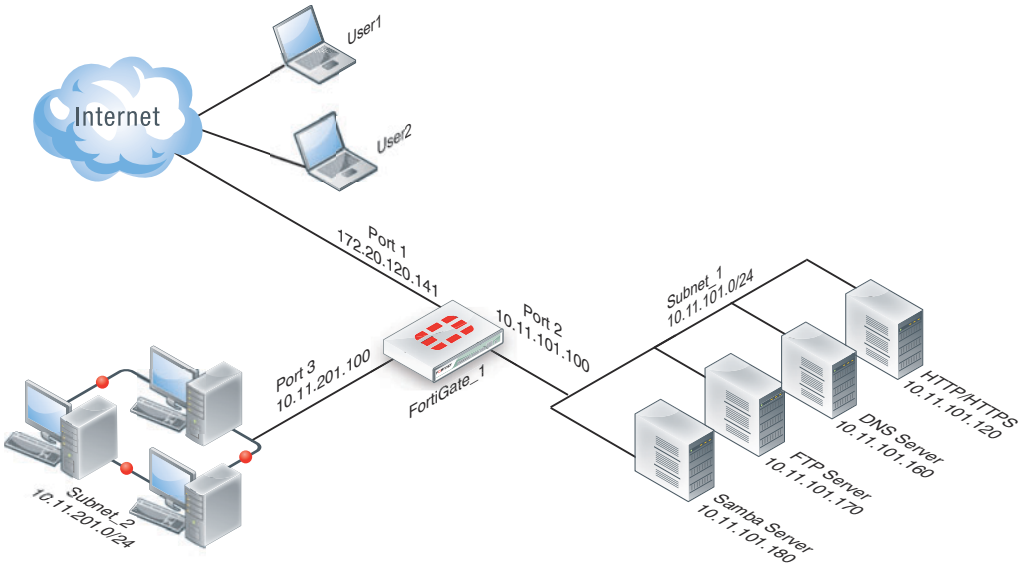
Using the FortiClient SSL VPN application on the remote PC, connect to the VPN using the address `https://172.20.120.136:10443/` and log in with the `twhite` user account. Once connected, you can connect to the head office server or browse to web sites on the Internet.

From the web-based manager go to *VPN* > *Monitor* > *SSL-VPN Monitor* to view the list of users connected using SSL VPN. The *Subsession* entry indicates the split tunnel which redirects SSL VPN sessions to the Internet.

Multiple user groups with different access permissions example

You might need to provide access to several user groups with different access permissions. Consider the following example topology in which users on the Internet have controlled access to servers and workstations on private networks behind a FortiGate unit.

Figure 161: SSL VPN configuration for different access permissions by user group



In this example configuration, there are two users:

- user1 can access the servers on Subnet_1
- user2 can access the workstation PCs on Subnet_2

You could easily add more users to either user group to provide them access to the user group's assigned web portal.

General configuration steps

1. Create firewall addresses for
   - the destination networks
   - two non-overlapping tunnel IP address ranges that the FortiGate unit will assign to tunnel clients in the two user groups
2. Create two web portals.
3. Create two user accounts, user1 and user2.
4. Create two user groups. For each group, add a user as a member and select a web portal. In this example, user1 will belong to group1, which will be assigned to portal1.
5. Create security policies:
   - two SSL VPN security policies, one to each destination
   - two tunnel-mode policies to allow each group of users to reach its permitted destination network
6. Create the static route to direct packets for the users to the tunnel.

Creating the firewall addresses

Security policies do not accept direct entry of IP addresses and address ranges. You must define firewall addresses in advance.

Creating the destination addresses

SSL VPN users in this example can access either Subnet_1 or Subnet_2.

To define destination addresses - web-based manager

1 Go to *Firewall Objectes* > *Address* > *Address.*

2 Select *Create New*, enter the following information, and select *OK*:

Address Name	Subnet_1
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0/24
Interface	port2

3 Select *Create New*, enter the following information, and select *OK*.

Address Name	Subnet_2
Type	Subnet / IP Range
Subnet / IP Range	10.11.201.0/24
Interface	port3

To define destination addresses - CLI

```
config firewall address
  edit Subnet_1
    set type ipmask
    set subnet 10.11.101.0/24
    set associated-interface port2
  next
  edit Subnet_2
    set type ipmask
    set subnet 10.11.201.0/24
    set associated-interface port3
  end
```

Creating the tunnel client range addresses

To accommodate the two groups of users, split an otherwise unused subnet into two ranges. The tunnel client addresses must not conflict with each other or with other addresses in your network.

To define tunnel client addresses - web-based manager

1 Go to *Firewall Objects* > *Address* > *Address.*

2 Select *Create New*, enter the following information, and select *OK*:

Address Name	Tunnel_group1
Type	Subnet / IP Range

Subnet / IP Range	10.11.254.[1-50]
Interface	Any

3 Select *Create New*, enter the following information, and select *OK*.

Address Name	Tunnel_group2
Type	Subnet / IP Range
Subnet / IP Range	10.11.254.[51-100]
Interface	Any

To define tunnel client addresses - CLI

```
config firewall address
  edit Tunnel_group1
    set type iprange
    set end-ip 10.11.254.50
    set start-ip 10.11.254.1
  next
  edit Tunnel_group2
    set type iprange
    set end-ip 10.11.254.100
    set start-ip 10.11.254.51
  end
```

Creating the web portals

To accommodate two different sets of access permissions, you need to create two web portals, portal1 and portal2, for example. Later, you will create two SSL VPN user groups, one to assign to portal1 and the other to assign to portal2.

To create the portal1 web portal

1 Go to *VPN* > *SSL* > *Portal* and select *Create New*.
2 Enter `portal1` in the *Name* field and select *OK*.
3 In *Applications*, select all of the application types that the users can access.
4 Select the *Edit* icon on the *Tunnel Mode* widget.
5 In *IP Pools*, select *Edit*.
6 In the *Available* list, select *Tunnel_ group1* and then select the down arrow button. Select *OK*.
7 Select *OK* in the *Tunnel Mode* widget.
8 Select *OK*.

To create the portal2 web portal

1 Go to *VPN* > *SSL* > *Portal* and select *Create New*.
2 Enter `portal2` in the *Name* field and select *OK*.
3 In *Applications*, select all of the application types that the users can access.
4 Select the *Edit* icon on the *Tunnel Mode* widget.
5 In *IP Pools*, select *Edit*.
6 In the *Available* list, select *Tunnel_ group2* and then select the down arrow button. Select *OK*.

7 Select *OK* in the *Tunnel Mode* widget.

8 Select *OK*.

To create the web portals - CLI

```
config vpn ssl web portal
  edit portal1
    set allow-access ftp ping rdp smb ssh telnet vnc web
    config widget
      edit 0
        set type tunnel
        set tunnel-status enable
        set ip-pools "Tunnel_group1"
      end
    next
  edit portal2
    set allow-access ftp ping rdp smb ssh telnet vnc web
    config widget
      edit 0
        set type tunnel
        set tunnel-status enable
        set ip-pools "Tunnel_group2"
      end
    end
  end
```

Later, you can configure these portals with bookmarks and enable connection tool capabilities for the convenience of your users.

Creating the user accounts and user groups

After enabling SSL VPN and creating the web portals that you need, you need to create the user accounts and then the user groups that require SSL VPN access.

Go to *User* > *User* and create user1 and user2 with password authentication. After you create the users, create the SSL VPN user groups.

To create the user groups - web-based manager

1 Go to *User* > *User Group* > *User Group*.

2 Select *Create New* and enter the following information:

Name	group1
Type	SSL VPN
Portal	portal1

3 From the *Available* list, select *user1* and move it to the *Members* list by selecting the right arrow button.

4 Select *OK*.

5 Repeat steps 2 through 4 to create group2, assigned to portal2, with user2 as its only member.

To create the user groups - CLI

```
config user group
  edit group1
```

```
    set group-type sslvpn
    set member user1
    set sslvpn-portal portal1
  next
  edit group2
    set group-type sslvpn
    set member user2
    set sslvpn-portal portal2
  end
```

Creating the security policies

You need to define security policies to permit your SSL VPN clients, web-mode or tunnel-mode, to connect to the protected networks behind the FortiGate unit. Before you create the security policies, you must define the source and destination addresses to include in the policy. See "Creating the firewall addresses" on page 1662.

Two types of security policy are required:

- An SSL VPN policy enables clients to authenticate and permits a web-mode connection to the destination network. In this example, there are two destination networks, so there will be two SSL VPN policies. The authentication, ensures that only authorized users access the destination network.
- A tunnel-mode policy is a regular ACCEPT security policy that enables traffic to flow between the SSL VPN tunnel interface and the protected network. Tunnel-mode policies are required if you want to provide tunnel-mode connections for your clients. In this example, there are two destination networks, so there will be two tunnel-mode policies.

To create the SSL VPN security policies - web-based manager

1 Go to *Policy* > *Policy* > *Policy.*

2 Select *Create New and* enter the following information:

Source Interface/Zone	port1
Source Address	All
Destination Interface/Zone	port2
Destination Address	Subnet_1
Action	SSL-VPN

3 Select *Add* and enter the following information:

User Group	group1
Service	Any

4 Select *OK*, and then select *OK* again.

5 Select *Create New and* enter the following information:

Source Interface/Zone	port1
Source Address	All
Destination Interface/Zone	port3

Destination Address	Subnet_2
Action	SSL-VPN

6 Select *Add* and enter the following information:

User Group	group2
Service	Any

7 Select *OK*, and then select *OK* again.

To create the SSL VPN security policies - CLI

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr Subnet_1
    set action ssl-vpn
    set nat enable
    config identity-based-policy
      edit 1
        set groups group1
        set schedule always
        set service ANY
      end
    next
  edit 0
    set srcintf port1
    set dstintf port3
    set srcaddr all
    set dstaddr Subnet_2
    set action ssl-vpn
    set nat enable
    config identity-based-policy
      edit 1
        set groups group2
        set schedule always
        set service ANY
      end
    end
```

To create the tunnel-mode security policies - web-based manager

1 Go to *Policy* > *Policy* > *Policy.*

2 Select *Create New,* enter the following information, and select *OK*:

Source Interface/Zone	sslvpn tunnel interface (ssl.root)
Source Address	Tunnel_group1
Destination Interface/Zone	port2
Destination Address	Subnet_1
Action	ACCEPT
NAT	Enable

3 Select *Create New,* enter the following information, and select *OK*:

Source Interface/Zone	sslvpn tunnel interface (ssl.root)
Source Address	Tunnel_group2
Destination Interface/Zone	port3
Destination Address	Subnet_2
Action	ACCEPT
NAT	Enable

To create the tunnel-mode security policies - CLI

```
config firewall policy
  edit 0
    set srcintf ssl.root
    set dstintf port2
    set srcaddr Tunnel_group1
    set dstaddr Subnet_1
    set action accept
    set schedule always
    set service ANY
    set nat enable
  next
  edit 0
    set srcintf ssl.root
    set dstintf port3
    set srcaddr Tunnel_group2
    set dstaddr Subnet_2
    set action accept
    set schedule always
    set service ANY
    set nat enable
  end
end
```

Create the static route to tunnel mode clients

Reply packets destined for tunnel mode clients must pass through the SSL VPN tunnel. You need to define a static route to accomplish this.

To add a route to SSL VPN tunnel mode clients - web-based manager

1 Go to *Router* > *Static* > *Static Route* and select *Create New*.

2 Enter the following information and select *OK*.

Destination IP/Mask	`10.11.254.0/24` This IP address range covers both ranges that you assigned to SSL VPN tunnel-mode users. See “Creating the tunnel client range addresses” on page 1662.
Device	Select the SSL VPN virtual interface, *ssl.root* for example.
Leave other settings at their default values.	

To add a route to SSL VPN tunnel mode clients - CLI

```
config router static
  edit 0
    set device ssl.root
    set dst 10.11.254.0/24
  end
```

Enabling SSL VPN operation

By default, SSL VPN is not enabled. SSL VPN is configured in the CLI only.

To enable SSL VPN and set tunnel address range - CLI

```
config vpn ssl settings
  set sslvpn-enable enable
  set tunnel-ip-pools SSL_tunnel_users
end
```

In this example, the *IP Pools* field on the *VPN* > *SSL* > *Config* page is not used because each web portal specifies its own tunnel IP address range.

Chapter 10 Advanced Routing

This chapter describes advanced static routing concepts and how to implement dynamic routing on FortiGate units.

This FortiOS Handbook chapter contains the following sections:

Advanced Static routing explains routing concepts, equal cost multipath (ECMP) and load balancing, policy routing, and routing in transparent mode.

Dynamic Routing Overview provides some basic routing concepts needed to explain dynamic routing, compares static and dynamic routing, and walks you through deciding which dynamic routing protocol is best for you.

Routing Information Protocol (RIP), Border Gateway Protocol (BGP), Open Shortest Path First (OSPF), and Intermediate System To Intermediate System Protocol (IS-IS) provide background on the protocol, explains the terms used, how the protocol works, looks at some troubleshooting, and examples on configuring the protocols in different situations.

Router Reference describes the web-based manager Router pages, providing explanations for each field.

Advanced Static routing

Advanced static routing includes features and concepts that are used in more complex networks. Dynamic routing is not addressed in this section.

This section includes:

Routing concepts

Many routing concepts apply to static routing. However without first understanding these basic concepts, it is difficult to understand the more complex dynamic routing.

This section includes:

Routing in VDOMs

Routing on FortiGate units is configured per-VDOM. This means if VDOMs are enabled, you must enter a VDOM to do any routing configuration. This allows each VDOM to operate independently, with its own default routes and routing configuration.

In this guide, the procedures assume your FortiGate unit has VDOMs disabled. This is stated in the assumptions for the examples. If you have VDOMs enabled you will need to perform the following steps in addition to the procedure's steps.

To route in VDOMs - web-based manager

Select the VDOM that you want to view or configure at the bottom of the main menu.

To route in VDOMs - CLI

Before following any CLI routing procedures with VDOMs enabled, enter the following commands. For this example, it is assumed you will be working in the root VDOM. Change root to the name of your selected VDOM as needed.

```
config vdom
  edit root
```

Following these commands, you can enter any routing CLI commands as normal.

Default route

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

All routers, including FortiGate units, are shipped with default routes in place. This allows customers to set up and become operational more quickly. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

FortiGate units come with a default static route with an IPv4 address of 0.0.0.0, an administration distance of 10, and a gateway IPv4 address.

Routing table

When two computers are directly connected, there is no need for routing because each computer knows exactly where to find the other computer. They communicate directly.

Networking computers allows many computers to communicate with each other. This requires each computer to have an IP address to identify its location to the other computers. This is much like a mailing address - you will not receive your postal mail at home if you do not have an address for people to send mail to. The routing table on a computer is much like an address book used to mail letters to people in that the routing table maintains a list of how to reach computers. Routing tables may also include information about the quality of service (QoS) of the route, and the interface associated with the route if the device has multiple interfaces.

Routing tables are also used in unicast reverse path forwarding (uRPF). In uRPF, the router not only looks up the destination information, but also the source information to ensure that it exists. If there is no source to be found, then that packet is dropped because the router assumes it to be an error or an attack on the network.

Looking at routing as delivering letters is more simple than reality. In reality, routers loose power or have bad cabling, network equipment is moved without warning, and other such events happen that prevent static routes from reaching their destinations. When any changes such as these happen along a static route, traffic can no longer reach the destination — the route goes down. Dynamic routing can address these changes to ensure traffic still reaches its destination. The process of realizing there is a problem, backtracking and finding a route that is operational is called convergence. If there is fast convergence in a network, users won't even know that re-routing is taking place.

The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes—the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Routing tables are also used in unicast reverse path forwarding (uRPF). In uRPF, the router not only looks up the destination information, but also the source information to ensure that it exists. If there is no source to be found, then that packet is dropped because the router assumes it to be an error or an attack on the network.

The routing table is used to store routes that are learned. The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes — the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Some actions you can perform on the routing table include:

- Viewing the routing table in the web-based manager
- Viewing the routing table in the CLI
- Searching the routing table

Viewing the routing table in the web-based manager

VDOM

By default, all routes are displayed in the Routing Monitor list. The default static route is defined as 0.0.0.0/0, which matches the destination IP address of "any/all" packets.

To display the routes in the routing table, go to *Router* > *Monitor* > *Routing Monitor*.

Figure 162 shows the Routing Monitor list belonging to a FortiGate unit that has interfaces named "port1", "port4", and "lan". The names of the interfaces on your FortiGate unit may be different.

Figure 163 shows the Routing Monitor list when IPv6 has been selected. Note that the information available for IPv6 is limited.

Figure 162: Routing Monitor list - IPv4

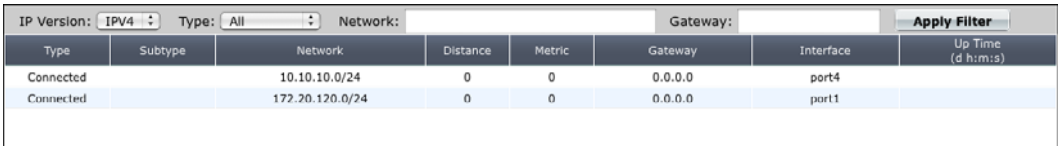


Figure 163: Routing Monitor list - IPv6

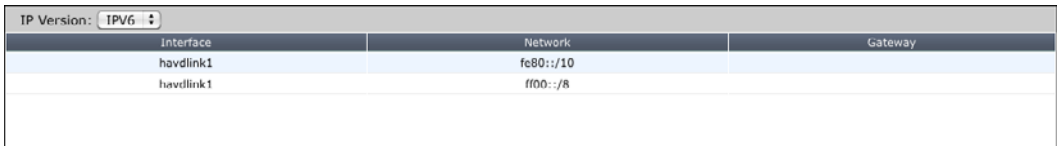


IP version:	Select IPv4 or IPv6. This is available only when IPv6 is enabled in the web-based manager. The fields displayed in the table depend on which IP version is selected.
Type:	Select one of the following route types to search the routing table and display routes of the selected type only: *All* — all routes recorded in the routing table. *Connected* — all routes associated with direct connections to FortiGate unit interfaces. *Static* — the static routes that have been added to the routing table manually. *RIP* — all routes learned through RIP. For more information see "Routing Information Protocol (RIP)" on page 1715. *BGP* — all routes learned through BGP. For more information see "Border Gateway Protocol (BGP)" on page 1751. *OSPF* — all routes learned through OSPF. For more information see "Open Shortest Path First (OSPF)" on page 1787. *IS-IS* — all routes learned through IS-IS. For more information see "Intermediate System To Intermediate System Protocol (IS-IS)" on page 1827. *HA* — RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you are viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster. Not displayed when IP version IPv6 is selected. For details about HA routing synchronization, see the ***FortiGate HA User Guide***.
Network:	Enter an IP address and netmask (for example, `172.16.14.0/24`) to search the routing table and display routes that match the specified network. Not displayed when IP version IPv6 is selected.
Gateway:	Enter an IP address and netmask (for example, `192.168.12.1/32`) to search the routing table and display routes that match the specified gateway. Not displayed when IP version IPv6 is selected.
Apply Filter	Select to search the entries in the routing table based on the specified search criteria and display any matching routes. Not displayed when IP version IPv6 is selected.

Type	The type values assigned to FortiGate unit routes (Static, Connected, RIP, OSPF, or BGP). Not displayed when IP version IPv6 is selected.
Subtype	If applicable, the subtype classification assigned to OSPF routes. An empty string implies an intra-area route. The destination is in an area to which the FortiGate unit is connected. *OSPF inter area* — the destination is in the OSPF AS, but the FortiGate unit is not connected to that area. *External 1* — the destination is outside the OSPF AS. This is known as OSPF E1 type. The metric of a redistributed route is calculated by adding the external cost and the OSPF cost together. *External 2* — the destination is outside the OSPF AS. This is known as OSPF E2 type. In this case, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. *OSPF NSSA 1* — same as External 1, but the route was received through a not-so-stubby area (NSSA). *OSPF NSSA 2* — same as External 2, but the route was received through a not-so-stubby area. For more information on OSPF subtypes, see "OSPF Background and concepts" on page 1787. Not displayed when IP version 6 is selected.
Network	The IP addresses and network masks of destination networks that the FortiGate unit can reach.
Distance	The administrative distance associated with the route. A value of 0 means the route is preferable compared to other routes to the same destination. Modifying this distance for dynamic routes is route distribution.
Metric	The metric associated with the route type. The metric of a route influences how the FortiGate unit dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to. *Hop count* — routes learned through RIP. *Relative cost* — routes learned through OSPF. *Multi-Exit Discriminator (MED)* — routes learned through BGP. However, several attributes in addition to MED determine the best path to a destination network. For more information on BGP attributes, see "BGP attributes" on page 1757.
Gateway	The IP addresses of gateways to the destination networks.
Interface	The interface through which packets are forwarded to the gateway of the destination network.
Up Time	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable. Not displayed when IP version IPv6 is selected.

Viewing the routing table in the CLI

In the CLI, you can easily view the static routing table just as in the web-based manager or you can view the full routing table.

When viewing the list of static routes using the CLI command `get route static`, it is the configured static routes that are displayed. When viewing the routing table using the CLI command `get router info routing-table all`, it is the entire routing table information that is displayed including configured and learned routes of all types. The two are different information in different formats.

If VDOMs are enabled on your FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To view the routing table

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS
   inter area
* - candidate default

S*      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S       1.0.0.0/8 [10/0] via 192.168.183.254, port2
S       2.0.0.0/8 [10/0] via 192.168.183.254, port2
C       10.142.0.0/23 is directly connected, port3
B       10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C       192.168.182.0/23 is directly connected, port2
```

Examining an entry:

```
B       10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates and administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

To view the kernel routing table

```
# get router info kernel

tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0-
>10.11.201.0/24 pref=10.11.201.4 gwy=0.0.0.0 dev=5(external1)
```

```
tab=254 vf=0 scope=253 type=1 proto=2 prio=0 0.0.0.0/0.0.0.0/0-
>172.20.120.0/24 pref=172.20.120.146 gwy=0.0.0.0 dev=6(internal)
```

The parts of the routing table entry are:

tab	table number. This will be either 254 (unicast) or 255 (multicast).
vf	virtual domain of the firewall. This is the vdom index number. If vdoms are not enabled, this number will be 0.
type	type of routing connection. Valid values include: 0 - unspecific 1 - unicast 2 - local 3 - broadcast 4 - anycast 5 - multicast 6 - blackhole 7 - unreachable 8 - prohibited
proto	type of installation. This indicates where the route came from. Valid values include: 0 - unspecific 2 - kernel 11 - ZebOS routing module 14 - FortiOS 15 - HA 16 - authentication based 17 - HA1
prio	priority of the route. Lower priorities are preferred.
->10.11.201.0/24 (->x.x.x.x/mask)	the IP address and subnet mask of the destination
pref	preferred next hop along this route
gwy	gateway - the IPv4 address of the gateway this route will use
dev	outgoing interface index. This number is associated with the interface for this route, and if VDOMs are enabled the VDOM will be included here as well. If an interface alias is set for this interface it will also be displayed here.

Searching the routing table

You can apply a filter to search the routing table and display certain routes only. For example, you can display one or more static routes, connected routes, routes learned through RIP, OSPF, or BGP, and routes associated with the network or gateway that you specify.

If you want to search the routing table by route type and further limit the display according to network or gateway, all of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed — an implicit AND condition is applied to all of the search parameters you specify.

For example, if the FortiGate unit is connected to network 172.16.14.0/24 and you want to display all directly connected routes to network 172.16.14.0/24, you must select *Connected* from the *Type* list, type `172.16.14.0/24` in the *Network* field, and then select *Apply Filter* to display the associated routing table entry or entries. Any entry that contains the word “Connected” in its *Type* field and the specified value in the *Gateway* field will be displayed.

In this example, you will apply a filter to search for an entry for static route to 10.10.10.10/24

To search the FortiGate unit routing table in the web-based manager

1. Go to *Router* > *Monitor* > *Routing Monitor*.
2. From the *Type* list, select the type of route to display. In our example, select *Static*.
3. If you want to display routes to a specific network, type the IP address and netmask of the network in the Networks field. In our example, enter `10.10.10.10/24`.
4. If you want to display routes to a specific gateway, type the IP address of the gateway in the *Gateway* field.
5. Select *Apply Filter*.

All of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed.

To search the FortiGate unit routing table in the CLI

```
FGT # get router info routing-table details 10.10.10.10
Routing entry for 10.10.10.10/24
  Known via "static", distance 10, metric 0, best
```

If there are multiple routes that match your filter, they will all be listed, with the best match at the top of the list as indicated by the word best.

Building the routing table

In the factory default configuration, the FortiGate unit routing table contains a single static default route. You can add routing information to the routing table by defining additional static routes.

It is possible that the routing table is faced with several different routes to the same destination — the IP addresses of the next-hop router specified in those routes or the FortiGate interfaces associated with those routes may vary. In this situation, the “best” route is selected from the table.

The FortiGate unit selects the “best” route for a packet by evaluating the information in the routing table. The “best” route to a destination is typically associated with the shortest distance between the FortiGate unit and the closest gateway, also known as a next-hop router. In some cases, the next best route may be selected if the best route is unavailable.

The FortiGate unit installs the best available routes in the unit's forwarding table, which is a subset of the unit's routing table. Packets are forwarded according to the information in the forwarding table.

Static routing security

Securing the information on your company network is a top priority for network administrators. Security is also required as the routing protocols used are internationally known standards that typically provide little or no inherent security by themselves.

The two reasons for securing your network are the sensitive and proprietary information on your network, and also your external bandwidth. Hackers not only can steal your information, but they can also steal your bandwidth. Routing is a good low level way to secure your network, even before UTM features are applied.

Routing provides security to your network in a number of ways including obscuring internal network addresses with NAT and blackhole routing, using RPF to validate traffic sources, and maintaining an access control list (ACL) to limit access to the network.

This section includes:

- Network Address Translation (NAT)
- Access Control List (ACL)
- Blackhole Route
- Reverse path lookup

Network Address Translation (NAT)

Network address translation (NAT) is a method of changing the address traffic appears to originate from. This practice is used to hide the IP address on company's internal networks, and helps prevent malicious attacks that use those specific addresses.

This is accomplished by the router connected to that local network changing all the IP addresses to its externally connected IP address before sending the traffic out to the other networks, such as the Internet. Incoming traffic uses the established sessions to determine which traffic goes to which internal IP address. This also has the benefit of requiring only the router to be very secure against external attacks, instead of the whole internal network as would be the case without NAT. Securing one computer is much cheaper and easier to maintain.

Configuring NAT on your FortiGate unit includes the following steps.

1. Configure your internal network. For example use the `10.11.101.0` subnet.
2. Connect your internal subnet to an interface on your FortiGate unit. For example use `port1`.
3. Connect your external connection, for example an ISP gateway of `172.20.120.2`, to another interface on your Fortigate unit, for example `port2`.
4. Configure security policies to allow traffic between port1 and port2 on your FortiGate unit, ensuring that the NAT feature is enabled.

The above steps show that traffic from your internal network will originate on the 10.11.101.0 subnet and pass on to the 172.20.120.0 network. The FortiGate unit moves the traffic to the proper subnet. In doing that, the traffic appears to originate from the FortiGate unit interface on that subnet — it does not appear to originate from where it actually came from.

NAT “hides” the internal network from the external network. This provides security through obscurity. If a hacker tries to directly access your network, they will find the Fortigate unit, but will not know about your internal network. The hacker would have to get past the security-hardened FortiGate unit to gain access to your internal network. NAT will not prevent hacking attempts that piggy back on valid connections between the internal network and the outside world. However other UTM security measures can deal with these attempts.

Another security aspect of NAT is that many programs and services have problems with NAT. Consider if someone on the Internet tries to initiate a chat with someone on the internal network. The outsider only can access the FortiGate unit’s external interface unless the security policy allows the traffic through to the internal network. If allowed in, the proper internal user would respond to the chat. However if its not allowed, the request to chat will be refused or time-out. This is accomplished in the security policy by allowing or denying different protocols.

Access Control List (ACL)

An access control list (ACL) is a table of addresses that have permission to send and receive data over a router’s interface or interfaces. The router maintains an ACL, and when traffic comes in on a particular interface it is buffered, while the router looks up in the ACL if that traffic is allowed over that port or not. If it is allowed on that incoming interface, then the next step is to check the ACL for the destination interface. If the traffic passes that check as well the buffered traffic is delivered to its accentuation. If either of those steps fail the ACL check, the traffic is dropped and an error message may be sent to the sender. The ACL ensures that traffic follows expected paths, and any unexpected traffic is not delivered. This stops many network attacks. However, to be effective the ACL must be kept up to date —when employees or computers are removed from the internal network their IP addresses must also be removed from the ACL. For more information on the ACL, see the router chapter of the FortiGate CLI Reference.

Blackhole Route

A blackhole route is a route that drops all traffic sent to it. It is very much like /dev/null in Linux programming.

Blackhole routes are used to dispose of packets instead of responding to suspicious inquiries. This provides added security since the originator will not discover any information from the target network.

Blackhole routes can also limit traffic on a subnet. If some subnet addresses are not in use, traffic to those addresses (traffic which may be valid or malicious) can be directed to a blackhole for added security and to reduce traffic on the subnet.

The loopback interface, a virtual interface that does not forward traffic, was added to enable easier configuration of blackhole routing. Similar to a normal interface, this loopback interface has fewer parameters to configure, and all traffic sent to it stops there. Since it cannot have hardware connection or link status problems, it is always available, making it useful for other dynamic routing roles. Once configured, you can use a loopback interface in security policies, routing, and other places that refer to interfaces. You configure this feature only from the CLI. For more information, see the system chapter of the *FortiGate CLI Reference*.

Reverse path lookup

Whenever a packet arrives at one of the FortiGate unit's interfaces, the unit determines whether the packet was received on a legitimate interface by doing a reverse lookup using the source IP address in the packet header. This is also called anti-spoofing. If the FortiGate unit cannot communicate with the computer at the source IP address through the interface on which the packet was received, the FortiGate unit drops the packet as it is likely a hacking attempt.

If the destination address can be matched to a local address (and the local configuration permits delivery), the FortiGate unit delivers the packet to the local network. If the packet is destined for another network, the Fortigate unit forwards the packet to a next-hop router according to a policy route and the information stored in the FortiGate forwarding table.

Multipath routing and determining the best route

Multipath routing occurs when more than one entry to the same destination is present in the routing table. When multipath routing happens, the FortiGate unit may have several possible destinations for an incoming packet, forcing the FortiGate unit to decide which next-hop is the best one.

It should be noted that some IP addresses will be rejected by routing protocols. These are called Martian addresses. They are typically IP addresses that are invalid and not routable because they have been assigned an address by a misconfigured system, or are spoofed addresses.

Two methods to manually resolve multiple routes to the same destination are to lower the administrative distance of one route or to set the priority of both routes. For the FortiGate unit to select a primary (preferred) route, manually lower the administrative distance associated with one of the possible routes. Setting the priority on the routes is a FortiGate unit feature and may not be supported by non-Fortinet routers.

Administrative distance is based on the expected reliability of a given route. It is determined through a combination of the number of hops from the source and the protocol used. A hop is when traffic moves from one router to the next. More hops from the source means more possible points of failure. The administrative distance can be from 1 to 255, with lower numbers being preferred. A distance of 255 is seen as infinite and will not be installed in the routing table.

Here is an example to illustrate how administration distance works — if there are two possible routes traffic can take between two destinations with administration distances of 5 (always up) and 31 (sometimes not available), the traffic will use the route with an administrative distance of 5. If for some reasons the preferred route (admin distance of 5) is not available, the other route will be used as a backup.

Different routing protocols have different default administrative distances. These different administrative distances are based on a number of factors of each protocol such as reliability, speed, and so on. The default administrative distances for any of these routing protocols are configurable.

Table 94: Default administrative distances for routing protocols and connections

Routing protocol	Default administrative distance
Direct physical connection	1
Static	10
EBGP	20
OSPF	110

Table 94: Default administrative distances for routing protocols and connections

RIP	120
IBGP	200

Another method to determine the best route is to manually change the priority of both routes in question. If the next-hop administrative distances of two routes on the FortiGate unit are equal, it may not be clear which route the packet will take. Manually configuring the priority for each of those routes will make it clear which next-hop will be used in the case of a tie. The priority for a route can only be set from the CLI. Lower priorities are preferred. Priority is a Fortinet value that may or may not be present in other brands of routers.

All entries in the routing table are associated with an administrative distance. If the routing table contains several entries that point to the same destination (the entries may have different gateways or interface associations), the FortiGate unit compares the administrative distances of those entries first, selects the entries having the lowest distances, and installs them as routes in the FortiGate unit forwarding table. As a result, the FortiGate unit forwarding table contains only those routes having the lowest distances to every possible destination. While only static routing uses administrative distance as its routing metric, other routing protocols such as RIP can use metrics that are similar to administrative distance.

Route priority

After the FortiGate unit selects static routes for the forwarding table based on their administrative distances, the priority field of those routes determines routing preference. Priority is a Fortinet value that may or may not be present in other brands of routers.

You can configure the priority field through the CLI or the web-based manager. Priority values can range from 0 to 4 294 967 295. The route with the lowest value in the priority field is considered the best route. It is also the primary route.

To change the priority of a route - web-based manager

1 Go to *Router* > *Static* > *Static Route*.

2 Select the route entry, and select *Edit*.

3 Select *Advanced*.

4 Enter the *Priority* value.

5 Select *OK*.

To change the priority of a route - CLI

The following command changes the priority to 5 for a route to the address `10.10.10.1` on the `port1` interface.

```
config router static
  edit 1
    set device port1
    set gateway 10.10.10.10
    set dst 10.10.10.1
    set priority 5
  end
```

If there are other routes set to priority 10, the route set to priority 5 will be preferred. If there are routes set to priorities less than 5, those other routes will be preferred instead.

In summary, because you can use the CLI to specify which sequence numbers or priority field settings to use when defining static routes, you can prioritize routes to the same destination according to their priority field settings. For a static route to be the preferred route, you must create the route using the `config router static` CLI command and specify a low priority for the route. If two routes have the same administrative distance and the same priority, then they are equal cost multipath (ECMP) routes.

Since this means there is more than one route to the same destination, it can be confusing which route or routes to install and use. However, if you have enabled load balancing with ECMP routes, then different sessions will resolve this problem by using different routes to the same address.

Troubleshooting static routing

When there are problems with your network that you believe to be static routing related, there are a few basic tools available to locate the problem.

These tools include:

- Ping
- Traceroute
- Examine routing table contents

Ping

Beyond the basic connectivity information, ping can tell you the amount of packet loss (if any), how long it takes the packet to make the round trip, and the variation in that time from packet to packet.

If there is no packet loss detected, your basic network connectivity is OK.

If there is some packet loss detected, you should investigate:

- possible ECMP, split horizon, network loops
- cabling to ensure no loose connections

If there is total packet loss, you should investigate:

- hardware - ensure cabling is correct, and all equipment between the two locations is accounted for
- addresses and routes - ensure all IP addresses and routing information along the route is configured as expected
- firewalls - ensure all firewalls are set to allow PING to pass through

To ping from a Windows PC

1. Go to a DOS prompt. Typically you go to *Start* > *Run*, enter `cmd` and select OK.
2. Enter `ping 10.11.101.100` to ping the default internal interface of the FortiGate unit with four packets.

To ping from a Linux PC

1. Go to a command line prompt.
2. Enter "`/bin/etc/ping 10.11.101.101`".

Traceroute

Where ping will only tell you if it reached its destination and came back successfully, traceroute will show each step of its journey to its destination and how long each step takes. If ping finds an outage between two points, traceroute can be used to locate exactly where the problem is.

To use traceroute on an MS Windows PC

1. Go to a DOS prompt. Typically you go to *Start* > *Run*, enter "`cmd`" and select OK.
2. Enter "`tracert fortinet.com`" to trace the route from the PC to the Fortinet website.

To perform a traceroute on a Linux PC

1. Go to a command line prompt.
2. Enter "`/bin/etc/traceroute fortinet.com`".

   The Linux traceroute output is very similar to the MS Windows traceroute output.

Examine routing table contents

The first place to look for information is the routing table.

The routing table is where all the currently used routes are stored for both static and dynamic protocols. If a route is in the routing table, it saves the time and resources of a lookup. If a route isn't used for a while and a new route needs to be added, the oldest least used route is bumped if the routing table is full. This ensures the most recently used routes stay in the table. Note that if your FortiGate unit is in Transparent mode, you are unable to perform this step.

If the FortiGate is running in NAT mode, verify that all desired routes are in the routing table: local subnets, default routes, specific static routes, and dynamic routing protocols.

To check the routing table in the web-based manager, use the Routing Monitor — go to *Router* > *Monitor* > *Routing Monitor*. In the CLI, use the command `get router info routing-table all`.

To examine the firewall session list in the web-based manager

1. Go to *System* > *Dashboard* > *Status* > *Top Sessions*.
2. Select *Detach*, and then *Details*.
3. Expand the session window to full screen to display the information.
4. Change filters, view associated security policy, column ordering, and so on to analyze the sessions in the table.
5. Select the delete icon to terminate the session.

ECMP route failover and load balancing

Equal Cost Multi-Path (ECMP) load balancing and failover are methods that extend basic static routing. They allow you to use your network bandwidth more effectively and with less down time than if you used basic static routing alone.

The concepts in this section include:

- Route priority
- Equal-Cost Multi-Path (ECMP)
- Configuring interface status detection for gateway load balancing
- Configuring spillover or usage-based ECMP
- Configuring weighted static route load balancing

Route priority

After the FortiGate unit selects static routes for the forwarding table based on their administrative distances, the priority field of those routes determines routing preference. Priority is a Fortinet value that may or may not be present in other brands of routers.

You can only configure the priority field through the CLI. Priority values can range from 0 to 255. The route with the lowest value in the priority field is considered the best route, and it is also the primary route.

For example, use the following command to change the priority of a route to 5 for a route to the address 10.10.10.1 on the port1 interface.

```
config router static
  edit 1
    set device port1
    set gateway 10.10.10.10
    set dst 10.10.10.1
    set priority 5
  end
```

If there are other routes at priority 10, this route will be preferred. If there are routes at priority less than 5, those other routes will be preferred instead.

In summary, because you can use the CLI to specify which sequence numbers or priority field settings to use when defining static routes, you can prioritize routes to the same destination according to their priority field settings. For a static route to be the preferred route, you must create the route using the `config router static` CLI command and specify a low priority for the route. If two routes have the same administrative distance and the same priority, then they are equal cost multipath (ECMP) routes.

Since this means there is more than one route to the same destination, it can be confusing which route or routes to install and use. However, if you have enabled load balancing with ECMP routes, then different sessions will resolve this problem by using different routes to the same address.

Equal-Cost Multi-Path (ECMP)

FortiOS uses equal-cost multi-path (ECMP) to distribute traffic to the same destination such as the Internet or another network. Using ECMP you can add multiple routes to the destination and give each of those routes the same distance and priority.

If multiple routes to the same destination have the same priority but different distances, the route with the lowest distance is used. If multiple routes to the same destination have the same distance but different priorities, the route with the lowest priority is used. Distance takes precedence over priority. If multiple routes to the same destination have different distances and different priorities, the route with the lowest distance is always used even if it has the highest priority.

Using ECMP, if more than one ECMP route is available you can configure how the FortiGate unit selects the route to be used for a communication session. If only one ECMP route is available (for example, because an interface cannot process traffic because interface status detection does not receive a reply from the configured server) then all traffic uses this route.

Previous versions of FortiOS provided source IP-based load balancing for ECMP routes, but now FortiOS includes three configuration options for ECMP route failover and load balancing:

Source based (also called source IP based)	The FortiGate unit load balances sessions among ECMP routes based on the source IP address of the sessions to be load balanced. This is the default load balancing method. No configuration changes are required to support source IP load balancing.
Weighted Load Balance (also called weight-based)	The FortiGate unit load balances sessions among ECMP routes based on weights added to ECMP routes. More traffic is directed to routes with higher weights. After selecting weight-based you must add weights to static routes.
Spillover (also called usage-based)	The FortiGate unit distributes sessions among ECMP routes based on how busy the FortiGate interfaces added to the routes are. After selecting spill-over you add route Spillover Thresholds to interfaces added to ECMP routes. The FortiGate unit sends all ECMP-routed sessions to the lowest numbered interface until the bandwidth being processed by this interface reaches its spillover threshold. The FortiGate unit then spills additional sessions over to the next lowest numbered interface. The Spillover Thresholds range is 0-2097000 KBps.

You can configure only one of these ECMP route failover and load balancing methods in a single VDOM. If your FortiGate unit is configured for multiple VDOM operation, each VDOM can have its own ECMP route failover and load balancing configuration.

To configure the ECMP load balancing method from the web-based manager

1 Go to *Router* > *Static* > *Settings*.

2 Set *ECMP Load Balance Method* to *Source IP based*, *Weighted Load Balance*, or *Spillover.*

To configure the ECMP load balancing method from the CLI

For example, to set the load balancing method to usage-based, enter the following:

```
config system settings
  set v4-ecmp-mode usage-based
end
```

ECMP routing of simultaneous sessions to the same destination IP address

When the FortiGate unit selects an ECMP route for a session, a route cache is created that matches the route with the destination IP address of the session. All new sessions to the same destination IP address use the same route until the route is flushed from the cache. Routes are flushed from the cache after a period of time when no new sessions to the destination IP address are received.

The route cache improves FortiGate unit routing performance by reducing how often the FortiGate unit looks up routes in the routing table.

If the FortiGate unit receives a large number of sessions with the same destination IP address, because all of these sessions will be processed by the same route, it may appear that sessions are not distributed according to the ECMP route failover and load balancing configuration.

Configuring interface status detection for gateway load balancing

Interface status detection is used for ECMP route failover and load balancing. Interface status detection consists of the unit confirming that packets sent from an interface result in a response from a server. You can use up to three different protocols to confirm that an interface can connect to the server. Usually the server is the next-hop router that leads to an external network or the Internet. Interface status detection sends a packet using the configured protocols. If a response is received from the server, the unit assumes the interface can connect to the network. If a response is not received, the unit assumes that the interface cannot connect to the network.

Since it is possible that a response may not be received, even if the server and the network are operating normally, the dead gateway detection configuration controls the time interval between testing the connection to the server and the number of times the test can fail before the unit assumes that the interface cannot connect to the server.

As long as the unit receives responses for at least one of the protocols that you select, the unit assumes the server is operating and can forward packets. Responding to more than one protocol does not enhance the status of the server or interface.

To configure gateway failover detection for an interface

1. Go to *Router* > *Static* > *Settings*.
2. Under *Dead Gateway Detection*, select *Create New*.

3 Enter the following information:

Interface		Select the interface to test.
Ping Server		Enter the IP address of the server to test.
Detect Protocol		Select one of the following protocols.
	Ping	Use standard ICMP ping to confirm that the server is responding. Ping confirms that the server can respond to an ICMP ping request.
	TCP Echo	Use TCP echo to confirm that the server is responding. Select this option if the server is configured to provide TCP echo services. In some cases a server may be configured to reply to TCP echo requests but not to reply to ICMP pings. TCP echo uses TCP packets on port number 7 to send a text string to the server and expect an echo reply back from the server. The echo reply just echoes back the same text to confirm that the server can respond to TCP requests. FortiGate units do not recognize RST (reset) packets from TCP Echo servers as normal TCP echo replies. If the unit receives an RST response to a TCP echo request, the unit assumes the server is unreachable.
	UDP Echo	Use UDP echo to detect the server. Select this option if the server is configured to provide UDP echo services. In some cases a server may be configured to reply to UDP echo requests but not to reply ICMP pings. UDP echo uses UDP packets on port number 7 to send a text string to the server and expects an echo reply from the server. The echo reply just echoes back the same text to confirm that the server can respond to UDP requests.
Ping Interval		Enter the interval between pings, in seconds.
Failover Threshold		Enter the number of times the test can fail before the unit assumes that the interface cannot connect to the server.
HA Priority		

For more information about TCP echo and UDP echo, see RFC 862.

4 Select *OK*.

To configure gateway failover detection for an interface - CLI

```
config router gwdetect
  edit port1
    set protocol ping
    set server 10.10.10.1
    set interval 5
    set failtime 5
  end
```

Configuring spillover or usage-based ECMP

Spill-over or usage-based ECMP routes new sessions to interfaces that have not reached a configured bandwidth limit (called the *Spillover Threshold* or a route-spillover threshold). To configure spill-over or usage-based ECMP routing, you enable spill-over ECMP, add ECMP routes, and add a *Spillover Threshold* to the interfaces used by the ECMP routes. Set the *Spillover Thresholds* to limit the amount of bandwidth processed by each interface. The range is 0 to 2 097 000 KBps. The threshold counts only outgoing traffic.

With spill-over ECMP routing configured, the FortiGate unit routes new sessions to an interface used by an ECMP route until that interface reaches its *Spillover Threshold*. Then, when the threshold of that interface is reached, new sessions are routed to one of the other interfaces used by the ECMP routes.

To add Spillover Thresholds to interfaces - web-based manager

Use the following steps to enable usage based ECMP routing, add Spillover Thresholds to FortiGate interfaces port3 and port4, and then to configure EMCP routes with device set to port3 and port4.

1 Go to *Router* > *Static* > *Settings*.

2 Set *ECMP Load Balance Method* to *Spillover*.

3 Go to *Router* > *Static* > *Static Route*.

4 Add ECMP routes for `port3` and `port4`.

Destination IP/Mask	192.168.20.0/24
Device	port3
Gateway	172.20.130.3
Advanced	
Distance	10

Destination IP/Mask	192.168.20.0/24
Device	port4
Gateway	172.20.140.4
Advanced	
Distance	10

5 Go to *System* > *Network* > *Interface*.

6 Edit `port3` and `port4` and add the following spillover-thresholds:

Interface	port3
Spillover Threshold	100

Interface	port4
Spillover Threshold	200

To add Spillover Thresholds to interfaces - CLI

```
config system settings
  set v4-ecmp-mode usage-based
```

```
end
config router static
  edit 1
    set device port3
    set dst 192.168.20.0 255.255.255.0
    set gateway 172.20.130.3
  next
  edit 2
    set device port4
    set dst 192.168.20.0 255.255.255.0
    set gateway 172.20.140.4
  end
config system interface
  edit port3
    set spillover-threshold 100
  next
  edit port4
    set spillover-threshold 200
  end
```

Detailed description of how spill-over ECMP selects routes

When you add ECMP routes they are added to the routing table in the order displayed by the routing monitor or by the `get router info routing-table static` command. This order is independent of the configured bandwidth limit.

The FortiGate unit selects an ECMP route for a new session by finding the first route in the routing table that sends the session out a FortiGate unit interface that is not processing more traffic that its configured route spill-over limit.

A new session to a destination IP address that already has an entry in the routing cache is routed using the route already added to the cache for that destination address. See “ECMP routing of simultaneous sessions to the same destination IP address” on page 1687.

For example, consider a FortiGate unit with interfaces port3 and port4 both connected to the Internet through different ISPs. ECMP routing is set to usage-based and route spillover for to 100 KBps for port3 and 200 KBps for port4. Two ECMP default routes are added, one for port3 and one for port4.

If the route to port3 is higher in the routing table than the route to port4, the FortiGate unit sends all default route sessions out port3 until port3 is processing 10Mbps of data. When port3 reaches its configured bandwidth limit, the FortiGate unit sends all default route sessions out port4. When the bandwidth usage of port3 falls below 10Mbps, the FortiGate again sends all default route sessions out port3.

New sessions with destination IP addresses that are already in the routing cache; however, use the cached routes. This means that even if port3 is exceeding its bandwidth limit, new sessions can continue to be sent out port3 if their destination addresses are already in the routing cache. As a result, new sessions are sent out port4 only if port3 exceeds its bandwidth limit and if the routing cache does not contain a route for the destination IP address of the new session.

Also, the switch over to port4 does not occur as soon as port3 exceeds its bandwidth limit. Bandwidth usage has to exceed the limit for a period of time before the switch over takes place. If port3 bandwidth usage drops below the bandwidth limit during this time period, sessions are not switched over to port4. This delay reduces route flapping.

FortiGate usage-based ECMP routing is not actually load balancing, since routes are not distributed evenly among FortiGate interfaces. Depending on traffic volumes, most traffic would usually be processed by the first interface with only spillover traffic being processed by other interfaces.

If you are configuring usage-based ECMP in most cases you should add spillover thresholds to all of the interfaces with ECMP routes. The default spillover threshold is 0 which means no bandwidth limiting. If any interface has a spillover threshold of 0, no sessions will be routed to interfaces lower in the list unless the interface goes down or is disconnected. An interface can go down if *Detect interface status for Gateway Load Balancing* does not receive a response from the configured server.

Determining if an interface has exceeded its Spillover Threshold

You can use the `diagnose netlink dstmac list` CLI command to determine if an interface is exceeding its Spillover Threshold. If the command displays *over_bps=1* the interface is exceeding its threshold. If *over_bps=0* the interface has not exceeded its threshold.

Configuring weighted static route load balancing

Configure weighted load balancing to control how the FortiGate unit distributes sessions among ECMP routes by adding weights for each route. Add higher weights to routes that you want to load balance more sessions to.

With the ECMP load balancing method set to weighted, the FortiGate unit distributes sessions with different destination IPs by generating a random value to determine the route to select. The probability of selecting one route over another is based on the weight value of each route. Routes with higher weights are more likely to be selected.

Large numbers of sessions are evenly distributed among ECMP routes according to the route weight values. If all weights are the same, sessions are distributed evenly. The distribution of a small number of sessions; however, may not be even. For example, its possible that if there are two ECMP routes with the same weight; two sessions to different IP addresses could use the same route. On the other hand, 10,000 sessions with different destination IPs should be load balanced evenly between two routes with equal rates. The distribution could be 5000:5000 or 50001:4999. Also, 10 000 sessions with different destination IP addresses should be load balanced as 3333:6667 if the weights for the two routes are 100 and 200.

Weights only affect how routes are selected for sessions to new destination IP addresses. New sessions to IP addresses already in the routing cache are routed using the route for the session already in the cache. So in practice sessions will not always be distributed according to the routing weight distribution.

To add weights to static routes from the web-based manager

1. Go to *Router* > *Static* > *Settings*.
2. Set *ECMP Load Balance Method* to *Weighted Load Balance*.
3. Go to *Router* > *Static* > *Static Route*.

4 If needed, add new static routes, for example:

Destination IP/Mask	192.168.20.0/24
Device	port1
Gateway	172.20.110.1
Distance	10

Destination IP/Mask	192.168.20.0/24
Device	port2
Gateway	172.20.120.2
Distance	10

5 Go to *System* > *Network* > *Interface*.

6 Edit each route's interface and set the *Weight* value.

For example, set the weight of port1 to 100 and the weight of port2 to 200.

Static routing tips

When your network goes beyond basic static routing, here are some tips to help you plan and manage your static routing.

Always configure a default route

The first thing configured on a router on your network should be the default route. And where possible the default routes should point to either one or very few gateways. This makes it easier to locate and correct problems in the network. By comparison, if one router uses a second router as its gateway which uses a fourth for its gateway and so on, one failure in that chain will appear as an outage for all the devices downstream. By using one or very few addresses as gateways, if there is an outage on the network it will either be very localized or network-wide — either is easy to troubleshoot.

Have an updated network plan

A network plan lists different subnets, user groups, and different servers. Essentially is puts all your resources on the network, and shows how the parts of your network are connected. Keeping your plan updated will also help you troubleshoot problems more quickly when they arise.

A network plan helps your static routing by eliminating potential bottlenecks, and helping troubleshoot any routing problems that come up. Also you can use it to plan for the future and act on any changes to your needs or resources more quickly.

Plan for expansion

No network remains the same size. At some time, all networks grow. If you take future growth into account, there will be less disruption to your existing network when that growth happens. For example allocating a block of addresses for servers can easily prevent having to re-assign IP addresses to multiple servers due to a new server.

With static routing, if you group parts of your network properly you can easily use network masks to address each part of your network separately. This will reduce the amount of administration required both to maintain the routing, and to troubleshoot any problems.

Configure as much security as possible

Securing your network through static routing methods is a good low level method to defend both your important information and your network bandwidth.

- Implement NAT to obscure your IP address is an excellent first step.
- Implement black hole routing to hide which IP addresses are in use or not on your local network.
- Configure and use access control list (ACL) to help ensure you know only valid users are using the network.

All three features limit access to the people who should be using your network, and obscure your network information from the outside world and potential hackers.

Policy Routing

Policy routing enables you to redirect traffic away from a static route. This can be useful if you want to route certain types of network traffic differently. You can use incoming traffic's protocol, source address or interface, destination address, or port number to determine where to send the traffic. For example, generally network traffic would go to the router of a subnet, but you might want to direct SMTP or POP3 traffic directly to the mail server on that subnet.

If you have configured the FortiGate unit with routing policies and a packet arrives at the FortiGate unit, the FortiGate unit starts at the top of the Policy Route list and attempts to match the packet with a policy. If a match is found and the policy contains enough information to route the packet (a minimum of the IP address of the next-hop router and the FortiGate interface for forwarding packets to it), the FortiGate unit routes the packet using the information in the policy. If no policy route matches the packet, the FortiGate unit routes the packet using the routing table.

Most policy settings are optional, so a matching policy alone might not provide enough information for forwarding the packet. The FortiGate unit may refer to the routing table in an attempt to match the information in the packet header with a route in the routing table. For example, if the outgoing interface is the only item in the policy, the FortiGate unit looks up the IP address of the next-hop router in the routing table. This situation could happen when the interfaces are dynamic (such as DHCP or PPPoE) and you do not want or are unable to specify the IP address of the next-hop router.

Policy route options define which attributes of a incoming packet cause policy routing to occur. If the attributes of a packet match all the specified conditions, the FortiGate unit routes the packet through the specified interface to the specified gateway.

To view policy routes go to *Router* > *Static* > *Policy Route*.

Create New	Add a policy route. See "Adding a policy route" on page 1694.
Delete icon	Delete the selected policy route.
Edit icon	Edit the selected policy route.
Move To icon	Move the selected policy route. Enter the new position and select OK. For more information, see "Moving a policy route" on page 1696.
#	The ID numbers of configured route policies. These numbers are sequential unless policies have been moved within the table.

Incoming	The interfaces on which packets subjected to route policies are received.
Outgoing	The interfaces through which policy routed packets are routed.
Source	The IP source addresses and network masks that cause policy routing to occur.
Destination	The IP destination addresses and network masks that cause policy routing to occur.

Adding a policy route

To add a policy route, go to *Router* > *Static* > *Policy Route* and select *Create New*.

Protocol	Enter the protocol number to match. The Internet Protocol Number is found in the IP packet header. RFC 5237 describes protocol numbers and you can find a list of the assigned protocol numbers here. The range is from 0 to 255. A value of `0` disables the feature. Commonly used *Protocol* settings include 6 for TCP sessions, 17 for UDP sessions, 1 for ICMP sessions, 47 for GRE sessions, and 92 for multicast sessions.
Incoming Interface	Select the name of the interface through which incoming packets subjected to the policy are received.
Source Address / Mask	To perform policy routing based on IP source address, type the source address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Address / Mask	To perform policy routing based on the IP destination address of the packet, type the destination address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Ports	To perform policy routing based on the port on which the packet is received, type the same port number in the From and To fields. To apply policy routing to a range of ports, type the starting port number in the From field and the ending port number in the To field. A value of 0 disables this feature. The Destination Ports fields are only used for TCP and UDP protocols. The ports are skipped over for all other protocols.
Type of Service	Use a two digit hexadecimal bit pattern to match the service, or use a two digit hexadecimal bit mask to mask out. For more information, see “Type of Service” on page 1695.
Outgoing Interface	Select the name of the interface through which packets affected by the policy will be routed.
Gateway Address	Type the IP address of the next-hop router that the FortiGate unit can access through the specified interface.

Example policy route

Configure the following policy route to send all FTP traffic received at `port1` out the `port10` interface and to a next hop router at IP address `172.20.120.23`. To route FTP traffic set protocol to 6 (for TCP) and set both of the destination ports to 21, the FTP port.

Protocol	6
Incoming interface	port1
Source address / mask	0.0.0.0/0.0.0.0
Destination address / mask	0.0.0.0/0.0.0.0
Destination Ports	From 21 to 21
Type of Service	bit pattern: 00 (hex) bit mask: 00 (hex)
Outgoing interface	port10
Gateway Address	172.20.120.23

Type of Service

Type of service (TOS) is an 8-bit field in the IP header that enables you to determine how the IP datagram should be delivered, with such qualities as delay, priority, reliability, and minimum cost.

Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority TOS is 0, the highest is 7 - when bits 3, 4, and 5 are all set to 1. The router tries to match the TOS of the datagram to the TOS on one of the possible routes to the destination. If there is no match, the datagram is sent over a zero TOS route.

Using increased quality may increase the cost of delivery because better performance may consume limited network resources. For more information, see RFC 791 and RFC 1349.

Table 95: The role of each bit in the IP header TOS 8-bit field

bits 0, 1, 2	**Precedence**	Some networks treat high precedence traffic as more important traffic. Precedence should only be used within a network, and can be used differently in each network. Typically you do not care about these bits.
bit 3	**Delay**	When set to 1, this bit indicates low delay is a priority. This is useful for such services as VoIP where delays degrade the quality of the sound.
bit 4	**Throughput**	When set to 1, this bit indicates high throughput is a priority. This is useful for services that require lots of bandwidth such as video conferencing.
bit 5	**Reliability**	When set to 1, this bit indicates high reliability is a priority. This is useful when a service must always be available such as with DNS servers.
bit 6	**Cost**	When set to 1, this bit indicates low cost is a priority. Generally there is a higher delivery cost associated with enabling bits 3,4, or 5, and bit 6 indicates to use the lowest cost route.
bit 7	**Reserved for future use**	Not used at this time.

For example, if you want to assign low delay, and high reliability, say for a VoIP application where delays are unacceptable, you would use a bit pattern of xxx1x1xx where an 'x' indicates that bit can be any value. Since all bits are not set, this is a good use for the bit mask; if the mask is set to 0x14, it will match any TOS packets that are set to low delay and high reliability.

Moving a policy route

A routing policy is added to the bottom of the routing table when it is created. If you prefer to use one policy over another, you may want to move it to a different location in the routing policy table.

The option to use one of two routes happens when both routes are a match, for example `172.20.0.0/255.255.0.0` and `172.20.120.0/255.255.255.0`. If both of these routes are in the policy table, both can match a route to `172.20.120.112` but you consider the second one as a better match. In that case the best match route should be positioned before the other route in the policy table.

To change the position of a policy route in the table, go to *Router* > *Static* > *Policy Route* and select *Move To* for the policy route you want to move.

Before/After	Select Before to place the selected Policy Route before the indicated route. Select After to place it following the indicated route.
Policy route ID	Enter the Policy route ID of the route in the Policy route table to move the selected route before or after.

Transparent mode static routing

FortiOS operating modes allow you to change the configuration of your FortiGate unit depending on the role it needs to fill in your network.

NAT/Route operating mode is the standard mode where all interfaces are accessed individually, and traffic can be routed between ports to travel from one network to another.

In transparent operating mode, all physical interfaces act like one interface. The FortiGate unit essentially becomes a bridge — traffic coming in over any interface is broadcast back out over all the interfaces on the FortiGate unit.

In transparent mode, there is no entry for routing at the main level of the menu on the web-based manager display as there is in NAT/Route mode. Routing is instead accessed through the network menu option.

To view the routing table in transparent mode, go to *System* > *Network* > *Routing Table*.

When viewing or creating a static route entry in transparent mode there are only three fields available.

Destination IP /Mask	The destination of the traffic being routed. The first entry is attempted first for a match, then the next, and so on until a match is found or the last entry is reached. If no match is found, the traffic will not be routed. Use 0.0.0.0 to match all traffic destinations. This is the default route.

Gateway	Specifies the next hop for the traffic. Generally the gateway is the address of a router on the edge of your network.
Priority	The priority is used if there is more than one match for a route. This allows multiple routes to be used, with one preferred. If the preferred route is unavailable the other routes can be used instead. Valid range of priority can be from 0 to 4 294 967 295. If more than one route matches and they have the same priority it becomes an ECMP situation and traffic is shared among those routes. See “Route priority” on page 1685.

When configuring routing on a FortiGate unit in transparent mode, remember that all interfaces must be connected to the same subnet. That means all traffic will be coming from and leaving on the same subnet. This is important because it limits your static routing options to only the gateways attached to this subnet. For example, if you only have one router connecting your network to the Internet then all static routing on the FortiGate unit will use that gateway. For this reason static routing on FortiGate units in transparent mode may be a bit different, but it is not as complex as routing in NAT/Route mode.

Dynamic Routing Overview

This section provides an overview of dynamic routing, and how it compares to static routing. For details on various dynamic routing protocols, see the following chapters for detailed information.

The following topics are included in this section:

What is dynamic routing?

Dynamic routing uses a dynamic routing protocol to automatically select the best route to put into the routing table. So instead of manually entering static routes in the routing table, dynamic routing automatically receives routing updates, and dynamically decides which routes are best to go into the routing table. Its this intelligent and hands-off approach that makes dynamic routing so useful.

Dynamic routing protocols vary in many ways and this is reflected in the various administrative distances assigned to routes learned from dynamic routing. These variations take into account differences in reliability, speed of convergence, and other similar factors. For more information on these administrative distances, see “Multipath routing and determining the best route” on page 1681.

This section includes:

Comparing static and dynamic routing

A common term used to describe dynamic routing is convergence. Convergence is the ability to work around a network problems and outages — for the routing to come together despite obstacles. For example if the main router between two end points goes down, convergence is the ability to find a way around that failed router and reach the destination. Static routing has zero convergence beyond trying the next route in its limited local routing table — if a network administrator doesn’t fix a routing problem manually, it will never be fixed resulting in a downed network. Dynamic routing solves this

problem by involving routers along the route to the destination in decision making about the route, and using the routing tables of these routes for potential routes around the outage. In general dynamic routing has better scalability, robustness, and convergence. However, the cost of these added benefits include more complexity and some overhead — bandwidth that is used by the routing protocol for its own administration.

Table 96: Comparing static and dynamic routing

Feature	Static Routing	Dynamic Routing
Hardware support	Supported by all routing hardware	May require special, more expensive routers
Router Memory Required	Minimal	Can require considerable memory for larger tables
Complexity	Simple	Complex
Overhead	None	Varying amounts of bandwidth used for routing protocol updates
Scalability	Limited to small networks	Very scalable, better for larger networks
Robustness	None - if a route fails it has to be fixed manually	Robust - traffic routed around failures automatically
Convergence	None	Varies from good to execellent

Dynamic routing protocols

A dynamic routing protocol is an agreed on method of routing that the sender, receiver, and all routers along the path (route) support. Typically the routing protocol involves a process running on all computers and routers along that route to enable each router to handle routes in the same way as the others. The routing protocol determines how the routing tables are populated along that route, how the data is formatted for transmission, and what information about a route is included with that route. For example RIP, and BGP use distance vector algorithms, where OSPF uses a shortest path first algorithm. Each routing protocol has different strengths and weaknesses — one protocol may have fast convergence, while another may be very reliable, and a third is very popular for certain businesses like Internet Service Providers (ISPs).

Dynamic routing protocols are different from each other in a number of ways, such as:

- Classful versus classless routing protocols
- Interior versus exterior routing protocols
- Distance vector versus link-state protocols

Classful versus classless routing protocols

Classful or classless routing refers to how the routing protocol handes the IP addresses. In classful addresses there is the specific address, and the host address of the server that address is connected to. Classless addresses use a combination of IP address and netmask.

Classless Inter-Domain Routing (CIDR) was introduced in 1993 (originally with RFC 1519 and most recently with RFC 4632) to keep routing tables from getting too large. With Classful routing, each IP address requires its own entry in the routing table. With Classless routing, a series of addresses can be combined into one entry potentially saving vast amounts of space in routing tables.

Current routing protocols that support classless routing out of necessity include RIPv2, BGP, IS-IS, and OSPF. Older protocols such as RIPv1 do not support CIDR addresses.

Interior versus exterior routing protocols

The names interior and exterior are very descriptive. Interior routing protocols are designed for use within a contained network of limited size, where exterior routing protocols are designed to link multiple networks together. For example, only border routers of a network run the exterior routing protocol, where all the routers on the network run the interior protocol. This overlap is required for the exterior routers to communicate with the interior routers — border routers almost always run multiple routing protocols.

Nearly all routing protocols are interior routing protocols. Only BGP is commonly used as an exterior routing protocol.

You may see interior gateway protocol (IGP) used to refer to interior routing protocols, and exterior gateway protocol (EGP) used to refer to interior routing protocols.

Distance vector versus link-state protocols

Every routing protocol determines the best route between two addresses using a different method. However, there are two main algorithms for determining the best route — Distance vector and Link-state.

Distance vector protocols

In distance vector protocols, routers are told about remote networks through neighboring routers. The distance part refers to the number of hops to the destination, and in more advanced routing protocols these hops can be weighted by factors such as available bandwidth and delay. The vector part determines which router is the next step along the path for this route. This information is passed along from neighboring routers with routing update packets that keep the routing tables up to date. Using this method, an outage along a route is reported back along to the start of that route, ideally before the outage is encountered.

On distance vector protocols, RFC 1058 which defines RIP v1 states the following:

> Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.

There are four main weaknesses inherent in the distance vector method. Firstly, the routing information is not discovered by the router itself, but is instead reported information that must be relied on to be accurate and up-to-date. The second weakness is that it can take a while for the information to make its way to all the routers who need the information — in other words it can have slow convergence. The third weakness is the amount of overhead involved in passing these updates all the time. The number of updates between routers in a larger network can significantly reduce the available bandwidth. The fourth weakness is that distance vector protocols can end up with routing-loops. Routing loops are when packets are routed for ever around a network, and often occur with slow convergence. The bandwidth required by these infinite loops will slow your network to a halt. There are methods of preventing these loops however, so this weakness is not as serious as it may first appear.

Link-state protocols

Link-state protocols are also known as shortest path first protocols. Where distance vector uses information passed along that may or may not be current and accurate, in link-state protocols each router passes along only information about networks and devices directly connected to it. This results in a more accurate picture of the network topology around your router, allowing it to make better routing decisions. This information is passed between routers using link-state advertisements (LSAs). To reduce the overhead, LSAs are only sent out when information changes, compared to distance vector sending updates at regular intervals even if no information has changed. The the more accurate network picture in link-state protocols greatly speed up convergence and avoid problems such as routing-loops.

Minimum configuration for dynamic routing

Dynamic routing protocols do not pay attention to routing updates from other sources, unless you specifically configure them to do so using CLI redistribute commands within each routing protocol.

The minimum configuration for any dynamic routing to function is dynamic routing configured on one interface the FortiGate unit and one other router configured as well. Some protocols require more

Table 97: Minimum configuration based on dynamic protocol

	BGP	RIP	OSPF
Interface	yes	yes	yes
Network	yes	yes	yes
AS	local and neighbor	no	yes
Neighbors	at least one	at least one	at least one
Version	no	yes	no
Router ID	no	no	yes

Comparison of dynamic routing protocols

Each dynamic routing protocol was designed to meet a specific routing need. Each protocol does some things well, and other things not so well. For this reason, choosing the right dynamic routing protocol for your situation is not an easy task.

Features of dynamic routing protocols

Each protocol is better suited for some situations over others.

Choosing the best dynamic routing protocol depends on the size of your network, speed of convergence required, the level of network maintenance resources available, what protocols the networks you connect to are using, and so on. For more information on these dynamic routing protocols, see "Routing Information Protocol (RIP)" on page 1715, "Border Gateway Protocol (BGP)" on page 1751, or "Open Shortest Path First (OSPF)" on page 1787.

Table 98: Comparing RIP, BGP, and OSPF dynamic routing protocols

Protocol	RIP	BGP	OSPF
Routing algorithm	Distance Vector, basic	Distance Vector, advanced	Link-state
Common uses	Small non-complex networks	Network backbone, ties multinational offices together	Common in large, complex enterprise networks
Strengths	Fast and simple to implement Near universal support Good when no redundant paths	Graceful restart BFD support Only needed on border routers Summarize routes	Fast convergence Robust Little management overhead No hop count limitation Scalable
Weakness	Frequent updates can flood network Slow convergence Maximum 15 hops may limit network configuration	Required full mesh in large networks can cause floods Route flap Load-balance multi-homed networks Not available on low end routers	Complex No support for unequal cost multipath routing Route summary can require network changes
Authentication	Optional authentication using text string or MD5 password. (RIP v1 has no authentication)		
IPv6 Support	Only in RIPng	Only in BGP4+	Only in OSPF6

Routing protocols

Routing Information Protocol (RIP) uses classful routing, as well as incorporating various methods to stop incorrect route information from propagating, such as poisoned horizon. However, on larger networks its frequent updates can flood the network and its slow convergence can be a problem.

Border Gateway Protocol (BGP) has been the core Internet backbone routing protocol since the mid 1990s, and is the most used interior gateway protocol (IGP). However, some configurations require full mesh connections which flood the network, and there can be route flap and load balancing issues for multihomed networks.

Open Shortest Path First (OSPF) is commonly used in large enterprise networks. It is the protocol of choice mainly due to its fast convergence. However, it can be complicated to setup properly.

Multicast addressing is used to broadcast from one source to many destinations efficiently. Protocol Independent Multicast (PIM) is the protocol commonly used in enterprises, multimedia content delivery, and stock exchanges. For more information, see "Multicast forwarding" on page 471 in the System Administration chapter.

Routing algorithm

Each protocol uses a slightly different algorithm for choosing the best route between two addresses on the network. The algorithm is the "intelligent" part of a dynamic protocol because the algorithm is responsible for deciding which route is best and should be added to the local routing table. RIP and BGP use distance vector algorithms, where OSPF uses link-state or a shortest path first algorithm.

Vector algorithms are essentially based on the number of hops between the originator and the destination in a route, possibly weighting hops based on how reliable, fast, and error-free they are.

The link-state algorithm used by OSPF is called the Dijkstra algorithm. Link-state treats each interface as a link, and records information about the state of the interface. The Dijkstra algorithm creates trees to find the shortest paths to the routes it needs based on the total cost of the parts of the routes in the tree.

For more information on the routing algorithm used, see "Distance vector versus link-state protocols" on page 1701.

Authentication

If an attacker gains access to your network, they can masquerade as a router on your network to either gain information about your network or disrupt network traffic. If you have a high quality firewall configured, it will help your network security and stop many of this type of threat. However, the main method for protecting your routing information is to use authentication in your routing protocol. Using authentication on your FortiGate unit and other routers prevents access by attackers — all routers must authenticate with passwords, such as MD5 hash passwords, to ensure they are legitimate routers.

When configuring authentication on your network, ensure you configure it the same on all devices on the network. Failure to do so will create errors and outages as those forgotten devices fail to connect to the rest of the network.

For example, to configure an MD5 key of `123` on an OSPF interface called `ospf_test`, enter the following CLI command:

```
config router ospf
  config ospf-interface
  edit ospf_test
    set authentication md5
    set md5-key 123
  end
end
```

Convergence

Convergence is the ability of a networking protocol to re-route around network outages. Static routing cannot do this. Dynamic routing protocols can all converge, but take various amounts of time to do this. Slow convergence can cause problems such as network loops which degrade network performance.

You may also hear robustness and redundancy used to describe networking protocols. In many ways they are the same thing as convergence. Robustness is the ability to keep working even though there are problems, including configuration problems as well as network outages. Redundancy involves having duplicate parts that can continue to function in the event of some malfunction, error, or outage. It is relatively easy to configure dynamic routing protocols to have backup routers and configurations that will continue to function no matter the network problem short of a total network failure.

IPv6 Support

IPv4 addressing is in common use everywhere around the world. IPv6 has much larger addresses and it is used by many large companies and government departments. IPv6 is not as common as IPv4 yet, but more companies are adopting it.

If your network uses IPv6, your dynamic routing protocol must support it. None of the dynamic routing protocols originally supported IPv6, but they all have additions, expansions, or new versions that do support IPv6. For more information, see "RIP and IPv6" on page 1716, "BGP and IPv6" on page 1752, or "OSPF and IPv6" on page 1788.

When to adopt dynamic routing

Static routing is more than enough to meet your networking needs when you have a small network. However, as your network grows, the question you need to answer is at what point do you adopt dynamic routing in your networking plan and start using it in your network? The main factors in this decision are typically:

- Budget
- Current network size and topology
- Expected network growth
- Available resources for ongoing maintenance

Budget

When making any business decision, the budget must always be considered. Static routing does not involve special hardware, fancy software, or expensive training courses.

Dynamic routing can include all of these extra expenses. Any new routing hardware such as routers and switches need to support your chosen protocols. Network management software to help configure and maintain your more complex network, and routing protocol drivers may be necessary as well. If the network administrators are not well versed in dynamic routing, either a training course or some hands on learning time must be budgeted so they can administer the new network with confidence. Together, these factors will use up your budget quickly.

Additionally people account for network starting costs in the budgets, but usually leave out the ongoing cost of network maintenance. Any budget must provide for the hours that will be spent on updating the network routing equipment, and fixing any problems. Without that money in the budget, you may end up back at static routing before you know it.

Current network size and topology

As stated earlier static routing works well on small networks. At those networks get larger, routing takes longer, routing tables get very large, and general performance isn't what it could be.

Topology is a concern as well. If all your computers are in one building, its much easier to stay with static routing longer. However, connecting a number of locations will be easier with the move to dynamic routing.

If you have a network of 20 computers, you can still likely use static routing. If those computers are in two or three locations, static routing will still be a good choice for connecting them. Also, if you just connect to your ISP and don't worry about any special routing to do that, you are likely safe with just static routing.

If you have a network of 100 computers in one location, you can use static routing but it will be getting slower, more complex, and there won't be much room for expansion. If those 100 computers are spread across three or more locations, dynamic routing is the way to go.

If you have 1000 comptuers, you definitely need to use dynamic routing no matter how many locations you have.

Hopefully this section has given you an idea of what results you will likely experience from different sized networks using different routing protocols. Your choice of which dynamic routing protocol to use is partly determined by the network size, and topology.

Expected network growth

You may not be sure if your current network is ready for dynamic routing. However, if you are expecting rapid growth in the near future, it is a good idea to start planning for that growth now so you are ready for the coming expansion.

Static routing is very labor intensive. Each network device's routing table needs to be configured and maintained manually. If there is a large number of new computers being added to the network, they each need to have the static routing table configured and maintained. If devices are being moved around the network frequently, they must also be updated each time.

Instead, consider putting dynamic routing in place before those new computers are installed on the network. The installation issues can be worked out with a smaller and less complex network, and when those new computers or routers are added to the network there will be nowhere near the level of manual configuration required. Depending on the level of growth, this labor savings can be significant. For example, in an emergency you can drop a new router into a network or AS wait for it to receive the routing updates from its neighbors, and then remove one of the neighbors. While the routes will not be the most effective possible, this method is much less work than static routing in the same situation with less chance of mistakes.

Also as your network grows and you add more routers, those new routers can help share the load in most dynamic routing configurations. For example if you have 4 OSPF routers and 20,000 external routes those few routers will be overwhelmed. But in a network with 15 OSPF routers they will better be able to handle that number of routes. Be aware though that adding more routers to your network will increase the amount of updates sent between the routers, which will take up some of your bandwidth.

Available resources for ongoing maintenance

As touched on in the budget section, there must be resources dedicated to ongoing network maintenance, upgrades, and troubleshooting. These resources include administrator hours to configure and maintain the network, training for the administrator if needed, extra hardware and software as needed, and possible extra staff to help the administrator in emergencies. Without these resources, you will quickly find the network reverting to static routing out of necessity. This is because:

- Routing software updates will require time.

- Routing hardware updates will require time.
- Office reorganizations or significant personnel movement will require time from a networking point of view.
- Networking problems that occur, such as failed hardware, require time to locate and fix the problem.

If the resources to accomplish these tasks are not budgeted, they will either not happen or not happen at the required level to continue operation. This will result in both the network administration staff and the network users being very frustrated.

A lack of maintenance budget will also result in increasingly heavy reliance on static routing as the network administrators are forced to use quick fixes for problems that come up. This invariably involves going to static routing, and dropping the more complex and time consuming dynamic routing.

Choosing a routing protocol

One of that hardest decisions in routing can be choosing which routing protocol to use on your network. It can be easy to decide when static routing will not meet your needs, but how can you tell which dynamic routing protocol is best for your network and situation?

Here is a brief look at the routing protocols including their strongest and weakest points. The steps to choosing your routing protocol are:

1. Answer questions about your network
2. Dynamic routing terminology
3. Evaluate your chosen protocol
4. Implement your dynamic routing protocol

Answer questions about your network

Before you can decide what is best for your situation, you need to examine what the details of your situation are such as what you have for budget, equipment, and users.

The following questions will help you form a clear idea of your routing needs:

How many computers or devices are on your network?

It matters if you only have a few computers, or if you have many and if they are all at one location or not as well. All routing protocols can be run on any sized network, however it can be inefficient to run some on very small networks. However, routers and network hardware that support dynamic routing can be more expensive than more generic routers for static routing.

What applications typically run over the network?

Finding out what application your users are running will help you determine their needs and the needs of the network regarding bandwidth, quality of service, and other such issues.

What level of service to the users expect from the network?

Different network users have different expectations of the network. Its not critical for someone surfing the Internet to have 100% uptime, but it is required for a stock exchange network or a hospital.

Is there network expansion in your near future?

You may have a small network now, but if it will be growing quickly, you should plan for the expected size so you don’t have to chance technologies again down the road.

What routing protocols do your networks connect to?

This is most often how routing protocol decisions are made. You need to be able to communicate easily with your service provider and neighbors, so often people simply use what everyone else is using.

Is security a major concern?

Some routing protocols have levels of authentication and other security features built in. Others do not. If security is important to you, be aware of this.

What is your budget — both initial and maintenance?

More robust and feature laden routing protocols generally mean more resources are required to keep them working well. Also more secure configurations require still more resources. This includes both set up costs, as well as ongoing maintenance costs. Ignore these costs at the risk of having to drop the adoption of the new routing protocol mid-change.

Evaluate your chosen protocol

Once you have examined the features of the routing protocols listed above and chosen the one that best meets your needs, you can set up an evaluation or test install of that protocol.

The test install is generally set up in a sandbox configuration so it will not affect critical network traffic. The aim of the test install is to prove that it will work on a larger scale on your network. So be sure that the test install mirrors your larger network well enough for you to discover any problems. If its too simplistic, these problems may not appear.

If your chosen protocol does not meet your goals choose a different protocol and repeat the evaluation process until either a protocol meets your needs, or you change your criteria.

Implement your dynamic routing protocol

You have examined your needs, selected the best matching dynamic routing protocol, tested it, and now you are ready to implement it with confidence.

This guide will help you configure your FortiGate unit to support your chosen dynamic routing protocol. Refer to the various sections in this guide as needed during your implementation to help ensure a smooth transition. Examples for each protocol have been included to show proper configurations for different types of networks.

Dynamic routing terminology

Dynamic routing is a complex subject. There are many routers on different networks and all can be configured differently. It become even more complicated when you add to this each routing protocol having slightly different names for similar features, and many configurable features for each protocol.

To better understand dynamic routing, here are some explanations of common dynamic routing terms.

- Aggregated routes and addresses
- Autonomous system (AS)
- Area border router (ABR)
- Neighbor routers
- Route maps

- Access lists
- Bi-directional forwarding detection (BFD)

For more details on a term as it applies to a dynamic routing protocol, see one of "Border Gateway Protocol (BGP)" on page 1751, "Routing Information Protocol (RIP)" on page 1715, or "Open Shortest Path First (OSPF)" on page 1787.

Aggregated routes and addresses

Just as an aggregate interface combines multiple interfaces into one virtual interface, an aggregate route combines multiple routes into one. This reduces the amount of space those routes require in the routing tables of the routers along that route. The trade-off is a small amount of processing to aggregate and de-aggregate the routes at either end.

The benefit of this method is that you can combine many addresses into one, potentially reducing the routing table size immensely. The weakness of this method is if there are holes in the address range you are aggregating you need to decide if its better to break it into multiple ranges, or accept the possibility of failed routes to the missing addresses.

To manually aggregate the range of IP addresses from 192.168.1.100 to 192.168.1.103

1 Convert the addresses to binary

```
192.168.1.100 = 11000000 10101000 00000001 01100100
192.168.1.101 = 11000000 10101000 00000001 01100101
192.168.1.102 = 11000000 10101000 00000001 01100110
192.168.1.103 = 11000000 10101000 00000001 01100111
```

2 Determine the maximum number of matching bits common to the addresses.

There are 30-bits in common, with only the last 2-bits being different.

3 Record the common part of the address.

```
11000000 10101000 00000001 0110010X = 192.168.1.100
```

4 For the netmask, assume all the bits in the netmask are 1 except those that are different which are 0.

```
11111111 11111111 11111111 11111100 = 255.255.255.252
```

5 Combine the common address bits and the netmask.

```
192.168.1.100/255.255.255.252
```

Alternately the IP mask may be written as a single number:

```
192.168.1.100/2
```

6 As required, set variables and attributes to declare the routes have been aggregated, and what router did the aggregating.

Autonomous system (AS)

An Autonomous System (AS) is one or more connected networks that use the same routing protocol, and appear to be a single unit to any externally connected networks. For example an ISP may have a number of customer networks connected to it, but to any networks connected externally to the ISP it appears as one system or AS. An AS may also be referred to as a routing domain.

It should be noted that while OSPF routing takes place within one AS, the only part of OSPF that deals with the AS is the AS border router (ASBR).

There are multiple types of AS defined by how they are connected to other ASes. A multihomed AS is connected to at least two other ASes and has the benefit of redundancy — if one of those ASes goes down, your AS can still reach the Internet through its other connection. A stub AS only has one connection, and can be useful in specific configurations where limited access is desirable.

Each AS has a number assigned to it, known as an ASN. In an internal network, you can assign any ASN you like (a private AS number), but for networks connected to the Internet (public AS) you need to have an officially registered ASN from Internet Assigned Numbers Authority (IANA). ASNs are typically 16-bit numbers — ASNs from 1 - 64,511 are designated for public use.

As of January 2010, AS numbers are 4 bytes long instead of the former 2 bytes. RFC 4893 introduced 32-bit ASNs, which FortiGate units support.

Do you need your own AS?

The main factors in deciding if you need your own AS or if you should be part of someone else's are:

- exchanging external routing information
- many prefixes should exist in one AS as long as they use the same routing policy
- when you use a different routing protocol than your border gateway peers (for example your ISP uses BGP, and you use OSPF)
- connected to multiple other AS (multi-homed)

You should not create an AS for each prefix on your network. Neither should you be forced into an AS just so someone else can make AS-based policy decisions on your traffic.

There can be only one AS for any prefix on the Internet. This is to prevent routing issues.

What AS number to use?

In addition to overseeing IP address allocation and Domain Name Systems (DNS), the Internet Assigned Numbers Authority (IANA) assigns public AS numbers. The public AS numbers are from 1 to 64,511. The ASNs 0, 54272–64511, and 65535 are reserved by the IANA. These ASNs should not be used.

ASNs are assigned in blocks by the Internet Assigned Numbers Authority (IANA) to Regional Internet Registries (RIRs) who then assign ASNs to companies within that RIRs geographic area. Usually these companies are ISPs, and to receive an ASN you must complete the application process of the local RIR and be approved before being assigned an ASN. The RIRs names and regions are:

AFRINIC	Serves the African continent
APNIC	Asia-Pacific including China, India, and Japan
ARIN	American registry including Canada and United States
LACNIC	Latin America, including Mexico, Caribbean, Central and South America
RIPE NCC	Europe, the Middle East, former USSR, and parts of Central Asia

AS numbers from 64512 to 65534 are reserved for private use. Private AS numbers can be used for any internal networks with no outside connections to the Internet such as test networks, classroom labs, or other internal-only networks that do not access the outside world. You can also configure border routers to filter out any private ASNs before routing traffic to the outside world. If you must use private ASNs with public networks, this is the only way to configure them. However, it is risky because many other private networks could be using the same ASNs and conflicts will happen. It would be very much like your local 192.168.0.0 network being made public — the resulting problems would be widespread.

In 1996, when RFC 1930 was written only 5,100 ASes had been allocated and a little under 600 ASes were actively routed in the global Internet. Since that time many more public ASNs have been assigned, leaving only a small number. For this reason 32-bit ASNs (four-octet ASNs) were defined to provide more public ASNs. RFC 4893 defines 32-bit ASNs, and FortiGate units support these larger ASNs as of FortiOS version 4.2

Area border router (ABR)

Routers within an AS advertise updates internally and only to each other. However, routers on the edge of the AS must communicate both with routers inside their AS and with routers external to their AS, often running a different routing protocol. These routers are called Area Border Routers (ABRs) or edge routers. Often ABRs run multiple routing protocols to be able to redistribute traffic between different ASes that are running different protocols, such as the edge between an ISP's IS-IS routing network and an large company's OSPF network.

OSPF defines ABRs differently from other routers. In OSPF, an ABR is an OSPF router that connects another AS to the backbone AS, and is a member of all the areas it connects to. An OSPF ABR maintains a LSA database for each area that it is connected to. The concept of the edge router is present, but its the edge of the backbone instead of the edge of the OSPF supported ASes.

Neighbor routers

Routing involves routers communicating with each other. To do this, routers need to know information about each other. These routers are called neighbor routers, and are configured in each routing protocol. Each neighbor has custom settings since some routers may have functionality others routers lack. Neighbour routers are sometimes called peers.

Generally neighbor routers must be configured, and discovered by the rest of the network before they can be integrated to the routing calculations. This is a combination of the network administrator configuring the new router with its neighbor router addresses, and the routing network discovering the new router, such as the hello packets in OSPF. That discovery initiates communication between the new router and the rest of the network.

Route maps

Route maps are a way for the FortiGate unit to evaluate optimum routes for forwarding packets or suppressing the routing of packets to particular destinations. Compared to access lists, route maps support enhanced packet-matching criteria. In addition, route maps can be configured to permit or deny the addition of routes to the FortiGate unit routing table and make changes to routing information dynamically as defined through route-map rules.

Route maps can be used for limiting both received route updates, and sent route updates. This can include the redistribution of routes learned from other types of routing. For example if you don't want to advertise local static routes to external networks, you could use a route map to accomplish this.

The FortiGate unit compares the rules in a route map to the attributes of a route. The rules are examined in ascending order until one or more of the rules in the route map are found to match one or more of the route attributes.

As an administrator, route maps allow you to group a set of addresses together and assign them a meaningful name. Then during your configuration, you can use these route-maps to speed up configuration. The meaningful names ensure fewer mistakes during configuration as well.

The default rule in the route map (which the FortiGate unit applies last) denies all routes. For a route map to take effect, it must be called by a FortiGate unit routing process.

The syntax for route maps are:

```
config router route-map
  edit <route_map_name>
    set comments
    config rule
    edit <route_map_rule_id>
      set action
      set match-*
      set set-*
```

The `match-*` commands allow you to match various parts of a route. The `set-*` commands allow you to set routing information once a route is matched.

For an example of how route maps can be used to create receiving or sending "groups" in routing, see "Redistributing and blocking routes in BGP" on page 1780.

Access lists

Use this command to add, edit, or delete access lists. Access lists are filters used by FortiGate unit routing processes. For an access list to take effect, it must be called by a FortiGate unit routing process (for example, a process that supports RIP or OSPF). Use `access-list6` for IPv6 routing.

Access lists can be used to filter which updates are passed between routers, or which routes are redistributed to different networks and routing protocols. You can create lists of rules that will match all routes for a specific router or group of routers.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

The syntax for access lists is:

```
config router access-list, access-list6
  edit <access_list_name>
    set comments
```

```
config rule
edit <access_list_id>
  set action
  set exact-match
  set prefix
  set prefix6
  set wildcard
```

For an example of how access lists can be used to create receiving or sending “groups” in routing, see “Redistributing and blocking routes in BGP” on page 1780.

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-protected router fail to arrive, then that router is declared down. BFD communicates this information to the routing protocol and the routing information is updated.

BFD neighbors establish if BFD is enabled in OSPF or BFP routers that establish as neighbors.

The CLI commands associated with BFD include:

```
config router bgp
  config neighbor
    set bfd

config router ospf
  set bfd
```

Per-VDOM configuration:

```
config system settings
  set bfd
  set bfd-desired-min-tx
  set bfd-required-min-rx
  set bfd-detect-mult
  set bfd-dont-enforce-src-port
```

Per-interface (override) configuration:

```
config system interface
  edit <interface_name>
    set bfd enable
    set bfd-desired-min-tx
    set bfd-detect-mult
    set bfd-required-min-rx
```

For more information about BFD in BGP, see “Bi-directional forwarding detection (BFD)” on page 1766.

IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming popular and new versions of the dynamic routing protocols have been introduced.

As of FortiOS v4.1, dynamic routing supports IPv6 on your FortiGate unit. The new versions of these protocols and the corresponding RFCs are:

- **BGP4+** — RFC 2545, and RFC 2858 Multiprotocol Extensions for IPv6 Inter-Domain Routing, and Multiprotocol Extensions for BGP-4 (MP-BGP) respectively. See "BGP and IPv6" on page 1752
- **RIP next generation (RIPng)** — RFC 2080 - Routing Information Protocol next generation (RIPng). See "RIP and IPv6" on page 1716.
- **OSPFv3** — RFC 2740 Open Shortest Path First version 3 (OSPFv3) for IPv6 support. See "OSPF and IPv6" on page 1788.

As with most advanced routing features on your Fortigate unit, IPv6 settings for dynamic routing protocols are CLI-only. To configure IPv6 for RIP, BGP, or OSPF protocols you must use the CLI commands.

Routing Information Protocol (RIP)

This section describes the Routing Information Protocol (RIP).

The following topics are included in this section:

RIP background and concepts

This section contains:

Background

Routing Information Protocol (RIP) is a distance-vector routing protocol intended for small, relatively homogeneous networks. Its widespread use started when an early version of RIP was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by RIP, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

RIP benefits include being well suited to smaller networks, is in widespread use, near universal support on routing hardware, quick to configure, and works well if there are no redundant paths. However, RIP updates are sent out node-by-node so it can be slow to find a path around network outages. RIP also lacks good authentication, can not choose routes based on different quality of service methods, and can create network loops if you are not careful.

The FortiGate implementation of RIP supports RIP version 1 (see RFC 1058), RIP version 2 (see RFC 2453), and the IPv6 version RIPng (see RFC 2080).

RIP v1

In 1988 RIP version 1, defined in RFC 1058, was released. The RFC even states that RIP v1 is based on Linux routed due to it being a “defacto standard”.

It uses classful addressing and uses broadcasting to send out updates to router neighbors. There is no subnet information included in the routing updates in classful routing, and it does not support CIDR addressing — subnets must all be the same size. Also, route summarization is not possible.

RIP v1 has no router authentication method, so it is vulnerable to attacks through packet sniffing, and spoofing.

RIP v2

In 1993, RIP version 2 was developed to deal with the limitations of RIP v1. It was not standardized until 1998. This new version supports classless routing, and subnets of various sizes.

Router authentication was added in RIP v2 — it supports MD5. MD5 hashes are an older encryption method, but this is much improved over no security at all.

In RIP v2 the hop count limit remained at 15 to be backwards compatible with RIP v1.

RIP v2 uses multicasting to send the entire routing table to router neighbors, thereby reducing the traffic for devices that are not participating in RIP routing.

Routing tags were added as well, which allow internal routes or redistributed routes to be identified as such.

RIPng

RIPng, defined in RFC 2080, is an extension of RIP2 designed to support IPv6. However, RIPng varies from RIPv2 in that it is not fully backwards compatible with RIPv1.

- RIPng does not support RIPv1 update authentication, it relies on IPsec
- RIPng does not allow attaching tags to routes as in RIPv2
- RIPng requires specific encoding of the next hop for a set of route entries, unlike RIPv2 that encodes the next-hop into each route entry .

Parts and terminology of RIP

Before you can understand how RIP functions, you need to understand some of the main concepts and parts of RIP.

This section includes:

- RIP and IPv6
- Default information originate option
- Garbage, timeout, and update timers
- Authentication and key-chain
- Access Lists

RIP and IPv6

RIP Next Generation (RIPng) is a new version of RIP was released that includes support for IPv6.

The FortiGate unit command `config router ripng` is almost the same as `config router rip`, except that IPv6 addresses are used. Also if you are going to use prefix or access lists with RIPng, you must use the `config router access-list6` or `config prefix-list6` versions of those commands.

If you want to troubleshoot RIPng, it is the same as with RIP but specify the different protocol, and use IPv6 addresses. This applies to commands such as `get router info6` when you want to see the routing table, or other related information.

If you want to route IPv4 traffic over an IPv6 network, you can use the command config system ip6-tunnel to configure the FortiGate unit to do this. The IPv6 interface is configured under `config system interface`. All subnets between the source and destination addresses must support IPv6. This command is not supported in Transparent mode.

For example, you want to set up a tunnel on the port1 interface starting at 2002:C0A8:3201:: on your local network and tunnel it to address 2002:A0A:A01:: where it will need access to an IPv4 network again. Use the following command:

```
config system ipv6-tunnel
  edit test_tunnel
    set destination 2002:A0A:A01::
    set interface port1
    set source 2002:C0A8:3201::
  end
end
```

The CLI commands associated with RIPng include:

```
config router ripng
config router access-list6
config router prefix-list6
config system ipv6-tunnel
get router info6 *
```

Default information originate option

This is the second advanced option for RIP in the web-based manager, right after metric. Enabling default-information-originate will generate and advertise a default route into the FortiGate unit's RIP-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. RIP does not create the default route unless you use the always option.

Select *Disable* if you experience any issues or if you wish to advertise your own static routes into RIP updates.

The CLI commands associated with default information originate include:

```
config router rip
  set default-information-originate
end
```

Garbage, timeout, and update timers

RIP uses various timers to regulate its performance including a garbage timer, timeout timer, and update timer. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations — if you change these settings, ensure that the new settings are compatible with local routers and access servers.

The Timeout period should be at least three times longer than the Update period. If the Update timer is smaller than Timeout or Garbage timers, you will experience an error.

The CLI commands associated with garbage, timeout, and update timers include:

```
config router rip
  set garbage-timer
  set timeout-timer
  set update-timer
end
```

Garbage timer

The garbage timer is the amount of time (in seconds) that the FortiGate unit will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This will result in a smaller routing table which is useful if you have a very large network, or if your network changes frequently.

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, otherwise you will experience an error.

If you are experiencing significant RIP traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience time outs that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the FortiGate unit will keep a reachable route in the routing table while no updates for that route are received. If the FortiGate unit receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the depute period, otherwise you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods — it may be considerable time before the time the FortiGate unit is done waiting for all the timers to expire on unresponsive routes.

Authentication and key-chain

RIP version 2 uses authentication keys to ensure that the routing information exchanged between routers is reliable. RIP version 1 has no authentication. For authentication to work both the sending and receiving routers must be set to use authentication, and must be configured with the same keys.

The sending and receiving routers need to have their system dates and times synchronized to ensure both ends are using the same keys at the proper times. However, you can overlap the key lifetimes to ensure that a key is always available even if there is some difference in the system times.

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. The FortiGate unit migrates from one key to the next according to the scheduled send and receive lifetimes.

Key-chain is a CLI router command. You use this command to manage RIP version 2 authentication keys. You can add, edit or delete keys identified by the specified key number.

This example shows how to configure a key-chain with two keys that are valid sequentially in time. This example creates a key-chain called “rip_key” that has a password of “fortinet”. The accepted and send lifetimes are both set to the same values — a start time of 9:00am February 23, 2010 and an end time of 9:00am March 17, 2010. A second key is configured with a password of “my_fortigate” that is valid from March 17, 2010 9:01am to April 1 2010 9:00am. This “rip_key” keychain is then used on the port1 interface in RIP.

```
config router key-chain
  edit "rip_key"
    config key
    edit 1
      set accept-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
      set key-string "fortinet"
      set send-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
    next
    edit 2
      set accept-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
      set key-string "my_fortigate"
      set send-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
    next
    end
  end
config router rip
  config interface
    edit port1
      set auth-keychain “rip_key”
    end
  end
```

The CLI commands associated with authentication keys include:

```
  config router key-chain

  config router rip
    config interface
    edit <interface>
      set auth-keychain
      set auth-mode
      set auth-string
    end
  end
```

Access Lists

Access lists are filters used by FortiGate unit RIP and OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also its easier to troubleshoot since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the RIPng or OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
  edit test_list
  config rule
    edit 1
      set prefix 10.10.10.10 255.255.255.255
      set action allow
      set exact-match enable
    next
    edit 2
      set prefix 11.11.11.11 255.255.255.255
      set action allow
      set exact-match enable
    end
  end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
  edit test_list_ip6
  config rule
    edit 1
      set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
      set action deny
    next
    edit 2
      set prefix6 2002:B0B:B0B:0:0:0:0:0/48
      set action deny
    end
  end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially increase . Enter the following command:

```
config router rip
  config offset-list
    edit 5
      set access-list test_list
```

```
    set direction in
    set interface port1
    set offset 3
    set status enable
  end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose

How RIP works

As one of the original modern dynamic routing protocols, RIP is straight forward. It's routing algorithm is not complex, there are some options to allow fine tuning, and its straight forward to configure RIP on FortiGate units.

From RFC 1058:

> Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.

This section includes:

- RIP versus static routing
- RIP metric — hop count
- The Bellman–Ford routing algorithm
- Passive versus active RIP interfaces
- RIP packet structure

RIP versus static routing

RIP was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, RIP is a big step forward from simple static routing.

While RIP may be slow in response to network outages, static routing has zero response. The same is true for convergence — static routing has zero convergence. Both RIP and static routing have the limited hop count, so its not a strength or a weakness. Count to infinity can be a problem, but typically can be fixed as it happens or is the result of a network outage that would cause even worse problems on static routing network.

Overall, RIP is a large step forward when compared to static routing.

RIP metric — hop count

RIP uses hop count as the metric for choosing the best route. A hop count of 1 represents a network that is connected directly to the FortiGate unit, while a hop count of 16 represents a network that cannot be reached. Each network that a packet travels through to reach its destination usually counts as one hop. When the FortiGate unit compares two routes to the same destination, it adds the route having the lowest hop count to the routing table. As you can see in "RIP packet structure" on page 1725, the hop count is part of a RIP v2 packet making it very important.

Similarly, when RIP is enabled on an interface, the FortiGate unit sends RIP responses to neighboring routers on a regular basis. The updates provide information about the routes in the FortiGate unit's routing table, subject to the rules that you specify for advertising those routes. You can specify how often the FortiGate unit sends updates, the period of time a route can be kept in the routing table without being updated, and for routes that are not updated regularly you can specify the period of time that the unit advertises a route as unreachable before it is removed from the routing table.

If hops are weighted higher than one, it becomes very easy to reach the upper limit. This higher weighting will effectively limit the size of your network depending on the numbers used. Merely changing from the default of 1.0 to 1.5 will lower the effective hop count from 15 to 10. This is acceptable for smaller networks, but can be a problem as your network expands over time.

In RIP, you can use the offset command to artificially increase the hop count of a route. Doing this will make this route less preferred, and in turn it will get less traffic. Offsetting routes is useful when you have network connections of different bandwidths, different levels of reliability, or different costs. In each of these situations you still want the redundancy of multiple route access, but you don't want the bulk of your traffic using these less preferred routes. For an example of RIP offset, see "Access Lists" on page 1719.

The Bellman–Ford routing algorithm

The routing algorithm used by RIP was first used in 1967 as the initial routing algorithm of the ARPANET. The Bellman–Ford algorithm is distributed because it involves a number of nodes (routers) within an Autonomous system, and consists of the following steps:

1. Each node calculates the distances between itself and all other nodes within the AS and stores this information as a table.
2. Each node sends its table to all neighboring nodes.
3. When a node receives distance tables from its neighbors, it calculates the shortest routes to all other nodes and updates its own table to reflect any changes.

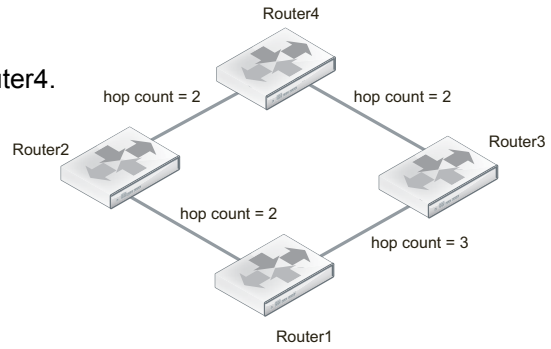
To examine how this algorithm functions let's look at a network with 4 routers — routers 1 through 4. The distance from router1 to router2 is 2 hops, 1 to 3 is 3 hops, and 2 to 3 is 4 hops. Router4 is only connected to routers 2 and 3, each distance being 2 hops.

1. Router1 finds all the distance to the other three routers — router 2 is 2, router 3 is 3. Router1 doesn't have a route to router 4.
2. Routers 2 through 4 do the same calculations from their point of views.
3. Once router 1 gets an update from router 2 or 3, it will get their route to router 4. At that point it now has a route to router 4 and installs that in its local table.
4. If router1 gets an update from router3 first, it has a hop count of 5 to reach router4. But when router2 sends its update, router1 will go with router2's shorter 4 hops to reach router4. Future updates don't change this unless they are shorter than 4 hops, or the routing table route goes down.

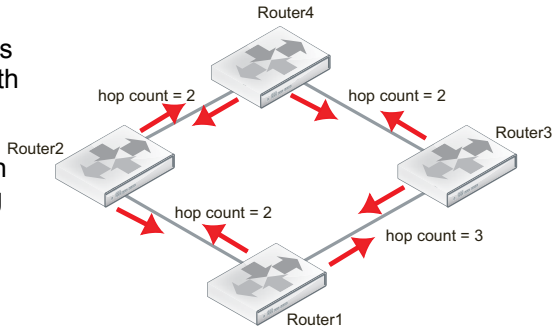
Figure 164: RIP algorithm example in 4 steps

Step 1. Router1 finds the distance to other routers. It has no route to router4.

Router1 table:
Distance to route2= 2 hops
Distance to router3 = 3 hops

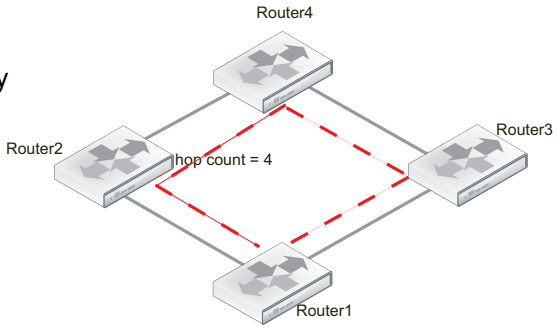


Step 2. All routers do the same as router1, and send out updates with the table of routes.
Note that router1 and router4 do not update each other, but rely on router2 and router3 to pass along deputes.



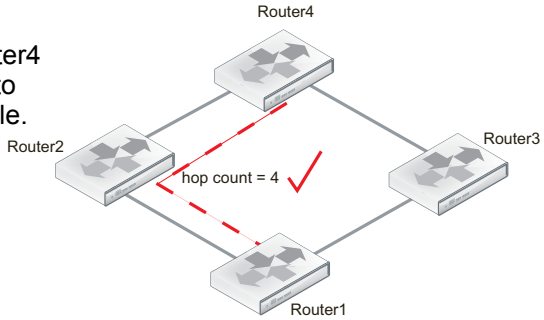
Step 3. Each router looks at the updates it receives, and adds any new or shorter routes to its table.

Router1 updated table:
Distance to router2 = 2 hops
Distance to router3 = 3 hops
Distance to router4 = 4 hops
Distance to router4 = 5 hops



Step 4. The shortest route to router4 is installed, and the other routes to router4 are removed from the table.

Router1 updated table:
Distance to router2 = 2 hops
Distance to router3 = 3 hops
Distance to router4 = 4 hops



The good part about the Bellman-Ford algorithm in RIP is that the router only uses the information it needs from the update. If there are no newer, better routes than the ones the router already has in its routing table, there is no need to change its routing table. And no change means no additional update, so less traffic. But even when there is update traffic, the RIP packets are very small so it takes many updates to affect overall network bandwidth. For more information about RIP packets, see "RIP packet structure" on page 1725.

The main disadvantage of the Bellman–Ford algorithm in RIP is that it doesn't take weightings into consideration. While it is possible to assign different weights to routes in RIP, doing so severely limits the effective network size by reducing the hop count limit. Also other dynamic routing protocols can take route qualities, such as reliability or delay, into consideration to provide not only the physically shortest but also the fastest or more reliable routes as you choose.

Another disadvantage of the Bellman-Ford algorithm is due to the slow updates passed from one RIP router to the next. This results in a slow response to changes in the network topology, which in turn results in more attempts to use routes that are down which wastes time and network resources.

Passive versus active RIP interfaces

Normally the FortiGate unit's routing table is kept up to date by periodically asking the neighbors for routes, and sending your routing updates out. This has the downside of generating a lot of extra traffic for large networks. The solution to this problem is passive interfaces.

An standard interface that supports RIP is active by default — it both sends and receives updates by actively communicating with its neighbors. A passive RIP interface does not send out updates — it just listens to the updates of other routers. This is useful in reducing network traffic, and if there are redundant routers in the network that would be sending out essentially the same updates all the time.

The following example shows how to create a passive RIP v2 interface on port1, using MD5 authentication and a key-chain called `passiveRIPv2` that has already been configured. Note that in the CLI, you enable passive by disabling `send-version2-broadcast`.

To create a passive RIP interface - web-based manager

1 Go to *Router* > *Dynamic* > *RIP*.
2 Under *Interfaces*, select *Create New*.
3 Select port1 as the *Interface*.
4 Select 2 as both the *Send Version* and *Receive Version*.
5 Select MD5 for *Authentication*.
6 Select the `passiveRIPv2` *Key-chain*.
7 Select *Passive Interface*.
8 Select *OK* to accept this configuration, and return to the main RIP display page.

To create a passive RIP v2 interface on port1 using MD5 authentication- CLI

```
config router rip
  config interface
  edit port1
    set send-version2-broadcast disable
    set auth-keychain "passiveRIPv2"
```

```
      set auth-mode md5
      set receive-version 2
      set send-version 2
    end
  end
```

RIP packet structure

It is hard to fully understand a routing protocol without knowing what information is carried in its packets. Knowing what information is exchanged between routers and how will help you better understand the RIP protocol, and better configure your network for it.

This section provides information on the contents of RIP 1 and RIP 2 packets.

RIP version 1

RIP version 1, or RIP IP packets are 24 bytes in length. The empty areas were left for future expansion.

Table 99: RIP IP packets

1-byte command	1-byte version	2-byte zero field	2-byte AFI	2-byte zero field
4-byte IP address	4-byte zero field	4-byte zero field	4-byte metric	

The following descriptions summarize the RIP version 1 packet fields.

Command — Indicates whether the packet is a request or a response. The request asks that a router send all or part of its routing table. The response can be an unsolicited regular routing update or a reply to a request. Responses contain routing table entries. Multiple RIP packets are used to convey information from large routing tables.

Version — Specifies the RIP version used. This field can signal different potentially incompatible versions.

Zero field — This field defaults to zero, and is not used by RFC 1058 RIP.

Address-family identifier (AFI) — Specifies the address family used. RIP is designed to carry routing information for several different protocols. Each entry has an address-family identifier to indicate the type of address being specified. The AFI for IP is 2.

IP Address — Specifies the IP address for the entry.

Metric — This is the number of hops or routers traversed along the route on its trip to the destination. The metric is between 1 and 15 for that number of hops. If the route is unreachable the metric is 16.

RIP version 2

RIP version 2 has more features that RIP 1 and this is reflected in its packets. RIP 2 packets are similar in format to RIP 1, but carry more information. All but one of the empty zero fields in RIP 1 packets now contain information.

Table 100: RIP 2 packets

1-byte command	1-byte version	2-byte unused	2-byte AFI	2-byte route tag	4-byte IP address	4-byte subnet	4-byte next hop	4-byte metric

The following descriptions summarize the fields RIP 2 adds to the RIP IP header. The other fields have been described above for RIP 1.

Unused — Has a value set to zero, and is intended for future use

Route tag — Provides a method for distinguishing between internal routes learned by RIP and external routes learned from other protocols.

Subnet mask — Contains the subnet mask for the entry. If this field is zero, no subnet mask has been specified for the entry.

Next hop — Indicates the IP address of the next hop to which packets for the entry should be forwarded.

Troubleshooting RIP

This section is about troubleshooting RIP. For general troubleshooting information, see the Troubleshooting chapter.

This section includes:

- Routing Loops
- Split horizon and Poison reverse updates
- Debugging IPv6 on RIPng

Routing Loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loops' effect on the network

In addition to this "traffic jam" of routed packets, every time the routing table for a router changes that router sends an update out to all of the RIP routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

Some methods to troubleshoot your outage include:

- Check your logs

- Use SNMP network monitoring
- Use dead gateway detection and e-mail alerts
- Look at the packet flow

If you aren't running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it. Ping, traceroute, and other basic troubleshooting tools are covered in "" on page 1714.

Check your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to *Log & Report* > *Log & Archive Access*. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Use SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1 Go to *System* > *Config* > *SNMP*.

2 Enable *SMTP Agent* and select *Apply*.

Optionally enter the *Description*, *Location*, and *Contact* information for this device for easier location of the problem report.

3 Under *SNMP v1/v2* or *SNMP v3* as appropriate, select *Create New*.

SNMP v3

User Name	Enter the SNMP user ID.
Security Level	Select authentication or privacy as desired. Select the authentication or privacy algorithms to use and enter the required passwords.
Notification Host	Enter the IP addresses of up to 16 hosts to notify.
Enable Query	Select. The *Port* should be 161. Ensure that your security policies allow ports 161 and 162 (SNMP queries and traps) to pass.

SNMP v1/v2

Hosts	Enter the IP addresses of up to 8 hosts to notify. You can also specify the network *Interface*, or leave it as *ANY*.
Queries	Enable *v1* and/or *v2* as needed. The *Port* should be 161. Ensure that your security policies allow port 161 to pass.
Traps	Enable v1 and/or v2 as needed. The Port should be 162. Ensure that your security policies allow port 162 to pass.

4 Select the events for which you want notification. For routing loops this should include *CPU usage is high*, *Memory is low*, and possibly *Log disk space is low* . If there are problems the log will be filling up quickly, and the FortiGate unit's resources will be overused.

5 Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Use dead gateway detection and e-mail alerts

Another tool available to you on FortiGate units is the dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with dead gateway detection and e-mail alerts

1 To configure dead gateway detection, go to *Router* > *Static* > *Settings* and select *Create New*.

2 Enter the *Ping Server* IP address and select the *Interface* that connects to it.

3 Set the *Ping Interval* (how often to send a ping), and *Failover Threshold* (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

To configure notification of failed gateways

1 Go to *Log&Report >Log Config* > *Alert E-mail*.

2 Enter your email details.

3 Select the *Configuration changes* event.

4 Select *Apply*.

You might also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email about the outage.

Look at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. This is same idea as police pulling over a car and asking the driver where they have been, and what the conditions were like.

The method used in the troubleshooting sections "Debugging IPv6 on RIPng" on page 1729 and on debugging the packet flow apply here as well. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable.

Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let's call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A's route to get to C. This route is A-B-C, so it will not work. However, if B tries to use it this begins an endless loop.

This situation is called a split horizon because from B's point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This "poisoned" route is marked as unreachable for routers that cannot use it. In RIP this means that route is marked with a distance of 16.

Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
FGT# diagnose debug enable
FGT# diagnose ipv6 router rip level info
FGT# diagnose ipv6 router rip all enable
```

These three commands will:

- turn on debugging in general

- set the debug level to information, a verbose reporting level
- turn on all rip router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

For more information, see "Testing the IPv6 RIPng information" on page 1750

RIP routing examples

The following examples for RIP:

- Simple RIP example
- RIPng — RIP and IPv6

Simple RIP example

This is an example of a typical medium sized network configuration using RIP routing.

Your company has 3 small local networks, one for each department. These networks are connected by RIP, and then connected to the Internet. Each subnet has more than one route, for redundancy. There are two central routers that are both connected to the internet, and to the other networks. If one of those routers goes down, the whole network can continue to function normally.

The ISP is running RIP, so no importing or exporting routes is required on the side of the network. However, since the internal networks have static networking running those will need to be redistributed through the RIP network.

To keep the example simple, there will be no authentication of router traffic.

With RIP properly configured, if the device fails or temporarily goes offline, the routes will change and traffic will continue to flow. RIP is good for a smaller network due to its lack of complex configurations.

This section includes the following topics:

- Network layout and assumptions
- General configuration steps
- Configuring the FortiGate units system information
- Configuring other networking devices
- Testing network configuration

Network layout and assumptions

Basic network layout

Your company has 3 departments each with their own network — Sales, R&D, and Accounting. Each network has routers that are not running RIP as well as FortiGate units running RIP.

The R&D network has two RIP routers, and each is connected to both other departments as well as being connected to the Internet through the ISP router. The links to the Internet are indicated in black.

The three internal networks do not run RIP. They use static routing because they are small networks. This means the FortiGate units have to redistribute any static routes they learn so that the internal networks can communicate with each other.

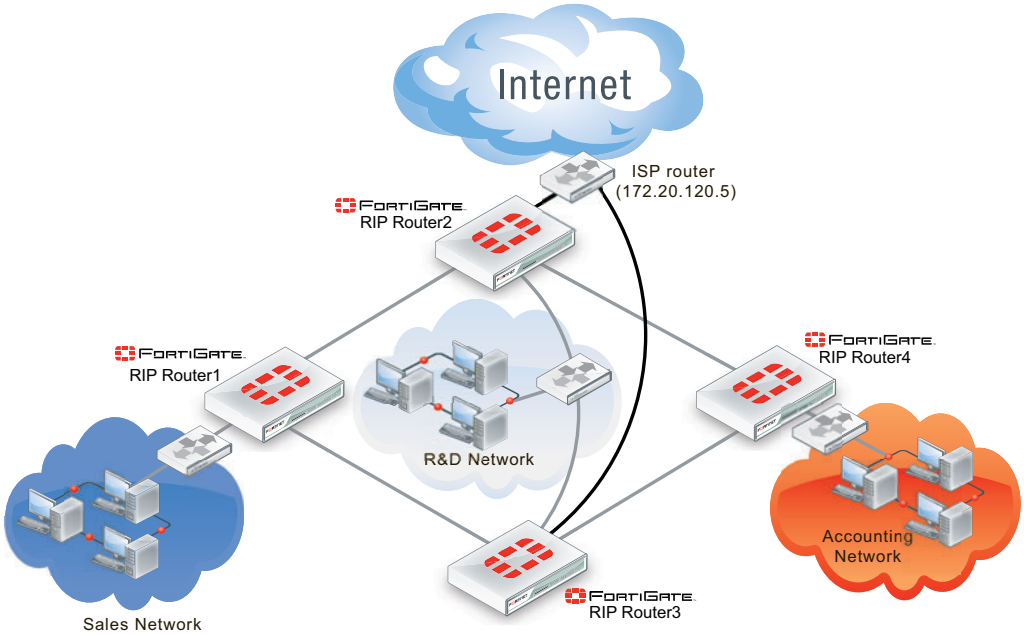
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows. Note that the Interfaces that connect Router2 and Router3 also connect to the R&D network.

Table 101: Rip example network topology

Network	Router	Interface & Alias	IP address
Sales	Router1	port1 (internal)	10.11.101.101
		port2 (router2)	10.11.201.101
		port3 (router3)	10.11.202.101
R&D	Router2	port1 (internal)	10.12.101.102
		port2 (router1)	10.11.201.102
		port3 (router4)	10.14.201.102
		port4 (ISP)	172.20.120.102
	Router3	port1 (internal)	10.12.101.103
		port2 (router1)	10.11.201.103
		port3 (router4)	10.14.202.103
		port4 (ISP)	172.20.120.103
Accounting	Router4	port1 (internal)	10.14.101.104
		port2 (router2)	10.14.201.104
		port3 (router3)	10.14.202.104

Figure 165: Network topology for the simple RIP example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 4.0 MR3 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 through port4 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- Only FortiGate units are running RIP on the internal networks.
- Router2 and Router3 are connected through the internal network for R&D.
- Router2 and Router3 each have their own connection to the Internet, indicated in black in Figure 165.

General configuration steps

This example is very straight forward. The only steps involved are:

- Configuring the FortiGate units system information
- Configuring FortiGate unit RIP router information
- Configuring other networking devices
- Testing network configuration

Configuring the FortiGate units system information

Each FortiGate unit needs their hostname, and interfaces configured.

For IP numbering, Router2 and Router3 use the other routers numbering where needed.

Router2 and Router3 have dead gateway detection enabled on the ISP interfaces using Ping. Remember to contact the ISP and confirm their server has ping enabled.

Configure the hostname, interfaces, and default route

To configure Router1 system information - web-based manager

1 Go to *System* > *Dashboard* > *Status* > *System Information*.

2 Next to *Host Name* select *Change*, and enter “Router1”.

3 Go to *Router* > *Static* > *Static Route*.

4 Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5 Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6 Go to *System* > *Network* > *Interface*.

7 Edit port1 (internal) interface.

8 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal sales network
Administrative Status	Up

9 Edit port2 (router2) interface.

10 Set the following information, and select *OK*.

Alias	router2
IP/Netmask	10.11.201.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & internet through Router2
Administrative Status	Up

11 Edit port3 (router3) interface.

12 Set the following information, and select *OK*.

Alias	router3
IP/Netmask	10.11.202.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and internet through Router3
Administrative Status	Up

To configure Router1 system information - CLI

```
config system global
   set hostname Router1
end

config router static
   edit 1
     set device "port2"
     set distance 45
     set gateway 10.11.201.102
   next
   edit 2
     set device “port3”
     set distance 45
     set gateway 10.11.202.103
   end
end

config system interface
   edit port1
     set alias internal
     set ip 10.11.101.101/255.255.255.0
     set allowaccess https ssh ping
     set description “Internal sales network”
   next
   edit port2
     set alias ISP
     set allowaccess https ssh ping
     set ip 10.11.201.101/255.255.255.0
     set description “Link to R&D network & internet through
        Router2”
   next
   edit port3
     set alias router3
     set ip 10.11.202.101/255.255.255.0
     set allowaccess https ssh ping
     set description “Link to R&D network & internet through
        Router2”
   end
end
```

To configure Router2 system information - web-based manager

1 Go to *System* > *Dashboard* > *Status* > *System Information*.

2 Next to *Host Name* select *Change*, and enter “Router2”.

3 Go to *Router* > *Static* > *Static Route*.

4 Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5 Go to *System* > *Network* > *Interface*.

6 Edit port1 (internal) interface.

7 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.12.101.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router3
Administrative Status	Up

8 Edit port2 (router1) interface.

9 Set the following information, and select *OK*.

Alias	router1
IP/Netmask	10.12.201.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and the Sales network
Administrative Status	Up

10 Edit port3 (router4) interface.

11 Set the following information, and select *OK*.

Alias	router4
IP/Netmask	10.12.301.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and the accounting network
Administrative Status	Up

12 Edit port4 (ISP) interface.

13 Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	172.20.120.102/255.255.255.0
Administrative Access	HTTPS SSH PING

Detect Interface Status for Gateway Load Balancing	enable
Detect Server	172.20.120.5
Detect Protocol	Ping
Detect Interface Status for Gateway Load Balancing	enable
Description	Internet through ISP
Administrative Status	Up

To configure Router2 system information - CLI

```
config system global
  set hostname Router2
end
config router static
  edit 1
    set device "port4"
    set distance 5
    set gateway 172.20.130.5
  end
end
config system interface
  edit port1
    set alias internal
    set ip 10.11.101.102/255.255.255.0
    set allowaccess https ssh ping
    set description “Internal RnD network and Router3”
  next
  edit port2
    set alias router1
    set allowaccess https ssh ping
    set ip 10.11.201.102/255.255.255.0
    set description “Link to Router1”
  next
  edit port3
    set alias router3
    set ip 10.14.202.102/255.255.255.0
    set allowaccess https ssh ping
    set description “Link to Router4”
  next
  edit port4
    set alias ISP
    set ip 172.20.120.102/255.255.255.0
    set allowaccess https ssh ping
    set description “ISP and internet”
  end
end
```

To configure Router3 system information - web-based manager

1 Go to *System* > *Dashboard* > *Status* > *System Information*.

2 Next to *Host Name* select *Change*, and enter “Router3”.

3 Go to *Router* > *Static* > *Static Route*.

4 Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5 Go to *System* > *Network* > *Interface*.

6 Edit port1 (internal) interface.

7 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.12.101.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router2
Administrative Status	Up

8 Edit port2 (router1) interface.

9 Set the following information, and select *OK*.

Alias	router1
IP/Netmask	10.13.201.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and Sales network
Administrative Status	Up

10 Edit port3 (router4) interface.

11 Set the following information, and select *OK*.

Alias	router4
IP/Netmask	10.13.301.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and accounting network
Administrative Status	Up

12 Edit port4 (ISP) interface.

13 Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	172.20.120.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect Interface Status for Gateway Load Balancing	enable
Detect Server	172.20.120.5

Detect Protocol	Ping
Description	Internet and ISP
Administrative Status	Up

To configure Router3 system information - CLI

```
config system global
  set hostname Router3
end

config router static
  edit 1
    set device "port4"
    set distance 5
    set gateway 172.20.130.5
  end
end

config system interface
  edit port1
    set alias internal
    set ip 10.12.101.103/255.255.255.0
    set allowaccess https ssh ping
    set description “Internal RnD network and Router2”
  next
  edit port2
    set alias ISP
    set allowaccess https ssh ping
    set ip 10.11.201.103/255.255.255.0
    set description “Link to Router1”
  next
  edit port3
    set alias router3
    set ip 10.14.202.103/255.255.255.0
    set allowaccess https ssh ping
    set description “Link to Router4”
  next
  edit port4
    set alias ISP
    set ip 172.20.120.103/255.255.255.0
    set allowaccess https ssh ping
    set description “ISP and internet”
  end
end
```

To configure Router4 system information - web-based manager

1 Go to *System* > *Dashboard* > *Status* > *System Information*.

2 Next to *Host Name* select *Change*, and enter “Router4”.

3 Go to *Router* > *Static* > *Static Route*.

4 Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5 Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6 Go to *System* > *Network* > *Interface*.

7 Edit port 1 (internal) interface.

8 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.14.101.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal accounting network
Administrative Status	Up

9 Edit port 2 (router2) interface.

10 Set the following information, and select *OK*.

Alias	router2
IP/Netmask	10.14.201.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & internet through Router2
Administrative Status	Up

11 Edit port 3 (router3) interface.

12 Set the following information, and select *OK*.

Alias	router3
IP/Netmask	10.14.301.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and internet through Router3
Administrative Status	Up

To configure Router4 system information - CLI

```
config system global
  set hostname Router4
```

```
end

config router static
  edit 1
    set device "port2"
    set distance 45
    set gateway 10.14.201.102
  next
  edit 2
    set device “port3”
    set distance 45
    set gateway 10.14.202.103
  end
end

config system interface
  edit port1
    set alias internal
    set ip 10.14.101.104/255.255.255.0
    set allowaccess https ssh ping
    set description “Internal sales network”
  next
  edit port2
    set alias router2
    set allowaccess https ssh ping
    set ip 10.14.201.104/255.255.255.0
    set description “Link to R&D network & internet through
       Router2”
  next
  edit port3
    set alias router3
    set ip 10.14.202.104/255.255.255.0
    set allowaccess https ssh ping
    set description “Link to R&D network & internet through
       Router2”
  end
end
```

Configuring FortiGate unit RIP router information

With the interfaces configured, RIP can now be configured on the FortiGate units.

This includes the following steps:

- configure RIP version used
- redistribute static networks
- add networks serviced by RIP
- add interfaces that support RIP on the Fortigate unit

Router1 and Router4 are configured the same. Router2 and Router3 are configured the same. These routers will be grouped accordingly for the following procedures — repeat the procedures once for each FortiGate unit.

Configure RIP settings on Router1 and Router4 - web-based manager

1 Go to *Router* > *Dynamic* > *RIP*.
2 Select 2 for *RIP Version*.
3 In *Advanced Options*, under *Redistribute* enable *Static*.
4 Leave the other Advanced Options at default values.
5 Enter the following networks, and select *Add* after each:

- 10.11.0.0/255.255.0.0
- 10.12.0.0/255.255.0.0
- 10.14.0.0/255.255.0.0
- 172.20.120.0/255.255.255.0

6 For interface, select *Create New* and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7 For interface, select *Create New* and set the following information.

Interface	port2 (router2)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

8 For interface, select *Create New* and set the following information.

Interface	port3 (router3)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router1 and Router4 - CLI

```
config router rip
  set version 2
  config interface
  edit "port1"
    set receive-version 1 2
    set send-version 1 2
  next
  edit "port2"
    set receive-version 1 2
```

```
    set send-version 1 2
  next
  edit "port3"
    set receive-version 1 2
    set send-version 1 2
  end
  config network
  edit 1
    set prefix 10.11.0.0 255.255.0.0
  next
  edit 2
    set prefix 10.12.0.0 255.255.0.0
  next
  edit 3
    set prefix 10.14.0.0 255.255.0.0
  next
  edit 4
    set prefix 172.20.120.0 255.255.255.0
  end
  config redistribute "static"
    set status enable
  end
end
```

Configure RIP settings on Router2 and Router3- web-based manager

1 Go to *Router* > *Dynamic* > *RIP*.

2 Select 2 for *RIP Version*.

3 In *Advanced Options*, under *Redistribute* enable *Static*.

4 Leave the other Advanced Options at default values.

5 Enter the following networks, and select *Add* after each:

- 10.11.0.0/255.255.0.0
- 10.12.0.0/255.255.0.0
- 10.14.0.0/255.255.0.0
- 172.20.120.0/255.255.255.0

6 For interface, select *Create New* and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7 For interface, select *Create New* and set the following information.

Interface	port2 (router1)
Send Version	Both
Receive Version	Both

Authentication	None
Passive Interface	disabled

8 For interface, select *Create New* and set the following information.

Interface	port3 (router4)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

9 For interface, select *Create New* and set the following information.

Interface	port4 (ISP)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router2 and Router3- web-based manager

```
config router rip
  set version 2
  config interface
    edit "port1"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port2"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port3"
      set receive-version 1 2
      set send-version 1 2
    end
    edit "port4"
      set receive-version 1 2
      set send-version 1 2
    end
  config network
    edit 1
      set prefix 10.11.0.0 255.255.0.0
    next
    edit 2
      set prefix 10.12.0.0 255.255.0.0
    next
    edit 3
      set prefix 10.14.0.0 255.255.0.0
    next
    edit 4
```

```
      set prefix 172.20.120.0 255.255.255.0
    end
  config redistribute "static"
    set status enable
  end
end
```

Configuring other networking devices

In this example there are two groups of other devices on the the network — internal devices, and the ISP.

The first is the internal network devices on the Sales, R&D, and Accounting networks. This includes simple static routers, computers, printers and other network devices. Once the FortiGate units are configured, the internal static routers need to be configured using the internal network IP addresses. Otherwise there should be no configuration required.

The second group of devices is the ISP. This consists of the RIP router the FortiGate routers 2 and 3 connect to. You need to contact your ISP and ensure they have your information for your network such as the IP addresses of the connecting RIP routers, what version of RIP your network supports, and what authentication (if any) is used.

Testing network configuration

Once the network has been configured, you need to test that it works as expected.

The two series of tests you need to run are to test the internal networks can communicate with each other, and that the internal networks can reach the internet.

Use ping, traceroute, and other networking tools to run these tests.

If you encounter problems, for troubleshooting help consult “Troubleshooting RIP” on page 1726, and the general “” on page 1714.

RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

This section includes the following topics:

Network layout and assumptions

Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

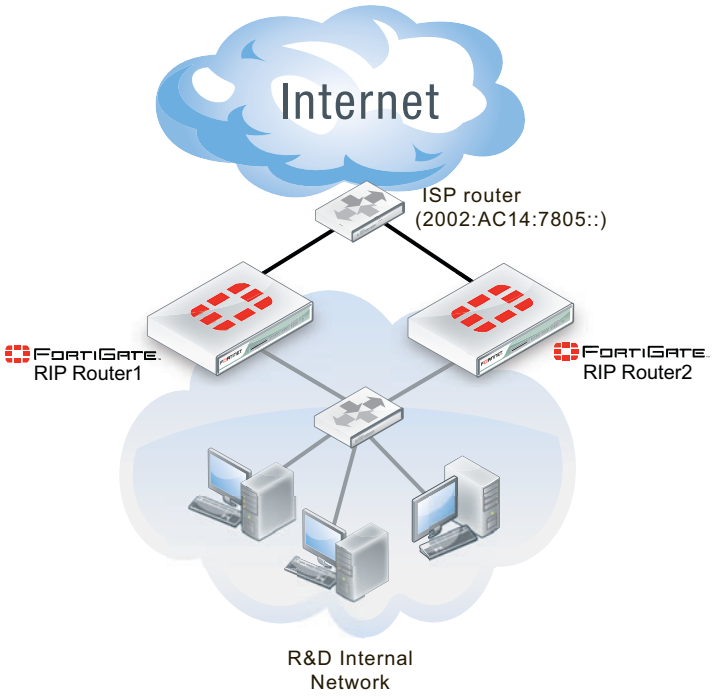
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows.

Table 102: Rip example network topology

Network	Router	Interface & Alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

Figure 166: Network topology for the IPV6 RIPng example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 4.0 MR3 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 and port2 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

General configuration steps

This example is very straight forward. The only steps involved are:

- Configuring the FortiGate units system information
- Configuring RIPng on FortiGate units
- Configuring other network devices
- Testing the configuration

Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

To configure system information on Router1 - web-based manager

1. Go to *System* > *Dashboard* > *Status*.
2. For *Host name*, select *Change*.
3. Enter “Router1”.

4 Go to *System* > *Admin* > *Settings*.

5 In *Display Options on GUI*, enable *IPv6*, and select *Apply*.

6 Go to *System* > *Network* > *Interface*.

7 Edit port1 (internal) interface.

8 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	2002:A0B:6565::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9 Edit port2 (ISP) interface.

10 Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	2002:AC14:7865::/0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router1 - CLI

```
config system global
  set hostname Router1
  set gui-ipv6 enable
end
config system interface
  edit port1
    set alias internal
    set allowaccess https ping ssh
    set description "Internal RnD network"
    config ipv6
      set ip6-address 2002:a0b:6565::/0
    end
  next
  edit port2
    set alias ISP
    set allowaccess https ping ssh
    set description "ISP and internet"
    config ipv6
      set ip6-address 2002:AC14:7865::
    end
end
```

To configure system information on Router2 - web-based manager

1 Go to *System* > *Dashboard* > *Status*.

2 For *Host name*, select *Change*.
3 Enter “Router2”.
4 Go to *System* > *Admin* > *Settings*.
5 In *Display Options on GUI*, enable *IPv6*, and select *Apply*.
6 Go to *System* > *Network* > *Interface*.
7 Edit port1 (internal) interface.
8 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	2002:A0B:6566::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9 Edit port2 (ISP) interface.
10 Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	2002:AC14:7866::/0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router2 - CLI

```
config system global
  set hostname Router2
  set gui-ipv6 enable
end
config system interface
  edit port1
    set alias internal
    set allowaccess https ping ssh
    set description “Internal RnD network”
    config ipv6
      set ip6-address 2002:a0b:6566::/0
    end
  next
  edit port2
    set alias ISP
    set allowaccess https ping ssh
    set description “ISP and internet”
    config ipv6
      set ip6-address 2002:AC14:7866::
    end
end
```

Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only confirmation, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

To configure RIPng on Router1 - CLI

```
config router ripng
  config interface
    edit port1
    next
    edit port2
    end
  config neighbor
    edit 1
      set interface port1
      set ipv6 2002:a0b:6566::/0
    next
    edit 2
      set interface port2
      set ipv6 2002:AC14:7805::/0
  end
```

To configure RIPng on Router2 - CLI

```
config router ripng
  config interface
    edit port1
    next
    edit port2
    end
  config neighbor
    edit 1
      set interface port1
      set ipv6 2002:a0b:6565::/0
    next
    edit 2
      set interface port2
      set ipv6 2002:AC14:7805::/0
    end
```

Configuring other network devices

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the Troubleshooting chapter.

For troubleshooting problems with RIP, see"Troubleshooting RIP" on page 1726.

Use the following section for testing and troubleshooting RIPng.

Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

```
FGT# diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

```
FGT# diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table.

```
FGT# get router info6 routing-table
```

View the routing table. This information is almost the same as the previous command (diagnose ipv6 route list) however it is presented in an easier to read format.

```
FGT# get router info6 rip interface external
```

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
FGT# get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

Border Gateway Protocol (BGP)

This section describes Border Gateway Protocol (BGP).

The following topics are included in this section:

BGP background and concepts

The border gateway protocol contains two distinct subsets — internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect many different networks together, and is the main routing protocol for the Internet backbone. FortiGate units support iBGP, and eBGP only for communities.

The following topics are included in this section:

Background

BGP was first used in 1989. The current version, BGP-4, was released in 1995 and is defined in RFC 1771. That RFC has since been replaced by the more recent RFC 4271. The main benefits of BGP-4 are classless inter-domain routing, and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol. Other routing protocols use UDP.

BGP makes routing decisions based on path, network policies and rulesets instead of the hop-count metric as RIP does, or cost-factor metrics as OSPF does.

BGP-4+ supports IPv6. It was introduced in RFC 2858 and RFC 2545. BGP-4+ also supports

BGP is the routing protocol used on the Internet. It was designed to replace the old Exterior Gateway Protocol (EGP) which had been around since 1982, and was very limited. In doing so, BGP enabled more networks to take part in the Internet backbone to effectively decentralize it and make the Internet more robust, and less dependent on a single ISP or backbone network.

Parts and terminology of BGP

In a BGP network, there are some terms that need to be explained before going ahead. Some parts of BGP are not explained here as they are common to other dynamic routing protocols as well. For more information on parts of BGP that are not listed here, see “Dynamic routing terminology” on page 1708.

The following topics are included in this section:

BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config netowrk6` or `set allowas-in6`. For more information about IPv6 BGP keywords, see the FortiGate CLI Reference.

IPv6 BGP commands include:

```
config bgp
  set allowas-in6 <max_num_AS_integer>
  set allowas-in-enable6 {enable | disable}
  set attribute-unchanged6 [as-path] [med] [next-hop]
  set capability-default-originate6 {enable | disable}
  set capability-graceful-restart6 {enable | disable}
  set capability-orf6 {both | none | receive | send}
  set default-originate-route-map6 <routemap_str>
  set distribute-list-in6 <access-list-name_str>
  set distribute-list-out6 <access-list-name_str>
  set filter-list-in6 <aspath-list-name_str>
  set filter-list-out6 <aspath-list-name_str>
  set maximum-prefix6 <prefix_integer>
  set maximum-prefix-threshold6 <percentage_integer>
  set maximum-prefix-warning-only6 {enable | disable}
  set next-hop-self6 {enable | disable}
  set prefix-list-in6 <prefix-list-name_str>
  set prefix-list-out6 <prefix-list-name_str>
  set remove-private-as6 {enable | disable}
  set route-map-in6 <routemap-name_str>
  set route-map-out6 <routemap-name_str>
  set route-reflector-client6 {enable | disable}
  set route-server-client6 {enable | disable}
  set send-community6 {both | disable | extended | standard}
  set soft-reconfiguration6 {enable | disable}
  set unsuppress-map6 <route-map-name_str>
  config network6
  config redistribute6
end
```

Roles of routers in BGP networks

Dynamic routing has a number of different roles routers can fill such as those covered in “Dynamic routing terminology” on page 1708. BGP has a number of custom roles that routers can fill. These include:

- Speaker routers
- Peer routers or neighbors
- Route reflectors (RR)

Speaker routers

Any router configured for BGP is considered a BGP speaker. This means that a speaker router advertises BGP routes to its peers.

Any routers on the network that are not speaker routers, are not treated as BGP routers.

Peer routers or neighbors

In a BGP network, all neighboring BGP routers or peer routers are routers that are connected to your FortiGate unit. Your FortiGate unit learns about all other routers through these peers.

You need to manually configure BGP peers on your FortiGate unit as neighbors. Otherwise these routers will not be seen as peers, but instead as simply other routers on the network that don't support BGP. You can optionally use MD5 authentication to password protect BGP sessions with those neighbors. (see RFC 2385).

You can configure up to 1000 BGP neighbors on your FortiGate unit. You can clear all or some BGP neighbor connections (sessions) using the `exec router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
FGT# exec router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

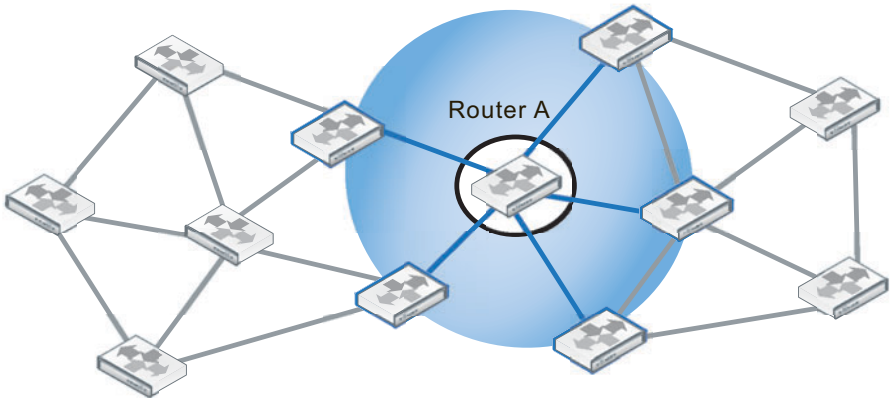
```
FGT# exec router clear bgp as 650001
```

To remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
FGT# exec router clear bgp dampening 10.10.0.0/16
```

In Figure 1, Router A is directly connected to five other routers in a network that contains 12 routers overall. These routers, the ones in the blue circle, are Router A's peers or neighbors.

Figure 167: Router A and its 5 peer routers



Router A's peer routers

As a minimum, when configuring BGP neighbors you must enter their IP address, and the AS number (remote-as). This is all the information the web-based manager interface allows you to enter for a neighbor.

The BGP commands related to neighbors are quite extensive and include:

```
config router bgp
  config neighbor
    edit <neighbor_address_ipv4>
      set activate {enable | disable}
      set advertisement-interval <seconds_integer>
      set allowas-in <max_num_AS_integer>
      set allowas-in-enable {enable | disable}
      set attribute-unchanged [as-path] [med] [next-hop]
      set bfd {enable | disable}
      set capability-default-originate {enable | disable}
      set capability-dynamic {enable | disable}
      set capability-graceful-restart {enable | disable}
      set capability-orf {both | none | receive | send}
      set capability-route-refresh {enable | disable}
      set connect-timer <seconds_integer>
      set description <text_str>
      set distribute-list-in <access-list-name_str>
      set distribute-list-out <access-list-name_str>
      set dont-capability-negotiate {enable | disable}
      set ebgp-enforce-multihop {enable | disable}
      set ebgp-multihop {enable | disable}
      set ebgp-multihop-ttl <seconds_integer>
      set filter-list-in <aspath-list-name_str>
      set filter-list-out <aspath-list-name_str>
      set holdtime-timer <seconds_integer>
      set interface <interface-name_str>
      set keep-alive-timer <seconds_integer>
      set maximum-prefix <prefix_integer>
      set maximum-prefix-threshold <percentage_integer>
      set maximum-prefix-warning-only {enable | disable}
      set next-hop-self {enable | disable}
      set override-capability {enable | disable}
      set passive {enable | disable}
      set password <string>
      set prefix-list-in <prefix-list-name_str>
      set prefix-list-out <prefix-list-name_str>
      set remote-as <id_integer>
      set remove-private-as {enable | disable}
      set retain-stale-time <seconds_integer>
      set route-map-in <routemap-name_str>
      set route-map-out <routemap-name_str>
      set route-reflector-client {enable | disable}
      set route-server-client {enable | disable}
      set send-community {both | disable | extended | standard}
      set shutdown {enable | disable}
      set soft-reconfiguration {enable | disable}
      set strict-capability-match {enable | disable}
      set unsuppress-map <route-map-name_str>
      set update-source <interface-name_str>
```

```
        set weight <weight_integer>
      end
    end
  end
```

Route reflectors (RR)

Route reflectors in BGP concentrate route updates so other routers need only talk to the route reflectors to get all the updates. This results in smaller routing tables, fewer connections between routers, faster responses to network topology changes, and less administration bandwidth. BGP route reflectors are defined in RFC 1966.

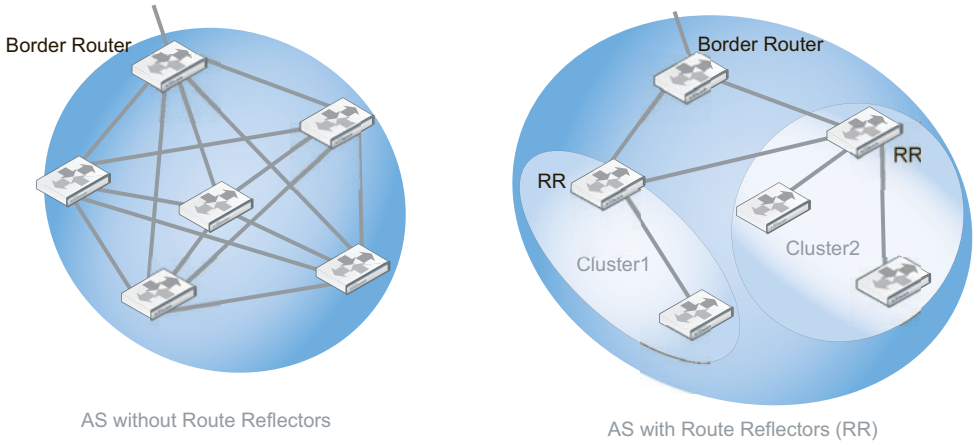
In a BGP route reflector configuration, the AS is divided into different clusters that each include client and reflector routers. The client routers supply the reflector routers with the client's route updates. The reflectors pass this information along to other route reflectors and border routers. Only the reflectors need to be configured, not the clients — the clients will find the closest reflector and communicate with it automatically. The reflectors communicate with each other as peers. FortiGate units can be configured as either reflectors or clients.

Since route reflectors are processing more than the client routers, the reflectors should have more resources to handle the extra workload.

Smaller networks running BGP typically don't require route reflectors (RR). However, RR is a useful feature for large companies, where their AS may include 100 routers or more. For example, for a full mesh 20 router configuration within an AS there would have to be 190 unique BGP sessions — just for routing updates within the AS. The number of sessions jumps to 435 sessions for just 30 routers, or 4950 sessions for 100 routers. From these numbers, its plain that updating this many sessions will quickly consume the limited bandwidth and processing resources of the routers involved.

The following diagram illustrates how route reflectors can improve the situation when only six routers are involved. The AS without route reflectors requires 15 sessions between the routers. In the AS with route reflectors, the two route reflectors receive route updates from the reflector clients (unlabeled routers in the diagram) in their cluster as well as other route reflectors and pass them on to the border router. The RR configuration only require six sessions. This example shows a reduction of 60% in the number of required sessions.

Figure 168: Required sessions within an AS with and without route reflectors



The BGP commands related to route reflectors includes:

```
config router bgp
  config neighbor
    set route-reflector-client {enable | disable}
    set route-server-client {enable | disable}
  end
end
```

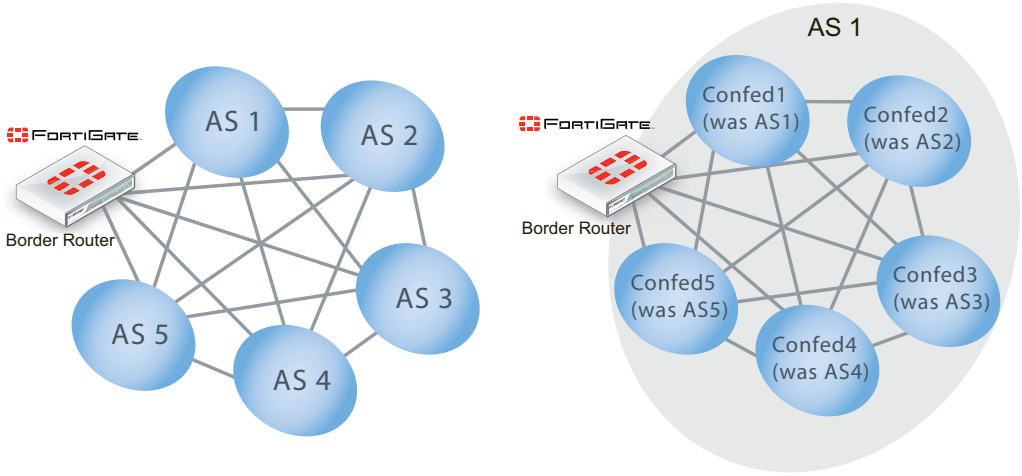
Confederations

Confederations were introduced to reduce the number of BGP advertisements on a segment of the network, and reduce the size of the routing tables. Confederations essentially break up an AS into smaller units. Confederations are defined in RFC 3065 and RFC 1965.

Within a confederation, all routers communicate with each other in a full mesh arrangement. Communications between confederations is more like inter-AS communications in that many of the attributes are changed as they would be for BGP communications leaving the AS, or eBGP.

Confederations are useful when merging ASs. Each AS being merged can easily become a confederation, requiring few changes. Any additional permanent changes can then be implemented over time as required. The figure below shows the group of ASs before merging, and the corresponding confederations afterward as part of the single AS with the addition of a new border router. It should be noted that after merging if the border router becomes a route reflector, then each confederation only needs to communicate with one other router, instead of five others.

Figure 169: AS merging using confederations



Multiple ASes before merging

Combined AS with confederations and new FortiGate unit border router

Confederations and route reflectors perform similar functions — they both sub-divide large ASes for more efficient operation. They differ in that route reflector clusters can include routers that are not members of a cluster, where routers in a confederation must belong to that confederation. Also, confederations place their confederation numbers in the AS_PATH attribute making it easier to trace.

It is important to note that while confederations essentially create sub-ASs, all the confederations within an AS appear as a single AS to external ASs.

Confederation related BGP commands include:

```
config router bgp
  set confederation-identifier <peerid_integer>
end
```

Network Layer Reachability Information (NLRI)

Network Layer Reachability Information (NLRI) is unique to BGP-4. It is sent as part of the update messages sent between BGP routers, and contains information necessary to supernet, or aggregate route, information. The NLRI includes the length and prefix that when combined are the address of the aggregated routes referred to.

There is only one NLRI entry per BGP update message.

BGP attributes

Each route in a BGP network has a set of attributes associated with it. These attributes define the route, and are modified as required along the route.

BGP can work well with mostly default settings, but if you are going to change settings you need to understand the roles of each attribute and how they affect those settings.

The BGP attributes include:

AS_PATH	A list of ASes a route has passed through. See “AS_PATH” on page 1757.
MULTI_EXIT_DESC (MED)	Which router to use to exit an AS with more than one external connection. See “MULTI_EXIT_DESC (MED)” on page 1758.
COMMUNITY	Used to apply attributes to a group of routes. See “COMMUNITY” on page 1758.
NEXT_HOP	Where the IP packets should be forwarded to, like a gateway in static routing. See “NEXT_HOP” on page 1759.
ATOMIC_AGGREGATE	Used when routes have been summarized to tell downstream routers not to de-aggregate the route. See “ATOMIC_AGGREGATE” on page 1759.
ORIGIN	Used to determine if the route is from the local AS or not. See“ORIGIN” on page 1759.
LOCAL_PREF	Used only within an AS to select the best route to a location (like MED)

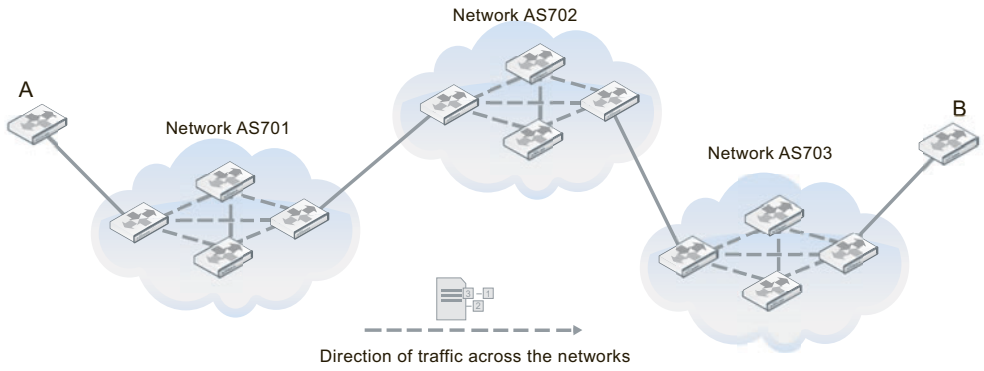
Inbound policies on FortiGate units can change the NEXT-HOP,LOCAL-PREF, MED and AS-PATH attributes of an internal BGP (iBGP) route for its local route selection purposes. However, outbound policies on the unit cannot affect these attributes.

AS_PATH

AS_PATH is the BGP attribute that keeps track of each AS a route advertisement has passed through. AS_PATH is used by confederations and by exterior BGP (EBGP) to help prevent routing loops. A router knows there is a loop if it receives an AS_PATH with that routers AS in it. The figure below shows the route between router A and router B. The AS_PATH from A to B would read 701,702,703 for each AS the route passes through.

As of the start of 2010, the industry is upgrading from 2-byte to 4-byte AS_PATHs. This upgrade was due to the imminent exhaustion of 2-byte AS_PATH numbers.

Figure 170: AS_PATH of 701,702, 703 between routers A and B



The BGP commands related to AS_PATH include:

```
config router bgp
  set bestpath-as-path-ignore {enable | disable}
end
```

MULTI_EXIT_DESC (MED)

BGP AS systems can have one or more routers that connect them to other ASes. For ASes with more than one connecting router, the Multi-Exit Discriminator (MED) lists which router is best to use when leaving the AS. The MED is based on attributes such as delay. It is a recommendation only, as some networks may have different priorities.

BGP updates advertise the best path to a destination network. When the FortiGate unit receives a BGP update, the FortiGate unit examines the Multi-Exit Discriminator (MED) attribute of potential routes to determine the best path to a destination network before recording the path in the local FortiGate unit routing table.

FortiGate units have the option to treat any routes without an MED attribute as the worst possible routing choice. This can be useful because a lack of MED information is a lack of routing information which can be suspicious — possibly a hacking attempt or an attack on the network. At best it is an unreliable route to select.

The BGP commands related to MED include:

```
config router bgp
  set always-compare-med {enable | disable}
  set bestpath-med-confed {enable | disable}
  set bestpath-med-missing-as-worst {enable | disable}
  set deterministic-med {enable | disable}
  config neighbor
    set attribute-unchanged [as-path] [med] [next-hop]
  end
end
```

COMMUNITY

A community is a group of routes that have the same routing policies applied to them. This saves time and resources. A community is defined by the COMMUNITY attribute of a BGP route.

The FortiGate unit can set the COMMUNITY attribute of a route to assign the route to predefined paths (see RFC 1997). The FortiGate unit can examine the COMMUNITY attribute of learned routes to perform local filtering and/or redistribution.

The BGP commands related to COMMUNITY include:

```
config router bgp
  set send-community {both | disable | extended | standard}
end
```

NEXT_HOP

The NEXT_HOP attribute says what IP address the packets should be forwarded to next. Each time the route is advertised, this value is updated. The NEXT_HOP attribute is much like a gateway in static routing.

FortiGate units allow you to to change the advertising of the FortiGate unit's IP address (instead of the neighbor's IP address) in the NEXT_HOP information that is sent to IBGP peers. This is changed with the config neighbor, set next-hop-self command.

The BGP commands related to NEXT_HOP include:

```
config router bgp
  config neighbor
    set attribute-unchanged [as-path] [med] [next-hop]
    set next-hop-self {enable | disable}
  end
end
```

ATOMIC_AGGREGATE

The ATOMIC_AGGREGATE attribute is used when routes have been summarized. It indicates which AS and which router summarize the routes. It also tells downstream routers not to de-aggregate the route. Summarized routes are routes with similar information that have been combined, or aggregated, into one route that is easier to send in updates. When it reaches its destination, the summarized routes are split back up into the individual routes.

Your FortiGate unit doesn't specifically set this attribute in the BGP router command, but it is used in the route map command.

The commands related to ATOMIC_AGGREGATE include:

```
config router route-map
  edit <route_map_name>
    config rule
    edit <route_map_rule_id>
      set set-aggregator-as <id_integer>
      set set-aggregator-ip <address_ipv4>
      set set-atomic-aggregate {enable | disable}
    end
  end
end
```

ORIGIN

The ORIGIN attribute records where the route came from. The options can be IBGP, EBGP, or incomplete. This information is important because internal routes (IBGP) are higher priority than external routes (EBGP). However incomplete ORIGINs are the lowest priority of the three.

The commands related to ORIGIN include:

```
config router route-map
  edit <route_map_name>
    set comments <string>
```

```
    config rule
    edit <route_map_rule_id>
      set match-origin {egp | igp |  incomplete | none}
    end
  end
end
```

How BGP works

BGP is a link-state routing protocol and keeps link-state information about the status of each network link it has connected. A BGP router receives information from its peer routers that have been defined as neighbors. BGP routers listen for updates from these configured neighboring routers on TCP port 179.

A BGP router is a finite state machine with six various states for each connection. As two BGP routers discover each other, and establish a connection they go from the idle state, through the various states until they reach the established state. An error cancan cause the connection to be dropped and the state of the router to be reset to either active or idle. These errors can be caused by: TCP port 179 not being open, a random TCP port above port 1023 not being open, the peer address being incorrect, or the AS number being incorrect.

When BGP routers start a connection, they negotiate which (if any) optional features will be used such as multiprotocol extensions that can include IPv6 and VPNs.

IBGP versus EBGP

When you read about BGP, often you see EBGP or IBGP mentioned. These are both BGP routing, but BGP used in different roles. Exterior BGP (EBGP) involves packets crossing multiple autonomous systems (ASes) where interior BGP (IBGP) involves packets that stay within a single AS. For example the AS_PATH attribute is only useful for EBGP where routes pass through multiple ASes.

These two modes are important because some features of BGP are only used for one of EBGP or IBGP. For example confederations are used in EBGP, and route reflectors are only used in IBGP. Also routes learned from IBGP have priority over EBGP learned routes.

FortiGate units have some commands specific to EBGP. These include:

- automatically resetting the session information to external peers if the connection goes down — `set fast-external-failover {enable | disable}`
- setting an administrative distance for all routes learned from external peers (must also configure local and internal distances if this is set) — `set distance-external <distance_integer>`
- enforcing EBGP multihops and their TTL (number of hops) — `set ebgp-enforce-multihop {enable | disable}` and `set ebgp-multihop-ttl <seconds_integer>`

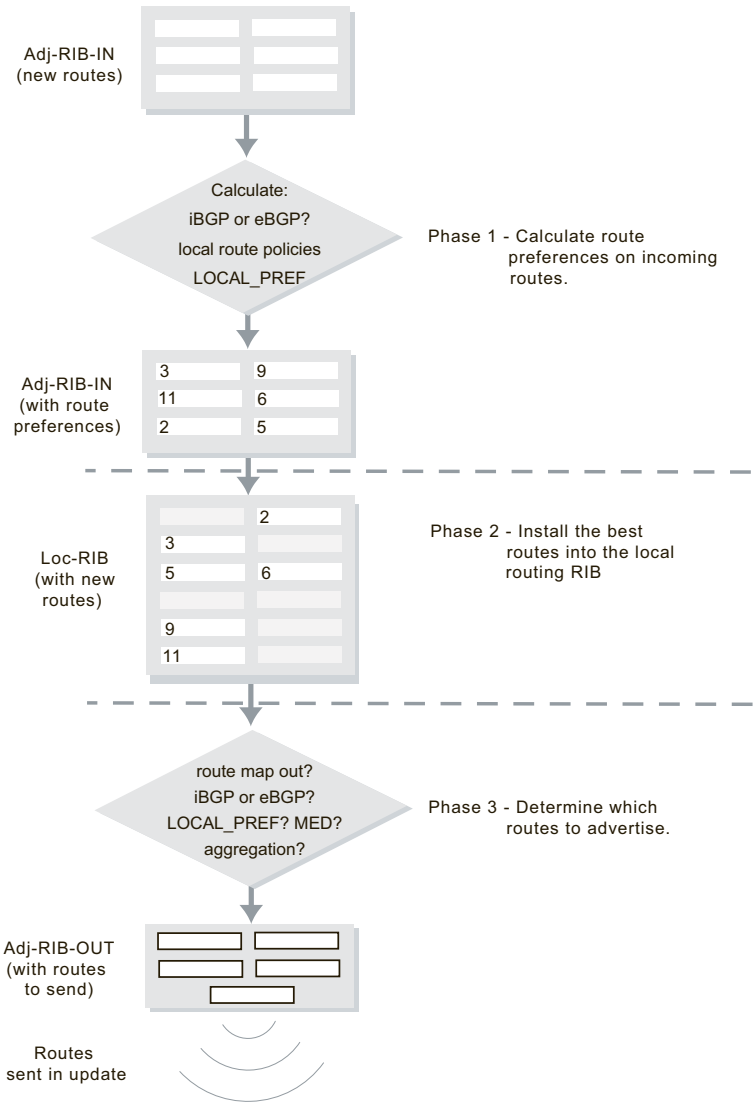
BGP path determination — which route to use

All learned routes and their attributes come into the BGP router in raw form. Before routes are installed in the routing table or are advertised to other routers, three levels of decisions must be made.

The three phases of BGP best path determination do not change. However, some manufacturers have added more information to the process, such as Cisco's WEIGHT attribute to enable an administrator to force one route's selection over another.

There is one Adj-RIB-IN and Adj-RIB-OUT for each configured neighbor. They are updated when the FortiGate unit receives BGP updates, or when the FortiGate unit sends out BGP updates.

Figure 171: Three phases of BGP routing decision



Decision phase 1

At this phase, the decision is to calculate how preferred each route and its NRLI are the Adjacent Routing Information Base Incoming (Adj-RIBs-In) compared to the other routes. For internal routes (IBGP), policy information or LOCAL_PREF is used. For external peer learned routes, it is based strictly on policy. These rules set up a list of which routes are most preferred going into Phase 2.

Decision phase 2

Phase 2 involves installing the best route to each destination into the local Routing Information Base (Loc-RIB). Effectively, the Loc-RIB is the master routing table. Each route from Phase 1 has their NEXT_HOP checked to ensure the destination is reachable. If it is reachable, the AS_PATH is checked for loops. After that, routes are installed based on the following decision process:

- If there is only one route to a location, it is installed.
- If multiple routes to the same location, use the most preferred route from Level 1.
- If there is a tie, break the tie based on the following in descending order of importance: shortest AS_PATH, smallest ORIGIN number, smallest MED, EBGP over IBGP, smallest metric or cost for reaching the NEXT_HOP, BGP identifier, and lowest IP address.

Note that the new routes that are installed into the Loc-RIB are in addition to any existing routes in the table. Once Phase 2 is completed the Loc-RIB will consist of the best of both the new and older routes.

Decision phase 3

Phase 3 is route distribution or dissemination. This is the process of deciding which routes the router will advertise. If there is any route aggregation or summarizing, it happens here. Also any route filtering from route maps happens here.

Once Phase 3 is complete, an update can be sent out to update the neighbor of new routes.

Aggregate routes and addresses

BGP4 allows classless routing, which uses netmasks as well as IP addresses. This classless routing enables the configuration of aggregate routes by stating the address bits the aggregated addresses have in common. For more information, see “Aggregated routes and addresses” on page 1709.

In BGP there is an ATOMIC_AGGREGATE attribute that when set informs routers that the route has been aggregated, and should not be de-aggregated. An associated AGGREGATOR attribute include the information about the router that did the aggregating including its AS.

The BGP commands associated with aggregate routes and addresses are:

```
config router bgp
  config aggregate-address
    edit <aggr_addr_id>
    set as-set {enable | disable}
    set prefix <address_ipv4mask>
    set summary-only {enable | disable}
  end
  config aggregate-address6
    edit <aggr_addr_id>
    set as-set {enable | disable}
    set prefix6 <address_ipv6mask>
    set summary-only {enable | disable}
  end
  end
```

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically the problems with a BGP network that has been configured, involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

This section includes:

- Clearing routing table entries
- Route flap

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `exec router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
FGT# exec router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

```
FGT# exec router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables which creates a lot of administration traffic on the network. And the same traffic happens again when that router comes back online. If the problem is something like a faulty network cable that wobbles on and offline every 10 seconds, there could easily be overwhelming amounts of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate units in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in traffic which is unpleasant for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they do not expire during the failover process. Also configuring graceful restart on the HA cluster will help with a smooth failover.

The first method of dealing with router flap should be to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either don't use that interface or swap in a good router. If the power source is bad on a router either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- Holddown timer
- Dampening
- Graceful restart
- Bi-directional forwarding detection (BFD)

Holddown timer

The first line of defence to a flapping route is the hold down timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holddown timer won't allow the FortiGate unit to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate unit — for the duration of the other outages there will be no changes because the Fortigate unit is essentially treating this router as down. After the timer expires, if the route is still flapping it will happen all over again.

Even if the route isn't flapping — if it goes down, comes up, and stays back up — the timer still counts down and the route is ignored for the duration of the timer. In this situation the route will be seen as down longer than it really is, but there will be only the one set of route updates. This is not a problem in normal operation because updates are not frequent.

Also the potential for a route to be treated as down when it is really up can be viewed as a robustness feature. Typically you do not want most of your traffic being routed over an unreliable route. So if there is route flap going on, it is best to avoid that route if you can. This is enforced by the holddown timer.

How to configure the holddown timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holddown timer.

For example, your network has two routes that you want to set the holddown timer for. One is your main route (to 10.12.101.4) that all your Internet traffic goes through, and it can't be down for long if its down. The second is a low speed connection to a custom network that is used infrequently (to 10.13.101.4). The holddown timer for the main route should be fairly short, lets say 60 seconds instead of the default 180 seconds. The second route timer can be left at the default or even longer since it is rarely used. In your BGP configuration this looks like:

```
config router bgp
  config neighbor
  edit 10.12.101.4
    set holddown-timer 60
  next
  edit 10.13.101.4
    set holddown-timer 180
  next
  end
end
```

Dampening

Dampening is a method used to limit the amount of network problems due to flapping routes. With dampening the flapping still occurs, but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second starts a timer where the router will not use that route — it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There is a period of time called the reachability half-life after which a route flap will only be suppressed for half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate units cache by using one of the `execute router clear bgp` commands:

```
execute router clear bgp dampening {<ip_address> | <ip/netmask>}
```

or

```
execute router clear bgp flap-statistics {<ip_address> |
   <ip/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
FGT# exec router clear bgp dampening 10.10.0.0/16
```

The BGP commands related to route dampening are:

```
config router bgp
  set dampening {enable | disable}
  set dampening-max-suppress-time <minutes_integer>
  set dampening-reachability-half-life <minutes_integer>
  set dampening-reuse <reuse_integer>
  set dampening-route-map <routemap-name_str>
  set dampening-suppress <limit_integer>
  set dampening-unreachability-half-life <minutes_integer>end
end
```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded, but the hardware can still function normally.

Graceful restart is best used for these situations where routing will not be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart does not have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster will advertise it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table — if there is a flap the HA cluster routing table will be out of date.

Scheduled time offline

Graceful restart is a means for a router to advertise it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that router will be offline for a long time.

FortiGate units support both graceful restart of their own BGP routing software, and also neighboring BGP routers.

For example, if a neighbor of your FortiGate unit, with an IP address of 172.20.120.120, supports graceful restart, enter the command:

```
config router bgp
  config neighbor
  edit 172.20.120.120
    set capapbility-graceful-restart enable
  end
end
```

If you want to configure graceful restart on your FortiGate unit where you expect the Fortigate unit to be offline for no more than 2 minutes, and after 3 minutes the BGP network should consider the FortiGate unit offline, enter the command:

```
config router bgp
  set graceful-restart enable
  set graceful-restart-time 120
  set graceful-stalepath-time 180
end
```

You can configure graceful restarting and other advanced settings only through CLI commands. For more information on advanced BGP settings, see the “router” chapter of the *FortiGate CLI Reference*.

The BGP commands related to BGP graceful restart are:

```
config router bgp
  set graceful-restart { disable| enable}
  set graceful-restart-time <seconds_integer>
  set graceful-stalepath-time <seconds_integer>
  config neighbor
    set capability-graceful-restart {enable | disable}
  end
end

execute router restart
```

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

While BGP can detect route failures, BFD can be configured to detect these failures more quickly allowing faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

Configurable granularity

BFD can run on the entire FortiGate unit, selected interfaces, or on BGP for all configured interfaces. The hierarchy allows each lower level to override the upper level's BFD setting. For example, if BFD was enabled for the FortiGate unit, it could be disabled only for a single interface or for BGP. For information about FortiGate-wide BFD options, see config system settings in the *FortiGate CLI Reference*.

BFD support was added in FortiOS v3.0 MR4, and can only be configured through the CLI.

The BGP commands related to BFD are:

```
config router bgp
  config neighbor
    edit <neighbor_address_ipv4>
    set bfd {enable | disable}
  end
end

execute router clear bfd session <src_ipv4> <dst_ipv4>
   <interface>
```

BGP routing examples

BGP is a complex dynamic routing protocol. There are many BGP configurations and features that can benefit from in-depth examples.

This section includes:

- Dual-homed BGP example
- Redistributing and blocking routes in BGP

Dual-homed BGP example

This is an example of a small network that uses BGP routing connections to two ISPs. This is a common configuration for companies that need redundant connections to the Internet for their business.

This configuration is for a small company connected to two ISPs. The company has one main office, the Head Office, and uses static routing for internal routing on that network.

Both ISPs use BGP routing, and connect to the Internet directly. They want the company to connect to the ISP networks using BGP. They also use graceful restart to prevent unneeded updates, and use smaller timer values to detect network failures faster.

As can be expected, the company wants to keep their BGP configuration relatively simple and easy to manage. The current configuration has only 3 routers to worry about — the 2 ISP border routers, and the FortiGate unit. This means the FortiGate unit will only have two neighbour routers to configure.

This configuration has the added benefit of being easy to expand if the Company wants to add a remote office in the future.

To keep the configuration simple, the Company is allowing only HTTP, HTTPS, FTP, and DNS traffic out of the local network. This will allow employees access to the Internet and their web-mail.

This section includes the following topics:

Why dual home?

Dual homing means having two separate independent connections to the Internet. Servers in this configuration have also been called bastion hosts and can include DNS servers which require multiple connections.

Benefits of dual homing can include:

- redundant Internet connection that essentially never fails
- faster connections through one ISP or the other for some destinations, such as other clients of those ISPs
- load balancing traffic to your Company network
- easier to enable more traffic through two connections than upgrading one connection to bigger bandwidth
- easier to create protection policies for different traffic through a specific ISP

Some companies require reliable internet access at all times as part of their business. Consider a doctor operating remotely who has their Internet connection fail — the consequences could easily be life or death.

Dual homing is extra expense for the second ISP connection, and more work to configure and maintain the more complex network topology.

Potential dual homing issues

BGP comes with load balancing issues, and dual homing is the same category. BGP does not inherently deal well with load balancing, or getting default routes through BGP. Ideally one connect may be best for certain destinations, but it may not have that traffic routed to it making the load balancing less than perfect. This kind of fine tuning can be very time consuming, and usually results in a best effort situation.

When dual coming is not configured properly, your network may become a link between your ISPs and result in very high traffic between the ISPs that does not originate from your network. The problems with this situation are that your traffic may not have the bandwidth it needs, and you will be paying for a large volume of traffic that is not yours. This problem can be solved by not broadcasting or redistributing BGP routes between the ISPs.

If you learn your default routes from the ISPs in this example, you may run into an asymmetric routing problem where your traffic loops out one ISP and back to you through the other ISP. If you think this may be happening you can turn on asymmetric routing on the FortiGate unit (config system settings, set asymmetric enable) to verify that really is the problem. Turn this feature off once this is established since it disables many features on the FortiGate by disabling stateful inspection. Solutions for this problem can include using static routes for default routes instead of learning them through BGP, or configuring VDOMs on your FortiGate unit to provide a slightly different path back that is not a true loop.

Network layout and assumptions

This section includes:

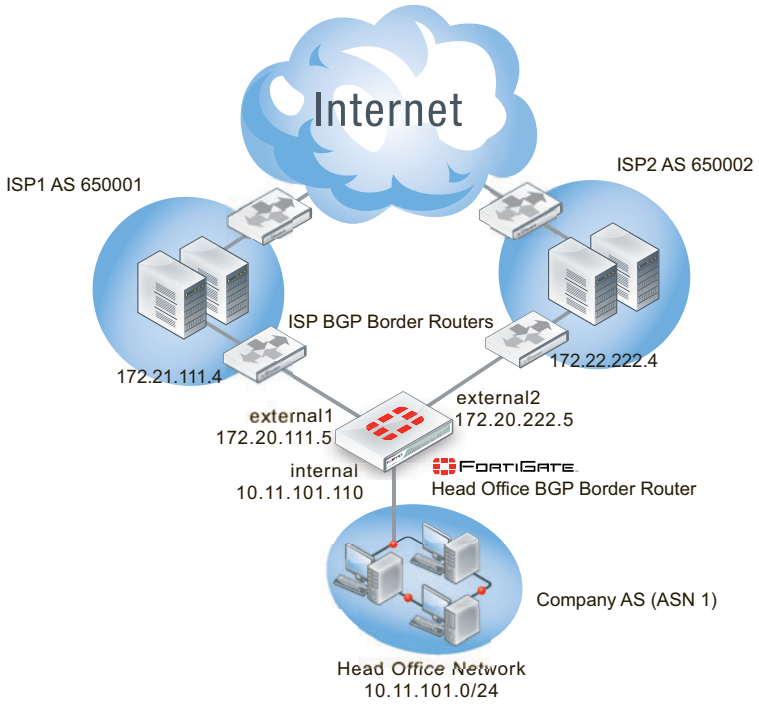
Network layout

The network layout for the basic BGP example involves the company network being connected to both ISPs as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, ISP1's AS, and ISP2's AS.

The components of the layout include:

- The Company AS (AS number 1) is connected to ISP1 and ISP2 through the FortiGate unit.
- The Company has one internal network — the Head Office network at 10.11.101.0/24.
- The FortiGate unit internal interface is on the the Company internal network with an IP address of 10.11.101.110.
- The FortiGate unit external1 interface is connected to ISP1's network with an IP address of 172.21.111.5, an address supplied by the ISP.
- ISP1 AS has an AS number of 6501, and ISP2 has an AS number of 6502
- Both ISPs are connected to the Internet.
- The ISP1 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.21.111.4.
- The ISP2 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.22.222.4.
- Apart from graceful restart, and shorter timers (holdtimer, and keepalive) default settings are to be used whenever possible.

Figure 172: Basic BGP network topology



Assumptions

The basic BGP configuration procedure follows these assumptions:

- ISP1 is the preferred route, and ISP2 is the secondary route
- all basic configuration can be completed in both GUI and CLI
- only one AS is used for the Company

For these reasons this example configuration does not include:

- Bi-directional forwarding detection (BFD)
- Route maps
- Access lists
- changing redistribution defaults — make link when example is set up
- IPv6

For more information on these features, see the corresponding section.

General configuration steps

In this basic example, only two routers need to be configured — the FortiGate unit, and the ISP BGP router. After they are configured, the network configuration should be tested to ensure its working as expected.

To configure a simple BGP network

1. Configuring the FortiGate unit
2. Configuring other networking devices
3. Testing this configuration

Configuring the FortiGate unit

In this topology, the FortiGate unit is the link between the Company Network and the ISP network. The FortiGate unit is the only BGP router on the Company Network, but there is at least one other BGP router on the ISP Network — there may be more but we don't have that information.

As mentioned in the general configuration steps, the ISP must be notified of the Company's BGP router configuration when complete as it will need to add the FortiGate BGP router as a neighbor router on its domain. This step is required for the FortiGate unit to receive BGP routing updates from the ISP network and outside networks.

If the ISP has any special BGP features enabled such as graceful restart, or route dampening that should be determined up front so those features can be enabled on the FortiGate unit.

To configure the FortiGate unit as a BGP router

1. Configure interfaces and default routes
2. Configure firewall services, addresses, and policies
3. Set the FortiGate BGP information
4. Add the internal network to the AS
5. Additional FortiGate BGP configuration

Configure interfaces and default routes

The FortiGate unit is connected to three networks — Company Network on the internal interface, ISP1 Network on external1interface, and ISP2 on external2 interface.

This example uses basic interface settings. Check with your ISP to determine if additional settings are required such as setting the maximum MTU size, or if gateway detection is supported.

High end FortiGate units do not have interfaces labeled Internal, or External. Instead, for clarity's sake, we are using the alias feature to name interfaces for these roles.

Default routes to both external interfaces are configured here as well. Both are needed in case one goes offline. ISP1 is the primary connection and has a smaller administrative distance so it will be preferred over ISP2. Both distances are set low so they will be preferred over any learned routes.

To configure the FortiGate interfaces - web-based manager

1. Go to *System* > *Network* > *Interface*.
2. Edit port 1 (internal) interface.
3. Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Company internal network
Administrative Status	Up

4. Edit port 2 (external1) interface.

5 Set the following information, and select *OK*.

Alias	external1
IP/Netmask	172.21.111.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP1 External BGP network
Administrative Status	Up

6 Edit port 3 (external2) interface.

7 Set the following information, and select *OK*.

Alias	external2
IP/Netmask	172.22.222.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP2 External BGP network
Administrative Status	Up

To configure the FortiGate interfaces - CLI

```
config system interface
  edit port1
    set alias internal
    set ip 10.11.101.110 255.255.255.0
    set allowaccess http https ssh
    set description "Company internal network"
    set status up
  next
  edit port2
    set alias external1
    set ip 172.21.111.5 255.255.255.0
    set allowaccess https ssh
    set description "ISP1 External BGP network"
    set status up
  next
  edit port3
    set alias external2
    set ip 172.22.222.5 255.255.255.0
    set allowaccess https ssh
    set description "ISP2 External BGP network"
    set status up
  next
end
```

To configure default routes for both ISPs - web-based manager

1 Go to *Router* > *Static* > *Static Route*.

2 Delete any existing routes with a IP/Mask of address of 0.0.0.0/0.0.0.0

3 Select *Create New*, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2

Gateway	172.21.111.5
Distance	10

4 Select OK.

5 Select *Create New*, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3
Gateway	172.22.222.5
Distance	15

6 Select OK.

To configure default routes for both ISPs - CLI

```
config router static
  edit 1
    set device "port2"
    set distance 10
    set gateway 172.21.111.5
  next
  edit 2
    set device "port3"
    set distance 15
    set gateway 172.22.222.5
  next
end
```

Configure firewall services, addresses, and policies

To create the security policies, first you must create the firewall services group that will include all the services that will be allowed, then you must define the addresses that will be used in the security policies, and lastly you configure the security policies themselves.

To keep the configuration simple, the Company is allowing only HTTP traffic out of the local network. This will allow employees access to the Internet and their web-mail. DNS services will also be allowed through the firewall.

The security policies will allow HTTP traffic (port 80 and port 8080), HTTPS traffic (port 443), FTP traffic (port 21), and DNS traffic (port 53 and port 953) in both directions. Also BGP (port 179) may need access through the firewall.

For added security, you may want to define a smaller range of addresses for the internal network. For example if only 20 addresses are used, only allow those addresses in the range.

In the interest of keeping things simple, a zone will be used to group the two ISP interfaces together. This will allow using one security policy to apply to both ISPs at the same time. Remember to block intra-zone traffic as this will help prevent one ISP sending traffic to the other ISP through your FortiGate unit using your bandwidth. The zone keeps configuration simple, and in the future if there is a need for separate policies for each ISP, they can be created and the zone can be deleted.

The addresses that will be used are the addresses of the FortiGate unit internal and external ports, and the internal network.

More policies or services can be added in the future as applications are added to the network. For more information on security policies, see the firewall chapter of the FortiGate Administration Guide.

When configuring security policies always enable logging to help you track and debug your traffic flow.

To create a firewall services group - web-based manager

1 Go to *Firewall Objects* > *Service* > *Group*, and select *Create New*.
2 For *Group Name*, enter “Basic_Services”.
3 From *Available Services*, move the following six services over to the *Member* list — BGP, FTP, FTP_GET, FTP_PUT, DNS, HTTP, and HTTPS.
4 Select *OK*.

To create a firewall services group - CLI

```
config firewall service group
  edit "Basic_Services"
    set member "BGP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP"
       "HTTPS"
  next
end
```

To create a zone for the ISP interfaces - web-based manager

1 Go to *System* > *Network* > *Interface.*
2 Select the caret to the right of *Create New* and then select *Zone*.
3 Enter the following information.

Zone Name	ISPs
Block Intra-zone traffic	enable
interface members	port2 port3

4 Select *OK*.

To create a zone for the ISP interfaces - CLI

```
config system zone
  edit "ISPs"
    set interface "dmz1" "dmz2"
    set intrazone block
  next
end
```

To add the firewall addresses - web-based manager

1 Go to *Firewall Objects* > *Address* > *Address*.
2 Select *Create New*, and set the following information.

Address Name	Internal_network
Type	Subnet / IP Range

Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	port1

3 Select OK.

To add the firewall addresses - CLI

```
config firewall address
  edit "Internal_network"
    set associated-interface "port1"
    set subnet 10.11.101.0 255.255.255.0
  next
end
```

To add the HTTP and DNS security policies - web-based manager

1 Go to *Policy* > *Policy* > *Policy*, and select *Create New*.

2 Set the following information.

Source Interface/Zone	port1(internal)
Source Address	Internal_network
Destination Interface/Zone	ISPs
Destination Address	All
Schedule	always
Service	Basic_services
Action	ACCEPT
Log Allowed Traffic	enable
Enable NAT	Enable
Comments	ISP1 basic services out policy

3 Select *OK*.

4 Select *Create New*, and set the following information.

Source Interface/Zone	ISPs
Source Address	all
Destination Interface/Zone	port1(internal)
Destination Address	Internal_network
Schedule	always
Service	Basic_services
Action	ACCEPT
Log Allowed Traffic	enable
NAT	Enable
Comments	ISP1 basic services in policy

To add the security policies - CLI

```
config firewall policy
  edit 1
    set srcintf "port1"
    set srcaddr "Internal_network"
    set dstintf "ISPs"
    set dstaddr "all"
    set schedule "always"
    set service "Basic_services"
    set action accept
    set nat enable
    set profile-status enable
    set logtraffic enable
    set comments "ISP1 basic services out policy"
  next
  edit 2
    set srcintf "ISPs"
    set srcaddr "all"
    set dstintf "port1"
    set dstaddr "Internal_network"
    set schedule "always"
    set service "Basic_services"
    set action accept
    set nat enable
    set profile-status enable
    set logtraffic enable
    set comments "ISP1 basic services in policy"
  next
end
```

Set the FortiGate BGP information

When using the default information, there are only two fields to set to configure the FortiGate unit as a BGP router.

For this configuration the FortiGate unit will be in a stub area with one route out — the ISP BGP router. Until you configure the ISP router as a neighbour, even that route out is not available. So while after this part of the configuration is complete your FortiGate unit will be running BGP, it won't know about any other routers running BGP until the next part of the configuration is complete.

To set the BGP router information - web-based mananger

1 Go to *Router* > *Dynamic* > *BGP*.

2 Set the following information, and select OK.

Local AS	1
Router ID	10.11.101.110

To set the BGP router information - CLI

```
config router BGP
  set as 1
  set router-id 10.11.101.110
end
```

Add the internal network to the AS

The Company is one AS with the FortiGate unit configured as the BGP border router connecting that AS to the two ISPs ASes. The internal network in the Company's AS must be defined. If there were other networks in the company such as regional offices, they would be added here as well.

To set the networks in the AS - web-based manager

1 Go to *Router* > *Dynamic* > *BGP*.

2 In *Networks*, set the following information and select *OK*.

IP/Netmask	10.11.101.0/255.255.255.0

To set the networks in the AS (CLI)

```
config router bgp
  config network
  edit 1
    set prefix 10.11.101.0 255.255.255.0
  next
  end
end
```

Additional FortiGate BGP configuration

At this point that is all the settings that can be done in both the web-based manger and the CLI. The remaining configuration must be completed in the CLI.

These additional settings are mainly determined by your ISP requirements. They will determine your timers such as keep alive timers, if extended features like BFD and graceful restart are being used, and so on. For this example, some common simply features are being used to promote faster detections of network failures which will result in better service for the Company's internal network users.

The ISPs do not require authentication between peer routers.

These commands will enable or modify the following features on the FortiGate unit, and where possible on neighboring routers as well:

- `bestpath-med-missing-as-worst` — treats a route without an MED as the worst possible available route due to expected unreliability
- `fast-external-failover` — immediately reset the session information associated with BGP external peers if the link used to reach them goes down
- `graceful-restart*` — advertise reboots to neighbors so they do not see the router as offline, wait before declaring them offline, and how long to wait when they reboot before advertising updates. These commands applies to neighbors and are part of the BGP capabilities. This prevents unneeded routing updates.
- `holdtime-timer` — how long the router will wait for a keepalive message before declaring a router offline. A shorter time will find an offline router faster.
- `keepalive-timer` — how often the router sends out keepalive messages to neighbor routers to maintain those sessions.
- `log-neighbor-changes` — log changes to neighbor routers' status. This can be useful for troubleshooting from both internal and external networks.
- `connect-timer` — how long in seconds the FortiGate unit will try to reach this neighbor before declaring it offline.

- `weight` — used to prefer routes from one neighbor over the other. In this example ISP1 is the primary connection so it is weighted higher than ISP2

To configure additional BGP options - CLI

```
config router bgp
  set bestpath-med-missing-as-worst enable
  set fast-external-failover enable
  set graceful-restart enable
  set graceful-restart-time 120
  set graceful-stalepath-time 180
  set graceful-update-delay 180
  set holdtime-timer 120
  set keepalive-timer 45
  set log-neighbor-changes enable
  config neighbor
    edit 172.21.111.4
      set connect-timer 60
      set description "ISP1"
      set holdtime-timer 120
      set keepalive-timer 45
      set weight 250
    next
    edit 172.22.222.4
      set connect-timer 60
      set description "ISP2"
      set holdtime-timer 120
      set keepalive-timer 45
      set weight 100
    next
  end
end
```

Configuring other networking devices

There are two other networking devices that need to be configured both ISPs' BGP routers.

The ISPs' routers must add the FortiGate unit as a neighbor so route updates can be sent in both directions. Note that ISP1 is not directly connected to ISP2 that we are aware of.

Inform both of your ISPs of your FortiGate unit's BGP information. Once they have configured their router, you can test your BGP connection to the internet.

They will require your FortiGate unit's:

- IP address of the connected interface
- Router ID
- your Company's AS number

Testing this configuration

With the dual-homed BGP configuration in place, you should be able to send and receive traffic, send and receive routes, and not have any routing loops. Testing the networks will confirm things are working as expected.

In general for routing you need to look at the routing table on different routers to see what routes are being installed. You also need to sniff packets to see how traffic is being routed in real time. These two sources of information will normally tell you what you need to know.

Basic networking tools and methods can be found in “” on page 1714.

Testing of this example’s network configuration should be completed in two parts:

- Testing network connectivity
- Verifying the FortiGate unit’s routing tables
- Verifying traffic routing
- Verifying the dual-homed side of the configuration

Testing network connectivity

A common first step in testing a new network topology is to test if you can reach the internet and other locations as you expect you should. If not, you may be prevented be cabling issues, software or other issues.

The easiest way to test connections is to use ping, once you ensure that all the FortiGate unit’s interfaces and ISP routers have ping support enabled. Also ensure that the security policies allow ping through the firewall.

Connections to test in this example are the internal network to ISP1’s router or the internet, and the same for ISP2. If you can connect on the external side of the Fortinet unit, try to ping the internal network. Those three tests should prove your basic network connections are working.

Once you have completed testing the network connectivity, turn off ping support on the external interfaces for additional security.

Verifying the FortiGate unit’s routing tables

The FortiGate routing table contains the routes stored for future use. If you are expecting certain routes to be there and they are not, that is a good indicator that your configuration is not what you expected.

The CLI command `get router info routing-table details` will provide you with every route’s routing protocol, destination address, gateway address, interface, weighting, and if the address is directly connected or not.

If you want to limit the display to BGP routes only, use the CLI command `get router info routing-table bgp`. If there are no BGP routes in the routing table, nothing will be displayed. In the CLI command you can replace BGP with static, or other routing protocols to only display those routes.

If you want to see the contents of the routing information database (RIB), use the CLI command `get router info routing-table database`. This will display the incoming routes that may or may not make it into the routing table.

Verifying traffic routing

Traffic may be reaching the internal network, but it may be using a different route than you think to get there.

Use a browser to try and access the Internet.

If needed, allow traceroute and other diag ports to be opened until things are working properly. Then remove access for them again.

Look for slow hops on the traceroute, or pings to a location, as they may indicate network loops that need to be fixed.

Any locations that have an unresolved traceroute or ping must be examined and fixed.

Use network packet sniffing to ensure traffic is being routed as you expect.

Verifying the dual-homed side of the configuration

Since there are two connections to the internet in this example, theoretically you can pull the plug on one of the ISP connections, and all traffic will go through the other connection. Alternately, you may choose to remove a default route to one ISP, remove that ISP's neighbor settings, or change the weightings to prefer other other ISP. These alternate ways to test dual-homing do not change physical cabling, which may be preferred in some situations.

If this does not work as expected, things to check include:

- default static routes — if these are wrong or don't exist, the traffic can't get out.
- BGP neighbor information — If the ISP router information is incorrect, the FortiGate unit won't be able to talk to it.

Redistributing and blocking routes in BGP

During normal BGP operation, peer routers redistribute routes from each other. However, in some specific situations it may be best to not advertise routes from one peer for various reasons. Some reasons may be the peer is redundant with another peer (they share the same routes exactly), it might be unreliable in some way, or some other reason.

The FortiGate can also take routes it learns from other protocols and advertise them in BGP, for example OSPF or RIP. If your Company hosts its own web or email servers, external locations will require routes to your networks to reach those services.

In this example the Company has a internal networks in an OSPF area, and is connected to a BGP AS and two BGP peers. Company goes through these two peers to reach the Internet. However, Peer 1 routes will not be advertised to Peer 2. The Company internal user and server networks are running OSPF, and will redistribute those routes to BGP so external locations can reach the web and email servers.

This section includes the following topics:

Network layout and assumptions

This section includes:

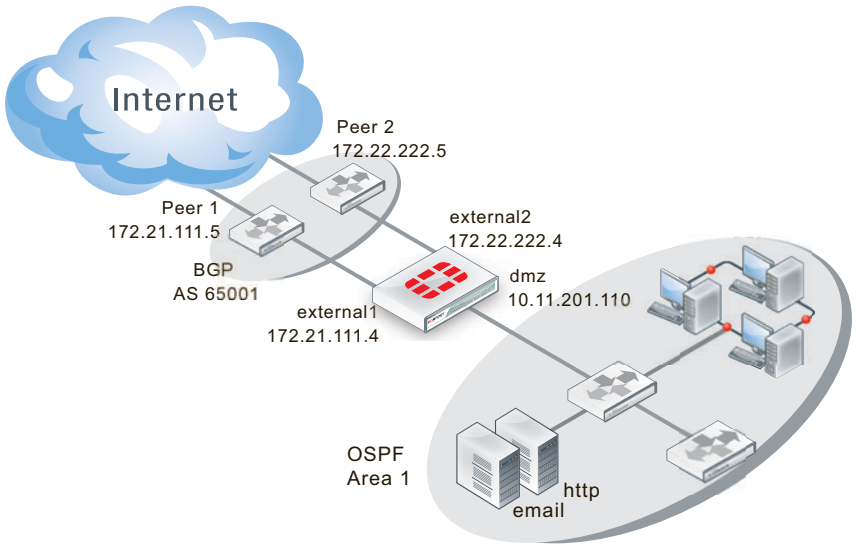
Network layout

The network layout for the BGP redistributing routes example involves the company network being connected to two BGP peers as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, and the peer routers.

The components of the layout include:

- There is only one BGP AS in this example — AS 65001, shared by the FortiGate unit and both peers.
- The Company's FortiGate unit connects to the Internet through two BGP peers.
- The Company internal networks on the dmz interface of the FortiGate unit with an IP of 10.11.201.0/24.
- The FortiGate units' interfaces are connected as follows:
  - port1 (dmz) has IP 10.11.201.110 and is the internal user and server network
  - port2 (external1) has IP 172.21.111.4 and is connected to Peer 1's network
  - port3 (external2) has IP 172.22.222.4 and is connected to Peer 2's network
- Peer 1 has IP 172.21.111.5, and Peer 2 has IP 172.22.222.5.
- OSPF Area 1 is configured on the dmz interface of the FortiGate unit, and is the routing protocol used by the internal users and servers.

Figure 173: BGP network topology



Assumptions

The the BGP redistributing routes configuration procedure follows these assumptions:

- the FortiGate unit has been configured following the Install Guide
- interfaces port1, port2, and port 3 exist on the FortiGate unit
- we don't know the router manufacturers of Peer 1 and Peer 2
- we don't know what other devices are on the BGP AS or OSPF Area
- all basic configuration can be completed in both GUI and CLI
- access lists and route maps will only be configured in CLI
- VDOMs are not enabled on the FortiGate unit

General Configuration Steps

1 Configuring the FortiGate unit — networks and firewalls

Configuring the FortiGate unit — networks and firewalls

The FortiGate unit has three interfaces connected to networks — two external and one dmz.

Security policies must be in place to allow traffic to flow between these networks.

Firewall services will change depending on which routing protocol is being used on that network — either BGP or OSPF. Beyond that, all services that are allowed will be allowed in both directions due to the internal servers. The services allowed are web-server services (DNS, HTTP, HTTPS, SSH, NTP, FTP*, SYSLOG, and MYSQL), email services (POP3, IMAP, and SMTP), and general troubleshooting services (PING, TRACEROUTE). Those last two can be removed once the network is up and working properly to increase security. Other services can be added later as needed.

To configure the interfaces - GUI

1 Go to *System* > *Network* > *Interface*.
2 Edit port1 (dmz) interface.
3 Set the following information, and select *OK*.

Alias	dmz
IP/Netmask	10.11.201.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	OSPF internal networks
Administrative Status	Up

4 Edit port2 (external1) interface.
5 Set the following information, and select *OK*.

Alias	external1
IP/Netmask	172.21.111.4/255.255.255.0
Administrative Access	HTTPS SSH
Description	BGP external Peer 1
Administrative Status	Up

6 Edit port3 (external2) interface.
7 Set the following information, and select *OK*.

Alias	external2
IP/Netmask	172.22.222.4/255.255.255.0
Administrative Access	HTTPS SSH
Description	BGP external2 Peer2
Administrative Status	Up

To configure the FortiGate interfaces (CLI)

```
config system interface
  edit port1
    set alias dmz
    set ip 10.11.101.110 255.255.255.0
    set allowaccess https ssh ping
    set description “OSPF internal networks”
    set status up
  next
  edit port2
    set alias external1
    set ip 172.22.222.5 255.255.255.0
    set allowaccess https ssh
    set description “external1 Peer 1”
    set status up
  next
  edit port3
    set alias external2
    set ip 172.22.222.5 255.255.255.0
    set allowaccess https ssh
    set description “external2 Peer 2”
    set status up
  next
end
```

To configure the firewall addresses - GUI

1. Go to *Firewall Objects* > *Address* > *Address*.
2. Select *Create New*, and set the following information.

Address Name	Internal_networks
Type	Subnet / IP Range
Subnet / IP Range	10.11.201.0 255.255.255.0
Interface	port1

3. Select *OK*.
4. Select *Create New*, and enter the following information:
5. Select *OK*.

To configure the firewall addresses - CLI

```
config firewall address
  edit "BGP_services"
```

To configure firewall service groups - GUI

1. Go to *Firewall Objects* > *Service* > *Group*.
2. Select *Create New*.
3. Name the group OSPF_Services.
4. Move the following services to the right list: DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, OSPF, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.

5 Select *OK*.

6 Select *Create New*.

7 Name the group BGP_Services.

8 Move the following services to the right list: BGP, DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.

9 Select *OK*.

To configure firewall service groups - CLI

```
config firewall service group
  edit "BGP_services"
    set member “BGP”, "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT"
       "HTTP" "HTTPS" "IMAP" "MYSQL" "NTP" "PING" "POP3" "SMTP"
       "SSH" "TRACEROUTE" "SYSLOG"
  next
  edit "OSPF_services"
    set member "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP"
       "HTTPS" "IMAP" "MYSQL" "NTP" "PING" "POP3" "SMTP" "SSH"
       "TRACEROUTE" "SYSLOG" "OSPF"
  next
end
```

Configuring the FortiGate unit - BGP

The only change from the standard BGP configuration for this example is configuring the blocking Peer 1’s routes from being advertised to Peer 2. From the network topology you can guess that both of these peers likely share many routes in common and it makes no sense to advertise unneeded routes.

Blocking Peer 1’s routes to Peer 2 is done with distribute-list-out keyword. They allow you to select which routes you will advertise to a neighbor using an access list. In this case we will block all incoming routes from Peer 1 when we send updates to Peer 2. Otherwise Peer 1 and Peer 2 are regular neighbors.

The FortiGate unit will redistribute routes learned from OSPF into BGP.

This is advanced configuration and the commands are only available in the CLI.

To create access list to block Peer 1 - CLI

```
config access-list
  edit “block_peer1”
    config rule
    edit 1
      set prefix 172.21.111.0 255.255.255.0
      set action deny
      set exact-match enable
    end
  end
end
```

To configure BGP on the FortiGate unit - CLI

```
config router bgp
  set as 65001
```

```
  set router-id 10.11.201.110
  config redistribute ospf
    set status enable
  end
  config neighbor
    edit 172.22.222.5
      set remote-as 65001
      set distribute-list-out "block_peer1"
    next
    edit 172.21.111.5
      set remote-as 65001
    end
end
```

Configuring the FortiGate unit - OSPF

This configuration involves only one OSPF Area, so all traffic will be intra-area. If there were two or more areas with traffic going between them it would be inter-area traffic. These two types are comparable to BGP's traffic within one AS (iBGP) or between multiple ASes (eBPG). Redistributing routes from OSPF to BGP is considered external because either the start or end point is a different routing protocol.

The OSPF configuration is basic apart from redistributing BGP routes learned.

To configure OSPF on the FortiGate unit - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. For Router ID enter `10.11.201.110` and then select *Apply*.
3. Under *Advanced Options* and *Redistribute*, select *BGP* and set BGP metric to 1.
4. For *Areas*, select *Create New,* enter the following information and then select *OK*.

Area (IP)	`0.0.0.0`
Type	Regular
Authentication	None

5. For *Networks*, select *Create New*.
6. Enter 10.11.201.0/255.255.255.0 for *IP/Netmask*, and select *OK*.
7. For *Interfaces*, select *Create New*.
8. Enter `OSPF_dmz_network` for *Name*.
9. Select `port1(dmz)` for *Interface*, and then select *OK*.

To configure OSPF on the FortiGate unit - CLI

```
config router ospf
  set router-id 10.11.201.110
  config area
    edit 0.0.0.0
      set type regular
      set authentication none
    end
  config network
    edit 1
      set area 0.0.0.0
      set prefix 10.11.201.0 255.255.255.0
```

```
    end
  config interface
    edit "OSPF_dmz_network"
      set interface port1(dmz)
      set status enable
    end
  config redistribute bgp
    set status enable
    set metric 1
  end
end
```

Configuring other networking devices

As with all BGP configurations, the peer routers will need to be updated with the FortiGate unit's BGP information including IP address, AS number, and what capabilities are being used such as IPv6, graceful restart, BFD, and so on.

Testing network configuration

Testing this configuration involves the standard connectivity checks, but also ensuring that routes are being passed between protocols as expected.

Check the routing table on the FortiGate unit to ensure that routes from both OSPF and BGP are present.

Check the routing table on devices on the OSPF network for routes redistributed from BGP. Also check those devices for connectivity to the Internet.

Check the routing table on Peer 2 to ensure no routes from Peer 1 are present, but routes from the internal OSPF network are present.

For help with troubleshooting, see "Troubleshooting BGP" on page 1763.

Open Shortest Path First (OSPF)

This section describes OSPF routing.

The following topics are included in this section:

- OSPF Background and concepts
- Troubleshooting OSPF
- OSPF routing examples

OSPF Background and concepts

This section includes:

- Background
- The parts and terminology of OSPF
- How OSPF works

Background

OSPF is a link-state interior routing protocol, that is widely used in large enterprise organizations. It only routes packets within a single autonomous system (AS). This is different from BGP as BGP can communicate between ASes.

The main benefit of OSPF is that it detects link failures in the network quickly and within seconds has converged network traffic successfully without any networking loops. Also OSPF has many features to control which routes are propagated and which are not, maintaining smaller routing tables. OSPF can also provide better load-balancing on external links than other interior routing protocols.

OSPF version 2 was defined in 1998 in RFC 2328. OSPF was designed to support classless IP addressing, and variable subnet masks. This was a shortcoming of the earlier RIP protocols.

Updates to OSPF version 2 are included in OSPF version 3 defined in 2008 in RFC 5340. OSPF3 includes support for IPv6 addressing where previously OSPF2 only supports IPv4 addressing.

The parts and terminology of OSPF

Parts and terminology of OSPF includes:

- OSPF and IPv6
- Router ID
- Adjacency
- Designated router (DR) and backup router (BDR)
- Area
- Authentication
- Hello and dead intervals

OSPF and IPv6

OSPF version 3 includes support for IPv6. Generally all IP addresses are in IPv6 format instead of IPv4.

OSPF3 area numbers use the same 32-bit numbering system as OSPF2.

Router ID

In OSPF, each router has a unique 32-bit number called its Router ID. Often this 32-bit number is written the same as a 32-bit IPv4 address would be written in dotted decimal notation. However some brands of routers, such as Cisco routers, support a router ID entered as an integer instead of an IP address.

It is a good idea to not use IP address in use on the router for the router ID number. The router ID does not have to be a particular IP address on the router. By choosing a different number, it will be harder to get confused which number you are looking at. A good idea can be to use the as much of the area's number as possible. For example if you have 15 routers in area 0.0.0.0 they could be numbered from 0.0.0.1 to 0.0.0.15. If you have an area 1.1.1.1, then routers in that area could start at 1.1.1.10 for example.

You can manually set the router ID on your FortiGate unit.

To manually set an OSPF router ID of 0.0.1.1 - web-based manager

1 Go to *Router* > *Dynamic* > *OSPF*.

2 For *Router ID*, enter `0.0.1.1`.

3 Select *OK*.

To manually set an OSPF router ID of 0.0.1.1 - CLI

```
config router ospf
  set router-id 0.0.1.1
end
```

Adjacency

In an OSPF routing network, when an OSPF router boots up it sends out OSPF Hello packets to find any neighbors, or routers that have access to the same network as the router booting up. Once neighbors are discovered and Hello packets are exchanged, updates are sent, and the Link State databases of both neighbors are synchronized. At this point these neighbors are said to be adjacent.

For two OSPF routers to become neighbors, the following conditions must be met.

- The subnet mask used on both routers must be the same subnet.
- The subnet number derived using the subnet mask and each router's interface IP address must match.
- The Hello interval & The Dead interval must match.
- The routers must have the same OSPF area ID. If they are in different areas, they are not neighbors.
- If authentication is used, they must pass authentication checks.

If any of these parameters are different between the two routers, the routers do not become OSPF neighbors and cannot be adjacent. If the routers become neighbors, they are adjacent.

Adjacency and neighbors

Neighbor routers can be in a Two-Way state, and not be adjacent. Adjacent routers normally have a neighbour state of FULL. Neighbors only exchange Hello packets, and do not exchange routing updates. Adjacent routers exchange LSAs (LSDB information) as well as Hello packets. A good example of an adjacent pair of routers is the DR and BDR.

You can check on the state of an OSPF neighbor using the CLI command `get router info ospf neighbor all`. See "Checking the state of OSPF neighbors" on page 1800.

Why adjacency is important

It is important to have adjacent pairs of routers in the OSPF routing domain because routing protocol packets are only passed between adjacent routers. This means adjacency is required for two OSPF routers to exchange routes. If there is no adjacency between two routers, such as one on the 172.20.120.0 network and another on the 10.11.101.0 network, the routers do not exchange routes. This makes sense because if all OSPF routers on the OSPF domain exchanged updates it would flood the network. Also its better for updates to progress through adjacent routers to ensure there are no outages along the way. Otherwise updates could skip over routers that are potentially offline, causing longer routing outages and delays while the OSPF domain learns of this outage later on.

If the OSPF network has multiple border routers and multiple connections to external networks, the designated router (DR) determines which router pairs become adjacent. The DR can accomplish this because it maintains the complete topology of the OSPF domain, including which router pairs are adjacent. The BDR also has this information in case the DR goes offline.

Designated router (DR) and backup router (BDR)

In OSPF a router can have a number of different roles to play.

A designated router (DR) is the designated broadcasting router interface for an AS. It looks after all the initial contact and other routing administration traffic. Having only one router do all this greatly reduces the network traffic and collisions.

If something happens and the designated router goes offline, the backup designated router (BDR) takes over. An OSPF FortiGate unit interface can become either a DR or BDR. Both the DR and the BDR cover the same area, and are elected at the same time. The election process doesn't have many rules, but the exceptions can become complex.

Benefits

The OSPF concept of the designated router is a big step above RIP. With all RIP routers doing their own updates all the time, RIP suffers from frequent and sometimes unnecessary updates that can slow down your network. With OSPF, not only do routing changes only happen when a link-state changes instead of any tiny change to the routing table, but the designated router reduces this overhead traffic even more.

However, smaller network topologies may only have a couple routers besides the designated router. This may seem excessive, but it maintains the proper OSPF form and it will still reduce the administration traffic but to a lesser extent than on a large network. Also your network topology is ready for when you expand your network.

DR and BDR election

An election chooses the DR and BDR from all the available routers. The election is primarily based on the priority setting of the routers—the highest priority becomes the DR, and the second highest becomes BDR. To resolve any ties, the router with the highest router ID wins. For example 192.168.0.1 would win over 10.1.1.2.

The router priority can vary from 0 to 255, but at 0 a router will never become a DR or BDR. If a router with a higher priority comes on line after the election, it must wait until after the DR and BDR go offline before it would become the DR.

If the original DR goes offline, but then is available when the BDR goes offline later on, the original DR will be promoted back to DR without an election leaving the new BDR as it is.

With your FortiGate unit, to configure the port1 interface to be a potential OSPF designated router or backup designed router called `ospf_DR` on the network, you need to raise the priority of the router to a very high number such as 250 out of 255. This will ensure the interface has a chance to be a DR, but will not guarantee that it will be one. Give the interface a low numbered IP address—such as 10.1.1.1 instead of 192.168.1.1—to help ensure it becomes a DR, but that is not part of this example. Enter the following command:

```
config router ospf
  config ospf-interface
  edit "ospf_DR"
    set priority 250
  end
end
```

Area

An OSPF area is a smaller part of the larger OSPF AS. Areas are used to limit the link-state updates that are sent out. The flooding used for these updates would overwhelm a large network, so it is divided into these smaller areas for manageability.

Within an area if there are two or more routers that are viable, there will always be a designated router (DR) and a backup DR (BDR). For more on these router roles, see "Designated router (DR) and backup router (BDR)" on page 1789.

Defining a private OSPF area, involves:

- assigning a 32-bit number to the area that is unique on your network
- defining the characteristics of one or more OSPF areas
- creating associations between the OSPF areas that you defined and the local networks to include in the OSPF area
- if required, adjusting the settings of OSPF-enabled interfaces.

IPv6 OSPF area numbers use the same 32-bit number notation as IPv4 OSPF

If you are using the web-based manager to perform these tasks, follow the procedures summarized below.

FortiGate units support the four main types of OSPF area:

- Backbone area
- NSSA
- Stub area

- Regular area

Backbone area

Every OSPF network has at least one AS, and every OSPF network has a backbone area. The backbone is the main area, or possibly the only area. All other OSPF areas are connected to a backbone area. This means if two areas want to pass routing information back and forth, that routing information will go through the backbone on its way between those areas. For this reason the backbone not only has to connect to all other areas in the network, but also be uninterrupted to be able to pass traffic to all points of the network.

The backbone area is referred to as area 0 because it has an IP address of 0.0.0.0.

Stub area

A stub area is an OSPF area that receives no outside routes advertised into it, and all routing in it is based on a default route. This essentially isolates it from outside areas.

Stub areas are useful for small networks that are part of a larger organization, especially if the networking equipment can't handle routing large amounts of traffic passing through, or there are other reasons to prevent outside traffic, such as security. For example most organizations don't want their accounting department to be the center of their network with everyone's traffic passing through there. It would increase the security risks, slow down their network, and it generally doesn't make sense.

A variation on the stub area is the totally stubby area. It is a stub area that does not allow summarized routes.

NSSA

A not-so-stubby-area (NSSA) is a stub area that allows for external routes to be injected into it. While it still does not allow routes from external areas, it is not limited to only using he default route for internal routing.

Regular area

A regular area is what all the other ASes are, all the non-backbone, non-stub, non-NSSA areas. A regular area generally has a connection to the backbone, does receive advertisements of outside routes, and does not have an area number of 0.0.0.0.

Authentication

In the OSPF packet header are two authentication related fields —AuType, and Authentication.

All OSPF packet traffic is authenticated. Multiple types of authentication are supported in OSPFv2. However in OSPFv3, there is no authentication built-in but it is assumed that IPsec will be used for authentication instead.

Packets that fail authentication are discarded.

Null authentication

Null authentication indicates there is no authentication being used. In this case the 16-byte Authentication field is not checked, and can be any value. However checksumming is still used to locate errors. On your FortiGate this is the `none` option for authentication.

Simple Password authentication

Simple password refers to a standard plain text string of characters. The same password is used for all transactions on a network. The main use of this type of authentication is to prevent routers from accidently joining the network. Simple password authentication is vulnerable to many forms of attack, and is not recommended as a secure form of authentication.

Cryptographic authentication

Cryptographic authentication involves the use of a shared secret key to authenticate all router traffic on a network. The key is never sent over the network in the clear—a packet is sent and a condensed and encrypted form of the packet is appended to the end of the packet. A non-repeating sequence number is included in the OSPF packet to protect against replay attacks that could try to use already sent packets to disrupt the network. When a packet is accepted as authentic the authentication sequence number is set to the packet sequence number. If a replay attack is attempted, the packet sent will be out of sequence and ignored.

Your FortiGate unit supports all three levels of authentication through the authentication keyword associated with creating an OSPF interface .

For example to create an OSPF interface called `Accounting` on the port1 interface that is a broadcast interface, has a hello interval of 10 seconds, has a dead interval of 40 seconds, uses text authentication (simple password) with a password of “ospf_test”, enter the command:

```
config router ospf
  config ospf-interface
  edit Accounting
    set interface port1
    set network-type broadcast
    set hello-interval 10
    set dead-interval 40
    set authentication text
    set authentication-key “ospf_test”
  end
end
```

Hello and dead intervals

The OSPF Hello protocol is used to discover and maintain communications with neighboring routers.

Hello packets are sent out at a regular interval for this purpose. The DR sends out the Hello packets. In a broadcast network, the multicast address of 224.0.0.5 is used to send out Hello packets. New routers on the network listen for and reply to these packets to join the OSPF area. If a new router never receives a Hello packet, other routers will not know it is there and will not communicate with it. However, once a new router is discovered the DR adds it to the list of routers in that area and it is integrated into the routing calculations.

Dead interval is the time it takes when a router doesn’t respond before it is declared dead, or offline. If this interval is too short routers will be declared offline when they aren’t and the link-state updates will happen more than they need to. If the dead interval is too long, it will slow down network traffic while that router it attempted to be contacted when it is already offline.

Access Lists

Access lists are filters used by FortiGate unit OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also its easier to troubleshoot since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
  edit test_list
  config rule
    edit 1
      set prefix 10.10.10.10 255.255.255.255
      set action allow
      set exact-match enable
    next
    edit 2
      set prefix 11.11.11.11 255.255.255.255
      set action allow
      set exact-match enable
    end
  end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
  edit test_list_ip6
    config rule
      edit 1
        set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
        set action deny
      next
      edit 2
        set prefix6 2002:B0B:B0B:0:0:0:0:0/48
        set action deny
      end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially increase. Enter the following command:

```
config router ospf
  config distribute-list
    edit 5
      set access-list test_list
      set protocol connected
    end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose

How OSPF works

An OSPF network one or more areas. An OSPF area is typically divided into logical areas linked by Area Border Routers. A group of contiguous networks form an area. An Area Border Router (ABR) links one or more areas to the OSPF network backbone (area ID 0). See "Area border router (ABR)" on page 1711.

OSPF is an interior routing protocol. It includes a backbone AS, and possibly additional ASes. The DR and BDR are elected from potential routers with the highest priorities. The DR handles much of the administration to lower the network traffic required. New routers are discovered through hello packets sent from the DR using the multicast address of 224.0.0.5. If the DR goes offline at any time, the BDR has a complete table of routes that is uses when it takes over as the DR router.

OSPF does not use UDP or TCP, but is encapsulated directly in IP datagrams as protocol 89. This is in contrast to RIP, or BGP. OSPF handles its own error detection and correction functions.

The OSPF protocol, when running on IPv4, can operate securely between routers, optionally using a variety of authentication methods to allow only trusted routers to participate in routing. OSPFv3, running on IPv6, no longer supports protocol-internal authentication. Instead, it relies on IPv6 protocol security (IPsec).

Other important parts of how OSPF works includes:

- OSPF router discovery
- How OSPF works on FortiGate units
- External routes
- Link-state Database (LSDB) and route updates
- OSPF packets

OSPF router discovery

OSPF-enabled routers generate Link-State Advertisements (LSA) and send them to their neighbors whenever the status of a neighbor changes or a new neighbor comes online. As long as the OSPF network is stable, LSAs between OSPF neighbors do not occur. An LSA identifies the interfaces of all OSPF-enabled routers in an area, and provides information that enables OSPF-enabled routers to select the shortest path to a destination. All LSA exchanges between OSPF-enabled routers are authenticated.

When a network of OSPF routers comes online, the follow steps occur.

1 When OSPF routers come online, they send out Hello packets to find other OSPF routers on their network segment.

2 When they discover other routers on their network segment, generally they become adjacent. Adjacent routers can exchange routing updates. See “Adjacency” on page 1788.

3 A DR and BDR are elected from the available routers using priority settings, and router ID. See “Designated router (DR) and backup router (BDR)” on page 1789, and “DR and BDR election issues” on page 1801.

4 Link state updates are sent between adjacent routers to map the topology of the OSPF area.

5 Once complete, the DR floods the network with the updates to ensure all OSPF routers in the area have the same OSPF route database. After the initial update, there are very few required updates if the network is stable.

How OSPF works on FortiGate units

When a FortiGate unit interface is connected to an OSPF area, that unit can participate in OSPF communications. FortiGate units use the OSPF Hello protocol to acquire neighbors in an area. A neighbor is any router that is directly connected to the same area as the FortiGate unit, and ideally is adjacent with a state of Full. After initial contact, the FortiGate unit exchanges Hello packets with its OSPF neighbors regularly to confirm that the neighbors can be reached.

The number of routes that a FortiGate unit can learn through OSPF depends on the network topology. A single unit can support tens of thousands of routes if the OSPF network is configured properly.

External routes

OSPF is an internal routing protocol. OSPF external routes are routes with the destination of the connection using a routing protocol other than OSPF. OSPF handles external routes by adjusting the cost of the route to include the cost of the other routing protocol. There are two methods of calculating this cost, used for OSPF E1 and OSPF E2.

OSPF external1 (E1)

In OSPF E1 the destination is outside of the OSPF domain. This requires a different metric to be used beyond the normal OSPF metrics. The new metric of a redistributed route is calculated by adding the external cost and the OSPF cost together.

OSPF external2 (E2)

OSPF E2 is the default external type when routes are redistributed outside of OSPF. OSPF E2 is similar to E1, except in this case, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. Dropping the OSPF portion can be useful in a number of situations, on border routers that have no OSPF portion for example or where the OSPF routing cost is negligible compared to the external routing cost.

Comparing E1 and E2

The best way to understand OSPF E1 and E2 routes is to check routing tables on OSPF routers. If you look at the routes on an OSPF border router, the redistributed routes will have an associated cost that represents only the external route, as there is no OSPF cost to the route due to it already being on the edge of the OSPF domain. However, if you look at that same route on a different OSPF router inside the OSPF routing domain, it will have a higher associated cost - essentially the external cost plus the cost over the OSPF domain to that border router. The border router uses OSPF E2, where the internal OSPF router uses OSPF E2 for the same route.

Viewing external routes

When you are trying to determine the costs for routes in your network to predict how traffic will be routed, you need to see the external OSPF routes and their associated costs. On your FortiGate unit, you find this information through your CLI.

To view external routes - CLI

You can view the whole routing table using `get router info routing-table all` to see all the routes including the OSPF external routes, or for a shorter list you can use the command `get router info routing-table ospf`. The letter at the left will be either E1 or E2 for external OSPF routes. The output of will look similar to the following, depending on what routes are in your routing table.

```
FGT620B# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS
   inter area
* - candidate default

O*E2   0.0.0.0/0 [110/10] via 10.1.1.3, tunnel_wan2, 00:02:11
O      10.0.0.1/32 [110/300] via 10.1.1.3, tunnel_wan2, 00:02:11
S      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S      1.0.0.0/8 [10/0] via 192.168.183.254, port2
```

Link-state Database (LSDB) and route updates

OSPF is based on links. The links between adjacent neighbor routers allow updates to be passed along the network. Network links allow the DR to flood the area with Link-state database (LSDB) updates. External links allow the OSPF area to connect to destinations outside the OSPF autonomous system. Information about these links is passed throughout the OSPF network as link-state updates.

The LSDB contains the information that defines the complete OSPF area, but the LSDB is not the routing table. It contains the information from all the link-state updates passed along the network. When there are no more changes required, and the network is stable then the LSDB on each router in the network will be the same. The DR will flood the LSDB to the area to ensure each router has the same LSDB.

To calculate the best route (shortest path) to a destination, the FortiGate unit applies the Shortest Path First (SPF) algorithm — based on Dijkstra's algorithm — to the accumulated link-state information. OSPF uses relative path cost metric for choosing the best route. The path cost can be any metric, but is typically the bandwidth of the path— how fast traffic will get from one point to another.

The path cost, similar to “distance” for RIP, imposes a penalty on the outgoing direction of a FortiGate unit interface. The path cost of a route is calculated by adding together all of the costs associated with the outgoing interfaces along the path to the destination. The lowest overall path cost indicates the best route, and generally the fastest route. Some brands of OSPF routers, such as Cisco, implement cost as a direct result of bandwidth between the routers. Generally this is a good cost metric because larger bandwidth means more traffic can travel without slowing down. To achieve this type of cost metric on FortiGate units, you need to set the cost for each interface manually in the CLI.

The inter-area routes may not be calculated when a Cisco type ABR has no fully adjacent neighbor in the backbone area. In this situation, the router considers summary-LSAs from all Actively summary-LSAs from all Actively Attached areas (RFC 3509).

The FortiGate unit dynamically updates its routing table based on the results of the SPF calculation to ensure that an OSPF packet will be routed using the shortest path to its destination. Depending on the network topology, the entries in the FortiGate unit routing table may include:

- the addresses of networks in the local OSPF area (to which packets are sent directly)
- routes to OSPF area border routers (to which packets destined for another area are sent)
- if the network contains OSPF areas and non-OSPF domains, routes to area boundary routers, which reside on the OSPF network backbone and are configured to forward packets to destinations outside the OSPF AS.

OSPF Route updates

Once the OSPF domain is established, there should be few updates required on a stable network. When updates occur and a decision is required concerning a new route, this is the general procedure.

1. Our router gets a new route, and needs to decide if it should go in the routing table.
2. The router has an up to date LSDB of the entire area, containing information about each router, the next hop to it, and most importantly the cost to get there.
3. Our router, turns the LSDB into a shortest path first (SPF) tree using Dijkstra’s algorithm. It doesn’t matter if there is more than one path to a router on the network, the SPF tree only cares about the shortest path to that router.
4. Once the SPF tree has been created, and shows the shortest paths to all the OSPF routers on the network, the work is done. If the new route is the best route, it will be part of that tree. If it is not the shortest route, it will not be included in the LSDB.
5. If there has been a change from the initial LSDB to the new SPF tree, a link state update will be sent out to let the other routers know about the change so they can update their LSDBs as well. This is vital since all routers on the OSPF area must have the same LSDB.
6. If there was no change between the LSDB and the SPF tree, no action is taken.

OSPF packets

Every OSPF packet starts with a standard 24-byte header, and another 24 bytes of information or more. The header contains all the information necessary to determine whether the packet should be accepted for further processing.

Table 103: OSPF packet

1-byte Version field	1-byte Type field	2-byte Packet length	3-byte Router ID
4-byte Area ID	2-byte Checksum	2-byte Auth Type	8-byte Authentication
4-byte Network Mask	2-bye Hello interval	1-byte Options field	1-byte Router Priority
4-byte Dead Router interval	4-byte DR field	4-byte BDR field	4-byte Neighbor ID

The following descriptions summarize the OSPF packet header fields.

Version field— The OSPF version number. This specification documents version 2 of the protocol.

Type field—There are 5 OSPF packet types. From one to five, respectively, they are Hello, Database Description, Link State Request, Link State Update, and Link State Acknowledgment.

Packet length—The length of the OSPF protocol packet in bytes. This length includes the standard OSPF 24-byte header, so all OSPF packets are at 24-bytes long.

Router ID—The Router ID of the packet's source.

Area ID—A 32-bit number identifying the area that this packet belongs to. All OSPF packets are associated with a single area. Most travel a single hop only. Packets travelling over a virtual link are labelled with the backbone Area ID of 0.0.0.0.

Checksum—The standard IP checksum of the entire contents of the packet, starting with the OSPF packet header but excluding the 64-bit authentication field. This checksum is calculated as the 16-bit one's complement of the one's complement sum of all the 16-bit words in the packet, excepting the authentication field. If the packet's length is not an integral number of 16-bit words, the packet is padded with a byte of zero before checksumming. The checksum is considered to be part of the packet authentication procedure; for some authentication types the checksum calculation is omitted.

Auth Type—Identifies the authentication procedure to be used for the packet. Authentication types include Null authentication (0), Simple password (1), Cryptographic authentication (2), and all others are reserved for future use.

Authentication—A 64-bit field for use by the authentication scheme. When AuType indicates no authentication is being used, the Authentication fields is not checked and can be any value. When AuType is set to 2 (Cryptographic authentication), the 64-bit authentication field is split into the following four fields: Zero field, Key ID field, Authentication data length field, and Cryptographic sequence field.

The Key ID field indicates the key and algorithm used to create the message digest appended to the packet. The authentication data length field indicates how many bytes long the message digest is, and the cryptographic sequence number is at non-decreasing number that is set when the packet is received and authenticated to prevent replay attacks.

Network Mask—The subnet where this packet is valid.

Hello interval—The period of time between sending out Hello packets. See "Hello and dead intervals" on page 1792.

Options field— The OSPF protocol defines several optional capabilities. A router indicates the optional capabilities that it supports in its OSPF Hello packets, Database Description packets and in its LSAs. This enables routers supporting a mix of optional capabilities to coexist in a single Autonomous System.

Router priority—The priority between 0 and 255 that determines which routers become the DR and BDR. See "Designated router (DR) and backup router (BDR)" on page 1789.

Dead router interval—The period of time when there is no response from a router before it is declared dead. See "Hello and dead intervals" on page 1792.

DR and BDR fields—The DR and BDR fields each list the router that fills that role on this network, generally the routers with the highest priorities. See "Designated router (DR) and backup router (BDR)" on page 1789.

Neighbor ID—The ID number of a neighboring router. This ID is used to discover new routers and respond to them.

Troubleshooting OSPF

As with other dynamic routing protocols, OSPF has some issues that may need troubleshooting from time to time. For basic troubleshooting, see the Troubleshooting chapter.

The more common issues include:

- Clearing OSPF routes from the routing table
- Checking the state of OSPF neighbors
- Passive interface problems
- Timer problems
- Authentication issues
- DR and BDR election issues

Clearing OSPF routes from the routing table

If you think the wrong route has been added to your routing table and you want to check it out, you first have to remove that route from your table before seeing if it is added back in or not. You can clear all or some OSPF neighbor connections (sessions) using the `exec router clear OSPF` command. The exec router clear command is much more limiting for OSPF than it is for BGP. See "Clearing routing table entries" on page 1763.

For example, if you have routes in the OSPF routing table and you want to clear the specific route to IP address 10.10.10.1, you will have to clear all the OSPF entries. Enter the command:

FGT# exec router clear ospf process

Checking the state of OSPF neighbors

In OSPF each router sends out link state advertisements to find other routers on its network segment, and to create adjacencies with some of those routers. This is important because routing updates are only passed between adjacent routers. If two routers you believe to be adjacent are not, that can be the source of routing failures.

To identify this problem, you need to check the state of the OSPF neighbors of your FortiGate unit. Use the CLI command `get router info ospf neighbor all` to see all the neighbors for your FortiGate unit. You will see output in the form of:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID  Pri  State    Dead Time   Address         Interface
10.0.0.2     1    Full/ -  00:00:39    10.1.1.2        tunnel_wan1
10.0.0.2     1    Full/ -  00:00:34    10.1.1.4        tunnel_wan2
```

The important information here is the `State` column. Any neighbors that are not adjacent to your FortiGate unit will be reported in this column as something other than `Full`. If the state is `Down`, that router is offline.

Passive interface problems

A passive OSPF interface doesn't send out any updates. This means it can't be a DR, BDR, or an area border router among other things. It will depend on other neighbor routers to update its link-state table.

Passive interfaces can cause problems when they aren't receiving the routing updates you expect from their neighbors. This will result in the passive OSPF FortiGate unit interface having an incomplete or out of date link-state database, and it will not be able to properly route its traffic. It is possible that the passive interface is causing a hole in the network where no routers are passing updates to each other, however this is a rare situation.

If a passive interface is causing problems, there are some easy methods to determine it is the cause. The easiest method is to make it an active interface, and if the issues disappear that was the cause. Another method is to examine the OSPF routing table and related information to see if it is incomplete compared to other neighbor routers. If this is the case.

If you cannot make the interface active for some reason, you will have to change your network to fix the "hole" by adding more routers, or changing the relationship between the passive router's neighbors to provide better coverage.

Timer problems

A timer mismatch is when two routers have different values set for the same timer. For example if one router declares a router dead after 45 seconds and another waits for 4 minutes that difference in time will result in those two routers being out of synch for that period of time—one will still see that offline router as being online.

The easiest method to check the timers is to check the configuration on each router. Another method is to sniff some packets, and read the timer values in the packets themselves from different routers. Each packet contains the hello interval, and dead interval periods, so you can compare them easily enough.

Bi-directional Forwarding Detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

Authentication issues

OSPF has a number of authentication methods you can choose from. You may encounter problems with routers not authenticating as you expect. This will likely appear simply as one or more routers that have a blind spot in their routing - they won't acknowledge a router. This can be a problem if that router connects areas to the backbone as it will appear to be offline and unusable.

To confirm this is the issue, the easiest method is to turn off authentication on the neighboring routers. With no authentication between any routers, everything should flow normally.

Another method to confirm that authentication is the problem is to sniff packets, and look at their contents. The authentication type and password are right in the packets which makes it easy to confirm they are what you expect during real time. Its possible one or more routers is not configured as you expect and may be using the wrong authentication. This method is especially useful if there are a group of routers with these problems—it may only be one router causing the problem that is seen in multiple routers.

Once you have confirmed the problem is authentication related, you can decide how to handle it. You can turn off authentication and take your time to determine how to get your preferred authentication type back online. You can try another type of authentication, text instead of md5 for example, which may have more success and still provide some level of protection. The important part is that once you confirm the problem, you can decide how to fix it properly.

DR and BDR election issues

You can force a particular router to become the DR and BDR by setting their priorities higher than any other OSPF routers in the area. This is a good idea when those routers have more resources to handle the traffic and extra work of the DR and BDR roles, since not all routers may be able to handle all that traffic.

However, if you set all the other routers to not have a chance at being elected, a priority of zero, you can run into problems if the DR and BDR go offline. The good part is that you will have some warning generally as the DR goes offline and the BDR is promoted to the DR position. But if the network segment with both the DR and BDR goes down, your network will have no way to send hello packets, send updates, or the other tasks the DR performs.

The solution to this is to always allow routers to have a chance at being promoted, even if you set their priority to one. In that case they would be the last choice, but if there are no other candidates you want that router to become the DR. Most networks would have already alerted you to the equipment problems, so this would be a temporary measure to keep the network traffic moving until you can find and fix the problem to get the real DR back online.

OSPF routing examples

This section includes:

Basic OSPF example

This example sets up an OSPF network at a small office. There are 3 routers, all running OSPF v2. The border router connects to a BGP network.

All three routers in this example are FortiGate units. Router1 will be the designated router (DR) and router2 will be the backup DR (BDR) due to their priorities. Router3 will not be considered for either the DR or BDR elections. Instead, Router3 is the area border router (ASBR) routing all traffic to the ISP's BGP router on its way to the Internet.

Router2 has a modem connected that provides dialup access to the Internet as well, at a reduced bandwidth. This is a PPPoE connection to a DSL modem. This provides an alternate route to the Internet if the other route goes down. The DSL connection is slow, and is charged by the amount of traffic. For these reasons OSPF will highly favor Router3's Internet access.

The DSL connection connects to an OSPF network with the ISP, so no redistribution of routes is required. The ISP network does have to be added to that router's configuration however.

This section includes the following topics:

Network layout and assumptions

This section includes:

Network layout

There are three FortiGate units acting as OSPF v2 routers on the network—Router1, Router2, and Router3. Router1 will be the designated router (DR), and Router 2 the BDR. Router3 is the area border router (ASBR) that connects to the external ISP router running BGP. Router2 has a PPPoE DSL connection that can access the Internet.

The Head Office network is connected to Router1 and Router2 on the 10.11.101.0 subnet.

Router1 and Router3 are connected over the 10.11.103.0 subnet.

Router2 and Router3 are connected over the 10.11.102.0 subnet.

The following table lists the router, interface, address, and role it is assigned.

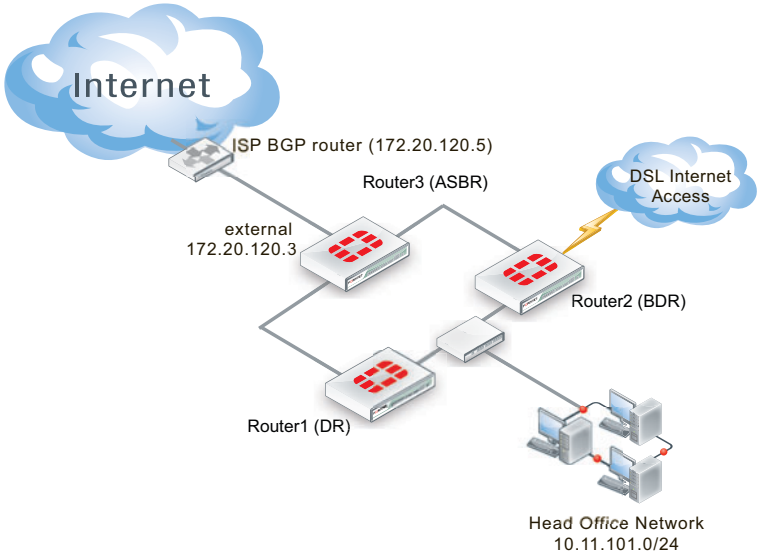
Table 104: Routers, interfaces, and IP addresses for basic OSPF example network

Router name	Interface	IP address	Interface is connected to:
Router1 (DR)	Internal (port1)	10.11.101.1	Head office network, and Router2
	External (port2)	10.11.102.1	Router3

Table 104: Routers, interfaces, and IP addresses for basic OSPF example network

Router2 (BDR)	Internal (port1)	10.11.101.2	Head office network, and Router1
	External (port2)	10.11.103.2	Router3
	DSL (port3)	10.12.101.2	PPPoE DSL access
Router3 (ASBR)	Internal1 (port1)	10.11.102.3	Router1
	Internal2 (port2)	10.11.103.3	Router2
	External (port3)	172.20.120.3	ISP's BGP network

Figure 174: Basic OSPF network topology



Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed, and are in NAT/Route operation mode.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF networks.
- Both Internet connections are always available.
- The modem connection is very slow and expensive.
- Other devices may be on the network, but do not affect this basic configuration.
- Router3 is responsible for redistributing all routes into and out of the OSPF AS.

General configuration steps

The general configuration steps involved are:

1 Configuring the FortiGate units
   - basic interface configuration
   - general system configuration
2 Configuring OSPF on the FortiGate units
   - configure OSPF for each interface
   - configure general OSPF settings for each router
   - Configure each router as one of DR, BDR, or ASBR
   - Configure route redistribution between BGP and OSPF
3 Configuring other networking devices
4 Testing network configuration

Configuring the FortiGate units

Each FortiGate unit needs the interfaces, and basic system information such as hostname configured.

This section includes:

- Configuring Router1
- Configuring Router2
- Configuring Router3

Configuring Router1

Router1 has two interfaces connected to the network—internal (port1) and external (port2). Its host name must be changed to Router1.

To configure Router1 interfaces - web-based manager

1 Go to *System* > *Dashboard* > *Status*.
2 Beside the host name, select *Change*.
3 Enter a hostname of `Router1`, and select *OK*.
4 Go to *System* > *Network* > *Interface*, edit port1, set the following information, and then select *OK*.

Alias	internal
IP/Netmask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router2
Administrative Status	Up

5 Edit port2, set the following information, and then select *OK*.

Alias	External
IP/Netmask	10.11.102.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

Configuring Router2

Router2 configuration is the same as Router1, except Router2 also has the DSL interface to configure.

The DSL interface is configured with a username of “user1” and a password of “ospf_example”. The default gateway will be retrieved from the ISP, and the defaults will be used for the rest of the PPPoE settings.

To configure Router2 interfaces - web-based manager

1 Go to *System* > *Dashboard* > *Status*.

2 Beside the host name, select *Change*.

3 Enter a hostname of `Router2`, and select *OK*.

4 Go to *System* > *Network* > *Interface*, edit port1, set the following information, and then select *OK*.

Alias	internal
IP/Netmask	10.11.101.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router1
Administrative Status	Up

5 Edit port2, set the following information, and then select *OK*.

Alias	External
IP/Netmask	10.11.103.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

6 Edit DSL (port3), set the following information, and then select *OK*.

Alias	DSL
Addressing Mode	PPPoE
Username	user1
Password	ospf_example
Unnumbered IP address	10.12.101.2/255.255.255.0
Retrieve default gateway from server	Enable
Administrative Access	HTTPS SSH PING
Description	DSL
Administrative Status	Up

Configuring Router3

Router3 is similar to Router1 and Router2 configurations. The main difference is the External (port3) interface connected to the ISP BGP network which has no administration access enabled for security reasons.

To configure Router3 interfaces - web-based manager

1. Go to *System* > *Status* > *Dashboard*.
2. Next to hostname, select *Change*.
3. Enter a hostname of `Router3`, and select *OK*.
4. Go to *System* > *Network* > *Interface, e*dit port1, set the following information, and then select *OK*.

Alias	internal
IP/Netmask	10.11.102.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router1
Administrative Status	Up

5. Edit port2, set the following information, and then select *OK*.

Alias	Internal2
IP/Netmask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2
Administrative Status	Up

6. Edit port3, set the following information, and then select *OK*.

Alias	External
IP/Netmask	172.20.120.3/255.255.255.0
Administrative Access	
Description	ISP BGP
Administrative Status	Up

Configuring OSPF on the FortiGate units

With the interfaces configured, now the FortiGate units can be configured for OSPF on those interfaces. All routers are part of the backbone 0.0.0.0 area, so there is no inter-area communications needed.

For a simple configuration there will be no authentication, no graceful restart or other advanced features, and timers will be left at their defaults. Also the costs for all interfaces will be left at 10, except for the modem and ISP interfaces where cost will be used to load balance traffic. Nearly all advanced features of OSPF are only available from the CLI.

The network that is defined covers all the subnets used in this example - 10.11.101.0, 10.11.102.0, and 10.11.103.0. All routes for these subnets will be advertised. If there are other interfaces on the FortiGate units that you do not want included in the OSPF routes, ensure those interfaces use a different subnet outside of the 10.11.0.0 network. If you want all interfaces to be advertised you can use an OSPF network of 0.0.0.0 .

Each router will configure:

- router ID
- area
- network
- two or three interfaces depending on the router
- priority for DR (Router1) and BDR (Router2)
- redistribute for ASBR (Router3)

This section includes:

Configuring OSPF on Router1

Router1 has a very high priority to ensure it becomes the DR for this area. Also Router1 has the lowest IP address to help ensure it will win in case there is a tie at some point.

Otherwise it is a standard OSPF configuration.

Setting the priority can only be done in the CLI, and it is for a specific OSPF interface.

To configure OSPF on Router1 - web-based manager

1 Go to *Router* > *Dynamic* > *OSPF*.

2 Set *Router ID* to `10.11.101.1` and select *Apply*.

3 In *Areas*, select *Create New,* set the following information, and then select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	none

4 In *Networks*, select *Create New*, set the following information, and then select *OK*.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5 In *Interfaces*, select *Create New*, set the following information, and then select *OK*.

Name		Router1-Internal-DR
Interface		port1 (Internal)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

6 In *Interfaces*, select *Create New*, set the following information, and then select *OK*.

Name		Router1-External
Interface		port2 (External)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

7 Using the CLI, enter the following commands to set the priority for the Router1-Internal OSPF interface to maximum, ensuring this interface becomes the DR.

```
config router ospf
  config ospf-interface
    edit Router1-Internal-DR
      set priority 255
    end
```

To configure OSPF on Router1 - CLI

```
config router ospf
  set router-id 10.11.101.1
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0/255.255.255.0
    next
  end
  config ospf-interface
    edit "Router1-Internal"
      set interface "port1"
      set priority 255
    next
    edit "Router1-External"
      set interface "port2"
    next
  end
end
```

Configuring OSPF on Router2

Router2 has a high priority to ensure it becomes the BDR for this area, and configures the DSL interface slightly differently—assume this will be a slower connection resulting in the need for longer timers, and a higher cost for this route.

Otherwise it is a standard OSPF configuration.

To configure OSPF on Router2 - web-based manager

1 Go to *Router* > *Dynamic* > *OSPF*.

2 Set *Router ID* to `10.11.101.2` and select *Apply*.

3 In *Areas*, select *Create New*, set the following information, and then select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	none

4 In *Networks*, select *Create New*, set the following information, and then select *OK*.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name		Router2-Internal
Interface		port1 (Internal)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

6 In *Interfaces*, select *Create New*, set the following information, and then select *OK*.

Name		Router2-External
Interface		port2 (External)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

7 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name		Router2-DSL
Interface		port3 (DSL)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	20
	Dead Interval	80

8 Using the CLI, enter the following commands to set the priority for the Router2-Internal OSPF interface to ensure this interface will become the BDR.

```
config router ospf
  config ospf-interface
    edit Router2-Internal
      set priority 250
```

```
    next
  end
```

9 Using the CLI, enter the following commands to set the cost of the DSL interface higher than the other routes to reflect its higher monetary cost, and slower speed.

```
config router ospf
  config ospf-interface
    edit DSL
      set cost 50
    next
  end
```

To configure OSPF on Router2 - CLI

```
config router ospf
  set router-id 10.11.101.2
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0/255.255.0.0
    next
  end
  config ospf-interface
    edit "Router2-Internal"
      set interface "port1"
      set priority 255
    next
    edit "Router2-External"
      set interface "port2"
    next
    edit "Router2-DSL"
      set interface "port3"
      set cost 50
    next
  end
end
```

Configuring OSPF on Router3

Router3 is more complex than the other two routers. The interfaces are straightforward, but this router has to import and export routes between OSPF and BGP. That requirement makes Router3 a border router or ASBR. Also Router3 needs a lower cost on its route to encourage all traffic to the Internet to route through it.

In the advanced OSPF options, Redistribute is enabled for Router3. It allows different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics are assigned to these other types of routes to make them more or less preferred to regular OSPF routes.

To configure OSPF on Router3 - web-based manager

1 Go to *Router* > *Dynamic* > *OSPF*.

2 Set *Router ID* to `10.11.101.2` and select *Apply*.

3 Expand *Advanced Options*.

4 In *Redistribute*, set the following information, and select *OK*.

Route type	Redistribute	Metric
Connected	Enable	15
Static	Enable	15
RIP	Disable	n/a
BGP	Enable	5

5 In *Areas*, select *Create New*, set the following information, and then select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	none

6 In *Networks*, select *Create New,* set the following information, and then select *OK*.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

7 In *Interfaces*, select *Create New, s*et the following information, and then select *OK*.

Name		Router3-Internal
Interface		port1 (Internal)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

8 In *Interfaces*, select *Create New, s*et the following information, and then select *OK*.

Name		Router3-Internal2
Interface		port2 (Internal2)
IP		0.0.0.0
Authentication		none
Timers (seconds)		
	Hello Interval	10
	Dead Interval	40

9 In *Interfaces*, select *Create New, s*et the following information, and then select *OK*.

Name	Router3-ISP-BGP
Interface	port3 (ISP-BGP)
IP	0.0.0.0

Authentication		none
Timers (seconds)		
	Hello Interval	20
	Dead Interval	80

10 Using the CLI, enter the following commands to set the priority for the Router2-Internal OSPF interface to ensure this interface will become the BDR.

```
config router ospf
  config ospf-interface
  edit Router3-Internal
    set priority 250
  next
end
```

11 Using the CLI, enter the following commands to set the cost of the DSL interface higher than the other routes to reflect its higher monetary cost, and slower speed.

```
config router ospf
  config ospf-interface
  edit ISP_BGP
    set cost 2
  next
end
```

To configure OSPF on Router3 - CLI

```
config router ospf
  set router-id 10.11.102.3
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0/255.255.255.0
    next
    edit 2
      set prefix 172.20.120.0/255.255.255.0
    next
  end
  config ospf-interface
    edit "Router3-Internal"
      set interface "port1"
      set priority 255
    next
    edit "Router3-External"
      set interface "port2"
    next
    edit "Router3-ISP-BGP"
      set interface "port3"
      set cost 2
    next
  end
end
```

Configuring other networking devices

The other networking devices required in this configuration are on the two ISP networks - the BGP network for the main Internet connection, and the DSL backup connection.

In both cases, the ISPs need to be notified of the OSPF network settings including router IP addresses, timer settings, and so on. The ISP will use this information to configure its routers that connect to this OSPF network.

Testing network configuration

Testing the network configuration involves two parts —testing the network connectivity, and testing the OSPF routing.

To test the network connectivity use ping, traceroute, and other network tools.

To test the OSPF routing in this example, refer to the troubleshooting outlined in "Troubleshooting OSPF" on page 1799.

Advanced inter-area OSPF example

This example sets up an OSPF network at a large office. There are 3 areas, each with 2 routers. Typically OSPF areas would not be this small, and if they were the areas would be combined into one bigger area. However, the stub area services the accounting department which is very sensitive about their network and do not want any of their network information broadcast through the rest of the company. The backbone area contains the bulk of the company network devices. The regular area was established by IT for various reasons such as hosting the company servers on a separate area with extra security

One area is a small stub area that has no independent Internet connection, and only one connection to the backbone area. That connection between the stub area and the backbone area is only through a default route - no routes outside the stub area are advertised into that area.

Another area is the backbone, which is connected to the other two areas. The third area has the Internet connection, and all traffic to and from the Internet must use that area's connection. If that traffic comes from the stub area, then that traffic is treating the backbone like a transit area - an area it only uses to get to another area.

In the stub area, a subnet of computers is running the RIP routing protocol and those routes must be redistributed into the OSPF areas.

This section includes the following topics:

Network layout and assumptions

This section includes:

Network layout

There are four FortiGate units in this network topology acting as OSPF routers.

Area 1.1.1.1 is a stub area with one FortiGate unit OSPF router called Router1 (DR). Its only access outside of that area is a default route to the backbone area, which is how it accesses the Internet—traffic must go from the stub area, through the backbone, to the third area to reach the Internet. The backbone area in this configuration is called a transit area. Also in area 1.1.1.1 there is a RIP router that will be providing routes to the OSPF area through redistribution.

Area 0.0.0.0 is the backbone area, and has two FortiGate unit routers named Router2 (BDR) and Router3 (DR).

Area 2.2.2.2 is a regular area that has an Internet connection accessed by both the other two OSPF areas. There is only one FortiGate unit router in this area called Router4 (DR). This area is more secure and requires MD5 authentication by routers.

All areas have user networks attached, but they are not important for configuring the network layout for this example.

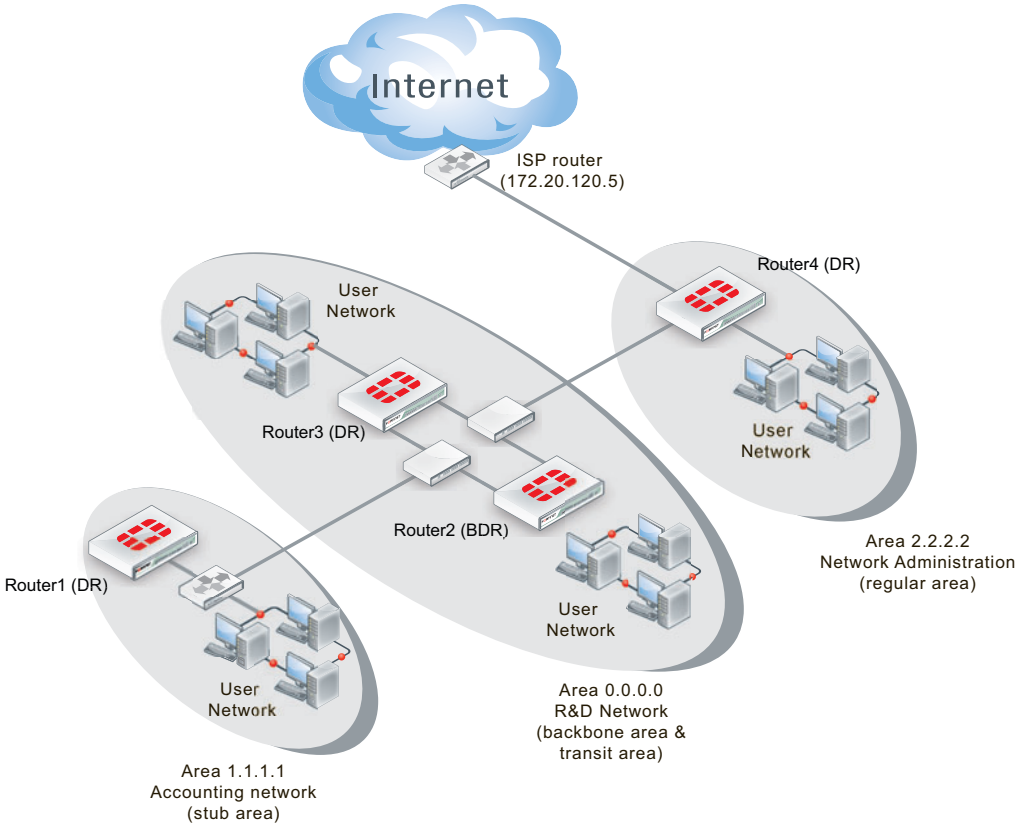
Internal interfaces are connected to internal user networks only. External1 interfaces are connected to the 10.11.110.0 network, joining Area 1.1.1.1 and Area 0.0.0.0.

External2 interfaces are connected to the 10.11.111.0 network, joining Area 0.0.0.0 and Area 2.2.2.2. The ISP interface is called ISP.

Table 105: Routers, areas, interfaces, IP addresses for advanced OSPF network

Router name	Area number and type	Interface	IP address
Router1 (DR)	1.1.1.1 - stub area (Accounting)	port1 (internal)	10.11.101.1
		port2 (external1)	10.11.110.1
Router2 (BDR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.102.2
		port2 (external1)	10.11.110.2
		port3 (external2)	10.11.111.2
Router3 (DR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.103.3
		port2 (external1)	10.11.110.3
		port3 (external2)	10.11.111.3
Router4 (DR)	2.2.2.2 - regular area (Network Admin)	port1 (internal)	10.11.104.4
		port2 (external2)	10.11.111.4
		port3 (ISP)	172.20.120.4

Figure 175: Advanced inter-area OSPF network topology



Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed, and are in NAT/Route operation mode.
- During configuration, if settings are not directly referred to they will be left at default settings.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF areas outside of this example.
- The Internet connection is always available.
- Other devices may be on the network, but do not affect this configuration.

General configuration steps

The general configuration steps involved are:

1 Configuring the FortiGate units
   - basic interface configuration
   - general system configuration

2 Configuring OSPF on the FortiGate units
   - configure OSPF for each interface
   - configure general OSPF settings for each router
   - Configure each router as one of DR, BDR, or ASBR
   - Configure route redistribution between BGP and OSPF
3 Configuring other networking devices
4 Testing network configuration

Configuring the FortiGate units

This section configures the basic settings on the FortiGate units to be OSPF routers in this example. These configurations include multiple interface settings, and hostname.

There are four FortiGate units in this example. The two units in the backbone area can be configured exactly the same except for IP addresses, so only router3 (the DR) configuration will be given with notes indicating router2 (the BDR) IP addresses. These addresses can also be obtained from the "Network layout" on page 1814.

Configuring the FortiGate units includes:

- Configuring Router1
- Configuring Router2
- Configuring Router3
- Configuring Router4

Configuring Router1

Router1 is part of the Accounting network stub area (1.1.1.1).

This section configures interfaces and hostname.

To configure Router1 interfaces - web-based manager

1 Go to *System* > *Dashboard* > *Status*.
2 Next to hostname, select *Change*.
3 Enter a hostname of `Router1`, and select *OK*.
4 Go to *System* > *Network* > *Interface,* edit port1, set the following information, and then select *OK*.

Alias	internal
IP/Netmask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

5 Edit port2, set the following information, and then select *OK*.

Alias	External1
IP/Netmask	10.11.110.1/255.255.255.0
Administrative Access	HTTPS SSH PING

Description	Backbone network and internet
Administrative Status	Up

Configuring Router2

Router2 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

Router2 has three interfaces configured—one to the internal network, and two to Router3 for redundancy.

This section configures interfaces and hostname.

To configure Router2 interfaces - web-based manager

1 Go to *System* > *Dashboard* > *Status*.

2 Next to hostname, select *Change*.

3 Enter a hostname of `Router2`, and select *OK*.

4 Go to *System* > *Network* > *Interface*, edit port1 (internal), set the following information, and then select *OK*.

Alias	internal
IP/Netmask	10.11.102.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5 Edit port2 (external1), set the following information, and then select *OK*.

Alias	external1
IP/Netmask	10.11.110.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3 first connection
Administrative Status	Up

6 Edit port3 (external2), set the following information, and then select *OK*.

Alias	external2
IP/Netmask	10.11.111.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3 second connection
Administrative Status	Up

Configuring Router3

Router3 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

This section configures interfaces and hostname.

To configure Router3 interfaces - web-based manager

1 Go to *System* > *Dashboard* > *Status*.
2 Next to hostname, select *Change*.
3 Enter a hostname of `Router3`, and select *OK*.
4 Go to *System* > *Network* > *Interface*, edit port1 (internal), set the following information, and then select *OK*.

Alias	internal
IP/Netmask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5 Edit port2 (external1), set the following information, and then select *OK*.

Alias	external1
IP/Netmask	10.11.110.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 first connection
Administrative Status	Up

6 Edit port3 (external2), set the following information, and then select *OK*.

Alias	external2
IP/Netmask	10.11.111.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 second connection
Administrative Status	Up

Configuring Router4

Router4 is part of the Network Administration regular area (2.2.2.2). This area provides internet access for both area 1.1.1.1 and the backbone area.

This section configures interfaces and hostname.

To configure Router4 interfaces - web-based manager

1 Go to *System* > *Dashboard* > *Status*.
2 Next to hostname, select *Change*.
3 Enter a hostname of `Router4`, and select *OK*.
1 Go to *System* > *Network* > *Interface*.
2 Edit port1 (internal).
3 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.4/255.255.255.0

Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

4 Edit port2 (external2).

5 Set the following information, and select *OK*.

Alias	external2
IP/Netmask	10.11.110.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone and Accounting network
Administrative Status	Up

6 Edit port3 (ISP).

7 Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	172.20.120.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

Configuring OSPF on the FortiGate units

Three of the routers are designated routers (DR) and one is a backup DR (BDR). This is achieved through the lowest router ID numbers, or OSPF priority settings.

Also each area needs to be configured as each respective type of area - stub, backbone, or regular. This affects how routes are advertised into the area.

To configure OSPF on Router1 - web-based manager

1 Go to *Router* > *Dynamic* > *OSPF*.

2 Enter `10.11.101.1` for the *Router ID* and then select *Apply*.

3 In *Areas*, select *Create New,* set the following information, and then select *OK*.

Area	1.1.1.1
Type	Stub
Authentication	None

4 In *Networks*, select *Create New,* set the following information, and then select *OK*.

IP/Netmask	10.11.101.0/255.255.255.0
Area	1.1.1.1

5 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name	Accounting
Interface	port1 (internal)

IP	10.11.101.1
Authentication	None

6 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.1
Authentication	None

To configure OSPF on Router2 - web-based manager

1 Go to *Router* > *Dynamic* > *OSPF*.

2 Enter `10.11.102.2` for the *Router ID* and then select *Apply*.

3 In *Areas*, select *Create New,* set the following information, and then select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	None

4 In *Networks*, select *Create New,* set the following information, and then select *OK*.

IP/Netmask	10.11.102.2/255.255.255.0
Area	0.0.0.0

5 In *Networks*, select *Create New,* set the following information, and then select *OK*.

IP/Netmask	10.11.110.2/255.255.255.0
Area	0.0.0.0

6 In *Networks*, select *Create New,* set the following information, and then select *OK*.

IP/Netmask	10.11.111.2/255.255.255.0
Area	0.0.0.0

7 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name	RnD network
Interface	port1 (internal)
IP	10.11.102.2
Authentication	None

8 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.2
Authentication	None

9 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name	Backbone2
Interface	port3 (external2)
IP	10.11.111.2
Authentication	None

To configure OSPF on Router3 - web-based manager

1 Go to *Router* > *Dynamic* > *OSPF*.

2 Enter `10.11.103.3` for the *Router ID* and then select *Apply*.

3 In *Areas*, select *Create New,* set the following information, and then select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	None

4 In *Networks*, select *Create New,* set the following information, and then select *OK*.

IP/Netmask	10.11.102.3/255.255.255.0
Area	0.0.0.0

5 In *Networks*, select *Create New,* set the following information, and then select *OK*.

IP/Netmask	10.11.110.3/255.255.255.0
Area	0.0.0.0

6 In *Networks*, select *Create New,* set the following information, and then select *OK*.

IP/Netmask	10.11.111.3/255.255.255.0
Area	0.0.0.0

7 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name	RnD network
Interface	port1 (internal)
IP	10.11.103.3
Authentication	None

8 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.3
Authentication	None

9 In *Interfaces*, select *Create New,* set the following information, and then select *OK*.

Name	Backbone2
Interface	port3 (external2)
IP	10.11.111.3
Authentication	None

To configure OSPF on Router4 - web-based manager

1 Go to *Router* > *Dynamic* > *OSPF*.

2 Enter `10.11.104.4` for the *Router ID* and then select *Apply*.

3 In *Areas*, select *Create New*.

4 Set the following information, and select *OK*.

Area	2.2.2.2
Type	Regular
Authentication	None

5 In *Networks*, select *Create New,* set the following information, and then select *OK*.

IP/Netmask	10.11.104.0/255.255.255.0
Area	0.0.0.0

6 In *Networks*, select *Create New*, set the following information, and then select *OK*.

IP/Netmask	10.11.111.0/255.255.255.0
Area	0.0.0.0

7 In *Networks*, select *Create New*, set the following information, and then select *OK*.

IP/Netmask	172.20.120.0/255.255.255.0
Area	0.0.0.0

8 In *Interfaces*, select *Create New*, set the following information, and then select *OK*.

Name	Network Admin network
Interface	port1 (internal)
IP	10.11.104.4
Authentication	None

9 In *Interfaces*, select *Create New*, set the following information, and then select *OK*.

Name	Backbone2
Interface	port2 (external2)
IP	10.11.111.4
Authentication	None

10 In *Interfaces*, select *Create New*, set the following information, and then select *OK*.

Name	ISP
Interface	port3 (ISP)
IP	172.20.120.4
Authentication	None

Configuring other networking devices

All network devices on this network are running OSPF routing. The user networks (Accounting, R&D, and Network Administration) are part of one of the three areas.

The ISP needs to be notified of your network configuration for area 2.2.2.2. Your ISP will not advertise your areas externally as they are intended as internal areas. External areas have assigned unique numbers. The area numbers used in this example are similar to the 10.0.0.0 and 192.168.0.0 subnets used in internal networking.

Testing network configuration

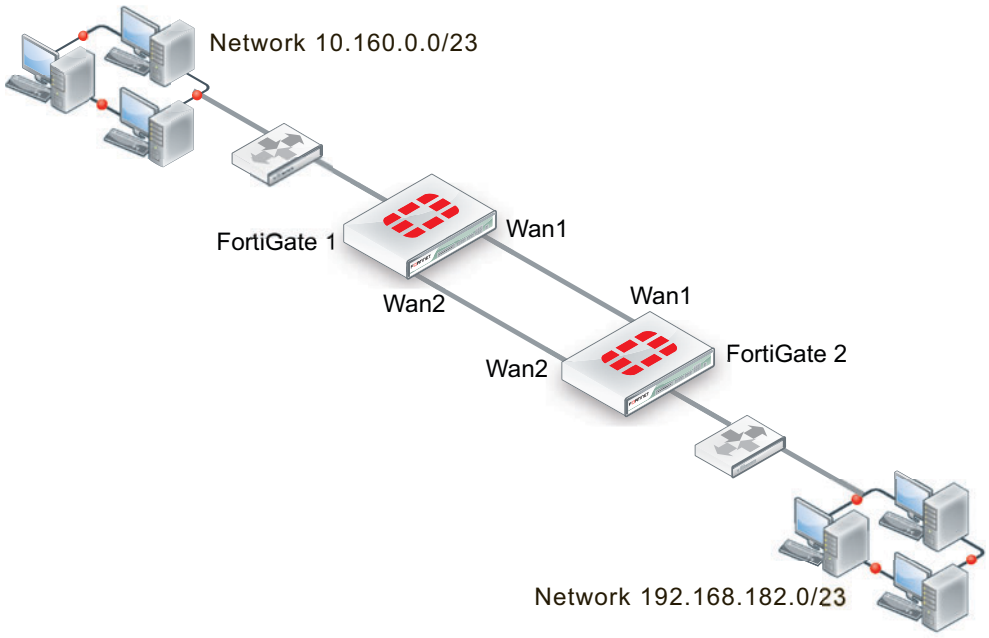
There are two main areas to test in this network configuration —network connectivity, and OSPF routing.

To test the network connectivity, see if computers on the Accounting or R&D networks can access the internet. If you need to troubleshoot network connectivity, see the Troubleshooting chapter.

To test the OSPF routing, check the routing tables on the FortiGate units to ensure the expected OSPF routes are present. If you need help troubleshooting OSPF routing, see “Troubleshooting OSPF” on page 1799.

Controlling redundant links by cost

In this scenario, two FortiGate units have redundant links: one link between their WAN1 interfaces and another between their WAN2 interfaces.



FortiGate 1 should learn the route to network 192.168.182.0 and FortiGate 2 should learn the route to network 10.160.0.0. Under normal conditions, they should learn these routes through the WAN1 link. The WAN2 link should be used only as a backup.

With the default settings, each FortiGate unit learns these routes from both WAN1 and WAN2.

FortiGate 1:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.2.2.2 1 Full/Backup 00:00:33 10.182.0.187 wan1
10.2.2.2 1 Full/Backup 00:00:31 10.183.0.187 wan2

FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:01
[110/10] via 10.182.0.187, wan1, 00:00:01
O 192.168.182.0/23 [110/20] via 10.183.0.187, wan2, 00:02:04
[110/20] via 10.182.0.187, wan1, 00:02:04
```

FortiGate 2:

```
FGT2 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.1.1.1 1 Full/DR 00:00:38 10.182.0.57 wan1
10.1.1.1 1 Full/DR 00:00:38 10.183.0.57 wan2

FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.183.0.57, wan2, 00:00:39
[110/20] via 10.182.0.57, wan1, 00:00:39
```

Adjusting the route costs

On both FortiGate units, the cost of the route through WAN2 is adjusted higher so that this route will only be used if the route through WAN1 is unavailable. The default cost is 10. The WAN2 route will be changed to a cost of 200.

On both FortiGate units:

```
config router ospf
  config ospf-interface
    edit "WAN2_higher_cost"
      set cost 200
      set interface "wan2"
    end
```

Now both FortiGate units use only the WAN1 route:

FortiGate 1:

```
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.182.0.187, wan1, 00:00:40
O 192.168.182.0/23 [110/20] via 10.182.0.187, wan1, 00:00:40
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.182.0.57, wan1, 00:09:37
```

LSDB check on FortiGate 1:

```
FGT1 # get router info ospf database router lsa
Router Link States (Area 0.0.0.0)
```

```
LS age: 81
Options: 0x2 (*|-|-|-|-|-|E|-)
Flags: 0x0
LS Type: router-LSA
Link State ID: 10.1.1.1
Advertising Router: 10.1.1.1
LS Seq Number: 8000000b
Checksum: 0xe637
Length: 60
Number of Links: 3

  Link connected to: Stub Network
  (Link ID) Network/subnet number: 10.160.0.0

LS Seq Number: 8000000e
Checksum: 0xfc9b
Length: 60
  Number of Links: 3

  Link connected to: Stub Network
  (Link ID) Network/subnet number: 192.168.182.0
  (Link Data) Network Mask: 255.255.254.0
  Number of TOS metrics: 0
  TOS 0 Metric: 10

  Link connected to: a Transit Network
  (Link ID) Designated Router address: 10.183.0.187
  (Link Data) Router Interface address: 10.183.0.187
  Number of TOS metrics: 0
  TOS 0 Metric: 200

  Link connected to: a Transit Network
  (Link ID) Designated Router address: 10.182.0.57
```

```
(Link Data) Router Interface address: 10.182.0.187
Number of TOS metrics: 0
TOS 0 Metric: 10
```

Verifying route redundancy

Bring down WAN1 and then check the routes on the two FortiGate units.

FortiGate 1:

```
FGT1 # get router info routing-table ospf
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:06
O 192.168.182.0/23 [110/210] via 10.183.0.187, wan2, 00:00:06
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/210] via 10.183.0.57, wan2, 00:00:14
```

The WAN2 interface is now in use on both units.

Intermediate System To Intermediate System Protocol (IS-IS)

This section describes the Intermediate System To Intermediate System Protocol (IS-IS).

The following topics are included in this section:

IS-IS background and concepts

This section contains:

Background

Intermediate System To Intermediate System Protocol (IS-IS) allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS).

IS-IS is an Interior Gateway Protocol (IGP). It it not intended to be used between Autonomous Systems (ASes). IS-IS is a link state protocol and uses Dijstra's algorithm to find the best path, as does OSPF.

IS-IS was developed by Digital Equipment Corporation and later standardized by ISO in 1992 as ISO 19589 (see RFC 1142—note this RFC is different from the ISO version). At roughly the same time the Internet Engineering Task Force developed OSPF. After the initial version, IP support was added to IS-IS and this version is called Integrated IS-IS (see RFC 1195).

While OSPF is more widely known, IS-IS is a viable alternative to OSPF in enterprise networks and ISP infrastructures.

How IS-IS works

As one of the original modern dynamic routing protocols, IS-IS is straight forward. It's routing algorithm is not complex, there are some options to allow fine tuning, and its straight forward to configure IS-IS on FortiGate units.

From RFC 1058:

> Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.

IS-IS versus static routing

IS-IS was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, IS-IS is a big step forward from simple static routing.

While IS-IS may be slow in response to network outages, static routing has zero response. The same is true for convergence — static routing has zero convergence. Both IS-IS and static routing have the limited hop count, so its not a strength or a weakness. Count to infinity can be a problem, but typically can be fixed as it happens or is the result of a network outage that would cause even worse problems on static routing network.

Overall, IS-IS is a large step forward when compared to static routing.

IS-IS packet structure

It is hard to fully understand a routing protocol without knowing what information is carried in its packets. Knowing what information is exchanged between routers and how will help you better understand the IS-IS protocol, and better configure your network for it.

This section provides information on the contents of IS-IS 1 and IS-IS 2 packets.

IS-IS version 1

IS-IS version 1 packets are 24 bytes long. The zero fields were left for future expansion.

Table 106: IS-IS IP packets

1-byte command	1-byte version	2-byte zero field	2-byte AFI	2-byte zero field
4-byte IP address	4-byte zero field	4-byte zero field	4-byte metric	

The following descriptions summarize the IS-IS version 1 packet fields.

Command — Indicates whether the packet is a request or a response. The request asks that a router send all or part of its routing table. The response can be an unsolicited regular routing update or a reply to a request. Responses contain routing table entries. Multiple IS-IS packets are used to convey information from large routing tables.

Version — Specifies the IS-IS version used. This field can signal different potentially incompatible versions.

Zero field — This field defaults to zero, and is not used by RFC 1058 IS-IS.

Address-family identifier (AFI) — Specifies the address family used. IS-IS is designed to carry routing information for several different protocols. Each entry has an address-family identifier to indicate the type of address being specified. The AFI for IP is 2.

IP Address — Specifies the IP address for the entry.

Metric — This is the number of hops or routers traversed along the route on its trip to the destination. The metric is between 1 and 15 for that number of hops. If the route is unreachable the metric is 16.

IS-IS version 2

IS-IS version 2 has more features that IS-IS 1 and this is reflected in its packets. IS-IS 2 packets are similar in format to IS-IS 1, but carry more information. Only one zero field remains.

Table 107: IS-IS 2 packets

1-byte command	1-byte version	2-byte unused	2-byte AFI	2-byte route tag	4-byte IP address	4-byte subnet	4-byte next hop	4-byte metric

The following descriptions summarize the fields IS-IS 2 adds to the IS-IS IP header. The other fields have been described above for IS-IS 1.

Unused — Has a value set to zero, and is intended for future use

Route tag — Provides a method for distinguishing between internal routes learned by IS-IS and external routes learned from other protocols.

Subnet mask — Contains the subnet mask for the entry. If this field is zero, no subnet mask has been specified for the entry.

Next hop — Indicates the IP address of the next hop to which packets for the entry should be forwarded.

Troubleshooting IS-IS

This section is about troubleshooting IS-IS. For general troubleshooting information, see the Troubleshooting chapter.

This section includes:

- Routing Loops
- Split horizon and Poison reverse updates

Routing Loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loops' effect on the network

In addition to this "traffic jam" of routed packets, every time the routing table for a router changes that router sends an update out to all of the IS-IS routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

Some methods to troubleshoot your outage include:

- Check your logs
- Use SNMP network monitoring
- Use dead gateway detection and e-mail alerts
- Look at the packet flow

If you aren't running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it.

Check your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to *Log & Report* > *Log & Archive Access*. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Use SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1. Go to *System* > *Config* > *SNMP*.
2. Enable *SNMP Agent*.
3. Optionally enter the *Description*, *Location*, and *Contact* information for this device for easier location of the problem report.
4. In either *SNMP v1/v2c* section or *SNMP v3* section, as appropriate, select *Create New*.
5. Enter the *Community Name* that you want to use.
6. In *Hosts*, select Add to add an IP address where you will be monitoring the FortiGate unit. You can add up to 8 different addresses.
7. Ensure that ports 161 and 162 (SNMP queries and traps) are allowed through your security policies.

8 In *SNMP Event*, select the events you want to be notified of. For routing loops this should include *CPU Overusage*, *Memory Low*, and possibly *Log disk space low*. If there are problems, the log will be filling up quickly, and the FortiGate unit's resources will be overused.

9 Select *OK*.

10 Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Use dead gateway detection and e-mail alerts

Another tool available to you on FortiGate units is the dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with dead gateway detection and e-mail alerts

1 To configure dead gateway detection, go to *Router* > *Static* > *Settings* and select *Create New*.

2 Set the *Ping Interval* (how often to send a ping), and *Failover Threshold* (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

3 To configure interface status change notification, go to *Log&Report* >*Log Config* > *Alert E-mail*.

4 After you enter your email details, select the events you want to be alerted about — in our case *Configuration changes*. You may also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email to the outage.

Look at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable. Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1 Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.

2 Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let's call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A's route to get to C. This route is A-B-C, so it will not work. However, if B tries to use it this begins an endless loop.

This situation is called a split horizon because from B's point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This "poisoned" route is marked as unreachable for routers that cannot use it. In IS-IS this means that route is marked with a distance of 16.

Simple IS-IS example

This is an example of a typical medium sized network configuration using IS-IS routing.

Your company has 3 small local networks, one for each department. These networks are connected by IS-IS, and then connected to the Internet. Each subnet has more than one route, for redundancy. There are two central routers that are both connected to the internet, and to the other networks. If one of those routers goes down, the whole network can continue to function normally.

The ISP is running IS-IS, so no importing or exporting routes is required on the side of the network. However, since the internal networks have static networking running those will need to be redistributed through the IS-IS network.

To keep the example simple, there will be no authentication of router traffic.

With IS-IS properly configured, if the device fails or temporarily goes offline, the routes will change and traffic will continue to flow. IS-IS is good for a smaller network due to its lack of complex configurations.

Basic network layout

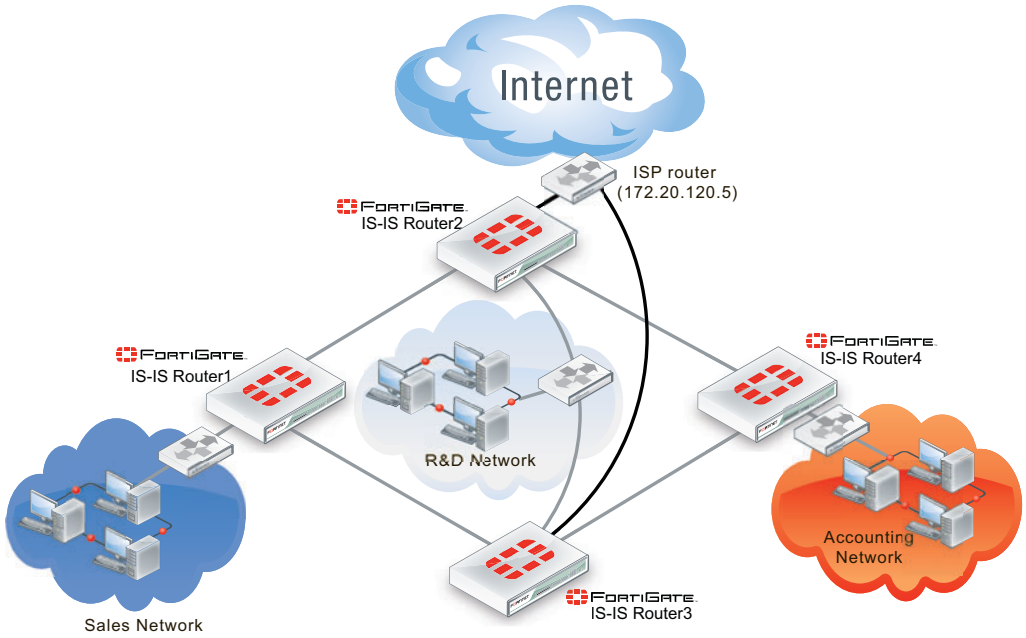
Table 108: IS-IS example network topology

Network	Router	Interface & Alias	IP address
Sales	Router1	port1 (internal)	10.11.101.101
		port2 (router2)	10.11.201.101
		port3 (router3)	10.11.202.101

Table 108: IS-IS example network topology

R&D	Router2	port1 (internal)	10.12.101.102
		port2 (router1)	10.11.201.102
		port3 (router4)	10.14.201.102
		port4 (ISP)	172.20.120.102
	Router3	port1 (internal)	10.12.101.103
		port2 (router1)	10.11.201.103
		port3 (router4)	10.14.202.103
		port4 (ISP)	172.20.120.103
Accounting	Router4	port1 (internal)	10.14.101.104
		port2 (router2)	10.14.201.104
		port3 (router3)	10.14.202.104

Figure 176: Network topology for the simple IS-IS example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 4.0 MR3 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 through port4 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- Only FortiGate units are running IS-IS on the internal networks.
- Router2 and Router3 are connected through the internal network for R&D.

- Router2 and Router3 each have their own connection to the Internet, indicated in black in Figure 176.

General configuration steps

This example is very straight forward. The only steps involved are:

- Configuring FortiGate hostnames, interfaces, and default routes
- Configuring FortiGate unit IS-IS router information
- Configuring other networking devices
- Testing network configuration

Configuring FortiGate hostnames, interfaces, and default routes

On each FortiGate unit, configure its hostname, interfaces, and default routes as follows:

To configure Router1 system information - web-based manager

1 Go to *System* > *Dashboard* > *Status* > *System Information*.
2 Next to *Host Name* select *Change*, and enter “Router1”.
3 Go to *Router* > *Static* > *Static Route*.
4 Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5 Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6 Go to *System* > *Network* > *Interface*.
7 Edit port1 (internal) interface.
8 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal sales network
Administrative Status	Up

9 Edit port2 (router2) interface.
10 Set the following information, and select *OK*.

Alias	router2
IP/Netmask	10.11.201.101/255.255.255.0

Administrative Access	HTTPS SSH PING
Description	Link to R&D network & internet through Router2
Administrative Status	Up

11 Edit port3 (router3) interface.

12 Set the following information, and select *OK*.

Alias	router3
IP/Netmask	10.11.202.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and internet through Router3
Administrative Status	Up

To configure Router2 system information - web-based manager

1 Go to *System* > *Dashboard* > *Status* > *System Information*.

2 Next to *Host Name* select *Change*, and enter “Router2”.

3 Go to *Router* > *Static* > *Static Route*.

4 Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5 Go to *System* > *Network* > *Interface*.

6 Edit port1 (internal) interface.

7 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.12.101.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router3
Administrative Status	Up

8 Edit port2 (router1) interface.

9 Set the following information, and select *OK*.

Alias	router1
IP/Netmask	10.12.201.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and the Sales network
Administrative Status	Up

10 Edit port3 (router4) interface.

11 Set the following information, and select *OK*.

Alias	router4
IP/Netmask	10.12.301.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and the accounting network
Administrative Status	Up

12 Edit port4 (ISP) interface.

13 Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	172.20.120.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internet through ISP
Administrative Status	Up

14 Go to *Router* > *Static* > *Settings,* select *Create New* and enter the following:

Interface	port4
Ping Server	172.20.120.5
Detect Protocol	ICMP Ping
Leave other settings at default values.	

15 Select *OK*.

To configure Router3 system information - web-based manager

1 Go to *System* > *Dashboard* > *Status* > *System Information*.

2 Next to *Host Name* select *Change*, and enter “Router3”.

3 Go to *Router* > *Static*.

4 Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5 Go to *System* > *Network* > *Interface*.

6 Edit port1 (internal) interface.

7 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.12.101.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router2
Administrative Status	Up

8 Edit port2 (router1) interface.

9 Set the following information, and select *OK*.

Alias	router1
IP/Netmask	10.13.201.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and Sales network
Administrative Status	Up

10 Edit port3 (router4) interface.

11 Set the following information, and select *OK*.

Alias	router4
IP/Netmask	10.13.301.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and accounting network
Administrative Status	Up

12 Edit port4 (ISP) interface.

13 Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	172.20.120.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Administrative Status	Up

14 Go to *Router* > *Static* > *Settings,* select *Create New* and enter the following:

Interface	port4
Ping Server	172.20.120.5
Detect Protocol	ICMP Ping
Leave other settings at default values.	

15 Select *OK*.

To configure Router4 system information - web-based manager

1 Go to *System* > *Dashboard* > *Status* > *System Information*.

2 Next to *Host Name* select *Change*, and enter “Router4”.

3 Go to *Router* > *Static*.

4 Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5 Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6 Go to *System* > *Network* > *Interface*.

7 Edit port 1 (internal) interface.

8 Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.14.101.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal accounting network
Administrative Status	Up

9 Edit port 2 (router2) interface.

10 Set the following information, and select *OK*.

Alias	router2
IP/Netmask	10.14.201.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & internet through Router2
Administrative Status	Up

11 Edit port 3 (router3) interface.

12 Set the following information, and select *OK*.

Alias	router3
IP/Netmask	10.14.301.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and internet through Router3
Administrative Status	Up

Configuring FortiGate unit IS-IS router information

With the interfaces configured, IS-IS can now be configured on the FortiGate units.

This includes the following steps:

- add interfaces that support IS-IS on the FortiGate unit
- add networks serviced by IS-IS
- redistribute static networks

This configuration is available only in the CLI.

Router1 and Router4 are configured the same. Router2 and Router3 are configured the same. These routers will be grouped accordingly for the following procedures — repeat the procedures once for each FortiGate unit.

Configure IS-IS settings on Router1 and Router4

```
config router isis
  config isis-interface
    edit port1
      set status enable
    next
    edit port2
      set status enable
  next
    edit port3
      set status enable
  next
    edit port4
      set status enable
  end
  config isis-net
    edit 1
      set net 10.11.0.0 255.255.0.0
    next
    edit 2
      set net 10.12.0.0 255.255.0.0
    next
    edit 3
      set net 10.14.0.0 255.255.0.0
    next
    edit 4
      set net 172.20.120.0 255.255.255.0
    end
  config redistribute static
    set status enable
  end
```

Configure IS-IS settings on Router2 and Router3

```
config router isis
  config isis-interface
    edit "port1"
      set status enable
    next
    edit "port2"
      set status enable
    next
    edit "port3"
      set status enable
    end
    edit "port4"
      set status enable
    end
  config isis-net
    edit 1
```

```
    set net 10.11.0.0 255.255.0.0
  next
  edit 2
    set net 10.12.0.0 255.255.0.0
  next
  edit 3
    set net 10.14.0.0 255.255.0.0
  next
  edit 4
    set net 172.20.120.0 255.255.255.0
  end
config redistribute "static"
  set status enable
end
```

Configuring other networking devices

In this example there are two groups of other devices on the the network — internal devices, and the ISP.

The first is the internal network devices on the Sales, R&D, and Accounting networks. This includes simple static routers, computers, printers and other network devices. Once the FortiGate units are configured, the internal static routers need to be configured using the internal network IP addresses. Otherwise there should be no configuration required.

The second group of devices is the ISP. This consists of the IS-IS router the FortiGate routers 2 and 3 connect to. You need to contact your ISP and ensure they have your information for your network such as the IP addresses of the connecting IS-IS routers, what version of IS-IS your network supports, and what authentication (if any) is used.

Testing network configuration

Once the network has been configured, you need to test that it works as expected.

The two series of tests you need to run are to test the internal networks can communicate with each other, and that the internal networks can reach the internet.

Use ping, traceroute, and other networking tools to run these tests.

If you encounter problems, for troubleshooting help consult “Troubleshooting IS-IS” on page 1829.

Router Reference

This section introduces you to the web-based manager Router menu.

This section contains the following topics:

- Static
- Dynamic
- Monitor

The word “unit” refers to the FortiGate unit. The words “FortiGate unit” are used when talking about different Fortinet products in one sentence. For example, “The Central Management menu provides the option of remotely managing your FortiGate unit by a FortiManager unit.”

Static

The Static menu provides settings for configuring both static and policy routes. A static route causes packets to be forwarded to a destination other than the factory configured default gateway. A policy route allows you to redirect traffic away from a static route, and can be useful when you want to route certain type of network traffic differently.

The factory configured static default route provides you with a starting point to configure the default gateway. You must either edit the factory configured static default route to specify a different default gateway for the unit, or delete the factory configured route and specify your own static default route that points to the default gateway for the unit.

Static routes are defined manually and control traffic exiting from the unit—you can specify through which interface the packet will leave and to which device the packet should be routed.

Route policies or policy routes, specify additional criteria for examining the properties of incoming packets. By using route policies, you can configure the unit to route packets based on the IP source and destination addresses in packet headers and other criteria such as on which interface the packet was received and which protocol (service) and port are being used to transport the packet.

The following topics are included in this section:

- Static Route
- Policy Route
- Settings

Static Route

Static routes are configured by defining the destination IP address and netmask of packets that you intend the unit to intercept, and by specifying a (gateway) IP address for those packets. The gateway address specifies the next-hop router to which traffic will be routed.

The Static Route page displays a list of routes that the unit compares to packet headers in order to route packets. Initially, the list contains the factory configured static default route. For more information, see “Default route and default gateway” on page 1844. You can add new entries manually.

When you add a static route to the Static Route list, the unit performs a check to determine whether a matching route and destination already exist in the FortiGate routing table. If no match is found, the unit adds the route to the routing table.

When IPv6 is enabled in the web-based manager, IPv6 routes are visible on the Static Route list and you can select IPv6 when creating a new static route. Otherwise, IPv6 routes are not displayed.

Static routing configuration settings

The following are static route configuration settings in *Router* > *Static* > *Static Route*.

Static Route page	
Lists all the static routes that you created, including the default static route. On this page, you can edit, delete or create a new static route.	
Create New	Creates a new static route. When you select *Create New*, you are automatically redirected to the New Static Route page. If you are configuring IPv6 addresses, select the down arrow beside *Create New* to create an IPv6 static Route. **Tip:** You can create a new static route by selecting the down arrow beside *Create New*, and then selecting *Route*.
Edit	Modifies settings within a static route. When you select *Edit*, you are automatically redirected to the Edit Static Route page.
Delete	Removes a static route from within the list on the Static Route page. To remove multiple static routes in the list, on the Static Route page, in each of the rows of the routes you want removed, select the check box and then select *Delete*. To remove all static routes in the list, on the Static Route page, select the check box in the check box column, and then select *Delete*.
Column Settings	Select to add, remove, or change the order of information columns. By default, the *Priority* and *Distance* columns are not displayed.
IP/Mask	The destination IP addresses and network masks of packets that the FortiGate unit intercepts.
Gateway	The IP addresses of the next-hop routers to which intercepted packets are forwarded.
Device	The names of the FortiGate interfaces through which intercepted packets are received and sent.
Comment	Optionally, add a description for this route.
Distance	The administrative distances associated with each route. The values represent distances to next-hop routers.
Weight	If ECMP Route Failover & Load Balance Method is set to *weighted,* add weights for each route. Add higher weights to routes that you want to assign more sessions to when load balancing.
New Static Route page	
Provides settings for defining the destination IP address and netmask of packets that you intend the unit to intercept, and by specifying a (gateway) IP address for those packets. **Tip:** You can display the priority and distance information on the Static Route page using *Column Settings*.	
Destination IP/Mask	Enter the destination IP address and netmask of the packets that you intend the unit to intercept.
Device	Select the interface through which intercepted packets are received and sent.

Gateway		Enter the gateway IP address for those packets that you intend the unit to intercept.
Comments		Enter a description about the static route.
Advanced		Select to show the options *Distance* and *Priority*.
	Distance	Enter the number that represents the distances to the next-hop routers. The administrative distance allows you to weight one route to be preferred over another. This is useful when one route is unreliable. For example, if route A has an administrative distance of 10 and route B has an administrative distance of 30, the preferred route is route A with the smaller administrative distance of 10. If you discover that route A is unreliable, you can change the administrative distance for route A from 10 to 40, which will make the route B the preferred route.
	Priority	Enter the number for the priority of the static route.

Unless otherwise specified, static route examples and procedures are for IPv4 static routes. You can use the `config router static6` CLI command to add, edit, or delete static routes for IPv6 traffic.

Default route and default gateway

In the factory default configuration, entry number 1 in the Static Route list is associated with a destination address of 0.0.0.0/0.0.0.0, which means any/all destinations. This route is called the static default route. If no other routes are present in the routing table and a packet needs to be forwarded beyond the unit, the factory configured static default route causes the unit to forward the packet to the default gateway.

To prevent this, you must either edit the factory configured static default route to specify a different default gateway for the unit, or delete the factory configured route and specify your own static default route that points to the default gateway for the unit.

Changing the gateway for the default route

The default gateway determines where packets matching the default route will be forwarded.

If you are using DHCP or PPPoE over a modem interface on your unit, you may have problems configuring a static route on this interface. After trying to either renew your DHCP license, or reconnect the PPPoE connection, go to the CLI and enable `dynamic-gateway` under `config system interface` for the modem interface. This will remove the need to specify a gateway for this interface's route.

For network traffic to pass, even with the correct routes configured, you must have the appropriate security policies.

To change the gateway for the default route

1. Go to *Router* > *Static* > *Static Route*.
2. Select the default route and then select *Edit*.

3 If the unit reaches the next-hop router through an interface other than the interface that is currently selected in the *Device* field, select the name of the interface from the *Device* field.

4 In the *Gateway* field, type the IP address of the next-hop router to which outbound traffic may be directed.

5 In the *Distance* field, optionally adjust the administrative distance value.

The default route distance should be set high enough to allow other routes to be configured at lower distances so they will be preferred over the default route.

6 Select *OK*.

Adding a static route to the routing table

Static routes are defined manually. They control traffic exiting the unit—you can specify through which interface the packet will leave and to which device the packet should be routed. When adding a static route to the routing table, use the "New Static Route page" on page 1843 table.

When you add a static route through the web-based manager, the unit adds the entry to the Static Route list.

However, if multiple routes to the same destination have the same priority but different distances, the route with the lowest distance is used. If multiple routes to the same destination have the same distance but different priorities, the route with the lowest priority is used. Distance takes precedence over priority. If multiple routes to the same destination have the different distances and different priorities, the route with the lowest distance is always used even if it has the highest priority.

Policy Route

Policy route options define which attributes of a incoming packet cause policy routing to occur. If the attributes of a packet match all the specified conditions, the unit routes the packet through the specified interface to the specified gateway.

The following are policy route configuration settings in *Router* > *Static* > *Policy Route*.

Policy Route page Lists all policy routes that you have created. On this page, you can edit, delete or create a new policy route.	
Create New	Creates a new policy route. When you select *Create New*, you are automatically redirected to the New Routing Policy page.
Edit	Modifies settings within a static route. When you select *Edit*, you are automatically redirected to the Edit Routing Policy page.
Delete	Removes a policy route from within the list on the Policy Route page. To remove multiple policy routes in the list, on the Policy Route page, in each of the rows of the routes you want removed, select the check box and then select *Delete*. To remove all policy routes in the list, on the Policy Route page, select the check box in the check box column, and then select *Delete*.

Move To	Moves a policy route to any position within the list on the Policy Route page. You must select the check box in the row of the policy route that you want moved so that it will be moved in the list. When you select *Move To*, the Move Policy Route window appears. Enter the policy route ID number for the route's new position in the *(Policy route ID)* field. Select either *Before* or *After* to indicate the new position of the policy route. Select *OK*.
#	The ID numbers of configured route policies. These numbers are sequential unless policies have been moved within the table.
Incoming	The interfaces on which packets subjected to route policies are received.
Outgoing	The interfaces through which policy routed packets are routed.
Source	The IP source addresses and network masks that cause policy routing to occur.
Destination	The IP destination addresses and network masks that cause policy routing to occur.
New Routing Policy page Provides settings for configuring how to redirect traffic away from the static route.	
If incoming traffic matches:	
Protocol	To perform policy routing based on the value in the protocol field of the packet, enter the protocol number to match. The Internet Protocol Number is found in the IP packet header. RFC 5237 describes protocol numbers and you can find a list of the assigned protocol numbers. The range is from 0 to 255. A value of `0` disables the feature. **Tip:** Commonly used *Protocol* settings include 6 to route TCP sessions, 17 for UDP sessions, 1 for ICMP sessions, 47 for GRE sessions, and 92 for multicast sessions. For protocols other than 6 and 17, the port number is ignored.
Incoming interfaces	Select the name of the interface through which incoming packets subjected to the policy are received.
Source address/mask	To perform policy routing based on the IP source address of the packet, type the source address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination address/mask	To perform policy routing based on the IP destination address of the packet, type the destination address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination ports	To perform policy routing based on the port on which the packet is received, type the same port number in the From and To fields. To apply policy routing to a range of ports, type the starting port number in the From field and the ending port number in the To field. A value of 0 disables this feature. The Destination Ports fields are only used for TCP and UDP protocols. The ports are skipped over for all other protocols.

Type of Service	Use a two digit hexadecimal bit pattern to match the service, or use a two digit hexadecimal bit mask to mask out. For more information, see "Type of Service" on page 1695.
Force traffic to:	
Outgoing interfaces	Select the name of the interface through which packets affected by the policy will be routed.
Gateway Address	Type the IP address of the next-hop router that the unit can access through the specified interface. A value of `0.0.0.0` is not valid.

Settings

In the Settings menu, you can configure dead gateway detection as well as the ECMP load balancing method.

Dead gateway detection is a way to detect the response between the connection to a server and the number of times the test fails before the unit assumes that the interface cannot connect to the server. ECMP load balancing is a load balancing method that helps to distribute traffic to the same destination, such as the Internet or network. For more information, see "ECMP route failover and load balancing" on page 1685.

The following are configuration settings in *Router* > *Static* > *Settings*.

Settings page	
Lists the dead gateway detection settings as well as the chosen ECMP load balancing method.	
ECMP Load Balancing Method	
Select from one of the following ECMP route failover and load balancing methods that will be used for static routes: • *Source IP based* – balances sessions among ECMP routes based on the source IP address of the sessions to be load balanced. There are no configuration changes required to support source IP load balancing. • *Weighted Load Balance* – balances sessions among ECMP routes based on weights that are added to ECMP routes. More traffic is directed to routes with higher weights. If you select this option, you must also add weights to the static routes. • *Spillover* – distributes sessions among ECMP routes based on how busy the FortiGate interfaces are that have been added to the routes. After selecting Spillover, you must then add spillover thresholds to the interfaces added to ECMP routes.	
Dead Gateway Detection	
Lists the dead gateways that you have created.	
Create New	Creates a new dead gateway. When you select *Create New*, you are automatically redirected to the New Dead Gateway Detection page.
Edit	Modifies settings within a dead gateway. When you select *Edit*, you are automatically redirected to the Edit Dead Gateway Detection page.

Delete	Removes a dead gateway from the list. To remove multiple dead gateways from the list, within the Dead Gateway Detection section, in each of the rows of the of gateways you want removed, select the check box and then select *Delete*. To remove all dead gateways in the list, within the Dead Gateway Detection section, select the check box in the check box column, and then select *Delete*.
Interface	The FortiGate interface that the dead gateway will be detected on.
Ping Server	The IP address of the ping server.
Detect Protocol	The protocol that is used to detect the dead gateway.
Interval	The ping interval in seconds.
Failover	The failover threshold. This is the number of consecutive pings that do not get a response.
New Dead Gateway Detection page Provides settings for configuring a dead gateway. You are automatically redirected to this page when you select Create New.	
Interface	Select the interface that will be detecting dead gateways.
Ping Server	Enter the IP address of the ping server.
Detect Protocol	Select a protocol that will be used in detecting the dead gateway.
Ping Interval (seconds)	Enter the number of seconds for the ping interval.
Failover Threshold (Ping lost consecutively)	Enter the number for the threshold.
HA Priority	Set the HA remote IP monitoring priority for this interface if HA remote IP monitoring is configured for this interface from the CLI.

Dynamic

The Dynamic menu provides settings for configuring dynamic routing. Dynamic routing protocols allow the unit to automatically share information about routes with neighboring routers and learn about routes and networks advertised by them.

The unit supports these dynamic routing protocols:

- Routing Information Protocol (RIP)
- Open Shortest Path First (OSPF)
- Border Gateway Protocol (BGP).

This topic contains the following:

A unit can operate as a Protocol Independent Multicast (PIM) version 2 router in the root virtual domain. FortiGate units support PIM sparse mode and dense mode and can service multicast servers or receivers on the network segment to which a FortiGate interface is connected. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations.

RIP

Routing Information Protocol (RIP) is a distance-vector routing protocol intended for small, relatively homogeneous networks. The FortiGate implementation of RIP supports RIP version 1 (see RFC 1058), RIP version 2 (see RFC 2453), as well as the IPv6 version RIPng (see RFC 2080).

For detailed information about RIP, see “RIP background and concepts” on page 1715.

RIP configuration settings

The following are RIP configuration settings in *Routing* > *Dynamic* > *RIP*.

RIP page		
Lists all the networks and interfaces that you have created. This page also allows you to configure basic RIP settings, including creating interfaces and networks.		
	RIP Version	Select the level of RIP compatibility needed at the unit. You can enable global RIP settings on all FortiGate interfaces connected to RIP-enabled networks: • *1* – send and receive RIP version 1 packets. • *2* – send and receive RIP version 2 packets. You can override the global settings for a specific FortiGate interface if required. For more information, see "RIP-enabled interface" on page 1853.
	Advanced Options	Select the Expand Arrow to view or hide advanced RIP options. For more information, see "Advanced RIP options" on page 1851.
Networks section of the RIP page		
The IP addresses and network masks of the major networks (connected to the unit) that run RIP. When you add a network to the Networks list, the FortiGate interfaces that are part of the network are advertised in RIP updates. You can enable RIP on all FortiGate interfaces whose IP addresses match the RIP network address space.		
	IP/Netmask	Enter the IP address and netmask that defines the RIP-enabled network.
	Add	Adds a new network IP address and netmask to the Networks section of the RIP page. When you select Add, the IP address and netmask is automatically added to the list.
	Delete	Removes an IP address and netmask from within the Networks section of the RIP page. To remove multiple IP addresses and netmasks in the list, within the Networks section, in each of the rows of the networks you want removed, select the check box and then select *Delete*. To remove all IP addresses and netmasks in the list, within the Networks section, select the check box in the check box column, and then select *Delete*.
Interfaces section of the RIP page		
Any additional settings needed to adjust RIP operation on a FortiGate interface.		
	Create New	Creates a new RIP interface. These parameters will override the global RIP settings for that interface. When you select *Create New* in the Interfaces section of the RIP page, you are automatically redirected to the New/Edit RIP Interface. See "RIP-enabled interface" on page 1853.
	Edit	Modifies settings within a RIP interface. When you select *Edit*, you are automatically redirected to the New/Edit RIP Interfaces.

	Delete	Removes a RIP interface from within the Interfaces section on the RIP page. To remove multiple interfaces in the list, within the Interfaces section, in each of the rows of the routes you want removed, select the check box and then select *Delete*. To remove all interfaces in the list, within the Interfaces section, select the check box in the check box column, and then select *Delete*.
	Interface	The name of the unit RIP interface.
	Send Version	The version of RIP used to send updates through each interface: *1*, *2*, or *both*.
	Receive Version	The versions of RIP used to listen for updates on each interface: *1*, *2*, or *both*.
	Authentication	The type of authentication used on this interface: *None, Text* or *MD5*.
	Passive	Permissions for RIP broadcasts on this interface. A green checkmark means the RIP broadcasts are blocked.

The `get router info rip` CLI command provides detailed information about configured RIP settings. You can view the entries in the RIP routing database or get status information about FortiGate interfaces.

Advanced RIP options

With advanced RIP options, you can specify settings for RIP timers and define metrics for redistributing routes that the unit learns through some means other than RIP updates. For example, if the unit is connected to an OSPF or BGP network or you add a static route to the FortiGate routing table manually, you can configure the unit to advertise those routes on RIP-enabled interfaces.

You can configure additional advanced options through customizable widgets, and the CLI. For example, you can filter incoming or outgoing updates by using a route map, an access list, or a prefix list. The unit also supports offset lists, which add the specified offset to the metric of a route.

Advanced RIP options are configured in *Router* > *Dynamic* > *RIP*, in the *Advanced Options* area of the page. You must expand Advanced Options to reveal the hidden settings so that you can configure these advanced options. Use the following table when configuring advanced RIP options.

Advanced Options section of the RIP page	
Advanced Options	Select the Expand Arrow to view or hide advanced options.
Default Metric	Enter the default hop count that the unit should assign to routes that are added to the FortiGate routing table. The range is from 1 to 16. This metric is the hop count, with 1 being best or shortest. This value also applies to Redistribute unless otherwise specified.
Enable Default-information-originate	Select to generate and advertise a default route into the unit's RIP-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both.

RIP Timers		Enter new values to override the default RIP timer settings. The default settings are effective in most configurations — if you change these settings, ensure that the new settings are compatible with local routers and access servers. If the update timer is smaller than *Timeout* or *Garbage* timers, you will get an error.
	Update	Enter the amount of time (in seconds) that the unit will wait between sending RIP updates. The update timer determines the interval between routing updates. The update time should be at least three times smaller than the timeout timer; otherwise you will experience an error.
	Timeout	Enter the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the unit will keep a reachable route in the routing table while no updates for that route are received. If the unit receives an update for the route before the timeout period expires, the timer is restarted. The *Timeout* period should be at least three times longer than the *Update* period. **Tip:** If you are experiencing problems with routers not responding in time to updates, increase this time; however, remember that longer timeout intervals result in longer overall update periods.
	Garbage	Enter the amount of time (in seconds) that the unit will advertise a route as being unreachable before deleting the route from the routing table. The value determines how long an unreachable route is kept in the routing table. The garbage timer is the amount of time that the unit will advertise a route as being unreachable before deleting the route from the routing table.
Redistribute		Select one or more of the options to redistribute RIP updates about routes that were not learned through RIP. The unit can use RIP to redistribute routes learned from directly connected networks, static routes, OSPF, and BGP.
	Connected	Select to redistribute routes learned from directly connected networks. To specify a hop count for those routes, select *Metric*, and enter the hop count in the *Metric* field. The valid hop count range is from 1 to 16.
	Static	Select to redistribute routes learned from static routes. To specify a hop count for those routes, select *Metric*, and enter the hop count in the *Metric* field. The range is from 1 to 16.
	OSPF	Select to redistribute routes learned through OSPF. To specify a hop count for those routes, select *Metric*, and enter the hop count in the *Metric* field. The range is from 1 to 16.
	BGP	Select to redistribute routes learned through BGP. To specify a hop count for those routes, select *Metric*, and enter the hop count in the *Metric* field. The range is from 1 to 16.

RIP-enabled interface

You can use RIP interface options to override the global RIP settings that apply to all unit interfaces connected to RIP-enabled networks. For example, if you want to suppress RIP advertising on an interface that is connected to a subnet of a RIP-enabled network, you can set the interface to operate passively. Passive interfaces listen for RIP updates but do not respond to RIP requests.

If RIP version 2 is enabled on the interface, you can optionally choose password authentication to ensure that the unit authenticates a neighboring router before accepting updates from that router. The unit and the neighboring router must both be configured with the same password. Authentication guarantees the authenticity of the update packet, not the confidentiality of the routing information in the packet.

RIP-enabled interface configuration settings

RIP-enabled interfaces are configured in *Router* > *Dynamic* > *RIP*. The following are RIP interface configuration settings.

Additional options such as split-horizon and key-chains can be configured per interface through the CLI.

New/Edit RIP Interface page	
Provides settings for configuring a RIP Interface. When you select *Create New* in the Interfaces section of the RIP page, you are automatically redirected to the New/Edit RIP Interface page.	
Interface	Select the name of the FortiGate interface to which these settings apply. The interface must be connected to a RIP-enabled network. The interface can be a virtual IPsec or GRE interface.
Send Version	Select to override the default RIP-compatibility setting for sending updates through the interface. You can choose either RIP version 1, 2, or both RIP versions.
Receive Version	Select to override the default RIP-compatibility setting for receiving updates through the interface. You can choose either RIP version 1, 2 or both RIP versions.
Authentication	Select an authentication method for RIP exchanges on the specified interface: • *None* — Disable authentication. • *Text* — Select if the interface is connected to a network that runs RIP version 2. Type a password (up to 35 characters) in the *Password* field. The unit and the RIP updates router must both be configured with the same password. The password is sent in clear text over the network.
Password	Enter the password for authentication.
Passive Interface	Select to suppress the advertising of unit routing information over the specified interface. Clear the check box to allow the interface to respond normally to RIP requests.

OSPF

Open Shortest Path First (OSPF) is a link-state routing protocol that is most often used in large heterogeneous networks to share routing information among routers in the same Autonomous System (AS). FortiGate units support OSPF version 2 (see RFC 2328). For detailed information about OSPF, see "OSPF Background and concepts" on page 1787.

The main benefit of OSPF is that it advertises routes only when neighbors change state instead of at timed intervals, so routing overhead is reduced.

When you configure OSPF settings, you have to define the AS in which OSPF is enabled and specify which of the FortiGate interfaces participate in the AS. As part of the AS definition, you specify the AS areas and specify which networks to include those areas. You may optionally adjust the settings associated with OSPF operation on the FortiGate interfaces.

Basic OSPF configuration settings

The following are OSPF configuration settings in *Router* > *Dynamic* > *OSPF*.

OSPF page		
Lists all areas, networks and interfaces that you created for OSPF.		
Router ID		Enter a unique router ID to identify the unit to other OSPF routers. By convention, the router ID is the numerically highest IP address assigned to any of the FortiGate interfaces in the OSPF AS. If you change the router ID while OSPF is configured on an interface, all connections to OSPF neighbors will be broken temporarily. The connections will re-establish themselves. If *Router ID* is not explicitly set, the highest IP address of the VDOM or unit will be used. **Note**: Make sure to select *Apply* to apply the settings.
Advanced Options		Expand to view or hide advanced OSPF settings. See "Advanced OSPF options" on page 1856.
Areas section of the OSPF page		
Information about the areas making up an OSPF AS. The header of an OSPF packet contains an area ID, which helps to identify the origination of a packet inside the AS.		
	Create New	Creates a new OSPF area. When you select *Create New*, you are automatically redirected to the New/Edit OSPF Area page.
	Edit	Modifies settings within the OSPF area. When you select *Edit*, you are automatically redirected to the New/Edit OSPF Area page.
	Delete	Removes an OSPF area from within the Areas section on the OSPF page. To remove multiple areas in the list, within the Areas section, in each of the rows of the OSPF areas you want removed, select the check box and then select *Delete*. To remove all areas in the list, within the Areas section, select the check box in the check box column, and then select *Delete*.
	Area	The unique 32-bit identifiers of areas in the AS, in dotted-decimal notation. Area ID 0.0.0.0 references the backbone of the AS and cannot be changed or deleted.

	Type	The types of areas in the AS: • *Regular* - a normal OSPF area • *NSSA* - a not so stubby area • *Stub* - a stub area. For more information, see “Defining OSPF areas” on page 1857.
	Authentication	The methods for authenticating OSPF packets sent and received through all FortiGate interfaces linked to each area: • *None* — authentication is disabled • *Text* — text-based authentication is enabled • *MD5* — MD5 authentication is enabled. A different authentication setting may apply to some of the interfaces in an area, as displayed under Interfaces. For example, if an area employs simple passwords for authentication, you can configure a different password for one or more of the networks in that area.
Networks section of the OSPF page The networks in the OSPF AS and their area IDs. When you add a network to the Networks list, all FortiGate interfaces that are part of the network are advertised in OSPF link-state advertisements. You can enable OSPF on all FortiGate interfaces whose IP addresses match the OSPF network address space. For more information, see “OSPF networks” on page 1858.		
	Create New	Creates a new OSPF network. When you select *Create New*, you are automatically redirected to the New/Edit OSPF Network page.
	Edit	Modifies settings within that OSPF network. When you select *Edit*, you are automatically redirected to the New/Edit OSPF Network page.
	Delete	Removes an OSPF network from within the Networks section on the OSPF page. To remove multiple networks in the list, within the Networks section, in each of the rows of the OSPF networks you want removed, select the check box and then select *Delete*. To remove all areas in the list, within the Networks section, select the check box in the check box column, and then select *Delete*.
	Network	The IP addresses and network masks of networks in the AS on which OSPF runs. The FortiGate unit may have physical or VLAN interfaces connected to the network.
	Area	The area IDs that have been assigned to the OSPF network address space.
Interfaces section of the OSPF page Any additional settings needed to adjust OSPF operation on a FortiGate interface. For more information, see “Operating parameters for an OSPF interface” on page 1859.		
	Create New	Create additional/different OSPF operating parameters for a unit’s interface and add the configuration to the Interfaces list. When you select *Create New*, you are automatically redirected to the New/Edit OSPF Interface page.

	Edit	Modifies settings within that OSPF interface. When you select *Edit*, you are automatically redirected to the New/Edit OSPF Interface page.
	Delete	Removes an OSPF interfaces from within the Interfaces section on the OSPF page. To remove multiple networks in the list, within the Interface section, in each of the rows of the OSPF interfaces you want removed, select the check box and then select *Delete*. To remove all areas in the list, within the Interfaces section, select the check box in the check box column, and then select *Delete*.
	Name	The names of OSPF interface definitions.
	Interface	The names of FortiGate physical or VLAN interfaces having OSPF settings that differ from the default values assigned to all other interfaces in the same area.
	IP	The IP addresses of the OSPF-enabled interfaces having additional/different settings.
	Authentication	The methods for authenticating LSA exchanges sent and received on specific OSPF-enabled interfaces. These settings override the area Authentication settings.

Advanced OSPF options

By selecting advanced OSPF options, you can specify metrics for redistributing routes that the unit learns through some means other than OSPF link-state advertisements. For example, if the unit is connected to a RIP or BGP network or you add a static route to the FortiGate routing table manually, you can configure the unit to advertise those routes on OSPF-enabled interfaces.

You can configure additional advanced options through customizable GUI widgets, and the CLI. For example, you can filter incoming or outgoing updates by using a route map, an access list, or a prefix list. The unit also supports offset lists, which add the specified offset to the metric of a route.

Advanced OSPF options are located in *Router* > *Dynamic* > *OSPF*. You must expand the Advanced Options on the page to access these options.

Advanced Options on the OSPF page		
Router ID		Enter a unique router ID to identify the unit to other OSPF routers.
Expand Arrow		Select to view or hide *Advanced Options*.
Default Information		Generate and advertise a default (external) route to the OSPF AS. You may base the generated route on routes learned through a dynamic routing protocol, routes in the routing table, or both.
	None	Prevent the generation of a default route.
	Regular	Generate a default route into the OSPF AS and advertise the route to neighboring autonomous systems only if the route is stored in the FortiGate routing table.
	Always	Generate a default route into the OSPF AS and advertise the route to neighboring autonomous systems unconditionally, even if the route is not stored in the FortiGate routing table.

Redistribute		Select one or more of the options listed to redistribute OSPF link-state advertisements about routes that were not learned through OSPF. The unit can use OSPF to redistribute routes learned from directly connected networks, static routes, RIP, and BGP.
	Connected	Select to redistribute routes learned from directly connected networks. Enter a cost for those routes in the Metric field. The range is from 1 to 16 777 214.
	Static	Select to redistribute routes learned from static routes. Enter a cost for those routes in the Metric field. The range is from 1 to 16 777 214.
	RIP	Select to redistribute routes learned through RIP. Enter a cost for those routes in the Metric field. The range is from 1 to 16 777 214.
	BGP	Select to redistribute routes learned through BGP. Enter a cost for those routes in the Metric field. The range is from 1 to 16 777 214.

Defining OSPF areas

An area logically defines part of the OSPF AS. Each area is identified by a 32-bit area ID expressed in dotted-decimal notation, for example 192.168.0.1. Area ID 0.0.0.0 is reserved for the OSPF network backbone. You can classify the remaining areas of an AS as regular, stub, or NSSA.

A regular area contains more than one router, each having at least one OSPF-enabled interface to the area.

To reach the OSPF backbone, the routers in a stub area must send packets to an area border router. Routes leading to non-OSPF domains are not advertised to the routers in stub areas. The area border router advertises to the OSPF AS a single default route (destination 0.0.0.0) into the stub area, which ensures that any OSPF packet that cannot be matched to a specific route will match the default route. Any router connected to a stub area is considered part of the stub area.

In a Not-So-Stubby Area (NSSA), routes that lead out of the area into a non-OSPF domain are made known to OSPF AS. However, the area itself continues to be treated like a stub area by the rest of the AS.

Regular areas and stub areas (including not-so-stubby areas) are connected to the OSPF backbone through area border routers.

The following are configuration settings for defining OSPF areas on the OSPF page in *Router* > *Dynamic* > *OSPF*.

If required, you can define a virtual link to an area that has lost its physical connection to the OSPF backbone. Virtual links can be set up only between two units that act as area border routers.

New/Edit OSPF Area page	
Provides settings for defining an OSPF area. When you select *Create New* in the *Areas* section of the OSPF page, you are automatically redirected to the New/Edit OSPF Area page.	
Area	Type a 32-bit identifier for the area. The value must resemble an IP address in dotted-decimal notation. Once you have created the OSPF area, the area IP value cannot be changed; you must delete the area and restart.
Type	Select an area type to classify the characteristics of the network that will be assigned to the area: • *Regular* — If the area contains more than one router, each having at least one OSPF-enabled interface to the area. • *NSSA* — If you want routes to external non-OSPF domains made known to OSPF AS and you want the area to be treated like a stub area by the rest of the AS. • *STUB* — If the routers in the area must send packets to an area border router in order to reach the backbone and you do not want routes to non-OSPF domains to be advertised to the routers in the area.
Authentication	Select the method for authenticating OSPF packets sent and received through all interfaces in the area: • *None* — Disable authentication. • *Text* — Enables text-based password authentication. to authenticate LSA exchanges using a plain-text password. The password is sent in clear text over the network. • *MD5* — Enable MD5-based authentication using an MD5 cryptographic hash (RFC 1321). If required, you can override this setting for one or more of the interfaces in the area. For more information, see "Operating parameters for an OSPF interface" on page 1859.

OSPF networks

OSPF areas group a number of contiguous networks together. When you assign an area ID to a network address space, the attributes of the area are associated with the network.

Assigning an OSPF area ID to a network is configured in *Router* > *Dynamic* > *OSPF*. You must be in the Network section of the page to assign an OSPF area ID to a network. The following are configuration settings for OSPF networks.

New/Edit OSPF Network page
Provides settings for configuring networks that are assigned to an area ID. When you select Create New in the Network section of the OSPF page, you are automatically redirected to the New/Edit OSPF Network page.

IP/Netmask	Enter the IP address and network mask of the local network that you want to assign to an OSPF area.
Area	Select an area ID for the network. The attributes of the area must match the characteristics and topology of the specified network. You must define the area before you can select the area ID. For more information, see "Defining OSPF areas" on page 1857.

Operating parameters for an OSPF interface

An OSPF interface definition contains specific operating parameters for a FortiGate OSPF-enabled interface. The definition includes the name of the interface (for example, external or VLAN_1), the IP address assigned to the interface, the method for authenticating LSA exchanges through the interface, and timer settings for sending and receiving OSPF Hello and dead-interval packets.

You can enable OSPF on all FortiGate interfaces whose IP addresses match the OSPF-enabled network space. For example, define an area of 0.0.0.0 and the OSPF network as 10.0.0.0/16. Then define vlan1 as 10.0.1.1/24, vlan2 as 10.0.2.1/24 and vlan3 as 10.0.3.1/24. All three VLANs can run OSPF in area 0.0.0.0. To enable all interfaces, you would create an OSPF network 0.0.0.0/0

When entering the operating parameters for MD5 keys for the interface, the following special characters are not supported:

- < >
- ( )
- ‘
- #
- “
-

You can configure different OSPF parameters for the same FortiGate interface when more than one IP address has been assigned to the interface. For example, the same FortiGate interface could be connected to two neighbors through different subnets. You could configure an OSPF interface definition containing one set of Hello and dead-interval parameters for compatibility with one neighbor's settings, and a second OSPF interface definition for the same interface to ensure compatibility with the second neighbor's settings.

The following are configuration settings for OSPF operating parameters in *Router* > *Dynamic* > *OSPF*, on the Interfaces section of the page.

New/Edit OSPF Interface page	
Provides settings for configuring an OSPF interface. When you select Create New in the Interface section of the OSPF page, you are automatically redirected to the New/Edit OSPF Interface page.	
Name	Enter a name to identify the OSPF interface definition. For example, the name could indicate to which OSPF area the interface will be linked.
Interface	Select the name of the FortiGate interface to associate with this OSPF interface definition (for example, port1, external, or VLAN_1). The unit can have physical, VLAN, virtual IPsec or GRE interfaces connected to the OSPF-enabled network.

IP	Enter the IP address that has been assigned to the OSPF-enabled interface. The interface becomes OSPF-enabled because its IP address matches the OSPF network address space. For example, if you defined an OSPF network of `172.20.120.0/24` and port1 has been assigned the IP address `172.20.120.140`, type `172.20.120.140`.
Authentication	Select an authentication method for LSA exchanges on the specified interface: • *None* — Disable authentication. • *Text* — Authenticate LSA exchanges using a plain-text password. The password can be up to 35 characters, and is sent in clear text over the network. • *MD5* — Use one or more keys to generate an MD5 cryptographic hash.
Password	Enter the plain-text password. Enter an alphanumeric value of up to 15 characters. The OSPF neighbors that send link-state advertisements to this FortiGate interface must be configured with an identical password. This field is available only if you selected plain-text authentication.
MD5 Keys	Enter the key identifier for the (first) password in the ID field (the range is from 1 to 255) and then type the associated password in the Key field. The password is a 128-bit hash, represented by an alphanumeric string of up to 16 characters. When entering the characters, do not use < >, ( ), #, " , and ' because they are not supported. The OSPF neighbors that send link-state advertisements to this FortiGate interface must be configured with an identical MD5 key. If the OSPF neighbor uses more than one password to generate MD5 hash, select the Add icon to add additional MD5 keys to the list. This field is available only if you selected MD5 authentication.
Timer(seconds) section of the page	
Hello Interval	Optionally, set the Hello Interval to be compatible with Hello Interval settings on all OSPF neighbors. This setting defines the period of time (in seconds) that the unit waits between sending Hello packets through this interface.
Dead Interval	Optionally, set the Dead Interval to be compatible with Dead Interval settings on all OSPF neighbors. This setting defines the period of time (in seconds) that the unit waits to receive a Hello packet from an OSPF neighbor through the interface. If the unit does not receive a Hello packet within the specified amount of time, the unit declares the neighbor inaccessible. By convention, the Dead Interval value is usually four times greater than the Hello Interval value.

BGP

Border Gateway Protocol (BGP) is an Internet routing protocol typically used by ISPs to exchange routing information between different ISP networks. For example, BGP enables the sharing of network paths between the ISP network and an autonomous system (AS) that uses RIP, OSPF, or both to route packets within the AS. The FortiGate implementation of BGP supports BGP-4 and complies with RFC 1771 and RFC 2385.

For more information, see “BGP background and concepts” on page 1751.

You can configure graceful restarting and other advanced settings only through CLI commands.

When you configure BGP settings, you need to specify the AS to which the unit belongs and enter a router ID to identify this unit to other BGP routers. You must also identify the unit’s BGP neighbors and specify which of the networks local to the unit should be advertised to BGP neighbors.

BGP configuration settings

The following are BGP configuration settings in *Router* > *Dynamic* > *BGP*. You can also configure many advanced BGP options through the CLI.

BGP page		
Lists all neighbors and networks that you have created. This page also allows you to configure neighbors, networks and a local AS. You can also configure four-byte AS paths as well. If you want additional information about configuring four-byte AS paths, see RFC 4893.		
Local AS		Enter the number of the local AS to which the FortiGate unit belongs. Select *Apply* to apply the local AS setting.
Router ID		Enter a unique router ID to identify the unit to other BGP routers. The router ID is an IP address written in dotted-decimal format, for example `192.168.0.1`. If you change the router ID while BGP is configured on an interface, all connections to BGP peers will be broken temporarily. The connections will re-establish themselves. If Router ID is not explicitly set, the highest IP address of the VDOM will be used. **Note:** You must select *Apply* after entering the router ID to save the setting.
Neighbors section of the BGP page		
The IP addresses and AS numbers of BGP peers in neighboring autonomous systems.		
	IP	Enter the IP address of the neighbor interface to the BGP-enabled network.
	Remote AS	Enter the number of the AS that the neighbor belongs to.
	Add/Edit	Add the neighbor information to the Neighbors list, or edit an entry in the list.
	Neighbor	The IP addresses of BGP peers.
	Remote AS	The numbers of the autonomous systems associated with the BGP peers.
	Delete	Removes a BGP neighbor from within the Neighbors section on the BGP page. To remove multiple neighbors in the list, within the Neighbors section, in each of the rows of the BGPneighbors you want removed, select the check box and then select *Delete*. To remove all neighbors in the list, within the Neighbors section, select the check box in the check box column, and then select *Delete*.
Networks section of the BGP page		
The IP addresses and network masks of networks to advertise to BGP peers. The unit may have a physical or VLAN interface connected to those networks.		
	IP/Netmask	Enter the IP address and netmask of the network to be advertised.
	Add	Add the network information to the Networks list.

	Network	The IP addresses and network masks of major networks that are advertised to BGP peers.
	Delete	Removes a BGP network from within the Networks section on the BGP page. To remove multiple networks in the list, within the Networks section, in each of the rows of the BGP networks you want removed, select the check box and then select *Delete*. To remove all networks in the list, within the Networks section, select the check box in the check box column, and then select *Delete*.

The `get router info bgp` CLI command provides detailed information about configured BGP settings.

Multicast

A FortiGate unit can operate as a Protocol Independent Multicast (PIM) version 2 router in the root virtual domain. FortiGate units support PIM sparse mode (RFC 2362) and PIM dense mode (RFC 3973) and can service multicast servers or receivers on the network segment to which a FortiGate interface is connected.

You can configure basic options through the web-based manager. Many additional options are available, but only through the CLI.

When multicast (PIM) routing is enabled, you can configure sparse mode or dense mode operation on any FortiGate interface.

Multicast (PIM) interface options are used to set operating parameters for FortiGate interfaces connected to PIM domains. For example, you can enable dense mode on an interface that is connected to a PIM-enabled network segment. When sparse mode is enabled, you can adjust the priority number that is used to advertise Rendezvous Point (RP) and/or Designated Router (DR) candidacy on the interface.

Multicast offloading is available only on accelerated modules, and only in NAT Route mode. Multicast offloading is available only in the CLI.

Sparse mode

Initially, all candidate BSRs in a PIM domain exchange bootstrap messages to select one BSR to which each RP sends the multicast address or addresses of the multicast group(s) that it can service. The selected BSR chooses one RP per multicast group and makes this information available to all of the PIM routers in the domain through bootstrap messages. PIM routers use the information to build packet distribution trees, which map each multicast group to a specific RP. Packet distribution trees may also contain information about the sources and receivers associated with particular multicast groups.

When a FortiGate interface is configured as a multicast interface, sparse mode is enabled on it by default to ensure that distribution trees are not built unless at least one downstream receiver requests multicast traffic from a specific source. If the sources of multicast traffic and their receivers are close to each other and the PIM domain contains a dense population of active receivers, you may choose to enable dense mode throughout the PIM domain instead.

An RP represents the root of a non-source-specific distribution tree to a multicast group. By joining and pruning the information contained in distribution trees, a single stream of multicast packets (for example, a video feed) originating from the source can be forwarded to a certain RP to reach a multicast destination.

Each PIM router maintains a Multicast Routing Information Base (MRIB) that determines to which neighboring PIM router join and prune messages are sent. An MRIB contains reverse-path information that reveals the path of a multicast packet from its source to the PIM router that maintains the MRIB.

To send multicast traffic, a server application sends IP traffic to a multicast group address. The locally elected DR registers the sender with the RP that is associated with the target multicast group. The RP uses its MRIB to forward a single stream of IP packets from the source to the members of the multicast group. The IP packets are replicated only when necessary to distribute the data to branches of the RP's distribution tree.

To receive multicast traffic, a client application can use Internet Group Management Protocol (IGMP) version 1 (RFC 1112), 2 (RFC 2236), or 3 (RFC 3376) control messages to request the traffic for a particular multicast group. The locally elected DR receives the request and adds the host to the multicast group that is associated with the connected network segment by sending a join message towards the RP for the group. Afterward, the DR queries the hosts on the connected network segment continually to determine whether the hosts are active. When the DR no longer receives confirmation that at least one member of the multicast group is still active, the DR sends a prune message towards the RP for the group.

Dense mode

The packet organization used in sparse mode is also used in dense mode. When a multicast source begins to send IP traffic and dense mode is enabled, the closest PIM router registers the IP traffic from the multicast source (S) and forwards multicast packets to the multicast group address (G). All PIM routers initially broadcast the multicast packets throughout the PIM domain to ensure that all receivers that have requested traffic for multicast group address G can access the information if needed.

To forward multicast packets to specific destinations afterward, the PIM routers build distribution trees based on the information in multicast packets. Upstream PIM routers depend on prune/graft messages from downstream PIM routers to determine if receivers are actually present on directly connected network segments. The PIM routers exchange state refresh messages to update their distribution trees. FortiGate units store this state information in a Tree Information Base (TIB), which is used to build a multicast forwarding table. The information in the multicast forwarding table determines whether packets are forwarded downstream. The forwarding table is updated whenever the TIB is modified.

PIM routers receive data streams every few minutes and update their forwarding tables using the source (S) and multicast group (G) information in the data stream. Superfluous multicast traffic is stopped by PIM routers that do not have downstream receivers—PIM routers that do not manage multicast groups send prune messages to the upstream PIM routers. When a receiver requests traffic for multicast address G, the closest PIM router sends a graft message upstream to begin receiving multicast packets.

Multicast configuration settings

The following are multicast configuration settings in *Router* > *Dynamic* > *Multicast*. Advanced PIM settings are configured in the CLI.

Multicast page	
Lists each individual multicast route that you created. This page also allows you to configure each multicast route and add RP addresses. **Note:** Multicast offload is available only on accelerated modules, and only in NAT Route mode. Multicast offload is available only in the CLI.	
Enable Multicast Routing	Select to enable PIM version 2 routing. A security policy must be created on PIM-enabled interfaces to pass encapsulated packets and decapsulated data between the source and destination.
Static Rendezvous Points (RPs)	If required for sparse mode operation, enter the IP address of a Rendezvous Point (RP) that may be used as the root of a packet distribution tree for a multicast group. Join messages from the multicast group are sent to the RP, and data from the source is sent to the RP. If an RP for the specified IP's multicast group is already known to the Boot Strap Router (BSR), the RP known to the BSR is used and the static RP address that you specify is ignored.
Apply	Save the specified static RP addresses.
Create New	Creates a new multicast entry for an interface. When you select *Create New*, you are automatically redirected to the New page. You can use the new entry to fine-tune PIM operation on a specific FortiGate interface or override the global PIM settings on a particular interface.
Edit	Modifies settings within the multicast route. When you select *Edit*, you are automatically redirected to the Edit page.

Delete	Removes a multicast route from within the Multicast page. To remove multiple routes in the list, on the Multicast Route page, in each of the rows of the routes you want removed, select the check box and then select *Delete*. To remove all neighbors in the list, on the Multicast Route page, select the check box in the check box column, and then select *Delete*.
Interface	The names of FortiGate interfaces having specific PIM settings.
Mode	The mode of PIM operation (*Sparse* or *Dense*) on that interface.
Status	The status of parse-mode RP candidacy on the interface. To change the status of RP candidacy on an interface, select the Edit icon in the row that corresponds to the interface.
Priority	The priority number assigned to RP candidacy on that interface. Available only when RP candidacy is enabled.
DR Priority	The priority number assigned to Designated Router (DR) candidacy on the interface. Available only when sparse mode is enabled.
New page Provides settings for configuring a new multicast interface. When you select *Create New* on the Multicast page, you are automatically redirected to the New page.	
Interface	Select the name of the root VDOM FortiGate interface to which these settings apply. The interface must be connected to a PIM version 2 enabled network segment.
PIM Mode	Select the mode of operation: Sparse Mode or Dense Mode. All PIM routers connected to the same network segment must be running the same mode of operation. If you select Sparse Mode, adjust the remaining options as described below.
DR Priority	Enter the priority number for advertising DR candidacy on the unit's interface. The range is from 1 to 4 294 967 295. The unit compares this value to the DR interfaces of all other PIM routers on the same network segment, and selects the router having the highest DR priority to be the DR.
RP Candidate	Enable RP candidacy on the interface.
RP Candidate Priority	Enter the priority number for advertising RP candidacy on the FortiGate interface. The range is from 1 to 255.

Multicast destination NAT

Multicast destination NAT (DNAT) allows you translate externally received multicast destination addresses to addresses that conform to an organization's internal addressing policy.

By using this feature that is available only in the CLI, you can avoid redistributing routes at the translation boundary into their network infrastructure for Reverse Path Forwarding (RPF) to work properly. They can also receive identical feeds from two ingress points in the network and route them independently.

Configure multicast DNAT in the CLI using the `firewall multicast policy` command.

Bi-directional Forwarding Detection (BFD)

The Bi-directional Forwarding Detection (BFD) protocol is designed to deal with dynamic routing protocols' lack of a fine granularity for detecting device failures on the network and re-routing around those failures. BFD can more quickly react to these failures, since it detects them on a millisecond timer, where other dynamic routing protocols can only detect them on a second timer.

Your unit supports BFD as part of OSPF and BGP dynamic networking. BFD is configured only in the CLI.

Configuring BFD

BFD is intended for networks that use BGP or OSPF routing protocols. This generally excludes smaller networks.

BFD configuration on your unit is very flexible. You can enable BFD for the whole unit, and turn it off for one or two interfaces. Alternatively you can specifically enable BFD for each neighbor router, or interface. Which method you choose will be determined by the amount of configuring required for your network

The timeout period determines how long the unit waits before labeling a connection as down. The length of the timeout period is important—if it is too short connections will be labeled down prematurely, and if it is too long time will be wasted waiting for a reply from a connection that is down. There is no easy number, as it varies for each network and unit. High end models will respond very quickly unless loaded down with traffic. Also the size of the network will slow down the response time—packets need to make more hops than on a smaller network. Those two factors (CPU load and network traversal time) affect how long the timeout you select should be. With too short a timeout period, BFD will not connect to the network device but it will keep trying. This state generates unnecessary network traffic, and leaves the device unmonitored. If this happens, you should try setting a longer timeout period to allow BFD more time to discover the device on the network.

For this example, BFD is enabled on the unit using the default values. This means that once a connection is established, your unit will wait for up to 150 milliseconds for a reply from a BFD router before declaring that router down and rerouting traffic—a 50 millisecond minimum transmit interval multiplied by a detection multiplier of 3. The port that BFD traffic originates from will be checked for security purposes as indicated by disabling `bfd-dont-enforce-src-port`.

```
config system settings
  set bfd enable
  set bfd-desired-min-tx 50
  set bfd-required-min-rx 50
  set bfd-detect-mult 3
  set bfd-dont-enforce-src-port disable
end
```

The minimum receive interval (`bfd-required-min-rx`) and the detection multiplier (`bfd-detect-mult`) combine to determine how long a period your unit will wait for a reply before declaring the neighbor down. The correct value for your situation will vary based on the size of your network and the speed of your unit's CPU. The numbers used in this example may not work for your network.

Disabling BFD for a specific interface

The previous example enables BFD for your entire unit. If an interface is not connected to any BFD enabled routers, you can reduce network traffic by disabling BFD for that interface. For this example, BFD is disabled for the internal interface using CLI commands.

```
config system interface
  edit <interface>
    set bfd disable
end
```

Access List

Access lists are filters used by the unit's routing processes to limit access to the network based on IP addresses. For an access list to take effect, it must be called by a unit routing process (for example, a process that supports RIP or OSPF). The offset list is part of the RIP and OSPF routing protocols. Access lists are configured only in the CLI.

For more information about access lists, see (for RIP) "Access Lists" on page 1719 or (for OSPF) "Access Lists" on page 1793.

Monitor

The Monitor menu provides a way to view the activity of configured routes. The Routing Monitor page allows you to view specific information as well as all routes. The list displays the entries in the FortiGate routing table.

This topic includes the following:

Viewing routing information

By default, all routes are displayed in the Routing Monitor list. The default static route is defined as 0.0.0.0/0, which matches the destination IP address of “any/all” packets.

View the list in *Router* > *Monitor* > *Routing Monitor*.

Routing Monitor page	
Lists all routes that are being monitored, including the default static route. On this page, you can also filter the information that is displayed on the page by applying a filter.	
IP version	Select IPv4 or IPv6 routes. Fields displayed vary depending on which IP version is selected. Displays only if IPv6 display is enabled on the web-based manager.
Type	Select one of the following route types to search the routing table and display routes of the selected type only: • *All* – all routes recorded in the routing table. • *Connected* – all routes associated with direct connections to FortiGate interfaces. • *Static* – the static routes that have been added to the routing table manually. • *RIP* – all routes learned through RIP. • *OSPF* – all routes learned through OSPF. • *BGP* – all routes learned through BGP. • *ISIS* – all routes learned through ISIS. • *HA* – RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you are viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster. Not displayed when IP version IPv6 is selected. For more information about HA routing synchronization, see the HA chapter.
Network	Enter an IP address and netmask (for example, `172.16.14.0/24`) to search the routing table and display routes that match the specified network. Not displayed when IP version IPv6 is selected.

Gateway	Enter an IP address and netmask (for example, `192.168.12.1/32`) to search the routing table and display routes that match the specified gateway. Not displayed when IP version IPv6 is selected.
Apply Filter	Select to search the entries in the routing table based on the specified search criteria and display any matching routes. Not displayed when IP version IPv6 is selected.
Type	The type values assigned to FortiGate routes (Static, Connected, RIP, OSPF, or BGP). Not displayed when IP version IPv6 is selected.
Subtype	If applicable, the subtype classification assigned to OSPF routes. • An empty string implies an intra-area route. The destination is in an area to which the unit is connected. • *OSPF inter area* — the destination is in the OSPF AS, but the unit is not connected to that area. • *External 1* — the destination is outside the OSPF AS. The metric of a redistributed route is calculated by adding the external cost and the OSPF cost together. • *External 2* — the destination is outside the OSPF AS. In this case, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. • *OSPF NSSA 1* — same as External 1, but the route was received through a not-so-stubby area (NSSA). • *OSPF NSSA 2* — same as External 2, but the route was received through a not-so-stubby area. Not displayed when IP version IPv6 is selected.
Network	The IP addresses and network masks of destination networks that the unit can reach.
Distance	The administrative distance associated with the route. A value of 0 means the route is preferable compared to routes to the same destination. To modify the administrative distance assigned to static routes, see "Adding a static route to the routing table" on page 1845.
Metric	The metric associated with the route type. The metric of a route influences how the unit dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to. • *Hop count* — routes learned through RIP. • *Relative cost* — routes learned through OSPF. • *Multi-Exit Discriminator (MED)* — routes learned through BGP. However, several attributes in addition to MED determine the best path to a destination network.
Gateway	The IP addresses of gateways to the destination networks.

Interface	The interface through which packets are forwarded to the gateway of the destination network.
Up Time (d h:m:s)	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable. This column does not display when IPv6 is selected.

Searching the routing monitor table

You can apply a filter to search the routing table and display certain routes only. For example, you can display one or more static routes, connected routes, routes learned through RIP, OSPF, or BGP, and routes associated with the network or gateway that you specify.

If you want to search the routing table by route type and further limit the display according to network or gateway, all of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed (an implicit AND condition is applied to all of the search parameters you specify).

For example, if the unit is connected to network 172.16.14.0/24 and you want to display all directly connected routes to network 172.16.14.0/24, you must select Connected from the Type list, type `172.16.14.0/24` in the Network field, and then select *Apply Filter* to display the associated routing table entry or entries. Any entry that contains the word “Connected” in its Type field and the specified value in the Gateway field will be displayed.

All of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed.

Chapter 11 Virtual Domains

This FortiOS Handbook chapter contains the following sections:

Virtual Domains provides an overview of the VDOM technologies, and the basic concepts and rules for using them. We recommend that you begin with this chapter before attempting to configuring VDOMs on your FortiGate unit.

Virtual Domains in NAT/Route mode provides detailed explanations and examples for configuring VDOM features in your FortiGate unit using the NAT/Route mode.

Virtual Domains in Transparent mode provides detailed explanations, as well as basic and advanced examples for configuring these features in your FortiGate unit using Transparent mode.

Inter-VDOM routing describes inter-VDOM routing concepts and scenarios, and gives examples that illustrate them.

Troubleshooting Virtual Domains provides diagnostic and troubleshooting information for some potential VDOM issues.

Virtual Domains

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. VDOMs can provide separate firewall policies and, in NAT/Route mode, completely separate configurations for routing and VPN services for each connected network or organization.

This chapter will cover the basics of VDOMs, how they change your FortiGate unit, and how to work with VDOMs.

VDOMs let you split your physical FortiGate unit into multiple virtual units. The resulting benefits range from limiting Transparent mode ports to simplified administration, and reduced space and power requirements.

When VDOMs are disabled on any FortiGate unit, there is still one VDOM active: the root VDOM. It is always there in the background. When VDOMs are disabled, the root VDOM is not visible but it is still there.

The root VDOM must be there because the FortiGate unit needs a management VDOM for management traffic among other things. It is also why when you enable VDOMs, all your configuration is preserved in the root VDOM-because that is where you originally configured it.

This section includes:

Benefits of Virtual Domains

VDOMs provide the following benefits:

Improving Transparent mode configuration

When VDOMs are not enabled, and you put your FortiGate unit into Transparent mode all the interfaces on your unit become broadcast interfaces. The problem is there are no interfaces free to do anything else.

With multiple VDOMs you can have one of them configured in Transparent mode, and the rest in NAT/Route mode. In this configuration, you have an available transparent mode FortiGate unit you can drop into your network for troubleshooting, and you also have the standard.

Easier administration

VDOMs provide separate security domains that allow separate zones, user authentication, firewall policies, routing, and VPN configurations. VDOMs separate security domains and simplify administration of complex configurations—you do not have to manage as many settings at one time. For more information, see "Global and per-VDOM settings" on page 1881.

By default, each FortiGate unit has a VDOM named root. This VDOM includes all of the unit's physical interfaces, modem, VLAN subinterfaces, zones, firewall policies, routing settings, and VPN settings.

Also, you can optionally assign an administrator account restricted to one VDOM. If the VDOM is created to serve an organization, this feature enables the organization to manage its own configuration. For more information, see "Administrators in Virtual Domains" on page 1898.

Each physical FortiGate unit requires a FortiGuard license to access security updates. VDOMs do not require any additional FortiGuard licenses, or updating — all the security updates for all the VDOMs are performed once per update at the global level. Combined this can be a potentially large money and time saving feature in your network.

Management systems such as SNMP, logging, alert email, FDN-based updates, and NTP-based time setting use addresses and routing in the management VDOM to communicate with the network. They can connect only to network resources that communicate with the management VDOM. Using a separate VDOM for management traffic enables easier management of the FortiGate unit global settings, and VDOM administrators can also manage their VDOMs more easily. For more information, see "Changing the management virtual domain" on page 1903.

Continued security

When a packet enters a VDOM, it is confined to that VDOM and is subject to any firewall policies for connections between VLAN subinterfaces or zones in that VDOM, just like those interfaces on a FortiGate unit without VDOMs enabled.

To travel between VDOMs, a packet must first pass through a firewall policy on a physical interface. The packet then arrives at another VDOM on that same FortiGate unit, but on a different interface, where it must pass through another firewall before entering. It doesn't matter if the interface is physical or virtual — inter-VDOM packets still require the same security measures as when passing through physical interfaces.

VDOMs provide an additional level of security because regular administrator accounts are specific to one VDOM — an administrator restricted to one VDOM cannot change information on other VDOMs. Any configuration changes and potential errors will apply only to that VDOM and limit any potential down time. Using this concept, you can farther split settings so that the management domain is only accessible by the super_admin and does not share any settings with the other VDOMs.

Savings in physical space and power

To increase the number of physical FortiGate units, you need more rack space, cables, and power to install the new units. You also need to change your network configuration to accommodate the new physical units. In the future, if you need fewer physical units you are left with expensive hardware that is idle.

Increasing VDOMs involves no additional hardware, no additional cabling, and very few changes to existing networking configurations. VDOMs save physical space and power. You are limited only by the size of the VDOM license you buy and the physical resources on the FortiGate unit.

For example if you are using one FortiGate 620B with 10 VDOMs instead of 10 of those units, over a year you will save an estimated 18,000 kWh. You could potentially save ten times that amount with a 100 VDOM license.

By default, FortiGate units support a maximum of 10 VDOMs in any combination of NAT/Route and Transparent modes. For FortiGate models numbered 3000 and higher, you can purchase a license key to increase the maximum number of VDOMs to 25, 50, 100, or 250. For more information on VDOM licences, see "Virtual Domain Licensing" on page 1892.

More flexible MSSP configurations

If you are a managed security and service provider (MSSP), VDOMs are fundamental to your business. As a service provider you have multiple customers, each with their own needs and service plans. VDOMs allow you to have a separate configuration for each customer, or group of customers; you can have up to 250 VDOMs configured on a FortiGate unit on high end models. See "Virtual Domain Licensing" on page 1892.

Not only does this provide the exact level of service needed by each customer, but administration of the FortiGate unit is easier as well - you can provide uninterrupted service generally with immediate changes as required. Most importantly, it allows you to only use the resources that each customer needs. Inter-VDOM links allow you to customize the level of interaction you need between each of your customers and your administrators. See "Inter-VDOM routing" on page 1941.

Enabling and accessing Virtual Domains

While Virtual Domains are essentially the same as your regular FortiGate unit for menu configuration, CLI command structure, and general task flow, there are some small differences.

After first enabling VDOMs on your FortiGate unit, you should take the time to familiarize yourself with the interface. This section will help walk you through virtual domains.

This section includes:

Enabling Virtual Domains

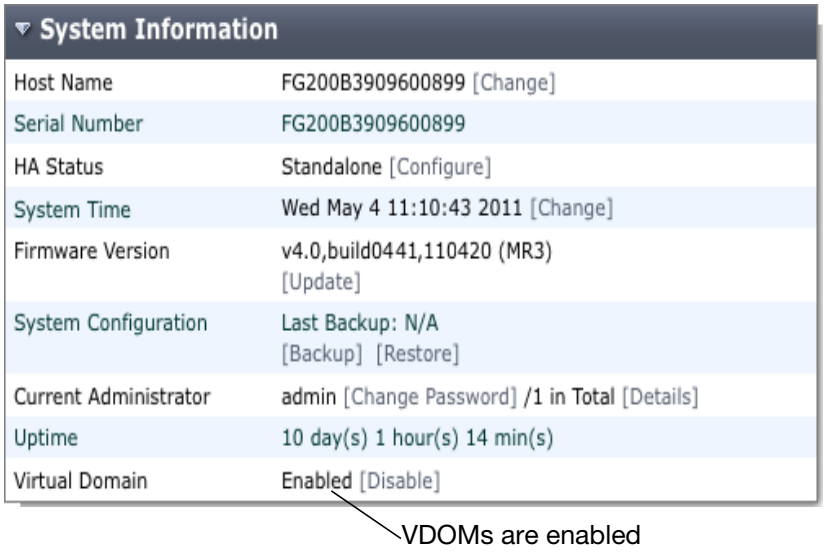
Using the default admin administration account, you can enable or disable VDOM operation on the FortiGate unit.

To enable VDOM configuration - web-based manager

1. Log in with a super_admin account.
2. Go to *System* > *Dashboard* > *Status*.
3. Under *System Information* > *Virtual Domain*, select *Enable* and confirm your selection.

The FortiGate unit logs off all sessions. You can now log in again as admin. For more information, see "Administrators in Virtual Domains" on page 1898.

Figure 177: System Information



To enable VDOM configuration - CLI

```
config system global
  set vdom-admin enable
end
```

Changes to the web-based manager and CLI

When Virtual Domains are enabled, your FortiGate unit will change. The changes will be visible in both the web-based manager and CLI, just the web-based manager, or just the CLI.

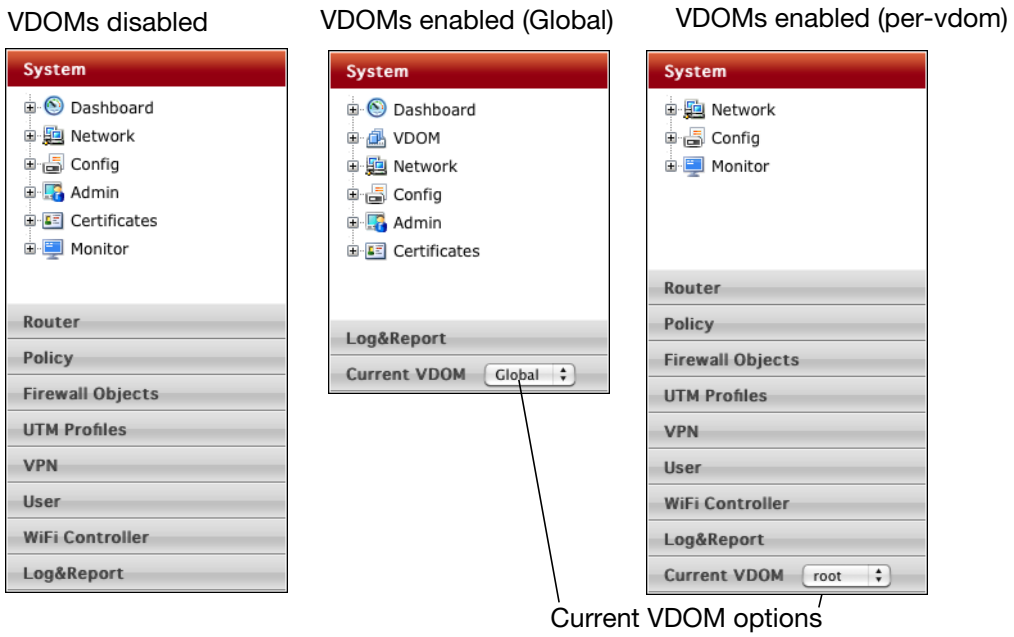
When enabling VDOMs, the web-based manager and the CLI are changed as follows:

- Global and per-VDOM configurations are separated. This is indicated in the Online Help by Global and VDOM icons. See “Global and per-VDOM settings” on page 1881.
- Only admin accounts using the super_admin profiles can view or configure global options. See “Administrators in Virtual Domains” on page 1898.
- Admin accounts using the super_admin profile can configure all VDOM configurations.
- All other administrator accounts can configure only the VDOM to which they are assigned.

The following changes are specific to the web-based manager:

- The *System* > *Dashboard* > *Status* view is different for VDOMs.
- In the Global view, the System menu includes a VDOM sub-menu.
- For admin accounts using the super_admin profile, a new control called Current VDOM is added at the bottom of the left menu. It indicates which VDOM you are in, and allows you to easily select either another VDOM or Global settings to configure. See Figure 178 on page 1879.

Figure 178: Menu with VDOMs disabled, at the global level, and VDOM level



In the CLI, admin accounts using the super_admin profile must specify either the global or a VDOM-specific shell before entering commands:

- To change FortiGate unit system settings, from the top level you must first enter

  ```
  config global
  ```

  before entering commands.
- To change VDOM settings, from the top level you must first enter

  ```
  config vdom
    edit <vdom_name>
  ```

  before entering your commands for that VDOM. For information on which commands are global and which are per-VDOM, see "Global and per-VDOM settings" on page 1881.

Changes to FortiGate unit settings

Settings configured outside of a VDOM are called global settings. These settings affect the entire FortiGate unit and include areas such as interfaces, HA, maintenance, some antivirus, and some logging. In general, any unit settings that should only be changed by the top level administrator are global settings.

Settings configured within a VDOM are called VDOM settings. These settings affect only that specific VDOM and include areas such as operating mode, routing, firewall, VPN, some antivirus, some logging, and reporting.

For more information, see "Global and per-VDOM settings" on page 1881.

Viewing the VDOM list

The VDOM list shows all virtual domains, their status, and which VDOM is the management VDOM. It is accessible if you are logged in on an administrator account with the super_admin profile such as the "admin" administrator account.

In the VDOM list you can create or delete VDOMs, edit VDOMs, change the management VDOM, and enable or disable VDOMs.

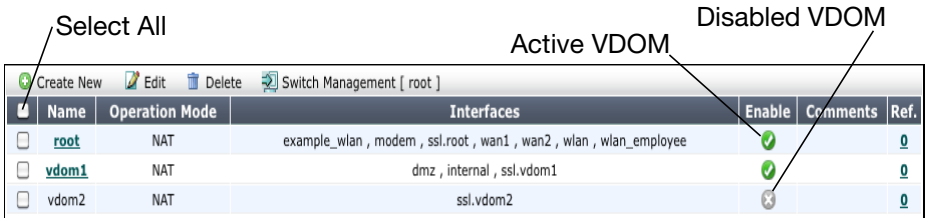
The root domain cannot be disabled, even if it is not the management VDOM.

To view the VDOM list

1 For *Current VDOM*, select *Global*.

2 Go to *System* > *VDOM* > *VDOM*.

Figure 179: List of VDOMs



Create New	Select to add a new VDOM. See “Creating a Virtual Domain” on page 1895.
Edit	Select to change an existing selected VDOM.
Delete	Select to delete the selected VDOM. See “Deleting a VDOM” on page 1897.
Switch Management	Select to switch the management VDOM. Also shows the current management VDOM. You must select an active non-management VDOM before this option becomes available. See “Changing the management virtual domain” on page 1903.
Selected	When checked, this checkbox indicates this VDOM has been selected. Nearly all operations such as Edit, Delete, and Switch Management require a VDOM to first be selected.
Name	The name of the VDOM. VDOMs are listed in alphabetical order. When the VDOM is active, you can select the VDOM name to enter that VDOM. See “Enabling and accessing Virtual Domains” on page 1877.
Operation Mode	Indicates the operation mode as either NAT (for NAT/Route mode) or TP (for Transparent mode).
Interfaces	The interfaces associated with this VDOM. Each VDOM also includes an interface that starts with “ssl.” that is created by default.
Enable	A green checkmark indicates this VDOM is active. See “Disabling a Virtual Domain” on page 1896. A grey X indicated this VDOM is disabled. See “Disabling a Virtual Domain” on page 1896.

Comments	Comments entered when the VDOM was created are displayed here.
Ref.	The number of references to this VDOM in the configuration.

Global and per-VDOM settings

Settings configured outside of a VDOM are called global settings. These settings affect the entire FortiGate unit and include areas such as interfaces, HA, maintenance, some antivirus, and some logging. In general, any unit settings that should only be changed by the top level administrator are global settings.

Settings configured within a VDOM are called VDOM settings. These settings affect only that specific VDOM and include areas such as operating mode, routing, firewall, VPN, some antivirus, some logging, and reporting.

When Virtual Domains are not enabled, the entire FortiGate unit is effectively a single VDOM. Per-VDOM limits apply. For some resource types, the global limit cannot be reached with only one VDOM.

Some FortiGate unit documentation indicates which parts of the web-based manager, or the CLI are global and which are per-VDOM using the icons shown below. These icons are also present in the Online Help, available on your FortiGate unit.

Figure 180: Global and VDOM icons

For more information on CLI commands, see the FortiGate CLI Reference.

This section includes:

- Global settings - web-based manager
- Per-VDOM settings - web-based manager
- Global settings - CLI
- Per-VDOM settings - CLI

Global settings - web-based manager

The following table lists commands in the web-based manager that are considered global settings when VDOMs are enabled.

The following configuration settings affect all virtual domains. When virtual domains are enabled, only accounts with the default super_admin profile can access global settings.

Table 109: Global configuration settings

System	Dashboard > Status - Host name
	Dashboard > Status - HA Status
	Dashboard > Status - System Time
	Dashboard > Status - Firmware version
	Dashboard > Status - Configuration backup and restore
	VDOM > VDOM - list
	VDOM > VDOM - edit VDOM (mode and resources)
	VDOM > Global Resources

Table 109: Global configuration settings (Continued)

	Network > Interfaces Network > DNS - DNS and DDNS settings Config > HA Config > SNMP Config > Replacement Message - messages and images Config > Firmware Config > FortiGuard - configuration Config > Advanced - scripts, USB Auto-install, debug log download Admin > Administrators Admin > Admin Profile Admin > Central Management - configuration Admin > Settings - web administration ports, password policy, display settings, timeouts, LCD panel Certificates - local, remote, and CA certificates, CRLs
Log&Report	Log Config - Log Setting and Alert E-mail

Per-VDOM settings - web-based manager

The following table lists commands in the web-based manager that are considered per-VDOM settings when VDOMs are enabled.

Table 110: VDOM configuration settings

System	Dashboard > Status - read-only except for administrator password Network > Interface (and zones) Network > DNS Server Network > DHCP Server Network > Explicit Proxy Network > Routing Table (Transparent mode only) Network > Modem Config > Replacement Message (messages and images) Config > Replacement Message Group Config > Tag Management Monitor > DHCP Monitor Monitor > Modem Monitor
Router	All settings, including dead gateway detection
Policy	All settings
Firewall Objects	All settings
UTM Profiles	All settings

Table 110: VDOM configuration settings (Continued)

VPN	All settings
User	All settings
WiFi Controller	All settings
Log&Report	Log & Archive Access for Events, UTM, Traffic Log & Archive Access - Vulnerability Scan Log Log Config > Log Setting Log Config > Alert E-mail
Monitor	Logging Monitor

Global settings - CLI

The following table lists commands in the web-based manager that are considered global settings when VDOMs are enabled.

From a super_admin profile account, use this command to configure features that apply to the complete FortiGate unit including all virtual domains. Virtual domain configuration (vdom-admin) must be enabled first.

This command syntax shows how you access the commands within config global. For information on these commands, refer to the relevant sections in this Reference. If there are multiple versions of the same command with a “2” or “3” added, the additional commands are not listed but fall under the unnumbered command of the same name.

```
config global
   config antivirus heuristic
   config antivirus quarfilepattern
   config antivirus service
   config application name
   config dlp settings

end
```

Per-VDOM settings - CLI

The following table lists commands in the web-based manager that are considered global settings when VDOMs are enabled.

From the super admin account, use this command to add and configure virtual domains. The number of virtual domains you can add is dependent on the FortiGate model. Virtual domain configuration (vdom-admin) must be enabled.

Once you add a virtual domain you can configure it by adding zones, firewall policies, routing settings, and VPN settings. You can also move physical interfaces from the root virtual domain to other virtual domains and move VLAN subinterfaces from one virtual domain to another.

By default all physical interfaces are in the root virtual domain. You cannot remove an interface from a virtual domain if the interface is part of any of the following configurations:

- routing
- proxy arp
- DHCP server
- zone
- firewall policy
- redundant pair
- link aggregate (802.3ad) group

Delete these objects, or modify them, to be able to remove the interface.

This command syntax shows how you access the commands within a VDOM. Refer to the relevant sections in this Reference for information on these commands.

```
config vdom
  edit <vdom_name>
    config antivirus profile
```

```
config antivirus quarantine
config antivirus settings
config application list
config application rule-settings

    execute ...
  end
end
```

For more information, see “Global and per-VDOM settings” on page 1881.

Resource settings

Your FortiGate unit has a limited amount of hardware resources such as memory, disk storage, CPU operations. When Virtual Domains are disabled, this limit is not a major concern because all sessions, users, and other processes share all the resources equally.

When using Virtual Domains, hardware resources can be divided differently between Virtual Domains as they are needed. Also minimum levels of resources can be set so that no Virtual Domain will suffer a complete lack of resources.

For example if one VDOM has only a web server and logging server connected, and a second VDOM has an internal network of 20 users these two VDOMs will require different levels of resources. The first VDOM will require many sessions but no user accounts. This compares to the second VDOM where user accounts and management resources are required, but fewer sessions.

Using the global and per-VDOM resource settings, you can customize the resources allocated to each VDOM to ensure the proper level of service is maintained on each VDOM.

This section includes:

- Global resource settings
- Per-VDOM resource settings

Global resource settings

Global Resources apply to the whole FortiGate unit. They represent all of the hardware capabilities of your unit. By default the values are set to their maximum values. These values vary by your model due to each model having differing hardware capabilities.

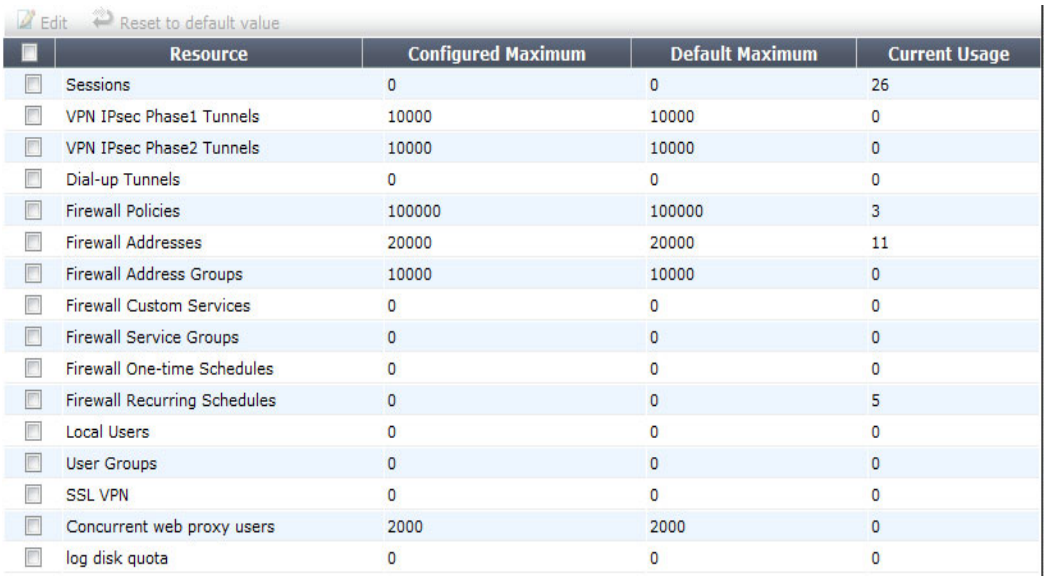
It can be useful to change the maximum values for some resources to ensure there is enough memory available for other resources that may be more important to your configuration.

To use the earlier example, if your FortiGate unit is protecting a number of web servers and other publicly accessible servers you would want to maximize the available sessions and proxies while minimizing other settings that are unused such as user settings, VPNs, and dial-up tunnels.

Global Resources are only configurable at the global level, and only the admin account has access to these settings.

Note that global resources, such as the log disk quote resource, will only be visible if your FortiGate unit hardware supports those resources, such as having a hard disk to support the log disk resource.

Figure 181: Global Resources- web-based manager



Resource	Configured Maximum	Default Maximum	Current Usage
Sessions	0	0	26
VPN IPsec Phase1 Tunnels	10000	10000	0
VPN IPsec Phase2 Tunnels	10000	10000	0
Dial-up Tunnels	0	0	0
Firewall Policies	100000	100000	3
Firewall Addresses	20000	20000	11
Firewall Address Groups	10000	10000	0
Firewall Custom Services	0	0	0
Firewall Service Groups	0	0	0
Firewall One-time Schedules	0	0	0
Firewall Recurring Schedules	0	0	5
Local Users	0	0	0
User Groups	0	0	0
SSL VPN	0	0	0
Concurrent web proxy users	2000	2000	0
log disk quota	0	0	0

To view global resource settings - web-based manager

1 For *Current VDOM*, select *Global*.

2 Select *System* > *VDOM* > *Global Resources*.

The following information is displayed:

Edit	Select to edit the *Configured Maximum* value for a single selected *Resource*. If multiple *Resources* are selected, *Edit* is not available.
Reset to default value	Select to return one or more selected *Resources* to factory default settings.
Checkbox	Select a *Resource* for editing or resetting to default values.
Resource	The name of the available global resources.
Configured Maximum	The currently configured maximum for this resource. This value can be changed by selecting the *Resource* and editing it.
Default Maximum	The factory configured maximum value for this resource. You cannot set the *Configured Maximum* higher than the *Default Maximum*.
Current Usage	The amount of this resource that is currently being used. This value is useful for determining when and if you may need to adjust *Configured Maximum* values for some resources on your FortiGate unit.

To view global resource settings - CLI

```
config global
  config system resource-limits
  get
```

When viewing the global resource limits in the CLI, the output appears similar to:

```
FGT1000A (global) # config system resource-limits
FGT1000A (resource-limits) # get

session             : 0
ipsec-phase1        : 10000
ipsec-phase2        : 10000
dialup-tunnel       : 0
firewall-policy     : 100000
firewall-address    : 20000
firewall-addrgrp    : 10000
custom-service      : 0
service-group       : 0
onetime-schedule    : 0
recurring-schedule  : 0
user                : 0
user-group          : 0
sslvpn              : 0
webproxy            : 2000
```

For explicit proxies when configuring limits on the number of concurrent users, you need to allow for the number of users based on their authentication method. Otherwise you may run out of user resources prematurely.

- Each session-based authenticated user is counted as a single user using their authentication membership (RADIUS, LDAP, FSAE, local database etc.) to match users in other sessions. So one authenticated user in multiple sessions is still one user.
- For all other situations, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.

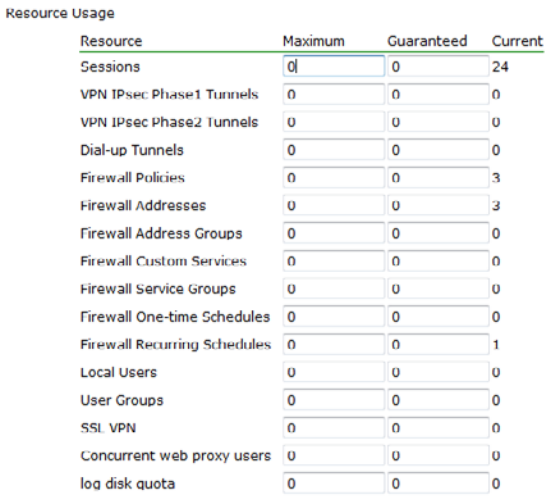
Per-VDOM resource settings

Global resources apply to resources shared by the whole FortiGate unit. Per-VDOM resources are specific to only one Virtual Domain.

By default all the per-VDOM resource settings are set to no limits. This means that any single VDOM can use up all the resources of the entire FortiGate unit if it needs to do so. This would starve the other VDOMs for resources to the point where they would be unable to function. For this reason, it is recommended that you set some maximums on resources that are most vital to your customers.

Each Virtual Domain has its own resource settings. These settings include both maximum, and minimum levels. The maximum level is the highest amount of that resource that this VDOM can use if it is available on the FortiGate unit. Minimum levels are a guaranteed level that this minimum level of the resource will always be available no matter what the other VDOMs may be using.

Figure 182: per-VDOM resources - web-based manager



For example your FortiGate unit has ten VDOMs configure. vdom1 has a maximum of 5000 sessions and a minimum of 1000 sessions. If the FortiGate unit has a global maximum of 20,000 sessions, it is possible that vdom1 will not be able to reach its 5000 session upper limit. However, at all times vdom1 is guaranteed to have 1000 sessions available that it can use. On the other hand, if the remaining nine VDOMs use only 1000 sessions each, vdom1 will be able to reach its maximum of 5000.

To view per-VDOM resource settings - web-based manager

1 For *Current VDOM*, select *Global*.

2 Select *System* > *VDOM* > *VDOM*.

3 Select the `root` VDOM, and select *Edit*. Adjust the settings in the *Resource Usage* section of the page.

Resource	Name of the resource. Includes dynamic and static resources.
Maximum	Override the global limit to reduce the amount of each resource available for this VDOM. The maximum must the same as or lower than the global limit. The default value is 0, which means the maximum is the same as the global limit. **Note:** If you set the maximum resource usage for a VDOM you cannot reduce the default maximum global limit for all VDOMs below this maximum.
Guaranteed	Enter the minimum amount of the resource available to this VDOM regardless of usage by other VDOMs. The default value is 0, which means that an amount of this resource is not guaranteed for this VDOM.
Current	The amount of the resource that this VDOM currently uses.

4 Select *OK*.

To view per-VDOM resource settings - CLI

```
config global
  config system vdom-property
    edit root
  get
```

When viewing the per-VDOM resource limits in the CLI, the output appears similar to the following. Note that the first two lines are not part of the resource limits. In the CLI, the first number is the maximum value, and the second number is the guaranteed minimum.

```
FGT1KA3607500810 (vdom-property) # edit root
FGT1KA3607500810 (root) # get

name                 : root
description          : property limits for vdom root
session              : 0 0
ipsec-phase1         : 0 0
ipsec-phase2         : 0 0
dialup-tunnel        : 0 0
firewall-policy      : 0 0
firewall-address     : 0 0
firewall-addrgrp     : 0 0
custom-service       : 0 0
service-group        : 0 0
onetime-schedule     : 0 0
recurring-schedule   : 0 0
user                 : 0 0
user-group           : 0 0
sslvpn               : 0 0
webproxy             : 0 0
```

Virtual Domain Licensing

All FortiGate models except the FortiGate-30B and FortiWiFi-30B models support VDOMs. By default 10 VDOMs are available.

For FortiGate models numbered 1240 and higher, you can purchase a license key to increase the maximum number of VDOMs. Model 1240B supports up to 25 VDOMs. Most Enterprise and Large Enterprise models can support 250 VDOMs. Chassis-based models can support up to 3000 VDOMs. For specific information, see the product data sheet.

Configuring 250 or more VDOMs will result in reduced system performance. See “FortiGate unit running very slowly” on page 1977.

Your FortiGate unit has limited resources that are divided among all configured VDOMs. These resources include system memory and CPU. You cannot run Unified Threat Management (UTM) features when running 250 or more VDOMs. UTM features include proxies, web filtering, and antivirus—your FortiGate unit can provide only basic firewall functionality.

It is important to backup your configuration before upgrading the VDOM license on your FortiGate unit or units, especially with FortiGate units in HA mode.

To obtain a VDOM license key

1 Log in with a super_admin account.

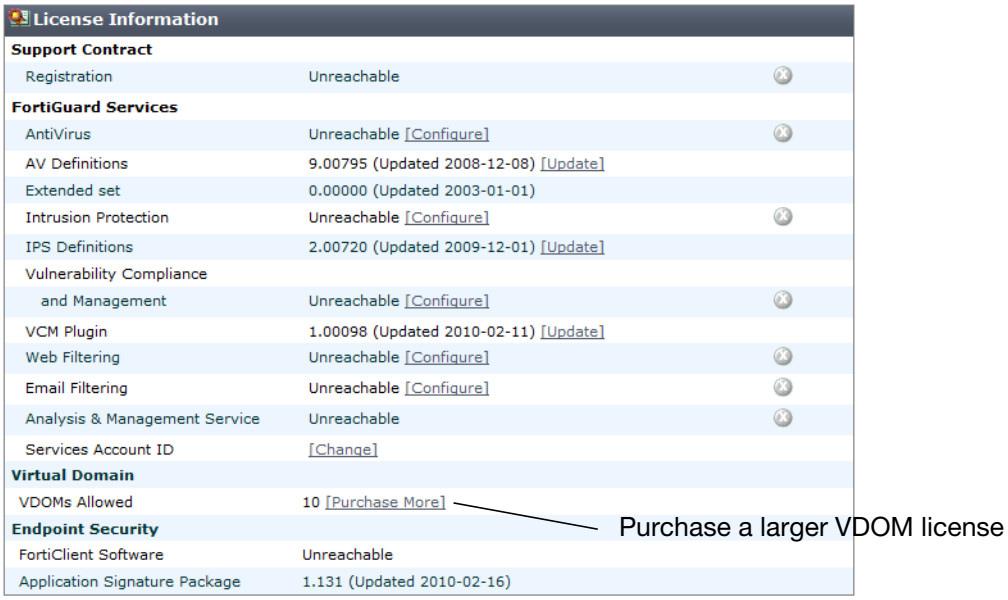
2 Go to *System* > *Dashboard* > *Status*.

3 Record your FortiGate unit serial number as shown in "System Information" on page 1878.

4 Under *License Information* > *Virtual Domain*, select *Purchase More*.

If you do not see the *Purchase More* option on the System Dashboard, your FortiGate model does not support more than 10 VDOMs.

Figure 183: VDOM License Information



5 You will be taken to the Fortinet customer support web site where you can log in and purchase a license key for 25, 50, 100, 250, or 500 VDOMs.

6 When you receive your license key, go to the Dashboard and select *Upload License* under *License Information*, *Virtual Domains*.

7 In the *Input License Key* field, enter the 32-character license key you received from Fortinet customer support.

8 Select *Apply*.

To verify the new VDOM license, in global configuration go to *System* > *Dashboard*. Under *License Information*, *Virtual Domains* the maximum number of VDOMs allowed is shown.

VDOMs created on a registered FortiGate unit are recognized as real devices by any connected FortiAnalyzer unit. The FortiAnalyzer unit includes VDOMs in its total number of registered devices. For example, if three FortiGate units are registered on the FortiAnalyzer unit and they contain a total of four VDOMs, the total number of registered FortiGate units on the FortiAnalyzer unit is seven. For more information, see the FortiAnalyzer Administration Guide.

Logging in to VDOMs

Only super_admin administrator accounts can access all global settings on the FortiGate unit and all of the VDOMs as well. Other administrator accounts can access and configure only their single VDOM and they must connect to an interface that is part of that VDOM. For example, administratorB is the admin for vdomB. If he tries to log into vdomA, or an interface that is part of vdomA he will not be able to log on. For more information on administrators in VDOMs, see "Administrators in Virtual Domains" on page 1898.

Management services communicate using the management VDOM, which is the root VDOM by default. For more information, see "Changing the management virtual domain" on page 1903.

Management traffic requires an interface that has access to the Internet. If there is no interface assigned to the VDOM containing the management traffic, services including updates will not function. For more information, see "Changing the management virtual domain" on page 1903.

To access a VDOM with a super_admin account - web-based manager

1 Log in with a super_admin account.

2 In *Current VDOM*, select the VDOM to configure.

The system network page for that VDOM opens.

3 When you have finished configuring the VDOM, you can

- in *Current VDOM,* select *Global* to return to global configuration
- log out.

To access a VDOM with a super_admin account - CLI

With the super_admin, logging into the CLI involves also logging into the specific VDOM. If you need a reminder, use `edit ?` to see a list of existing VDOMs before you editing a VDOM.

If you misspell a VDOM you are trying to switch to, you will create a new VDOM by that name. Any changes you make will be part of the new VDOM, and not the intended VDOM. If you are having problems where your changes aren't visible, back up to the top level and use `edit ?` to see a list of VDOMs to ensure this has not happened. If it has happened, see "Deleting a VDOM" on page 1897.

```
config vdom
  edit ?
  edit <chosen_vdom>
    ..
    <enter vdom related commands>
    ..
  end
exit
```

To access a VDOM with a non super_admin account - web-based manager

1 Connect to the FortiGate unit using an interface that belongs to the VDOM to be configured.

2 Log in using an administrator account that has access to the VDOM.

The main web-based manager page opens. From here you can access VDOM-specific settings.

To access a VDOM with a non-super_admin account - CLI

A non-super_admin account has access to only one VDOM and must log in through an interface that belongs to the same VDOM.

```
Login: regular_admin
Password: <password>
..
<enter vdom related commands>
..
exit
```

Configuring Virtual Domains

Only a super_admin administrator account such as the default “admin” account can create, disable, or delete VDOMs. That account can create additional administrators for each VDOM.

This section includes:

- Creating a Virtual Domain
- Disabling a Virtual Domain
- Deleting a VDOM
- Administrators in Virtual Domains

Creating a Virtual Domain

Once you have enabled Virtual Domains on your FortiGate unit, you can create additional Virtual Domains beyond the default root Virtual Domain.

By default new Virtual Domains are set to NAT/Route operation mode. If you want a Virtual Domain to be in Transparent operation mode, you must manually change it. See “Virtual Domains in Transparent mode” on page 1921.

You can name new Virtual Domains as you like with the following restrictions:

- only letters, numbers, “-”, and “_” are allowed
- no more than 11 characters are allowed
- no spaces are allowed
- VDOMs cannot have the same names as interfaces, zones, switch interfaces, or other VDOMs.

When creating large numbers of VDOMs (up to 250), you cannot enable advanced features such as proxies, web filtering, and antivirus due to limited FortiGate unit resources. Also when creating large numbers of VDOMs, you may experience reduced performance for the same reason.

To create a VDOM - web-based manager

1 Log in with a super_admin account.

2 Go to *System* > *Dashboard* > *Status* and ensure that Virtual Domains are enabled. If not, see “Enabling and accessing Virtual Domains” on page 1877.

3 Select *System* > *VDOM* > *VDOM*.
4 Select *Create New*.
5 Enter a unique name for your new VDOM.
6 Enter a short and descriptive comment to identify this VDOM.
7 Select *OK*.

Repeat Steps 4 through 7 to add additional VDOMs.

To create a VDOM - CLI

```
config vdom
  edit <new_vdom_name>
end
```

If you want to edit an existing Virtual Domain in the CLI, and mistype the name a new Virtual Domain will be created with this new misspelled name. If you notice expected configuration changes are not visible, this may be the reason. You should periodically check your VDOM list to ensure there are none of these misspelled VDOMs present.

Disabling a Virtual Domain

The status of a VDOM can be Enabled, or Disabled.

Active status VDOMs can be configured. Active is the default status when a VDOM is created. The management VDOM must be an Active VDOM. For more information on the management VDOM, see “Changing the management virtual domain” on page 1903.

Disabled status VDOMs are considered “offline”. The configuration remains, but you cannot use the VDOM, and only the super_admin administrator can view it. You cannot delete a disabled VDOM without first enabling it, and removing references to it like usual—there is no *Delete* icon for disabled status VDOMs. You can assign interfaces to a disabled VDOM. See “Deleting a VDOM” on page 1897.

The following procedures show how to disable a VDOM called “test-vdom”.

To disable a VDOM - web-based manager

1 In *Current VDOM*, select Global.
2 Go to *System* > *VDOM* > *VDOM*.
3 Open the VDOM for editing.
4 Ensure *Enable* is not selected and then select *OK*.

The VDOM’s Enable icon in the VDOM list is a grey X.

To disable a VDOM - CLI

```
config vdom
  edit test-vdom
    config system settings
      set status disable
    end
end
```

To enable a VDOM - web-based manager

1 For Current VDOM, select Global.
2 Go to *System* > *VDOM* > *VDOM*.
3 Open the VDOM for editing.

4 Ensure *Enable* is selected and then select *OK*.

The VDOM's Enable icon in the VDOM list is a green checkmark.

To enable a VDOM - CLI

```
config vdom
  edit test-vdom
    config system settings
      set status enable
    end
end
```

Deleting a VDOM

Deleting a VDOM removes it from the FortiGate unit configuration.

Before you can delete a VDOM, all references to it must be removed. This includes any objects listed in "Per-VDOM settings - web-based manager" on page 1882. If there are any references to the VDOM remaining, you will see an error message and not be able to delete the VDOM.

The VDOM must also be enabled. A disabled VDOM cannot be deleted. You cannot delete the root VDOM or the management VDOM.

Before deleting a VDOM, a good practice is to reset any interface referencing that VDOM to its default configuration, with "root" selected as the Virtual Domain.

The following procedures show how to delete the `test-vdom` VDOM.

To delete a VDOM - web-based manager

1 For *Current VDOM*, select Global.

2 Go to *System* > *VDOM* > *VDOM*.

3 Select the check box for the VDOM and then select the *Delete* icon.

If the *Delete* icon is not active, there are still references to the VDOM that must first be removed. The *Delete* icon is available when all the references to this VDOM are removed.

4 Confirm the deletion.

To delete a VDOM - CLI

```
config vdom
  delete test-vdom
end
```

Removing references to a VDOM

When you are doing to delete a VDOM, all references to that VDOM must first be removed. It can be difficult to find all the references to the VDOM. This section provides a list of common objects that must be removed before a VDOM can be deleted, and a CLI command to help list the dependencies.

Interfaces are an important part of VDOMs. If you can move all the interfaces out of a VDOM, generally you will be able to delete that VDOM.

Common objects that refer to VDOMs

When you are getting ready to delete a VDOM check for, and remove the following objects that refer to that VDOM or its components:

- Routing - both static and dynamic routes
- Firewall addresses, policies, groups, or other settings
- UTM
- VPN configuration
- Users or user groups
- Logging
- DHCP servers
- Network interfaces, zones, custom DNS servers
- VDOM Administrators

Administrators in Virtual Domains

When Virtual Domains are enabled, permissions change for administrators. Administrators are now divided into per-VDOM administrators, and `super_admin` administrators. Only `super_admin` administrator accounts can create other administrator accounts and assign them to a VDOM.

This section includes:

- Administrator VDOM permissions
- Creating administrators for Virtual Domains
- Virtual Domain administrator dashboard display

Administrator VDOM permissions

Different types of administrator accounts have different permissions within VDOMs. For example, if your are using a super_admin profile account, you can perform all tasks. However, if you are using a regular admin account, the tasks available to you depend on whether you have read only or read/write permissions. The following table shows what tasks can performed by which administrators.

Table 111: Administrator VDOM permissions

Tasks	Regular administrator account		Super_admin profile administrator account
	Read only permission	Read/write permission	
View global settings	yes	yes	yes
Configure global settings	no	no	yes
Create or delete VDOMs	no	no	yes
Configure multiple VDOMs	no	no	yes
Assign interfaces to a VDOM	no	no	yes
Revision Control Backup and Restore	no	no	yes

Table 111: Administrator VDOM permissions

Create VLANs	no	yes - for 1 VDOM	yes - for all VDOMs
Assign an administrator to a VDOM	no	no	yes
Create additional admin accounts	no	yes - for 1 VDOM	yes - for all VDOMs
Create and edit protection profiles	no	yes - for 1 VDOM	yes - for all VDOMs

The only difference in admin accounts when VDOMs are enabled is selecting which VDOM the admin account belongs to. Otherwise, by default the administration accounts are the same as when VDOMs are disabled and closely resemble the `super_admin` account in their privileges.

Creating administrators for Virtual Domains

Using the admin administrator account, you can create additional administrator accounts and assign them to VDOMs.

The newly-created administrator can access the FortiGate unit only through network interfaces that belong to their assigned VDOM or through the console interface. The network interface must be configured to allow management access, such as HTTPS and SSH. Without these in place, the new administrator will not be able to access the FortiGate unit and will have to contact the super_admin administrator for access.

The following procedure creates a new Local administrator account called `admin_sales` with a password of `fortinet` in the `sales` VDOM using the `admin_prof` default profile.

To create an administrator for a VDOM - web-based manager

1. Log in with a super_admin account.
2. Go to *System* > *Admin* > *Administrators*.
3. Select *Create New*.
4. Select *Regular* for Type, as you are creating a Local administrator account.
5. If this admin will be accessing the VDOM from a particular IP address or subnet, enter it in *Trusted Host #1*. See "Using trusted hosts" on page 1900.
6. Select `prof_admin` for the *Admin Profile*.
7. Select `sales` from the list of *Virtual Domains*.
8. Select *OK*.

To create administrators for VDOMs - CLI

```
config global
  config system admin
    edit <new_admin_name>
      set vdom <vdom_for_this_account>
      set password <pwd>
      set accprofile <an_admin_profile>
      ...
    end
```

Using trusted hosts

Setting trusted hosts for all of your administrators increases the security of your network by further restricting administrative access. In addition to knowing the password, an administrator must connect only through the subnet or subnets you specify. You can even restrict an administrator to a single IP address if you define only one trusted host IP address with a netmask of 255.255.255.255.

When you set trusted hosts for all administrators, the FortiGate unit does not respond to administrative access attempts from any other hosts. This provides the highest security. If you leave even one administrator unrestricted, the unit accepts administrative access attempts on any interface that has administrative access enabled, potentially exposing the unit to attempts to gain unauthorized access.

The trusted hosts you define apply both to the web-based manager and to the CLI when accessed through Telnet or SSH. CLI access through the console is not affected.

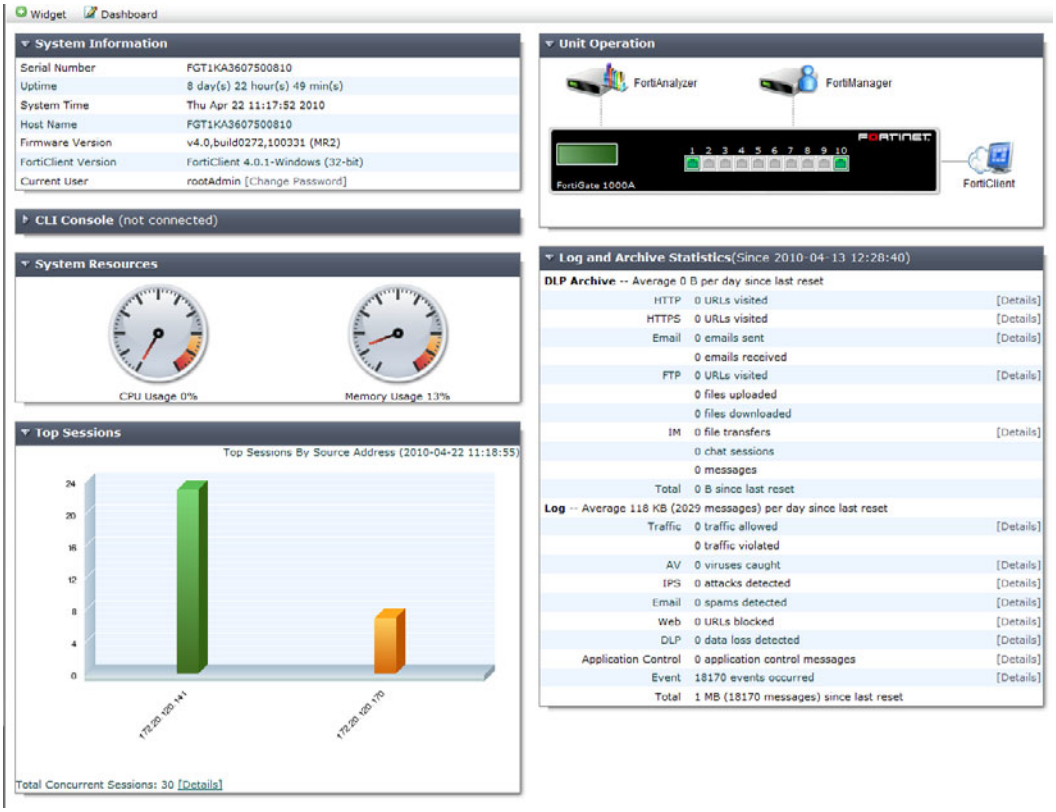
The trusted host addresses all default to 0.0.0.0/0.0.0.0 for IPv4, or ::/0 for IPv6. If you set one of the zero addresses to a non-zero address, the other zero addresses will be ignored. The only way to use a wildcard entry is to leave the trusted hosts at 0.0.0.0/0.0.0.0 or ::0. However, this configuration is less secure.

Virtual Domain administrator dashboard display

When administrators logs into their virtual domain, they see a different dashboard than the global administrator will see. The VDOM dashboard displays information only relevant to that VDOM — no global or other VDOM information is displayed.

Information	per-VDOM	Global
System Information	read-only	yes
License Information	no	yes
CLI console	yes	yes
Unit Operation	read-only	yes
Alert Message Console	no	yes
Top Sessions	limited to VDOM sessions	yes
Traffic	limited to VDOM interfaces	yes
Statistics	yes	yes

Figure 184: VDOM administrator dashboard



Virtual Domains in NAT/Route mode

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that each function as independent units. Each virtual domain has separate routing and security policies. A single FortiGate unit with virtual domains is flexible enough to serve multiple departments of an organization, separate organizations, or be the basis for a service provider's managed security service.

The examples in this chapter are intended to be followed in order as procedures build on previous procedures. If you do not complete the previous procedures, the procedure you are working on may not work properly. If this happens, consult previous procedures or FortiGate documentation.

This chapter contains the following sections:

Virtual domains in NAT/Route mode

Once you have enabled virtual domains and created one or more VDOMs, you need to configure them. Configuring VDOMs on your FortiGate unit includes tasks such as the ones listed here; while you may not require all for your network topology, it is recommended that you perform them in the order given:

Changing the management virtual domain

The management virtual domain is the virtual domain where all the management traffic for the FortiGate unit originates. This management traffic needs access to remote servers, such as FortiGuard services and NTP, to perform its duties. It needs access to the Internet to send and receive this traffic.

Management traffic includes, but is not limited to:

- DNS lookups
- logging to FortiAnalyzer or syslog
- FortiGuard service
- sending alert emails
- Network time protocol traffic (NTP)
- Sending SNMP traps
- Quarantining suspicious files and email.

By default the management VDOM is the root domain. When other VDOMs are configured on your FortiGate unit, management traffic can be moved to one of these other VDOMs.

Reasons to move the management VDOM include selecting a non-root VDOM to be your administration VDOM, or the root VDOM not having an interface with a connection to the Internet.

You cannot change the management VDOM if any administrators are using RADIUS authentication.

The following procedure will change the management VDOM from the default `root` to a VDOM named `mgmt_vdom`. It is assumed that `mgmt_vdom` has already been created and has an interface that can access the Internet.

To change the management VDOM - web-based manager

1 In *Current VDOM*, select Global.
2 Select *System* > *VDOM* > *VDOM.*
3 Select the checkbox next to the required VDOM.
4 Select *Switch Management*

The current management VDOM is shown in square brackets, “[root]” for example.

To change the management VDOM - CLI

```
config global
  config system global
    set management-vdom mgmt_vdom
  end
```

Management traffic will now originate from `mgmt_vdom`.

Configuring interfaces in a NAT/Route VDOM

A VDOM must contain at least two interfaces to be useful. These can be physical interfaces or VLAN interfaces. By default, all physical interfaces are in the root VDOM. When you create a new VLAN, it is in the root VDOM by default.

When there are VDOMs on the FortiGate unit in both NAT and Transparent operation modes, some interface fields will be displayed as “-” on *System* > *Network* > *Interface*. Only someone with a super_admin account can view all the VDOMs.

When moving an interface to a different VDOM, firewall IP pools and virtual IPs for this interface are deleted. You should manually delete any routes that refer to this interface. Once the interface has been moved to the new VDOM, you can add these services to the interface again.

When configuring VDOMs on FortiGate units with accelerated interfaces, such as NP2 or NP4 interfaces, you must assign both interfaces in the pair to the same VDOM for those interfaces to retain their acceleration. Otherwise they will become normal interfaces.

This section includes the following topics:

Adding a VLAN to a NAT/Route VDOM

The following example shows one way that multiple companies can maintain their security when they are using one FortiGate unit with VLANs that share interfaces on the unit.

This procedure will add a VLAN interface called `client1-v100` with a VLAN ID of 100 to an existing VDOM called `client1` using the physical interface called `port2`.

The physical interface does not need to belong to the VDOM that the VLAN belongs to.

To add a VLAN subinterface to a VDOM - web-based manager

1 In *Current VDOM*, select Global.

2 Go to *System* > *Network* > *Interface*.

3 Select *Create New*.

4 Enter the following information and select *OK*:

Name	client1-v100
Interface	port2
VLAN ID	100
Virtual Domain	Client1
Addressing mode	Manual
IP/Netmask	172.20.120.110/255.255.255.0
Administrative Access	HTTPS, SSH

You will see an expand arrow added to the port2 interface. When the arrow is expanded, the interface shows the `client1-v100` VLAN subinterface.

To add a VLAN subinterface to a VDOM - CLI

```
config global
  config system interface
    edit client1-v100
      set type vlan
      set vlanid 100
      set vdom Client1
      set interface port2
      set ip 172.20.120.110 255.255.255.0
      set allowaccess https ssh
    end
```

Moving an interface to a VDOM

Interfaces belong to the root VDOM by default. Moving an interface is the same procedure no matter if its moving from the root VDOM or a any other VDOM.

If you have an accelerated pair of physical interfaces, such as NP2 interfaces, both interfaces must be in the same VDOM or you will loose their acceleration.

The following procedure will move the port3 interface to the Client2 VDOM. This is a common action when configuring a VDOM. It is assumed that the Client2 VDOM has already been created. It is also assumed that your FortiGate unit has a port3 interface. If you are using a different model, your physical interfaces may not be named `port2`, `external` or `port3`.

To move an existing interface to a different VDOM - web-based manager

1 For Current VDOM, select Global.
2 Go to *System* > *Network* > *Interface*.
3 Select *Edit* for the port3 interface.
4 Select `Client2` as the new *Virtual Domain*.
5 Select *OK*.

To move an existing interface to a different VDOM - CLI

```
config global
  config system interface
    edit port3
      set vdom Client2
    end
```

Deleting an interface

Before you can delete a virtual interface, or move an interface from one VDOM to another, all references to that interface must be removed. For a list of objects that can refer to an interface see "Per-VDOM settings - web-based manager" on page 1882.

The easiest way to be sure an interface can be deleted is when the Delete icon is no longer greyed out. If it remains greyed out when an interface is selected, that interface still has objects referring to it, or it is a physical interface that cannot be deleted.

To delete a virtual interface - web-based manager

1 Ensure all objects referring to this interface have been removed.
2 In *Current VDOM*, select Global.
3 Select *System* > *Network* > *Interface*.
4 Select the interface to delete.
5 Select the delete icon.

Adding a zone to a VDOM

Grouping interfaces and VLAN subinterfaces into zones simplifies policy creation. You can configure policies for connections to and from a zone, but not between interfaces in a zone.

Zones are VDOM-specific. A zone cannot be moved to a different VDOM. Any interfaces in a zone cannot be used in another zone. To move a zone to a new VDOM requires deleting the current zone and re-creating a zone in the new VDOM.

The following procedure will create a zone called `accounting` in the `client2` VDOM. It will not allow intra-zone traffic, and both `port3` and `port2` interfaces belong to this zone. This is a method of grouping and isolating traffic over particular interfaces—it is useful for added security and control within a larger network.

To add a zone to a VDOM - web-based manager

1 In *Current VDOM*, select the client2 VDOM.

2 Go to *System* > *Network* > *Interface*.

3 Select *Create New* > *Zone*.

4 Enter the following information and select *OK*:

Zone Name	accounting
Block intra-zone traffic	Select
Interface Members	port3, port2

To add a zone to a VDOM - CLI

```
config vdom
  edit client2
    config system zone
      edit accounting
        set interface port3 port2
        set intrazone deny
      end
  end
```

Configuring VDOM routing

Routing is VDOM-specific. Each VDOM should have a default static route configured as a minimum. Within a VDOM, routing is the same as routing on your FortiGate unit without VDOMs enabled.

When configuring dynamic routing on a VDOM, other VDOMs on the FortiGate unit can be neighbors. The following topics give a brief introduction to the routing protocols, and show specific examples of how to configure dynamic routing for VDOMs. Figures are included to show the FortiGate unit configuration after the successful completion of the routing example.

This section includes:

Default static route for a VDOM

The routing you define applies only to network traffic entering non-ssl interfaces belonging to this VDOM. Set the administrative distance high enough, typically 20, so that automatically configured routes will be preferred to the default.

In the following procedure, it is assumed that a VDOM called “Client2” exists. The procedure will create a default static route for this VDOM. The route has a destination IP of 0.0.0.0, on the port3 interface. It has a gateway of 10.10.10.1, and an administrative distance of 20.

The values used in this procedure are very standard, and this procedure should be part of configuring all VDOMs.

To add a default static route for a VDOM - web-based manager

1 For Current VDOM, select Global.
2 Go to *System* > *VDOM* > *VDOM*.
3 Select the *Client2* VDOM and select *Enter*.
4 Go to *Router* > *Static* > *Static Route*.
5 Select *Create New*.
6 Enter the following information and select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2
Gateway	10.10.10.1
Distance	20

To add a default static route for a VDOM - CLI

```
config vdom
  edit Client2
    config router static
      edit 4
        set device port2
        set dst 0.0.0.0 0.0.0.0
        set gateway 10.10.10.1
        set distance 20
      end
  end
```

Dynamic Routing in VDOMs

Dynamic routing is VDOM-specific, like all other routing. Dynamic routing configuration is the same with VDOMs as with your FortiGate unit without VDOMs enabled, once you are at the routing menu. If you have multiple VDOMs configured, the dynamic routing configuration between them can become quite complex.

VDOMs provide some interesting changes to dynamic routing. Each VDOM can be a neighbor to the other VDOMs. This is useful in simulating a dynamic routing area or AS or network using only your FortiGate unit.

You can separate different types of routing to different VDOMs if required. This allows for easier troubleshooting. This is very useful if your FortiGate unit is on the border of a number of different routing domains.

For more information on dynamic routing in FortiOS, see “Dynamic Routing Overview” on page 1699.

Inter-VDOM links must have IP addresses assigned to them if they are part of a dynamic routing configuration. Inter-VDOM links may or may not have IP addresses assigned to them. Without IP addresses, you need to be careful how you configure routing. While the default static route can be assigned an address of 0.0.0.0 and rely instead on the interface, dynamic routing almost always requires an IP address.

RIP

The RIP dynamic routing protocol uses hop count to determine the best route, with a hop count of 1 being directly attached to the interface and a hop count of 16 being unreachable. For example if two VDOMs on the same FortiGate unit are RIP neighbors, they have a hop count of 1.

OSPF

OSPF communicates the status of its network links to adjacent neighbor routers instead of the complete routing table. When compared to RIP, OSPF is more suitable for large networks, it is not limited by hop count, and is more complex to configure. For smaller OSPF configurations its easiest to just use the backbone area, instead of multiple areas.

BGP

BGP is an Internet gateway protocol (IGP) used to connect autonomous systems (ASes) and is used by Internet service providers (ISPs). BGP stores the full path, or path vector, to a destination and its attributes which aid in proper routing.

Configuring security policies for NAT/Route VDOMs

Security policies are VDOM-specific. This means that all firewall settings for a VDOM, such as firewall addresses and security policies, are configured within the VDOM.

In VDOMs, all firewall related objects are configured per-VDOM including addresses, service groups, UTM profiles, schedules, traffic shaping, and so on. If you want firewall addresses, you will have to create them on each VDOM separately. If you have many addresses, and VDOMs this can be tedious and time consuming. Consider using a FortiManager unit to manage your VDOM configuration — it can get firewall objects from a configured VDOM or FortiGate unit, and push those objects to many other VDOMs or FortiGate units. See the FortiManager Administration Guide.

You can customize the *Policy* display by including some or all columns, and customize the column order onscreen. Due to this feature, security policy screenshots may not appear the same as on your screen.

Configuring a security policy for a VDOM

Your security policies can involve only the interfaces, zones, and firewall addresses that are part of the current VDOM, and they are only visible when you are viewing the current VDOM. The security policies of this VDOM filter the network traffic on the interfaces and VLAN subinterfaces in this VDOM.

A firewall service group can be configured to group multiple services into one service group. When a descriptive name is used, service groups make it easier for an administrator to quickly determine what services are allowed by a security policy.

In the following procedure, it is assumed that a VDOM called `Client2` exists. The procedure will configure an outgoing security policy. The security policy will allow all HTTPS and SSH traffic for the `SalesLocal` address group on VLAN_200 going to all addresses on port3. This traffic will be scanned and logged.

To configure a security policy for a VDOM - web-based manager

1. Go to *System* > *VDOM* > *VDOM*.
2. Select the *Client2* VDOM and select *Enter*.
3. Go to *Policy* > *Policy*.
4. Select *Create New*.

5 Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200
Source Address	SalesLocal
Destination Interface/Zone	port3
Destination Address	any
Schedule	always
Service	Multiple - HTTPS, SSH
Action	ACCEPT
Log Allowed Traffic	enable

To configure a security policy for a VDOM - CLI

```
config vdom
  edit Client2
    config firewall policy
      edit 12
        set srcintf VLAN_200
        set srcaddr SalesLocal
        set dstintf port3(dmz)
        set dstaddr any
        set schedule always
        set service HTTPS SSH
        set action accept
        set status enable
        set logtraffic enable
      end
  end
```

Configuring UTM profiles for NAT/Route VDOMs

In NAT/Route VDOMs, UTM profiles are exactly like regular FortiGate unit operation with one exception. In VDOMs, there are no default UTM profiles.

If you want UTM profiles in VDOMs, you must create them yourself. If you have many UTM profiles to create in each VDOM, you should consider using a FortiManager unit. It can get existing profiles from a VDOM or FortiGate unit, and push those profiles down to multiple other VDOMs or FortiGate units. See FortiManager Administration Guide.

When VDOMs are enabled, you only need one FortiGuard license for the physical unit, and download FortiGuard updates once for the physical unit. This can result in a large time and money savings over multiple physical units if you have many VDOMs.

Configuring VPNs for a VDOM

Virtual Private Networking (VPN) settings are VDOM-specific, and must be configured within each VDOM. Configurations for IPsec Tunnel, IPsec Interface, PPTP and SSL are VDOM-specific. However, certificates are shared by all VDOMs and are added and configured globally to the FortiGate unit.

Example NAT/Route VDOM configuration

Company A and Company B each have their own internal networks and their own ISPs. They share a FortiGate unit that is configured with two separate VDOMs, with each VDOM running in NAT/Route mode enabling separate configuration of network protection profiles. Each ISP is connected to a different interface on the FortiGate unit.

This network example was chosen to illustrate one of the most typical VDOM configurations.

This example has the following sections:

Network topology and assumptions

Both companies have their own ISPs and their own internal interface, external interface, and VDOM on the FortiGate unit.

For easier configuration, the following IP addressing is used:

- all IP addresses on the FortiGate unit end in ".2" such as 10.11.101.2.
- all IP addresses for ISPs end in ".7", such as 172.20.201.7.
- all internal networks are 10.*.*.* networks, and sample internal addresses end in ".55".

The IP address matrix for this example is as follows.

Address	Company A	Company B
ISP	`172.20.201.7`	`192.168.201.7`
Internal network	`10.11.101.0`	`10.012.101.0`
FortiGate / VDOM	`172.20.201.2 (port1)` `10.11.101.2 (port4)`	`192.168.201.2 (port3)` `10.012.101.2 (port2)`

The Company A internal network is on the 10.11.101.0/255.255.255.0 subnet. The Company B internal network is on the 10.12.101.0/255.255.255.0 subnet.

There are no switches or routers required for this configuration.

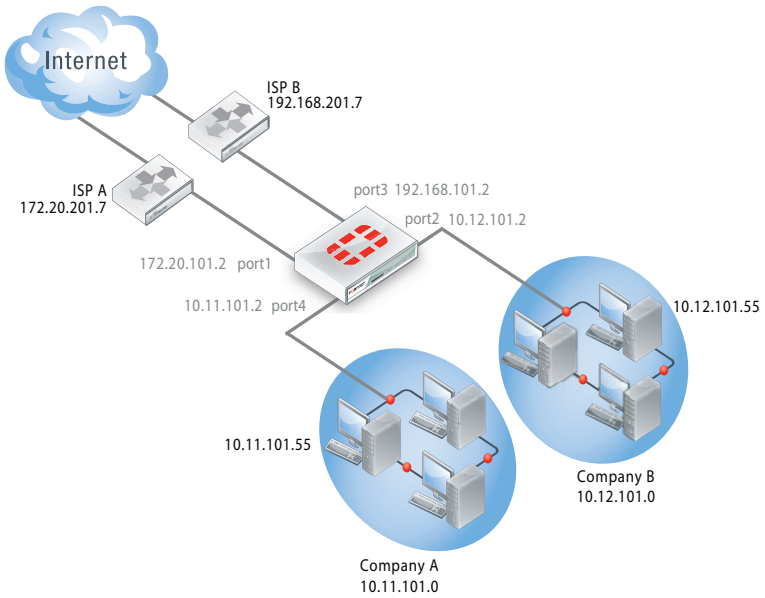
There are no VLANs in this network topology.

The interfaces used in this example are port1 through port4. Different FortiGate models may have different interface labels. port1 and port3 are used as external interfaces. port2 and port4 are internal interfaces.

The administrator is a super_admin account. If you are a using a non-super_admin account, refer to "Global and per-VDOM settings" on page 1881 to see which parts a non-super_admin account can also configure.

When configuring security policies in the CLI always choose a policy number that is higher than any existing policy numbers, select `services` before `profile-status`, and `profile-status` before `profile`. If these commands are not entered in that order, they will not be available to enter.

Figure 185: Example VDOM configuration



General configuration steps

For best results in this configuration, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Creating the VDOMs
2. Configuring the FortiGate interfaces
3. Configuring the vdomA VDOM, and Configuring the vdomB VDOM
4. Testing the configuration

Creating the VDOMs

In this example, two new VDOMs are created — vdomA for Company A and vdomB for Company B. These VDOMs will keep the traffic for these two companies separate while enabling each company to access its own ISP.

To create two VDOMs - web-based manager

1. Log in with a super_admin account.
2. For *Current VDOM*, select Global.
3. Go to *System* > *VDOM* > *VDOM*, and select *Create New*.
4. Enter `vdomA` and select *OK*.
5. Select *OK* again to return to the VDOM list.
6. Select *Create New*.
7. Enter `vdomB` and select *OK*.

To create two VDOMs - CLI

```
config vdom
  edit vdomA
  next
```

```
edit vdomB
end
```

Configuring the FortiGate interfaces

This section configures the interfaces that connect to the companies' internal networks, and to the companies' ISPs.

All interfaces on the FortiGate unit will be configured with an IP address ending in ".2" such as 10.11.101.2. This will simplify network administration both for the companies, and for the FortiGate unit global administrator. Also the internal addresses for each company differ in the second octet of their IP address - Company A is 10.11.*, and Company B is 10.12.*.

This section includes the following topics:

- Configuring the vdomA interfaces
- Configuring the vdomB interfaces

If you cannot change the VDOM of an network interface it is because something is referring to that interface that needs to be deleted. Once all the references are deleted the interface will be available to switch to a different VDOM. For example a common reference to the external interface is the default static route entry. See "Configuring interfaces in a NAT/Route VDOM" on page 1904.

Configuring the vdomA interfaces

The `vdomA` VDOM includes two FortiGate unit interfaces: port1 and external.

The port4 interface connects the Company A internal network to the FortiGate unit, and shares the internal network subnet of 10.11.101.0/255.255.255.0.

The external interface connects the FortiGate unit to ISP A and the Internet. It shares the ISP A subnet of 172.20.201.0/255.255.255.0.

To configure the vdomA interfaces - web-based manager

1. For Current VDOM, select Global.
2. Go to *System* > *Network* > *Interface*.
3. Select *Edit* on the port1 interface.
4. Enter the following information and select *OK*:

Virtual Domain	vdomA
Addressing mode	Manual
IP/Netmask	172.20.201.2/255.255.255.0

5. Select *Edit* on the port4 interface.
6. Enter the following information and select *OK*:

Virtual Domain	vdomA
Addressing mode	Manual
IP/Netmask	10.11.101.2/255.255.255.0

To configure the vdomA interfaces - CLI

```
config global
  config system interface
    edit port1
      set vdom vdomA
      set mode static
      set ip 172.20.201.2 255.255.255.0
    next
    edit port4
      set vdom ABCdomain
      set mode static
      set ip 10.11.101.2 255.255.255.0
    end
  end
```

Configuring the vdomB interfaces

The `vdomB` VDOM uses two FortiGate unit interfaces: port2 and port3.

The port2 interface connects the Company B internal network to the FortiGate unit, and shares the internal network subnet of 10.12.101.0/255.255.255.0.

The port3 interface connects the FortiGate unit to ISP B and the Internet. It shares the ISP B subnet of 192.168.201.0/255.255.255.0.

To configure the DEFdomain interfaces - web-based manager

1. For Current VDOM, select Global.
2. Go to *System* > *Network* > *Interface***.**
3. Select *Edit* on the port3 interface.
4. Enter the following information and select *OK*:

Virtual domain	vdomB
Addressing mode	Manual
IP/Netmask	192.168.201.2/255.255.255.0

5. Select *Edit* on the port2 interface.
6. Enter the following information and select *OK*:

Virtual domain	vdomB
Addressing mode	Manual
IP/Netmask	10.12.101.2/255.255.255.0

To configure the vdomB interfaces - CLI

```
config global
  config system interface
    edit port3
      set vdom vdomB
      set mode static
      set ip 192.168.201.2 255.255.255.0
    next
    edit port2
      set vdom vdomB
```

```
    set mode static
    set ip 10.12.101.2 255.255.255.0
  end
```

Configuring the vdomA VDOM

With the VDOMs created and the ISPs connected, the next step is to configure the vdomA VDOM.

Configuring the vdomA includes the following:

- Adding vdomA firewall addresses
- Adding the vdomA security policy
- Adding the vdomA default route

Adding vdomA firewall addresses

You need to define the addresses used by Company A's internal network for use in security policies. This internal network is the 10.11.101.0/255.255.255.0 subnet.

The FortiGate unit provides one default address, "all", that you can use when a security policy applies to all addresses as the source or destination of a packet.

To add the vdomA firewall addresses - web-based manager

1 For Current VDOM, select *vdomA*.

2 Go to *Firewall Objects* > *Address* > *Address*.

3 Select *Create New*.

4 Enter the following information and select *OK*:

Address Name	Ainternal
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0/255.255.255.0
Interface	port4

To add the ABCdomain VDOM firewall addresses - CLI

```
config vdom
  edit vdomA
    config firewall address
      edit Ainternal
        set type ipmask
        set subnet 10.11.101.0 255.255.255.0
      end
  end
```

Adding the vdomA security policy

You need to add the `vdomA` security policy to allow traffic from the internal network to reach the external network, and from the external network to internal as well. You need two policies for this domain.

To add the vdomA security policy - web-based manager

1 In Current VDOM, select *vdomA*.

2 Go to *Policy* > *Policy*.

3 Select *Create New*.

4 Enter the following information and select *OK*:

Source Interface/Zone	port4
Source Address	Ainternal
Destination Interface/Zone	port1
Destination Address	all
Schedule	Always
Service	ANY
Action	ACCEPT

5 Select *Create New*.

6 Enter the following information and select *OK*:

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	port4
Destination Address	Ainternal
Schedule	Always
Service	ANY
Action	ACCEPT

To add the vdomA security policy - CLI

```
config vdom
  edit vdomA
    config firewall policy
      edit 1
        set srcintf port4
        set srcaddr Ainternal
        set dstintf port1
        set dstaddr all
        set schedule always
        set service ANY
        set action accept
        set status enable
      next
      edit 2
        set srcintf port1
        set srcaddr all
        set dstintf port4
        set dstaddr Ainternal
        set schedule always
        set service ANY
        set action accept
        set status enable
      end
```

Adding the vdomA default route

You also need to define a default route to direct packets from the Company A internal network to ISP A. Every VDOM needs a default static route, as a minimum, to handle traffic addressed to external networks such as the Internet.

The administrative distance should be set slightly higher than other routes. Lower admin distances will get checked first, and this default route will only be used as a last resort.

To add a default route to the vdomA - web-based manager

1 For Current VDOM, select *vdomA*

2 Goo to *Router* > *Static* > *Static Route*.

3 Select *Create New*.

4 Enter the following information and select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port1
Gateway	172.20.201.7
Distance	20

To add a default route to the vdomA - CLI

```
config vdom
  edit vdomA
    config router static
      edit 1
        set device port1
        set gateway 172.20.201.7
      end
```

Configuring the vdomB VDOM

In this example, the vdomB VDOM is used for Company B. Firewall and routing settings are specific to a single VDOM.

vdomB includes the FortiGate port2 interface to connect to the Company B internal network, and the FortiGate port3 interface to connect to ISP B. Security policies are needed to allow traffic from port2 to external and from external to port2 interfaces.

This section includes the following topics:

Adding the vdomB firewall address

You need to define addresses for use in security policies. In this example, the vdomB VDOM needs an address for the port2 interface and the “all” address.

To add the vdomB firewall address - web-based manager

1 In *Current VDOM*, select *vdomB*.

2 Go to *Firewall Objects* > *Address* > *Address*.

3 Select *Create New*.

4 Enter the following information and select *OK*:

Address Name	Binternal
Type	Subnet / IP Range
Subnet / IP Range	10.12.101.0/255.255.255.0
Interface	port2

To add the vdomB firewall address - CLI

```
config vdom
  edit vdomB
    config firewall address
      edit Binternal
        set type ipmask
        set subnet 10.12.101.0 255.255.255.0
      end
  end
```

Adding the vdomB security policy

You also need a security policy for the Company B domain. In this example, the security policy allows all traffic.

To add the vdomB security policy - web-based manager

1 Log in with a super_admin account.

2 In *Current VDOM*, select vdomB.

3 Go to *Policy* > *Policy*.

4 Select *Create New*.

5 Enter the following information and select *OK*:

Source Interface/Zone	port2
Source Address	Binternal
Destination Interface/Zone	port3
Destination Address	all
Schedule	Always
Service	ANY
Action	ACCEPT

6 Select *Create New*.

7 Enter the following information and select *OK*:

Source Interface/Zone	port3
Source Address	all
Destination Interface/Zone	port2
Destination Address	Binternal
Schedule	Always

Service	ANY
Action	ACCEPT

To add the vdomB security policy - CLI

```
config vdom
  edit vdomB
    config firewall policy
      edit 1
        set srcintf port2
        set dstintf port3
        set srcaddr Binternal
        set dstaddr all
        set schedule always
        set service ANY
        set action accept
        set status enable
      edit 1
        set srcintf port3
        set dstintf port2
        set srcaddr all
        set dstaddr Binternal
        set schedule always
        set service ANY
        set action accept
        set status enable
      end
  end
```

Adding a default route to the vdomB VDOM

You need to define a default route to direct packets to ISP B.

To add a default route to the vdomB VDOM - web-based manager

1. Log in as the super_admin administrator.
2. In *Current VDOM*, select vdomB.
3. Go to *Router* > *Static* > *Static Route*.
4. Select *Create New*.
5. Enter the following information and select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3
Gateway	192.168.201.7
Distance	20

To add a default route to the vdomB VDOM - CLI

```
config vdom
  edit vdomB
    config router static
      edit 1
        set dst 0.0.0.0/0
```

```
        set device external
        set gateway 192.168.201.7
      end
    end
```

Testing the configuration

Once you have completed configuration for both company VDOMs, you can use diagnostic commands, such as `tracert` in Windows, to test traffic routed through the FortiGate unit. Alternately, you can use the `traceroute` command on a Linux system with similar output.

Possible errors during the traceroute test are:

- "`***Request timed out`" - the trace was not able to make the next connection towards the destination fast enough
- "`Destination host unreachable`" - after a number of timed-out responses the trace will give up

Possible reasons for these errors are bad connections or configuration errors.

For additional troubleshooting, see "Troubleshooting Virtual Domains" on page 1977.

Testing traffic from the internal network to the ISP

In this example, a route is traced from the Company A internal network to ISP A. The test was run on a Windows PC with an IP address of 10.11.101.55.

The output here indicates three hops between the source and destination, the IP address of each hop, and that the trace was successful.

From the Company A internal network, access a command prompt and enter this command:

```
C:\>tracert 172.20.201.7
Tracing route to 172.20.201.7 over a maximum of 30 hops:
  1    <10 ms    <10 ms    <10 ms  10.11.101.2
  2    <10 ms    <10 ms    <10 ms  172.20.201.2
  3    <10 ms    <10 ms    <10 ms  172.20.201.7

Trace complete.
```

You can customize the Firewall Policy display by including some or all columns, and customize the column order onscreen. Due to this feature, firewall policy screenshots may not appear the same as on your screen.

To complete the setup, configure devices on the VLANs with default gateways. The default gateway for VLAN 10 is the FortiGate VLAN 10 subinterface. Configure the rest of the devices, similarly matching the default gateway and FortiGate VLAN subinterface numbers.

Virtual Domains in Transparent mode

In Transparent mode, the FortiGate unit behaves like a layer-2 bridge but can still provide services such as antivirus scanning, web filtering, spam filtering and intrusion protection to traffic. There are some limitations in Transparent mode in that you cannot use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in Transparent mode apply to IEEE 802.1Q VLAN trunks passing through the unit.

VDOMs can each be configured to operate either in Transparent or NAT/Route operation mode, with each VDOM behaving like a separate FortiGate unit operating in the respective mode. VLANs configured on a VDOM in Transparent mode are the same as VLANs configured on the FortiGate unit when VDOMs are disabled.

This chapter includes the following sections:

Before you begin

Before you begin using this chapter, take a moment to note the following:

- The information in this chapter applies to all FortiGate units. All FortiGate models except the FortiGate-30B model support VDOMs, and all FortiGate models support VLANs.
- By default, your FortiGate unit supports a maximum of 10 VDOMs in any combination of NAT/Route and Transparent operating modes. For FortiGate models numbered 1240 and higher, you can purchase a license key to increase the maximum number of VDOMs. Model 1240B supports up to 25 VDOMs. Most Enterprise and Large Enterprise models can support 250 VDOMs. Chassis-based models can support up to 3000 VDOMs. For specific information, see the product data sheet.
- This chapter uses port1 through port4 for interfaces in examples, where possible aliases have been assigned to the interfaces for extra clarity. The interface names on some models will vary. For example, some models do not have interfaces labeled external or internal.
- A super_admin administrator account is assumed for the procedures and examples; however, if you are an administrator restricted to a VDOM, you may be able to perform some procedures. For more information, see “Administrators in Virtual Domains” on page 1898.

Transparent operation mode

In transparent mode, the FortiGate unit becomes a layer-2 IP forwarding bridge. This means that Ethernet frames are forwarded based on destination MAC address, and no other routing is performed. All incoming traffic that is accepted by the firewall, is broadcast out on all interfaces.

In transparent mode the FortiGate unit is a forwarding bridge, not a switch. A switch can develop a port table and associated MAC addresses, so that it can bridge two ports to deliver the traffic instead of broadcasting to all ports. In transparent mode, the FortiGate unit does not following this switch behavior, but instead is the forwarding bridge that broadcasts all packets out over all interfaces, subject to security policies.

Features such as broadcast domains, forwarding domains, and STP apply to both FortiGate units and VDOMs in Transparent mode.

Broadcast domains

A broadcast domain is a network segment in which any network equipment can transmit data directly to another device without going through a routing device. All the devices share the same subnet. The subnets are separated by layer-3 devices, such as routers, that can forward traffic from one broadcast domain to the next.

Broadcast domains are important to transparent mode FortiGate units because the broadcast domain is the limit of where the FortiGate unit can forward packets when it is in transparent mode.

Forwarding domains

Address Resolution Protocol (ARP) packets are vital to communication on a network, and ARP support is enabled on FortiGate unit interfaces by default. Normally you want ARP packets to pass through the FortiGate unit. However, in Transparent mode ARP packets arriving on one interface are sent to all other interfaces including VLANs giving the appearance of duplicates of the same MAC address on different interfaces. Some layer-2 switches become unstable when they detect these duplicate MAC addresses. Unstable switches may become unreliable or reset and cause network traffic to slow down considerably.

When you are using VLANs in Transparent mode, the solution to the duplicate MAC address issue is to use the `forward-domain` CLI command. This command tags VLAN traffic as belonging to a particular collision group, and only VLANs tagged as part of that collision group receive that traffic—it is like an additional set of VLANs. By default, all interfaces and VLANs are part of forward-domain collision group 0.

To assign VLAN 200 to collision group 2, VLAN 300 to collision group 3, and all other interfaces to stay in the default collision group 0 enter the following CLI commands:

```
config system interface
  edit vlan200
    set vlanid 200
    set forward_domain 2
  next
  edit vlan300
    set vlanid 300
    set forward_domain 3
  next
end
```

When using forwarding domains, you may experience connection issues with layer-2 traffic, such as ping, if your network configuration has

- packets going through the FortiGate unit in Transparent mode multiple times,
- more than one forwarding domain (such as incoming on one forwarding domain and outgoing on another)
- IPS and AV enabled.

Spanning Tree Protocol

VDOMs and FortiGate units do not participate in the Spanning Tree Protocol (STP). STP is an IEEE 802.1 protocol that ensures there are no layer-2 loops on the network. Loops are created when there is more than one route for traffic to take and that traffic is broadcast back to the original switch. This loop floods the network with traffic, quickly reducing available bandwidth to zero.

If you use your VDOM or FortiGate unit in a network topology that relies on STP for network loop protection, you need to make changes to your FortiGate configuration. Otherwise, STP recognizes your FortiGate unit as a blocked link and forwards the data to another path. By default, your FortiGate unit blocks STP as well as other non-IP protocol traffic. Using the CLI, you can enable forwarding of STP and other layer-2 protocols through the interface. In this example, layer-2 forwarding is enabled on the port2 interface:

```
config global
  config system interface
    edit port2
      set l2forward enable
      set stpforward enable
    next
  end
```

There are different CLI commands to allow other common layer-2 protocols such as IPX, PPTP or L2TP on the network. For more information, see the FortiOS CLI Reference.

Differences between NAT/Route and Transparent mode

The differences between NAT/Route mode and Transparent mode include:

Table 112: Differences between NAT/Route and Transparent modes

Features	NAT/Route mode	Transparent mode
Specific Management IP address required	No	Yes
Perform Network Address Translation (NAT)	Yes	Yes
Stateful packet inspection	Yes	Yes
Layer-2 forwarding	Yes	Yes
Layer-3 routing	Yes	No
Unicast Routing / Policy Based routing	Yes	No
DHCP server	Yes	No
IPsec VPN	Yes	Yes
PPTP/L2TP VPN	Yes	No
SSL VPN	Yes	No

Table 112: Differences between NAT/Route and Transparent modes

UTM features	Yes	Yes
VLAN support	Yes	Yes - limited to VLAN trunks.
Ping servers (dead gateway detection)	Yes	No

To provide administrative access to a FortiGate unit or VDOM in Transparent mode, you must define a management IP address and a gateway. This step is not required in NAT/Route mode where you can access the FortiGate unit through the assigned IP address of any interface where administrative access is permitted.

If you incorrectly set the Transparent mode management IP address for your FortiGate unit, you will be unable to access your unit through the web-based manager. In this situation, you will need to connect to the FortiGate unit using the console cable and change the settings so you can access the unit. Alternately, if your unit has an LCD panel, you can change the operation mode and interface information through the LCD panel.

Operation mode differences in VDOMs

A VDOM, such as root, can have a maximum of 255 interfaces in Network Address Translation (NAT) mode or Transparent mode. This includes VLANs, other virtual interfaces, and physical interfaces. To have more than a total of 255 interfaces configured, you need multiple VDOMs with multiple interfaces on each.

In Transparent mode without VDOMs enabled, all interfaces on the FortiGate unit act as a bridge — all traffic coming in on one interface is sent back out on all the other interfaces. This effectively turns the FortiGate unit into a two interface unit no matter how many physical interfaces it has. When VDOMs are enabled, this allows you to determine how many interfaces to assign to a VDOM running in Transparent mode. If there are reasons for assigning more than two interfaces based on your network topology, you are able to. However, the benefit of VDOMs in this case is that you have the functionality of Transparent mode, but you can use interfaces for NAT/Route traffic as well.

You can add more VDOMs to separate groups of VLAN subinterfaces. When using a FortiGate unit to serve multiple organizations, this configuration simplifies administration because you see only the security policies and settings for the VDOM you are configuring. For information on adding and configuring virtual domains, see “Benefits of Virtual Domains” on page 1875.

One essential application of VDOMs is to prevent problems caused when a FortiGate unit is connected to a layer-2 switch that has a global MAC table. FortiGate units normally forward ARP requests to all interfaces, including VLAN subinterfaces. It is then possible for the switch to receive duplicate ARP packets on different VLANs. Some layer-2 switches reset when this happens. As ARP requests are only forwarded to interfaces in the same VDOM, you can solve this problem by creating a VDOM for each VLAN. For a configuration example, see “Example of VDOMs in Transparent mode” on page 1926.

Configuring VDOMs in Transparent mode

In Transparent mode, your FortiGate unit becomes a layer-2 bridge — any traffic coming in on one port is broadcast out on all the other ports. If your FortiGate unit has many interfaces, this is not the best use of those interfaces. VDOMs can limit Transparent mode to only a few interfaces while allowing the rest of the FortiGate unit to remain in NAT/Route mode.

The essential steps to configure your FortiGate unit to work with VLANs in Transparent mode are:

- Switching to Transparent mode
- Adding VLAN subinterfaces
- Creating security policies.

You can also configure the UTM profiles that manage antivirus scanning, web filtering and spam filtering. For more information, see "UTM overview" on page 879.

In Transparent mode, you can access the FortiGate web-based manager by connecting to an interface configured for administrative access and using HTTPS to access the management IP address. On the FortiGateunit used for examples in this guide, administrative access is enabled by default on the internal interface and the default management IP address is `10.11.0.1`.

Switching to Transparent mode

A VDOM is in NAT/Route mode by default when it is created. You must switch it to Transparent mode, and add a management IP address so you can access the VDOM from your management computer.

Before applying the change to Transparent mode, ensure the VDOM has administrative access on the selected interface, and that the selected management IP address is reachable on your network.

To switch the `tpVDOM` VDOM to Transparent mode - web-based manager

1. Go to *Current VDOM* menu and select *Global*.
2. Go to *System* > *VDOM* > *VDOM*.
3. Edit the *tpVDOM*.
4. Select `Transparent` for *Operation mode*.
5. Enter the management IP/Netmask.

   The IP address must be accessible to the subnet where the management computer is located. For example 10.11.0.99/255.255.255.0 will be able to access the 10.11.0.0 subnet.
6. Select *Apply*.

When you select *Apply*, the FortiGate unit will log you out. When you log back in, the VDOM will be in Transparent mode.

To switch the `tpVDOM` VDOM to Transparent mode - CLI

```
config vdom
  edit tpVDOM
    config system settings
      set opmode transparent
      set mangeip 10.11.0.99 255.255.255.0
    end
  end
```

Adding VLAN subinterfaces

There are a few differences when adding VLANs in Transparent mode compared to NAT/Route mode.

In Transparent mode, VLAN traffic is trunked across the VDOM. That means VLAN traffic cannot be routed, changed, or inspected. For this reason when you assign a VLAN to a Transparent mode VDOM, you will see the *Addressing Mode* section of the interface configuration disappear in from the web-based manager. It is because with no routing, inspection, or any activities able to be performed on VLAN traffic the VDOM simply re-broadcasts the VLAN traffic. This requires no addressing.

Also any routing related features such as dynamic routing or Virtual Router Redundancy Protocol (VRRP) are not available in Transparent mode for any interfaces.

Creating security policies

Security policies permit communication between the FortiGate unit's network interfaces based on source and destination IP addresses. Typically you will also limit communication to desired times and services for additional security.

In Transparent mode, the FortiGate unit performs antivirus and antispam scanning on each packet as it passes through the unit. You need security policies to permit packets to pass from the VLAN interface where they enter the unit to the VLAN interface where they exit the unit. If there are no security policies configured, no packets will be allowed to pass from one interface to another. For more information, see the FortiGate Administration Guide, or FortiGate Fundamentals Guide.

Example of VDOMs in Transparent mode

In this example, the FortiGate unit provides network protection to two organizations — Company A and Company B. Each company has different policies for incoming and outgoing traffic, requiring three different security policies and protection profiles.

VDOMs are not required for this configuration, but by using VDOMs the profiles and policies can be more easily managed on a per-VDOM basis either by one central administrator or separate administrators for each company. Also future expansion is simply a matter of adding additional VDOMs, whilst not disrupt the existing VDOMs.

For this example, firewalls are only included to deal with web traffic. This is to provide an example without making configuration unnecessarily complicated.

This example includes the following sections:

- Network topology and assumptions
- General configuration steps
- Configuring common items
- Creating virtual domains
- Configuring the Company_A VDOM
- Configuring the Company_B VDOM
- Configuring the VLAN switch and router
- Testing the configuration

Network topology and assumptions

Each organization's internal network consists of a different range of IP addresses:

- 10.11.0.0/255.255.0.0 for Company A.

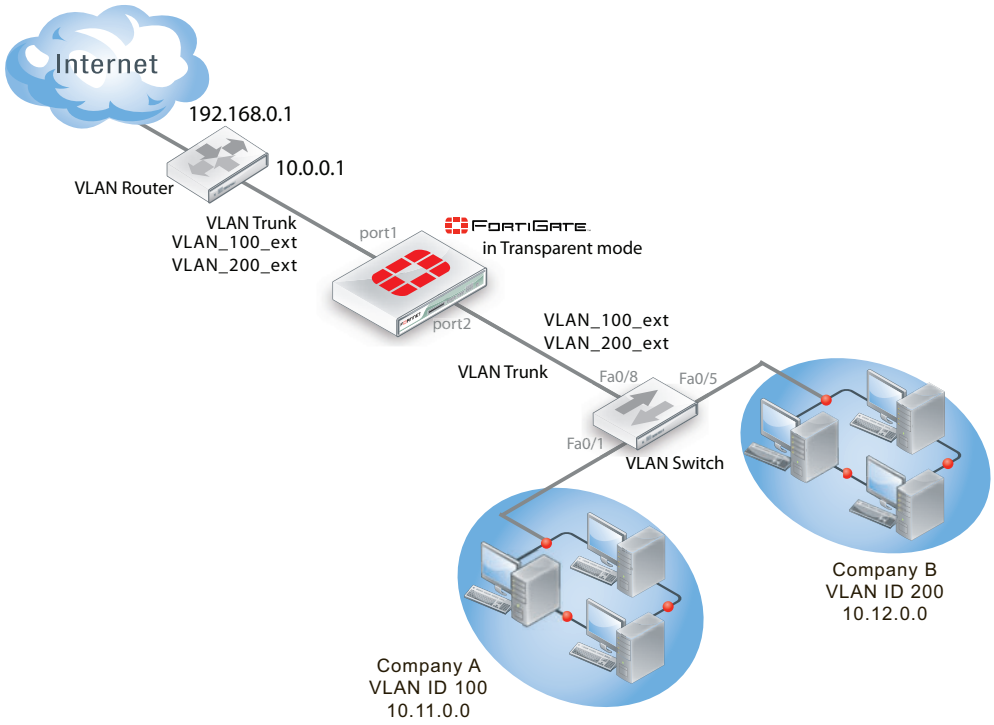
- 10.12.0.0/255.255.0.0 for Company B.

For the procedures in this section, it is assumed that you have enabled VDOM configuration on your FortiGate unit. For more information, see "Enabling and accessing Virtual Domains" on page 1877.

The VDOM names are similar to the company names for easy recognition. The root VDOM cannot be renamed and is not used in this example.

Interfaces used in this example are port1 and port2. Some FortiGate models may not have interfaces with these names. port1 is an external interface. port2 is an internal interface.

Figure 186: VLAN and VDOM Transparent example network topology



General configuration steps

The following steps summarize the configuration for this example. For best results, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Configuring common items
2. Creating virtual domains
3. Configuring the Company_A VDOM
4. Configuring the Company_B VDOM
5. Configuring the VLAN switch and router
6. Testing the configuration

Configuring common items

Both VDOMs require you configure UTM profiles. These will be configured the same way, but need to be configured in both VDOMs.

The relaxed profile allows users to surf websites they are not allowed to visit during normal business hours. Also a quota is in place to restrict users to one hour of access to these websites to ensure employees do not take long and unproductive lunches.

To create a strict web filtering profile - web-based manager

1 Go to the proper VDOM, and select *UTM Profiles* > *Web Filter* > *Profile*.
2 Select *Create New*.
3 Enter `strict` for the *Name*.
4 Expand FortiGuard Web Filtering, and select block for all Categories except Business Oriented, and Other.
5 Block all Classifications except Cached Content, and Image Search.
6 Ensure *FortiGuard Quota* for all Categories and Classifications is Disabled.
7 Select *OK*.

To create a strict web filtering profile - CLI

```
config vdom
  edit <vdom_name>
    config webfilter profile
      edit strict
        config ftgd-wf
          set allow g07 g08 g21 g22 c01 c03
          set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
        end
        set web-ftgd-err-log enable
      end
```

To create a relaxed web filtering profile - web-based manager

1 Go to the proper VDOM, and select *UTM Profiles* > *Web Filter* > *Profile*.
2 Select *Create New*.
3 Enter `relaxed` for the *Name*.
4 Expand FortiGuard Web Filtering, and select block for Potentially Security Violating Category, and Spam URL Classification.
5 Enable FortiGuard Quotas to allow 1 hour for all allowed Categories and Classifications.

Creating virtual domains

The FortiGate unit supports 10 virtual domains. Root is the default VDOM. It cannot be deleted or renamed. The root VDOM is not used in this example. New VDOMs are created for Company A and Company B

To create the virtual domains - web-based manager

1 With VDOMs enabled, select *System* > *VDOM* > *VDOM*.
2 Select *Create New*.
3 Enter `Company_A` for Name, and select *OK*.
4 Select *Create New*.
5 Enter `Company_B` for Name, and select *OK*.

To create the virtual domains - CLI

```
config system vdom
  edit Company_A
  next
  edit Company_B
  end
```

Configuring the Company_A VDOM

This section describes how to add VLAN subinterfaces and configure security policies for the Company_A VDOM.

This section includes the following topics:

Adding VLAN subinterfaces

You need to create a VLAN subinterface on the port2 interface and another one on the port1 interface, both with the same VLAN ID.

To add VLAN subinterfaces - web-based manager

1 Go to *System* > *Network* > *Interface*.

2 Select *Create New*.

3 Enter the following information and select *OK*:

Name	VLAN_100_int
Interface	port2
VLAN ID	100
Virtual Domain	Company_A

4 Select *Create New*.

5 Enter the following information and select *OK*:

Name	VLAN_100_ext
Interface	port1
VLAN ID	100
Virtual Domain	Company_A

To add the VLAN subinterfaces - CLI

```
config system interface
  edit VLAN_100_int
    set interface port2
    set vlanid 100
    set vdom Company_A
  next
  edit VLAN_100_ext
    set interface port1
```

```
    set vlanid 100
    set vdom Company_A
  end
```

Creating the Lunch schedule

Both organizations have the same lunch schedule, but only Company A has relaxed its security policy to allow employees more freedom in accessing the Internet during lunch. Lunch schedule will be Monday to Friday from 11:45am to 2:00pm (14:00).

To create a recurring schedule for lunchtime - web-based manager

1. In Company_A VDOM, go to *Firewall Objects* > *Schedule* > *Recurring*.
2. Select *Create New*.
3. Enter `Lunch` as the name for the schedule.
4. Select *Mon*, *Tues*, *Wed*, *Thu*, and *Fri*.
5. Set the *Start* time as `11:45` and set the *Stop* time as `14:00`.
6. Select *OK*.

To create a recurring schedule for lunchtime - CLI

```
config vdom
  edit Company_A
    config firewall schedule recurring
      edit Lunch
        set day monday tuesday wednesday thursday friday
        set start 11:45
        set end 14:00
      end
```

Configuring Company_A firewall addresses

For Company A, its networks are all on the 10.11.0.0 network, so restricting addresses to that domain provides added security.

To configure Company_A firewall addresses - web-based manager

1. In the Company_A VDOM, go to *Firewall Objects* > *Address* > *Address*.
2. Select *Create New*.
3. Enter `CompanyA` in the *Address Name* field.
4. Type 10.11.0.0/255.255.0.0 in the *Subnet* / *IP Range* field.
5. Select *OK*.

To configure vdomA firewall addresses - CLI

```
config firewall address
  edit CompanyA
    set type ipmask
    set subnet 10.11.0.0 255.255.0.0
  end
```

Creating Company_A security policies

A security policy can include varying levels of UTM protection. This example only deals with web filtering. The following security policies use the custom UTM `strict` and `relaxed` profiles configured earlier. See "Configuring common items" on page 1927.

For these security policies, we assume that all protocols will be on their standard ports, such as port 80 for http traffic. If the ports are changed, such as using port 8080 for http traffic, you will have to create custom services for protocols with non-standard ports, and assign them different names.

The firewalls configured in this section are:

- internal to external — always deny all
- external to internal — always deny all
- internal to external — always allow all, UTM - web filtering: strict
- internal to external — Lunch allow all, UTM - web filtering:relaxed

Security policies allow packets to travel between the internal VLAN_100 interface to the external interface subject to the restrictions of the protection profile. Entering the policies in this order means the last one configured is at the top of the policy list, and will be checked first. This is important because the policies are arranged so if one does not apply the next is checked until the end of the list.

To configure Company_A security policies - web-based manager

1 Go to *Policy* > *Policy*.

2 Select *Create New*.

3 Enter the following information and select *OK*:

Source Interface/Zone	VLAN_100_int
Source Address	CompanyA
Destination Interface/Zone	VLAN_100_ext
Destination Address	all
Schedule	always
Service	all
Action	DENY

This policy is a catch all for outgoing traffic to ensure that if it doesn't match any of the other policies, it will not be allowed. This is standard procedure.

4 Select *Create New*.

5 Enter the following information and select *OK*:

Source Interface/Zone	VLAN_100_ext
Source Address	all
Destination Interface/Zone	VLAN_100_int
Destination Address	CompanyA
Schedule	always

Service	all
Action	DENY

This policy is a catch all for incoming traffic to ensure that if it doesn't match any of the other policies, it will not be allowed. This is standard procedure.

6 Select *Create New*.

7 Enter the following information and select *OK*:

Source Interface/Zone	VLAN_100_int
Source Address	CompanyA
Destination Interface/Zone	VLAN_100_ext
Destination Address	all
Schedule	always
Service	all
Action	ACCEPT
UTM	Enable
Web Filtering	strict

This policy enforces strict scanning at all times, while allowing all traffic. It ensures company policies are met for network security.

8 Select *Create New*.

9 Enter the following information and select *OK*:

Source Interface/Zone	VLAN_100_int
Source Address	CompanyA
Destination Interface/Zone	VLAN_100_ext
Destination Address	all
Schedule	Lunch
Service	all
Action	ACCEPT
UTM	enable
Web Filtering	relaxed

This policy provides relaxed protection during lunch hours — going from strict down to scan for protocol options and web filtering. AntiVirus and Email Filtering remain at strict for security — relaxing them would not provide employees additional access to the Internet and it would make the company vulnerable.

10 Verify that the policies entered appear in the list with the last policy (lunch) at the top, and the first policy (deny all) at the bottom. Otherwise traffic will not flow as expected.

To configure Company_A security policies - CLI

```
config vdom
  edit Company_A
    config firewall policy
      edit 1
        set srcintf VLAN_100_int
```

```
    set dstintf VLAN_100_ext
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule Lunch
    set UTM enabled
    set webfiltering relaxed
  next
  edit 3
    set srcintf VLAN_100_int
    set dstintf VLAN_100_ext
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule BusinessDay
    set service HTTP
    set profile_status enable
    set profile BusinessOnly
  end
```

Configuring the Company_B VDOM

This section describes how to add VLAN subinterfaces and configure security policies for the Company B VDOM.

This section includes the following topics:

- Adding VLAN subinterfaces
- Creating Company_B service groups
- Configuring Company_B firewall addresses
- Configuring Company_B security policies

Adding VLAN subinterfaces

You need to create a VLAN subinterface on the internal interface and another one on the external interface, both with the same VLAN ID.

To add VLAN subinterfaces - web-based manager

1. Go to *System* > *Network* > *Interface*.
2. Select *Create New*.
3. Enter the following information and select *OK*:

Name	VLAN_200_int
Interface	port2
VLAN ID	200
Virtual Domain	Company_B

4. Select *Create New*.
5. Enter the following information and select *OK*:

Name	VLAN_200_ext
Interface	port1

VLAN ID	200
Virtual Domain	Company_B

To add the VLAN subinterfaces - CLI

```
config system interface
  edit VLAN_200_int
    set interface internal
    set vlanid 200
    set vdom Company_B
  next
  edit VLAN_200_ext
    set interface external
    set vlanid 200
    set vdom Company_B
  end
```

Creating Company_B service groups

Company_B does not want its employees to use online gaming software or any online chat software except NetMeeting, which the company uses for net conferencing. To simplify the creation of a security policy for this purpose, you create a service group that contains all of the services you want to restrict. A security policy can manage only one service or one group. The administrator decided to simply name this group “Games” although it also restricts chat software.

To create a games service group - web-based manager

1. Go to *Firewall Objects* > *Service* > *Group*.
2. Select *Create New*.
3. Enter `Games` in the *Group Name* field.
4. For each of AOL, IRC, QUAKE, SIP-MSNmessenger and TALK, select the service in the *Available Services* list and select the right arrow to add it to the *Members* list.
5. Select *OK*.

To create a games and chat service group - CLI

```
config firewall service group
  edit Games
    set member IRC QUAKE AOL TALK
  end
```

Configuring Company_B firewall addresses

Company B’s network is all in the 10.12.0.0 network. Security can be improved by only allowing traffic from IP addresses on that network.

To configure Company_B firewall address - web-based manager

1. In the Company_B VDOM, go to *Firewall Objects* > *Address* > *Address.*
2. Select *Create New*.
3. Enter `new` in the *Address Name* field.
4. Type 10.12.0.0/255.255.0.0 in the *Subnet* / *IP Range* field.
5. Select *OK*.

To configure DEFdomain firewall addresses - CLI

```
config vdom
  edit Company_B
    config firewall address
      edit all
        set type ipmask
        set subnet 10.12.0.0 255.255.0.0
      end
```

Configuring Company_B security policies

Security policies allow packets to travel between the internal and external VLAN_200 interfaces subject to the restrictions of the protection profile.

To configure Company_B security policies - web-based manager

1 Go to *Policy* > *Policy*.

2 Select *Create New*.

3 Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200_int
Source Address	all
Destination Interface/Zone	VLAN_200_ext
Destination Address	all
Schedule	BusinessDay
Service	games-chat
Action	DENY

This policy prevents the use of network games or chat programs (except NetMeeting) during business hours.

4 Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200_int
Source Address	all
Destination Interface/Zone	VLAN_200_ext
Destination Address	all
Schedule	Lunch
Service	HTTP
Action	ACCEPT
Protection Profile	Relaxed

This policy relaxes the web category filtering during lunch hour.

5 Select *Create New*.

6 Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200_int
Source Address	all
Destination Interface/Zone	VLAN_200_ext
Destination Address	all
Schedule	BusinessDay
Service	HTTP
Action	ACCEPT
Protection Profile	BusinessOnly

This policy provides rather strict web category filtering during business hours.

7 Select *Create New*.

8 Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200_int
Source Address	all
Destination Interface/Zone	VLAN_200_ext
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT
Protection Profile	Relaxed

Because it is last in the list, this policy applies to the times and services not covered in preceding policies. This means that outside of regular business hours, the Relaxed protection profile applies to email and web browsing, and online chat and games are permitted. Company B needs this policy because its employees sometimes work overtime. The other companies in this example maintain fixed hours and do not want any after-hours Internet access.

To configure Company_B security policies - CLI

```
config firewall policy
  edit 1
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set schedule BusinessDay
    set service Games
    set action deny
  next
  edit 2
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
```

```
    set dstaddr all
    set action accept
    set schedule Lunch
    set service HTTP
    set profile_status enable
    set profile Relaxed
  next
  edit 3
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set action accept
    set schedule BusinessDay
    set service HTTP
    set profile_status enable
    set profile BusinessOnly
  next
  edit 4
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set profile_status enable
    set profile Relaxed
  end
```

Configuring the VLAN switch and router

The Cisco switch is the first VLAN device internal passes through, and the Cisco router is the last device before the Internet or ISP.

This section includes the following topics:

- Configuring the Cisco switch
- Configuring the Cisco router

Configuring the Cisco switch

On the Cisco Catalyst 2900 ethernet switch, you need to define the VLANs 100, 200 and 300 in the VLAN database, and then add configuration files to define the VLAN subinterfaces and the 802.1Q trunk interface.

Add this file to Cisco VLAN switch:

```
!
interface FastEthernet0/1
 switchport access vlan 100
!
interface FastEthernet0/5
 switchport access vlan 300
!
interface FastEthernet0/6
 switchport trunk encapsulation dot1q
```

```
 switchport mode trunk
!
```

Switch 1 has the following configuration:

Port 0/1	VLAN ID 100
Port 0/3	VLAN ID 200
Port 0/6	802.1Q trunk

Configuring the Cisco router

The configuration for the Cisco router in this example is the same as in the basic example, except we add VLAN_300. Each of the three companies has its own subnet assigned to it.

The IP addressees assigned to each VLAN on the router are the gateway addresses for the VLANs. For example, devices on VLAN_100 would have their gateway set to 10.11.0.1/255.255.0.0.

```
!
interface FastEthernet0/0
!
interface FastEthernet0/0.1
 encapsulation dot1Q 100
 ip address 10.11.0.1 255.255.0.0
!
interface FastEthernet0/0.3
 encapsulation dot1Q 200
 ip address 10.12.0.1 255.255.0.0
!
```

The router has the following configuration:

Port 0/0.1	VLAN ID 100
Port 0/0.3	VLAN ID 200
Port 0/0	802.1Q trunk

Testing the configuration

Use diagnostic commands, such as tracert, to test traffic routed through the network.

You should test traffic between the internal VLANs as well as from the internal VLANs to the Internet to ensure connectivity.

For additional troubleshooting, see “Troubleshooting Virtual Domains” on page 1977.

This section includes the following topics:

Testing traffic from VLAN_100 to the Internet

In this example, a route is traced from VLANs to a host on the Internet. The route target is www.example.com.

From a host on VLAN_100, access a command prompt and enter this command:

```
C:\>tracert www.example.com
Tracing route to www.example.com [208.77.188.166]
```

```
over a maximum of 30 hops:
 1   <10 ms   <10 ms   <10 ms  10.100.0.1
...
14   172 ms   141 ms   140 ms  208.77.188.166
Trace complete.
```

The number of steps between the first and the last hop, as well as their IP addresses, will vary depending on your location and ISP. However, all successful tracerts to www.example.com will start and end with these lines.

Repeat the tracert for VLAN_200.

The tracert for each VLAN will include the gateway for that VLAN as the first step. Otherwise, the tracert should be the same for each VLAN.

Testing traffic from VLAN_100 to VLAN_200

In this example, a route is traced between two internal networks. The route target is a host on VLAN_200. The Windows traceroute command `tracert` is used.

From VLAN_100, access a Windows command prompt and enter this command:

```
C:\>tracert 10.12.0.2
Tracing route to 10.12.0.2 over a maximum of 30 hops:
  1   <10 ms   <10 ms   <10 ms  10.100.0.1
  2   <10 ms   <10 ms   <10 ms 10.12.0.2
Trace complete.
```

You can repeat this for different routes in the topology. In each case the IP addresses will be the gateway for the starting VLAN, and the end point at the ending VLAN.

Inter-VDOM routing

In the past, virtual domains (VDOMs) were separate from each other—there was no internal communication. Any communication between VDOMs involved traffic leaving on a physical interface belonging to one VDOM and re-entering the FortiGate unit on another physical interface belonging to another VDOM to be inspected by firewall policies in both directions.

Inter-VDOM routing changes this. With VDOM links, VDOMs can communicate internally without using additional physical interfaces.

Inter-VDOM routing is the communication between VDOMs. VDOM links are virtual interfaces that connect VDOMs. A VDOM link contains a pair of interfaces with each one connected to a VDOM, and forming either end of the inter-VDOM connection.

This chapter contains the following sections:

Benefits of inter-VDOM routing

Inter-VDOM routing has a number of advantages over independent VDOM routing. These benefits include:

Freed-up physical interfaces

Tying up physical interfaces on the FortiGate unit presents a problem. With a limited number of interfaces available, configuration options for the old style of communication between VDOMs are very limited. VLANs can be an answer to this, but they have some limitations.

For example, the FortiGate-800 has 8 physical ethernet ports. If they are assigned 2 per VDOM (one each for external and internal traffic) there can only be 4 VDOMs at most configured, not the 10 VDOMs the license will allow. Adding even one additional interface per VDOM to be used to communicate between VDOMs leaves only 2 VDOMs for that configuration, since it would required 9 interfaces for 3 VDOMs. Even using one physical interface for both external traffic and inter-VDOM communication would severely lower the available bandwidth for external traffic on that interface.

With the introduction of inter-VDOM routing, traffic can travel between VDOMs internally, freeing up physical interfaces for external traffic. Using the above example we can use the 4 VDOM configuration and all the interfaces will have their full bandwidth.

More speed than physical interfaces

Internal interfaces are faster than physical interfaces. Their speed depends on the FortiGate unit CPU and its load. That means that an inter-VDOM link interface will be faster than a outbound physical interface connected to another inbound physical interface.

Inter-VDOM links are CPU bound, and cannot be part of an accelerated pair of interfaces.

However, while one virtual interface with normal traffic would be considerably faster than on a physical interface, the more traffic and more internal interfaces you configure, the slower they will become until they are slower than the physical interfaces. CPU load can come from other sources such as AV or content scanning. This produces the same effect—internal interfaces such as inter-VDOM links will be slower.

Continued support for secure firewall policies

VDOMs help to separate traffic based on your needs. This is an important step in satisfying regulations that require proof of secure data handling. This is especially important to health, law, accounting, and other businesses that handle sensitive data every day.

By keeping things separate, traffic has to leave the FortiGate unit and re-enter to change VDOMs. This forces traffic to go through the firewall when leaving and enter through another firewall, keeping traffic secure.

With inter-VDOM routing, the need for the physical interfaces is greatly reduced. However, firewall policies still need to be in place for traffic to pass through any interface, physical or virtual, and thus provide the same level of security both internally and externally. Configuration of firewall policies is the same for inter-VDOM links as for any other interface, and your data will continue to have the high level of security.

Configuration flexibility

A typical VDOM uses at least two interfaces, typically physical interfaces, one for internal and one for external traffic. Depending on the configuration, more interfaces may be required. The one exception to this is possibly one-armed IPS.

As explained earlier, the maximum number of VDOMs configurable on a FortiGate unit is the number of physical interfaces available divided by two. VLANs can increase the number by providing multiple virtual interfaces over a single physical interface, but VLANs have some limitations.

Using physical interfaces for inter-VDOM communication severely limits the number of possible configurations on your FortiGate unit, but inter-VDOM routing allows these connections to be moved inside the FortiGate unit. Using virtual interfaces, VDOM links, frees up the physical interfaces for external traffic. Using VDOM links on a FortiGate unit with 8 interfaces, you can have 4 VDOMs communicating with each other (meshed configuration) and continue to have 2 physical interfaces each for internal and external connections. This configuration would have required 20 physical interfaces without inter-VDOM routing. With inter-VDOM routing it only requires 8 physical interfaces, with the other 12 interfaces being internal VDOM links.

Inter-VDOM routing allows you to select Standalone VDOM configuration, Management VDOM configuration and Meshed VDOM configuration without being limited by the number of physical interfaces on your FortiGate unit.

Getting started with VDOM links

Once VDOMs are configured on your FortiGate unit, configuring inter-VDOM routing and VDOM-links is very much like creating a VLAN interface.

VDOM-links are managed through the web-based manager or CLI. In the web-based manager, VDOM link interfaces are managed in the network interface list.

This section includes the following topics:

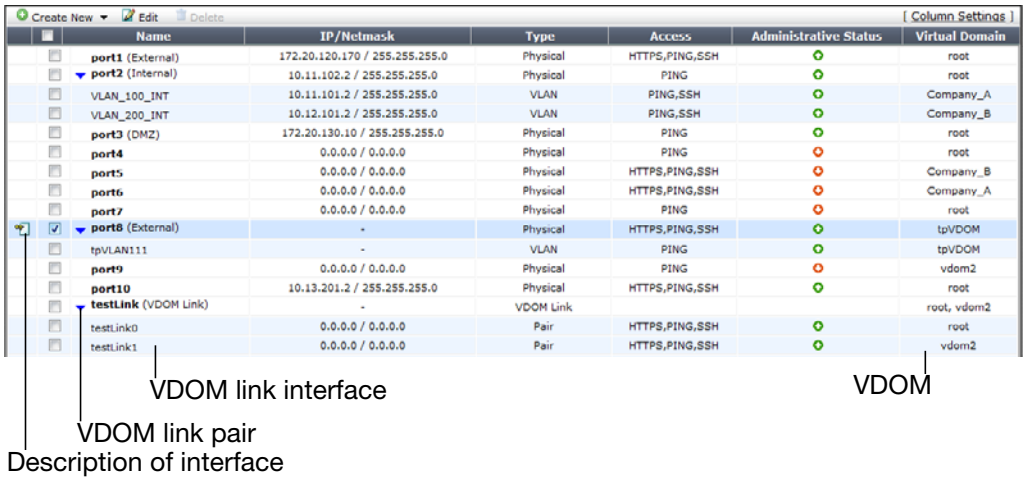
Viewing VDOM links

VDOM links are displayed on the network interface list in the web-based manager.

You can view VDOM links only if you are using a super_admin account and in global configuration.

To view the network interface list, in the Global menu go to *System* > *Network* > *Interface.*

Figure 187: Interface list displaying interface names and information



Create New	Select the arrow to create a new interface or VDOM link. Interface options include VLAN, Aggregate, Redundant, or loopback interfaces. For more information, see "Creating VDOM links" on page 1944.
Edit	Select to change interface configuration for the selected interface. This option not available if no interfaces or multiple interfaces are selected.
Delete	Select to remove an interface from the list. One or more interfaces must be selected for this option to be available. You cannot delete permanent physical interfaces, or any interfaces that have configuration referring to them. See "Deleting VDOM links" on page 1946 or "Deleting an interface" on page 1906.

Column Settings	Select to change which information is displayed about the interfaces, and in which order the columns appear. Use to display VDOM, VLAN, and other information.
Checkbox	Select the checkbox for an interface to edit or delete that interface. Select multiple interfaces to delete those interfaces. Optionally select the check box at the top of the column to select or unselect all checkboxes.
Name	The name of the interface. The name of the VDOM link (`vlink1`) has an expand arrow to display or hide the pair of VDOM link interfaces. For more information, see "Viewing VDOM links" on page 1943.
IP/Netmask	The IP address and netmask assigned to this interface.
Type	The type of interface such as physical, VLAN, or VDOM link pair.
Access	The protocols allowed for administrators to connect to the FortiGate unit.
Administrative Status	The status of this interface, either set to up (active) or down (disabled).
Virtual Domain	The virtual domain this interface belongs to. For more information on VDOMs, see "Virtual Domains in NAT/Route mode" on page 1903.

Creating VDOM links

VDOM links connect VDOMs together to allow traffic to pass between VDOMs as per firewall policies. Inter-VDOM links are virtual interfaces that are very similar to VPN tunnel interfaces except inter-VDOM links do not require IP addresses. See "IP addresses are not required for inter-VDOM links" on page 1945.

To create a VDOM link, you first create the point-to-point interface, and then bind the two interface objects associated with it to the virtual domains.

In creating the point-to-point interface, you also create two additional interface objects by default. They are called `vlink10` and `vlink11` - the interface name you chose with a 1 or a 0 to designate the two ends of the link.

Once the interface objects are bound, they are treated like normal FortiGate interfaces and need to be configured just like regular interfaces.

The assumptions for this example are as follows:

- Your FortiGate unit has VDOMs enabled and you have 2 VDOMs called `customer1` and `customer2` already configured. For more information on configuring VDOMs see "Only a super_admin administrator account such as the default "admin" account can create, disable, or delete VDOMs. That account can create additional administrators for each VDOM." on page 1895.
- You are using a super_admin account

Inter-VDOM links cannot include VDOMs in Transparent mode.

To configure an inter-VDOM link - web-based manager

1 For Current VDOM, select Global..

2 Select *System* > *Network* > *Interface*.

3 Select *Create New* > *VDOM link*, enter the following information, and select *OK*.

Name		vlink1 (The name can be up to 11 characters long. Valid characters are letters, numbers, “-”, and “_”. No spaces are allowed.)
Interface #0		
	Virtual Domain	customer1
	IP/Netmask	10.11.12.13/255.255.255.0
	Administrative Access	HTTPS, SSL
Interface #1		
	Virtual Domain	customer2
	IP/Netmask	172.120.100.13/255.255.255.0
	Administrative Access	HTTPS, SSL

If your inter-VDOM links have names longer than 8 characters, and you upgrade from FortiOS 3.0 MR3, the names will be truncated to 8 characters and will not function. The solution is to change the names of your inter-VDOM links before you upgrade.

To configure an inter-VDOM link - CLI

```
config global
  config system vdom-link
    edit vlink1
    end
  config system interface
    edit vlink10
      set vdom customer1
    next
    edit vlink11
      set vdom customer2
    end
```

Once you have created and bound the interface ends to VDOMs, configure the appropriate firewall policies and other settings that you require. To confirm the inter-VDOM link was created, find the VDOM link pair and use the expand arrow to view the two VDOM link interfaces. You can select edit to change any information.

IP addresses are not required for inter-VDOM links

Besides being virtual interfaces, here is one main difference between inter-VDOM links and regular interfaces—inter-VDOM links do not require IP addresses. This introduces three possible situations with inter-VDOM links that are:

- **unnumbered** - an inter-VDOM link with no IP addresses for either end of the tunnel

- **half numbered** - an inter-VDOM link with one IP address for one end and none for the other end
- **full numbered** - an inter-VDOM link with two IP addresses, one for each end.

An IP address is not required for inter-VDOM links because it is an internal connection that can be referred to by the interface name in firewall policies, and other system references.

Not using an IP address in the configuration can speed up and simplify configuration for you Also you will not use up all the IP addresses in your subnets if you have many inter-VDOM links.

Half or full numbered interfaces are required if you are doing NAT, either SNAT or DNAT as you need an IP number on both ends to translate between.

You can use unnumbered interfaces in static routing, by naming the interface and using `0.0.0.0` for the gateway. Running traceroute will not show the interface in the list of hops. However you can see the interface when you are sniffing packets, which is useful for troubleshooting.

Deleting VDOM links

When you delete the VDOM link, the two link objects associated with it will also be deleted. You cannot delete the objects by themselves. The example uses a VDOM routing connection called “vlink1”. Removing vlink1 will also remove its two link objects vlink10 and vlink11.

Before deleting the VDOM link, ensure all policies, firewalls, and other configurations that include the VDOM link are deleted, removed, or changed to no longer include the VDOM link.

To remove a VDOM link - web-based manager

1 For Current VDOM, select Global..
2 Select *System* > *Network* > *Interface*.
3 Select *Delete* for the VDOM link *vlink1*.

To remove a VDOM link - CLI

```
config global
  config system vdom-link
    delete vlink1
  end
```

For more information, see the FortiGate CLI Reference.

Once the inter-VDOM link is created, you cannot change these IP addresses without deleting the link.

Inter-VDOM configurations

By using fewer physical interfaces to inter-connect VDOMs, inter-VDOM links provide you with more configuration options.

None of these configurations use VLANs to reduce the number of physical interfaces. It is generally assumed that an internal or client network will have its own internal interface and an external interface to connect to its ISP and the Internet.

These inter-VDOM configurations can use any FortiGate model with possible limitations based on the number of physical interfaces. VLANs can be used to work around these limitations.

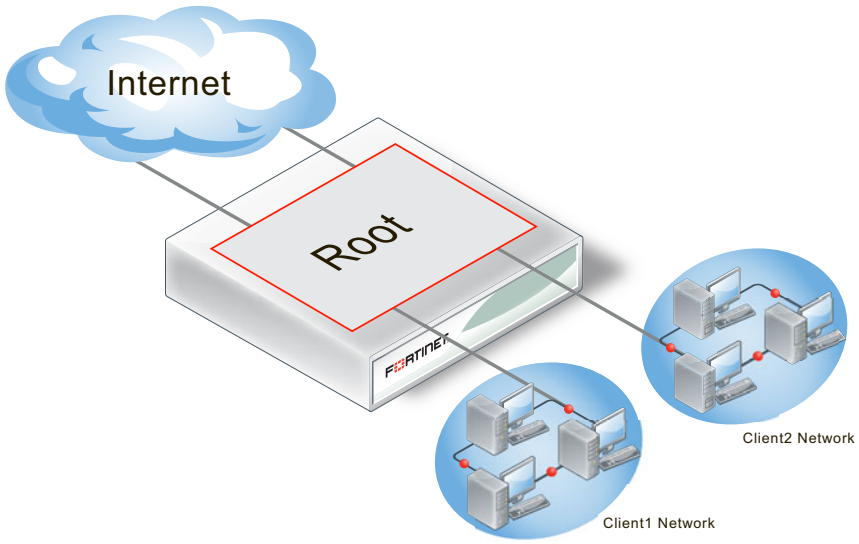
In the following inter-VDOM diagrams, red indicates the physical FortiGate unit, grey indicate network connections external to the FortiGate unit, and black is used for inter-VDOM links and VDOMs.

This section includes the following topics:

Standalone VDOM configuration

The standalone VDOM configuration uses a single VDOM on your FortiGate unit — the root VDOM that all FortiGate units have by default. This is the VDOM configuration you are likely familiar with. It is the default configuration for FortiGate units before you create additional VDOMs.

Figure 188: Standalone VDOM



The configuration shown in Figure 188 has no VDOM inter-connections and requires no special configurations or settings.

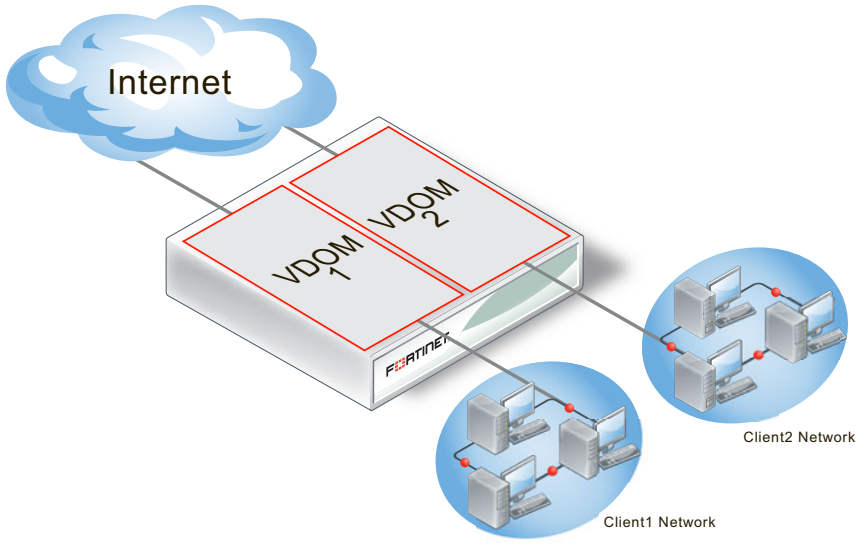
The standalone VDOM configuration can be used for simple network configurations that only have one department or one company administering the connections, firewalls and other VDOM-dependent settings.

However, with this configuration, keeping client networks separate requires many interfaces, considerable firewall design and maintenance, and can quickly become time consuming and complex. Also, configuration errors for one client network can easily affect other client networks, causing unnecessary network downtime.

Independent VDOMs configuration

The independent VDOMs configuration uses multiple VDOMs that are completely separate from each other. This is another common VDOM configuration.

Figure 189: Independent VDOMs



This configuration has no communication between VDOMs and apart from initially setting up each VDOM, it requires no special configurations or settings. Any communication between VDOMs is treated as if communication is between separate physical devices.

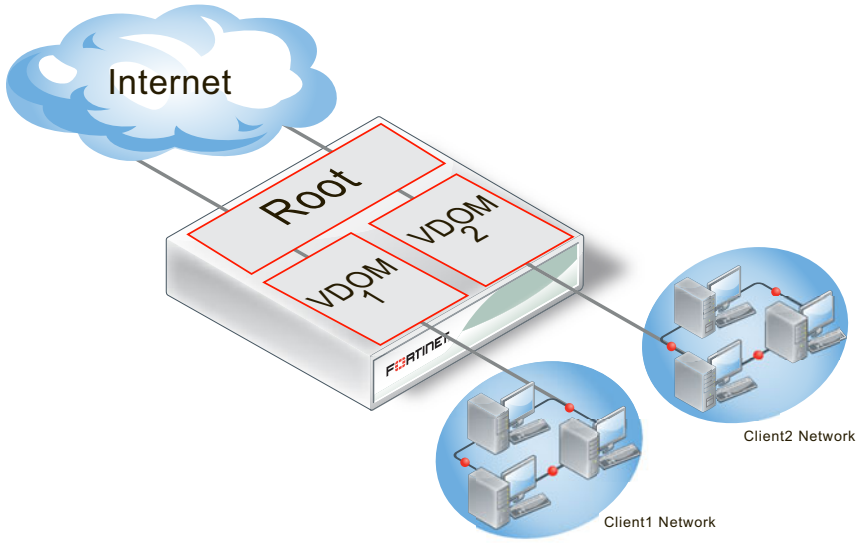
The independent inter-VDOM configuration can be used where more than one department or one company is sharing the FortiGate unit. Each can administer the connections, firewalls and other VDOM-dependent settings for only its own VDOM. To each company or department, it appears as if it has its own FortiGate unit. This configuration reduces the amount of firewall configuration and maintenance required by dividing up the work.

However, this configuration lacks a management VDOM for VDOMs 1, 2, and 3. This is illustrated in Figure 50. This management VDOM would enable an extra level of control for the FortiGate unit administrator, while still allowing each company or department to administer its own VDOM.

Management VDOM configuration

In the management VDOM configuration, the root VDOM is the management VDOM. The other VDOMs are connected to the management VDOM with inter-VDOM links. There are no other inter-VDOM connections.

Figure 190: Management VDOM configuration



The inter-VDOM links connect the management VDOM to the other VDOMs. This does not require any physical interfaces, and the bandwidth of inter-VDOM links can be faster than physical interfaces, depending on the CPU workload.

Only the management VDOM is connected to the Internet. The other VDOMs are connected to internal networks. All external traffic is routed through the management VDOM using inter-VDOM links and firewall policies between the management VDOM and each VDOM. This ensures the management VDOM has full control over access to the Internet, including what types of traffic are allowed in both directions. There is no communication directly between the non-root VDOMs. Security is greatly increased with only one point of entry and exit. Only the management VDOM needs to be fully managed to ensure network security in this case. Each client network can manage its own configuration without compromising security or bringing down another client network.

The management VDOM configuration is ideally suited for a service provider business. The service provider administers the management VDOM with the other VDOMs as customers. These customers do not require a dedicated IT person to manage their network. The service provider controls the traffic and can prevent the customers from using banned services and prevent Internet connections from initiating those same banned services. One example of a banned service might be Instant Messaging (IM) at a company concerned about intellectual property. Another example could be to limit bandwidth used by file-sharing applications without banning that application completely. Firewall policies control the traffic between the customer VDOM and the management VDOM and can be customized for each customer.

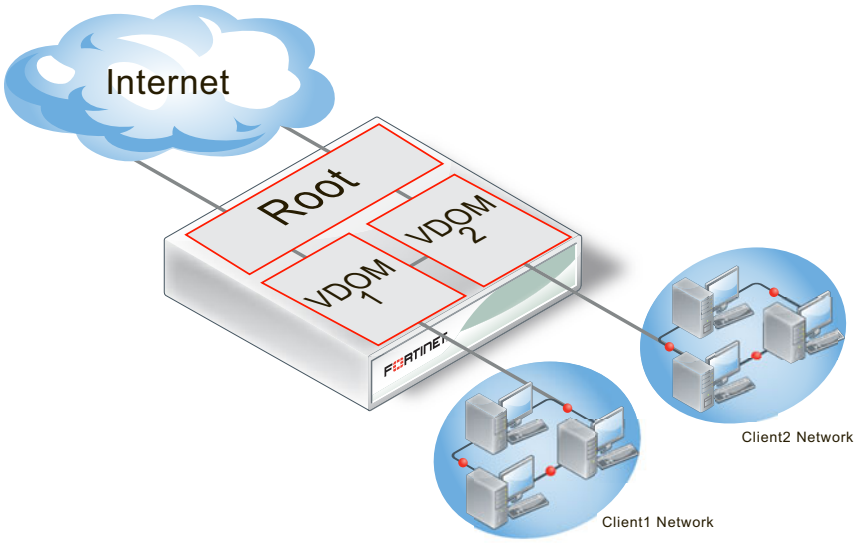
The management VDOM configuration is limited in that the customer VDOMs have no inter-connections. In many situations this limitation is ideal because it maintains proper security. However, some configurations may require customers to communicate with each other, which would be easier if the customer VDOMs were inter-connected.

Meshed VDOM configuration

The meshed VDOMs configuration, including partial and full mesh, has VDOMs inter-connected with other VDOMs. There is no special feature to accomplish this—they are just complex VDOM configurations.

Partial mesh means only some VDOMs are inter-connected. In a full mesh configuration, all VDOMs are inter-connected to all other VDOMs. This can be useful when you want to provide full access between VDOMs but handle traffic differently depending on which VDOM it originates from or is going to.

Figure 191: Meshed VDOMs



With full access between all VDOMs being possible, it is extra important to ensure proper security. You can achieve this level of security by establishing extensive firewall policies and ensuring secure account access for all administrators and users.

Meshed VDOM configurations can become complex very quickly, with full mesh VDOMs being the most complex. Ensure this is the proper solution for your situation before using this configuration. Generally, these configurations are seen as theoretical and are rarely deployed in the field.

Dynamic routing over inter-VDOM links

BGP is supported over inter-VDOM links. Unless otherwise indicated, routing works as expected over inter-VDOM links.

If an inter-VDOM link has no assigned IP addresses to it, it may be difficult to use that interface in dynamic routing configurations. For example BGP requires an IP address to define any BGP router added to the network.

In OSPF, you can configure a router using a router ID and not its IP address. In fact, having no IP address avoids possible confusing between which value is the router ID and which is the IP address. However for that router to become adjacent with another OSPF router it will have to share the same subnet, which is technically impossible without an IP address. For this reason, while you can configure an OSPF router using an IP-less inter-VDOM link, it will likely be of limited value to you.

In RIP the metric used is hop count. If the inter-VDOM link can reach other nodes on the network, such as through a default route, then it may be possible to configure a RIP router on an inter-VDOM link. However, once again it may be of limited value due to limitations.

As stated earlier, BGP requires an IP address to define a router — an IP-less inter-VDOM link will not work with BGP.

In Multicast, you can configure an interface without using an IP address. However that interface will be unable to become an RP candidate. This limits the roles available to such an interface.

HA virtual clusters and VDOM links

FortiGate HA is implemented by configuring two or more FortiGate units to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate unit, processing network traffic and providing normal security services such as firewall, VPN, IPS, virus scanning, web filtering, and spam filtering.

Virtual clustering extends HA features to provide failover protection and load balancing for a FortiGate unit operating with virtual domains. A virtual cluster consists of a cluster of two FortiGate units operating with virtual domains. Traffic on different virtual domains can be load balanced between the cluster units.

With virtual clusters (vclusters) configured, inter-VDOM links must be entirely within one vcluster. You cannot create links between vclusters, and you cannot move a VDOM that is linked into another virtual cluster. If your FortiGate units are operating in HA mode, with multiple vclusters when you create the vdom-link, the CLI command `config system vdom-link` includes an option to set which vcluster the link will be in. For more information, see the FortiGate HA Guide.

What is virtual clustering?

Virtual clustering is an extension of the FGCP for FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Virtual clustering and failover protection

Virtual clustering operates on a cluster of two (and only two) FortiGate units with VDOMs enabled. Each VDOM creates a cluster between instances of the VDOMs on the two FortiGate units in the virtual cluster. All traffic to and from the VDOM stays within the VDOM and is processed by the VDOM. One cluster unit is the primary unit for each VDOM and one cluster unit is the subordinate unit for each VDOM. The primary unit processes all traffic for the VDOM. The subordinate unit does not process traffic for the VDOM. If a cluster unit fails, all traffic fails over to the cluster unit that is still operating.

Virtual clustering and heartbeat interfaces

The HA heartbeat provides the same HA services in a virtual clustering configuration as in a standard HA configuration. One set of HA heartbeat interfaces provides HA heartbeat services for all of the VDOMs in the cluster. You do not have to add a heartbeat interface for each VDOM.

Virtual clustering and HA override

For a virtual cluster configuration, override is enabled by default for both virtual clusters when you:

- Enable VDOM portioning from the web-based manager by moving virtual domains to virtual cluster 2
- Enter set vcluster2 enable from the CLI config system ha command to enable virtual cluster 2.

Usually you would enable virtual cluster 2 and expect one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. For this distribution to occur override must be enabled for both virtual clusters. Otherwise you will need to restart the cluster to force it to renegotiate.

Virtual clustering and load balancing or VDOM partitioning

There are two ways to configure load balancing for virtual clustering. The first is to set the HA mode to active-active. The second is to configure VDOM partitioning. For virtual clustering, setting the HA Mode to active-active has the same result as active-active HA for a cluster without virtual domains. The primary unit receives all sessions and load balances them among the cluster units according to the load balancing schedule. All cluster units process traffic for all virtual domains.

Note: If override is enabled the cluster may renegotiate too often. You can choose to disable override at any time. If you decide to disable override, for best results, you should disable it for both cluster units.

In a VDOM partitioning virtual clustering configuration, the HA mode is set to active-passive. Even though virtual clustering operates in active-passive mode you can configure a form of load balancing by using VDOM partitioning to distribute traffic between both cluster units. To configure VDOM partitioning you set one cluster unit as the primary unit for some virtual domains and you set the other cluster unit as the primary unit for other virtual domains. All traffic for a virtual domain is processed by the primary unit for that virtual domain. You can control the distribution of traffic between the cluster units by adjusting which cluster unit is the primary unit for each virtual domain.

For example, you could have 4 VDOMs, two of which have a high traffic volume and two of which have a low traffic volume. You can configure each cluster unit to be the primary unit for one of the high volume VDOMs and one of the low volume VDOMs. As a result each cluster unit will be processing traffic for a high volume VDOM and a low volume VDOM, resulting in an even distribution of traffic between the cluster units. You can adjust the distribution at any time. For example, if a low volume VDOM becomes a high volume VDOM you can move it from one cluster unit to another until the best balance is achieved. From the web-based manager you configure VDOM partitioning by setting the HA mode to active-passive and distributing virtual domains between Virtual Cluster 1 and Virtual Cluster 2. You can also configure different device priorities, port monitoring, and remote link failover, for Virtual Cluster 1 and Virtual Cluster 2.

From the CLI you configure VDOM partitioning by setting the HA mode to a-p. Then you configure device priority, port monitoring, and remote link failover and specify the VDOMs to include in virtual cluster 1. You do the same for virtual cluster 2 by entering the config secondary-vcluster command.

Failover protection does not change. If one cluster unit fails, all sessions are processed by the remaining cluster unit. No traffic interruption occurs for the virtual domains for which the still functioning cluster unit was the primary unit. Traffic may be interrupted temporarily for virtual domains for which the failed unit was the primary unit while processing fails over to the still functioning cluster unit. If the failed cluster unit restarts and rejoins the virtual cluster, VDOM partitioning load balancing is restored.

Example of inter-VDOM routing

This example shows how to configure a FortiGate unit to use inter-VDOM routing.

This section contains the follow topics:

Network topology and assumptions

Two departments of a company, Accounting and Sales, are connected to one FortiGate-800 unit. To do its work, the Sales department receives a lot of email from advertising companies that would appear to be spam if the Accounting department received it. For this reason, each department has its own VDOM to keep firewall policies and other configurations separate. A management VDOM makes sense to ensure company policies are followed for traffic content.

The traffic between Accounting and Sales will be email and HTTPS only. It could use a VDOM link for a meshed configuration, but we will keep from getting too complex. With the configuration, inter-VDOM traffic will have a slightly longer path to follow than normal—from one department VDOM, through the management VDOM, and back to the other department VDOM. Since inter-VDOM links are faster than physical interfaces, this longer path should not be noticed.

Firewall policies will be in place. For added security, firewall policies will allow only valid office services such as email, web browsing, and FTP between either department and the Internet. Any additional services that are required can be added in the future.

The company uses a single ISP to connect to the Internet. The ISP uses DHCP to provide an IP address to the FortiGate unit. Both departments use the same ISP to reach the Internet.

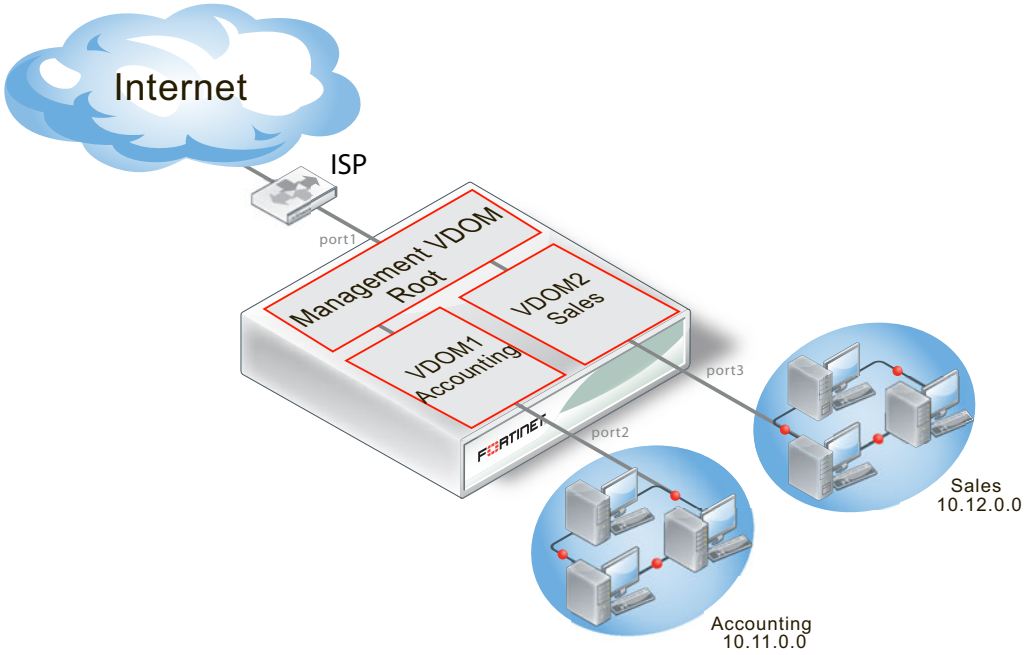
Other assumptions for this example are as follows:

- Your FortiGate unit has interfaces labelled port1 through port4 and VDOMs are not enabled.
- You are using the super_admin account.
- You have the FortiClient application installed.

- You are familiar with configuring interfaces, firewalls, and other common features on your FortiGate unit.

All configuration is available to a super_admin. A non-super_admin account may also perform certain procedures, but only for the VDOM that the account has access to. For more information, see “Administrators in Virtual Domains” on page 1898.

Figure 192: Management VDOM for two departments



General configuration steps

This example includes the following general steps. For best results, follow the steps in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1 Creating the VDOMs
2 Configuring the physical interfaces
3 Configuring the VDOM links
4 Configuring the firewall and UTM settings
5 Testing the configuration

Creating the VDOMs

This procedure enables VDOMs and creates the Sales and Accounting VDOMs.

To create the VDOMs - web-based manager

1 Log in as the super_admin administrator.
2 Go to *System* > *Dashboard* > *Status* > *System Information* > *Virtual Domain*, and select *Enable*.
3 Log in again.

4 Go to *System* > *VDOM* > *VDOM*.

5 Select *Create New*, enter `Accounting` for the VDOM Name, and select *OK*.

6 Select *Create New*, enter `Sales` for the VDOM Name, and select *OK*.

To create the VDOMs - CLI

```
config system global
  set vdom enable
end

config system vdom
  edit Accounting
  next
  edit Sales
  next
end
```

Configuring the physical interfaces

Next, the physical interfaces must be configured. This example uses three interfaces on the FortiGate unit - port2 (internal), port3(dmz), and port1(external). port2 and port3 interfaces each have a department's network connected. port1 is for all traffic to or from the Internet and will use DHCP to configure its IP address, which is common with many ISPs.

To configure the physical interfaces - web-based manager

1 In *Current VDOM*, select Global.

2 Select *System* > *Network* > *Interface*.

3 Select *Edit* for the port2 interface, enter the following information, and select *OK.*

Alias	AccountingLocal
Virtual Domain	Accounting
Addressing mode	Manual
IP/Netmask	172.100.1.1/255.255.0.0
Administrative Access	HTTPS, PING, SSH
Description	This is the accounting department internal interface.

4 Select *Edit* for the port3 interface, enter the following information, and select *OK*.

Alias	SalesLocal
Virtual Domain	Sales
Addressing mode	Manual
IP/Netmask	192.168.1.1/255.255.0.0
Administrative Access	HTTPS, PING, SSH
Description	This is the sales department internal interface.

5 Select *Edit* for the port1 interface, enter the following information, and select *OK*.

Alias	ManagementExternal
Virtual Domain	root
Addressing Mode	DHCP
Distance	5
Retrieve default gateway from server	Enable
Override internal DNS	Enable
Administrative Access	HTTPS, SSH, SNMP
Description	This is the accounting department internal interface.

hen the mode is set to DHCP or PPoE on an interface you can set the distance field. This is the administrative distance for any routes learned through the gateway for this interface. The gateway is added to the static route table with these values. A lower distance indicates a preferred route.

To configure the physical interfaces - CLI

```
config global
  config system interface
    edit port2
      set alias AccountingLocal
      set vdom Accounting
      set mode static
      set ip 172.100.1.1 255.255.0.0
      set allowaccess https ping ssh
      set description "The accounting dept internal interface"
    next
    edit port3
      set alias SalesLocal
      set vdom Sales
      set mode static
      set ip 192.168.1.1 255.255.0.0
      set allowaccess https ping ssh
      set description "The sales dept. internal interface"
    next
    edit port1
      set alias ManagementExternal
      set vdom root
      set mode DHCP
      set distance 5
      set gwdetect enable
      set dns-server-override enable
      set allowaccess https ssh snmp
      set description “The systemwide management interface.”
    end
```

Configuring the VDOM links

To complete the connection between each VDOM and the management VDOM, you need to add the two VDOM links; one pair is the Accounting - management link and the other is for Sales - management link.

When configuring inter-VDOM links, you do not have to assign IP addresses to the links unless you are using advanced features such as dynamic routing that require them. Not assigning IP addresses results in faster configuration, and more available IP addresses on your networks.

If you require them, or if you simply want to assign IP addresses for clarity can do so.

To configure the Accounting and management VDOM link - web-based manager

1 In *Current VDOM*, select Global..

2 Select *System* > *Network* > *Interface*.

3 Select the expand arrow to select *Create New* > *VDOM link*.

4 Enter the following information, and select *OK*.

Name	AccountVlnk
Interface #0	
Virtual Domain	Accounting
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Accounting VDOM side of the link.
Interface #1	
Virtual Domain	root
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Management VDOM side of the link.

To configure the Accounting and management VDOM link - CLI

```
config global
  config system vdom-link
    edit AccountVlnk
    next
  end
  config system interface
    edit AccountVlnk0
      set vdom Accounting
      set ip 0.0.0.0 0.0.0.0
      set allowaccess https ping ssh
      set description "Accounting side of the VDOM link"
    next
    edit AccountVlnk1
      set vdom root
      set ip 0.0.0.0 0.0.0.0
      set allowaccess https ping ssh
      set description "Management side of the VDOM link"
    end
```

To configure the Sales and management VDOM link - web-based manager

1 In *Current VDOM*, select Global.

2 Select *System* > *Network* > *Interface*.

3 Select the expand arrow and select *Create New* > *VDOM link*.

4 Enter the following information, and select *OK*.

Name	SalesVlnk
Interface #0	
Virtual Domain	Sales
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Sales VDOM side of the link.
Interface #1	
Virtual Domain	root
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Management VDOM side of the link.

To configure the Sales and management VDOM link - CLI

```
config global
  config system vdom-link
    edit SalesVlnk
  end
  config system interface
    edit SalesVlnk0
      set vdom Accounting
      set ip 0.0.0.0 0.0.0.0
      set allowaccess https ping ssh
      set description "Sales side of the VDOM link"
    next
    edit SalesVlnk1
      set vdom root
      set ip 0.0.0.0 0.0.0.0
      set allowaccess https ping ssh
      set description "Management side of the VDOM link"
    end
  end
```

Configuring the firewall and UTM settings

With the VDOMs, physical interfaces, and VDOM links configured the firewall must now be configured to allow the proper traffic. Firewalls are configured per-VDOM, and firewall objects must be created for each VDOM separately.

For this example, the firewall group of services allowed between the internal networks and the Internet are the basic services for web browsing, file transfer, and email. These include: HTTP, HTTPS, SSL, FTP, DNS, NTP, POP3, and SMTP.

The only services allowed between Sales and Accounting are secure web browsing (HTTPS) and email (POP3 and SMTP)

The limited number of services ensures security between departments. The list of services can be expanded in the future if needed.

UTM settings will block all non-essential business websites while logging all web traffic, scan and file filter all web and email protocols, and block game and peer-to-peer applications using application control.

For added security, FortiClient is required on internal computers with AntiVirus scanning configured. This is enforced by *Endpoint NAC* in firewall policies.

Using firewall addresses makes the firewall policies easier to read. Also if any changes need to be made in the future, you can simply update the addresses without changing the firewall policies. The addresses required are:

- `AccountingLocal` - all traffic from the internal accounting network
- `AccountingVlnk` - all traffic from the VDOM link between accounting and management VDOMs
- `SalesLocal` - all traffic from the internal sales network
- `SalesVlnk` - all traffic from the VDOM link between sales and management VDOM.

The Accounting VDOM requires `AccountingLocal`, `AccountingVlnk`, and `SalesLocal`. The Sales VDOM requires `SalesLocal`, `SalesVlnk`, and `AccountingLocal`.

The firewall policies required on the Accounting VDOM are

- AccountingLocal to Internet
- Internet to AccountingLocal
- SalesLocal to AccountingLocal
- AccountingLocal to SalesLocal

The firewall policies required on the Sales VDOM are

- SalesLocal to Internet
- Internet to SalesLocal
- SalesLocal to AccountingLocal
- AccountingLocal to SalesLocal

This section includes the following topics:

Configuring firewall service groups

Service groups are an easy way to manage multiple services, especially if the same services are used on different networks.

The two service groups used here are intended for normal office traffic to the Internet, and for restricted traffic between departments. In both cases network traffic will be limited to the services listed to prevent any potential security risks or bandwidth-robbing applications.

These service groups can be changed as needed to either include additional valid services that are being used on the network, or to exclude services that are not required. Also, custom services can be created as needed for applications that are not listed.

To configure two firewall service groups - web-based manager

1 In *Current VDOM*, select Accounting.

2 Go to *Firewall Objects* > *Service* > *Group.*

3 Select *Create New*, enter the following information, and select *OK.*

Group Name	OfficeServices
Members	HTTP, HTTPS, SSL, FTP, DNS, NTP, POP3, PING, SMTP

4 Select *Create New*, enter the following information, and select *OK*.

Group Name	AccountingSalesServices
Members	HTTPS, POP3, PING, SMTP

To configure two firewall service groups - CLI

```
config vdom
  edit Accounting
    config firewall service group
      edit OfficeServices
        set member HTTP HTTPS SSL FTP DNS NTP POP3 PING SMTP
      next
      edit AccountingSalesServices
        set member HTTPS POP3 PING SMTP
      end
  end
```

Configuring UTM settings for the Accounting VDOM

UTM settings include web filtering, antivirus, application control, and other features. This example just uses those three features to ensure that

- the business environment is free from viruses
- employees do not surf grossly inappropriate websites, and
- employees do not use games or peer-to-peer applications at work.

To configure web filtering for the Accounting VDOM - web-based manager

1 In *Current VDOM*, select Accounting.

2 Go to *UTM Profiles* > *Web Filter* > *Profile*.

3 Select *Create New*.

4 Enter `webStrict` for the *Name*.

5 Select the arrow to expand the *FortiGuard Web Filtering* section.
6 Block all *Categories* except Business Oriented, Other, and Unrated.
7 Block all *Classifications* except Image Search..
8 Log all *Categories* and *Classifications*.
9 Select *OK*.

To configure web filtering for the Accounting VDOM - CLI

```
config vdom
  edit Accounting
    config webfilter profile
      edit webStrict
        config ftgd-wf
          set allow g07 g08 g21 g22 c01 c03
          set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
        end
      set web-ftgd-err-log enable
      end
  end
```

To configure AntiVirus for the Accounting VDOM - web-based manager

1 In *Current VDOM*, select Accounting.
2 Go to *UTM Profiles* > *AntiVirus* > *Profile*.
3 Select *Create New*.
4 Enter `avStrict` for the *Name*.
5 Enable *Scan* for all protocols.
6 Enable *File filter* for all protocols, and select `built-in-patterns` for *Option*.
7 Enable logging for both *Scan* and *File Filter*.
8 Select *OK*.

To configure AntiVirus for the Accounting VDOM - CLI

```
config vdom
  edit Accounting
    config antivirus profile
      edit avStrict
        config http
          set options scan file-filter
        end
        config ftp
          set options scan file-filter
        end
        config imap
          set options scan file-filter
        end
        config pop3
          set options scan file-filter
        end
        config smtp
          set options scan file-filter
        end
```

```
        config nntp
          set options scan file-filter
        end
        config im
          set options scan file-filter
        end
        set filepattable 1
        set av-virus-log enable
        set av-block-log enable
      end
  end
```

To configure application control for the Accounting VDOM - web-based manager

1 In *Current VDOM*, select Accounting.
2 Go to *UTM Profiles* > *Application Control* > *Application Sensor.*
3 Select *Create New* (+ button at top right of page).
4 Enter `appStrict` for *Name* and select OK.
5 Select *Create New*.
6 In *Filters*, set *Category* to *game*.
7 In *Applications/Settings*, enter the following, and select *OK*.

Action	Block
Packet Logging	Enable

8 Select *Create New*.
9 In *Filters*, set *Category* to *p2p*.
10 In *Applications/Settings*, enter the following, and select *OK*.

Action	Block
Packet Logging	Enable

11 Select *Apply*.

To configure application control for the Accounting VDOM - CLI

```
config vdom
  edit Accounting
    config application list
      edit appStrict
        config entries
          edit 1
            set category 2
          next
          edit 2
            set category 8
          end
      end
  end
```

Configuring firewall settings for the Accounting VDOM

This configuration includes two firewall addresses and two firewall policies for the Accounting VDOM - one for the internal network, and one for the VDOM link with the management VDOM (root).

For added security, all traffic allowed will be scanned. Only valid office traffic will be allowed using the service group `OfficeServices`. The FortiClient application must be used to ensure additional protection for the sensitive accounting information.

All sales and accounting computers have the FortiClient application installed, so the firewall policies check that FortiClient is installed and that antivirus scanning is enabled.

Note the spelling of `AccountVlnk` which is due to the eleven character limit on VDOM link names.

To configure firewall addresses - web-based manager

1 For Current VDOM, select *Accounting*.

2 Select *Firewall Objects* > *Address* > *Address*

3 Select *Create New*, enter the following information, and select *OK*.

Address Name	AccountingLocal
Type	Subnet/ IP Range
Subnet / IP Range	172.100.0.0
Interface	port1

4 Select *Create New*, enter the following information, and select *OK*.

Address Name	AccountManagement
Type	Subnet/ IP Range
Subnet / IP Range	10.0.1.0
Interface	AccountVlnk

To configure firewall addresses - CLI

```
config vdom
  edit Accounting
    config firewall address
      edit AccountingLocal
        set type iprange
        set subnet 172.100.0.0
        set associated-interface port1
      next
      edit AccountManagement
        set type iprange
        set subnet 10.0.1.0
        set associated-interface AccountVlnk
      end
    end
```

To configure protocol options for Accounting VDOM - web-based manager

1 In *Current VDOM*, select Accounting.

2 Select *Policy* > *Policy* > *Protocol Options.*

3 Select *Create New*.

4 Enter `default` for the *Name*.

5 Select *OK*.

To configure the firewall policies from AccountingLocal to the Internet - web-based manager

1 In *Current VDOM*, select Accounting.

2 Go to *Policy* > *Policy*.

3 Select *Create New*, enter the following information, and then select *OK*.

Source Interface/Zone	port2
Source Address	AccountingLocal
Destination Interface/Zone	AccountVlnk
Destination Address	AccountManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
UTM	enabled
Protocol Option	default
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict
Enable Endpoint NAC	Enforce_FortiClient_AV

4 In *Current VDOM*, select root.

5 Go to *Policy* > *Policy.*

6 Select *Create New*, enter the following information, and then select *OK*.

Source Interface/Zone	AccountVlnk
Source Address	AccountManagement
Destination Interface/Zone	port2
Destination Address	all
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
UTM	enable
Protocol Option	default
Web Filtering	webStrict
AntiVirus Filtering	avStrict

Application Control	appStrict
Enable Endpoint NAC	disabled

To configure the firewall policies from AccountingLocal to Internet - CLI

```
config vdom
  edit Accounting
    config firewall policy
      edit 1
        set srcintf "port2"
        set dstintf "AccountVlnk"
        set srcaddr "AccountingLocal"
        set dstaddr "AccountManagement"
        set action accept
        set schedule "always"
        set service "OfficeServices"
        set nat enable
        set utm-status enable
        set av-profile avStrict
        set webfilter-profile webStrict
        set application-list appStrict
        set profile-protocol-options default
        set endpoint-check enable
        set endpoint-profile "FortiClient_installed"
      end
  end

config vdom
  edit root
    config firewall policy
      edit 2
        set srcintf AccountVlnk
        set dstintf port1
        set srcaddr AccountManagement
        set dstaddr all
        set action accept
        set schedule always
        set service OfficeServices
        set nat enable
        set utm-status enable
        set av-profile "scan"
        set webfilter-profile "scan"
        set application-list "AppControlList"
        set profile-protocol-options default
        set endpoint-check disable
      end
  end
```

To configure the firewall policies from Internet to AccountingLocal - web-based manager

1 In *Current VDOM*, select root.

2 Go to *Policy* > *Policy*.

3 Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	AccountVlnk
Destination Address	AccountManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
UTM	enable
Protocol Option	default
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict
Enable Endpoint NAC	disabled

4 In *Current VDOM*, select *Accounting*.

5 Go to *Policy* > *Policy.*

6 Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	AccountVlnk
Source Address	AccountManagement
Destination Interface/Zone	port2
Destination Address	AccountingLocal
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
UTM	enable
Protocol Option	default
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict
Enable Endpoint NAC	disabled

To configure the firewall policies from Internet to AccountingLocal - CLI

```
config vdom
  edit root
    config firewall policy
```

```
        edit 3
          set srcintf port1
          set dstintf AccountVlnk
          set srcaddr all
          set dstaddr AccountManagement
          set action accept
          set schedule always
          set service OfficeServices
          set nat enable
          set utm-status enable
          set av-profile avStrict
          set webfilter-profile webStrict
          set application-list appstrict
          set profile-protocol-options default
          set endpoint-check disable
        end
    end
config vdom
    edit Accounting
      config firewall policy
        edit 4
          set srcintf AccountVlnk
          set dstintf port2
          set srcaddr AccountManagement
          set dstaddr AccountingLocal
          set action accept
          set schedule always
          set service OfficeServices
          set nat enable
          set utm-status enable
          set av-profile avStrict
          set webfilter-profile webStrict
          set application-list appstrict
          set profile-protocol-options default
          set endpoint-check disable
        end
    end
```

Configuring UTM settings for the Sales VDOM

UTM settings include web filtering, antivirus, application control, and other features. This example just uses those three features to ensure that

- the business environment is free from viruses
- employees do not surf grossly inappropriate websites, and
- employees do not use games or peer-to-peer applications at work.

Note that Sales web traffic is different from Accounting, and web filtering is different to account for this.

To configure web filtering for the Sales VDOM - web-based manager

1 In *Current VDOM*, select Sales.

2 Go to *UTM Profiles* > *Web Filter* > *Profile*.

3 Select *Create New*.

4 Enter `webStrict` for the *Name*.
5 In *FortiGuard Categories*, select all of the categories except *Bandwidth Consuming*, *General Interest - Business* and *Unrated*.
6 In *Change Action for Selected Categories* select *Block*.
7 Select *Apply*.

To configure web filtering for the Sales VDOM - CLI

```
config vdom
  edit Sales
    config webfilter profile
      edit webStrict
        config ftgd-wf
          set allow g07 g08 g21 g22 c01 c03
          set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
        end
        set web-ftgd-err-log enable
      end
  end
```

To configure AntiVirus for the Sales VDOM - web-based manager

1 In *Current VDOM*, select Sales.
2 Go to *UTM Profiles* > *AntiVirus* > *Profile*.
3 Select *Create New*.
4 Enter `avStrict` for the *Name*.
5 Enable virus scan for all protocols.
6 Select *Apply*.

To configure AntiVirus for the Sales VDOM - CLI

```
config vdom
  edit Sales
    config antivirus profile
      edit "avStrict"
        config http
          set options scan file-filter
        end
        config ftp
          set options scan file-filter
        end
        config imap
          set options scan file-filter
        end
        config pop3
          set options scan file-filter
        end
        config smtp
          set options scan file-filter
        end
        config nntp
          set options scan file-filter
        end
```

```
        config im
          set options scan file-filter
        end
        set filepattable 1
        set av-virus-log enable
        set av-block-log enable
      end
  end
```

To configure application control for the Sales VDOM - web-based manager

1. In *Current VDOM*, select Accounting.
2. Go to *UTM Profiles* > *Application Control* > *Application Sensor.*
3. Select *Create New* (+ button at top right of page).
4. Enter `appStrict` for *Name* and select OK.
5. Select *Create New*.
6. In *Filters*, set *Category* to *game*.
7. In *Applications/Settings*, enter the following, and select *OK*.

Action	Block
Packet Logging	Enable

8. Select *Create New*.
9. In *Filters*, set *Category* to *p2p*.
10. In *Applications/Settings*, enter the following, and select *OK*.

Action	Block
Packet Logging	Enable

11. Select *Apply*.

To configure application control for the Sales VDOM - CLI

```
config vdom
  edit Sales
    config application list
      edit "appStrict"
        config entries
          edit 1
            set category 2
          next
          edit 2
            set category 8
          end
      end
  end
```

Configuring firewall settings for the Sales VDOM

Like the Accounting firewall settings, this configuration includes two firewall addresses and two firewall policies for the sales VDOM: one for the internal network, and one for the VDOM link with the management VDOM.

When entering the CLI commands, the number of the firewall policies must be high enough to be a new policy. Depending on the number of firewall policies on your FortiGate unit, this may require starting at a higher number than the 6 required for the default configuration. This number is added automatically when you configure firewall policies using the web manager interface.

The FortiClient application must be used on Sales network computers to ensure additional protection for the sensitive information and for protection against spam.

To configure firewall addresses - web-based manager

1 In *Current VDOM*, select *Sales*.

2 Go to *Firewall Objects* > *Address* > *Address.*

3 Select *Create New,* enter the following information, and select *OK*.

Address Name	SalesLocal
Type	Subnet / IP Range
Subnet / IP Range	172.100.0.0
Interface	port3

4 Go to *Firewall Objects* > *Addresses.*

5 Select *Create New*, enter the following information, and select OK.

Address Name	SalesManagement
Type	Subnet / IP Range
Subnet / IP Range	10.0.1.0
Interface	SalesVlnk

To configure the firewall addresses - CLI

```
config vdom
  edit Sales
    config fireall address
      edit SalesLocal
        set type iprange
        set subnet 172.100.0.0
        set associated-interface port2
      next
      edit SalesManagement
        set type iprange
        set subnet 10.0.1.0
        set associated-interface SalesVlnk
      end
  end
```

To configure the firewall policies from SalesLocal to the Internet - web-based manager

1 In *Current VDOM*, select *Sales*.

2 Go to *Policy* > *Policy.*

3 Select *Create New*, enter the following information, and select OK.

Source Interface/Zone	port3
Source Address	SalesLocal
Destination Interface/Zone	SalesVlnk
Destination Address	SalesManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled
Redirect Non-conforming Clients to Download Portal	enabled

4 In *Current VDOM*, select *root*.

5 Go to *Policy* > *Policy.*

6 Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	SalesVlnk
Source Address	SalesManagement
Destination Interface/Zone	external
Destination Address	all
Schedule	always
Service	OfficeServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled

To configure the firewall policies from SalesLocal to the Internet - CLI

```
config vdom
  edit root
    config firewall policy
      edit 6
        set srcintf port2
        set srcaddr SalesLocal
        set dstintf SalesVlnk
        set dstaddr SalesManagement
        set schedule always
        set service OfficeServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
```

```
        set endpoint-redir-portal enable
      end
  end

config vdom
  edit Sales
    config firewall policy
      edit 7
        set srcintf SalesVlnk
        set srcaddr SalesManagement
        set dstintf external
        set dstaddr all
        set schedule always
        set service OfficeServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
      end
  end
```

To configure the firewall policies from the Internet to SalesLocal - web-based manager

1 In Current VDOM, select *root*.

2 Go to *Policy* > *Policy.*

3 Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	external
Source Address	all
Destination Interface/Zone	SalesVlnk
Destination Address	SalesManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled

4 In *Current VDOM*, select *Sales*.

5 Go to *Policy* > *Policy.*

6 Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	SalesVlnk
Source Address	SalesManagement
Destination Interface/Zone	port2
Destination Address	SalesLocal

Schedule	always
Service	OfficeServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled
Redirect Non-conforming Clients to Download Portal	enabled

To configure the firewall policies from the Internet to SalesLocal - CLI

```
config vdom
  edit root
    config firewall policy
      edit 8
        set srcintf external
        set srcaddr all
        set dstintf SalesVlnk
        set dstaddr SalesManagement
        set schedule always
        set service OfficeServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
        set endpoint-redir-portal enable
      end
  end

config vdom
  edit Sales
    config firewall policy
      edit 9
        set srcintf SalesVlnk
        set srcaddr SalesManagement
        set dstintf port2
        set dstaddr SalesLocal
        set schedule always
        set service OfficeServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
        set endpoint-redir-portal enable
      end
  end
```

Configuring firewall settings between the Accounting and Sales VDOMs

Firewall policies are required for any communication between each internal network and the Internet. Policies are also required for the two internal networks to communicate with each other through the management VDOM.

The more limited AccountingSalesServices group of services will be used between Sales and Accounting to ensure the traffic is necessary business traffic only. These policies will result in a partially meshed VDOM configuration. The FortiClient application must be used to ensure additional protection for the sensitive accounting information.

Two firewall policies are required to allow traffic in both directions between Sales and Accounting.

To configure the firewall policy between Sales and Accounting on the management VDOM - web-based manager

1 For Current VDOM, select *root*.

2 Go to *Policy* > *Policy.*

3 Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	SalesVlnk
Source Address	SalesManagement
Destination Interface/Zone	AccountVlnk
Destination Address	AccountingManagement
Schedule	always
Service	AccountingSalesServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled
Redirect Non-conforming Clients to Download Portal	enabled

4 Go to *Policy* > *Policy.*

5 Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	AccountVlnk
Source Address	AccountingManagement
Destination Interface/Zone	SalesVlnk
Destination Address	SalesManagement
Schedule	always
Service	AccountingSalesServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled

Enable Endpoint Control Check	disabled
Redirect Non-conforming Clients to Download Portal	enabled

To configure the firewall policy between Sales and Accounting on the management VDOM - CLI

```
config vdom
  edit root
    config system firewall policy
      edit 9
        set srcintf SalesVlnk
        set srcaddr SalesManagement
        set dstintf AccountVlnk
        set dstaddr AccountManagement
        set schedule always
        set service AccountingSalesServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
        set endpoint-redir-portal enable
      next
      edit 10
        set srcintf AccountVlnk
        set srcaddr AccountManagement
        set dstintf SalesVlnk
        set dstaddr SalesManagement
        set schedule always
        set service AccountingSalesServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
        set endpoint-redir-portal enable
      end
  end
```

Testing the configuration

Once the inter-VDOM routing has been configured, tests must be conducted to confirm proper operation. If there are any problems, use the troubleshooting tips to resolve them.

This section includes the following topics:

- Testing connectivity
- Troubleshooting Tips

Testing connectivity

Testing connectivity ensures that physical networking connections as well as FortiGate unit interface configurations, including firewall policies, are properly configured.

The easiest way to test connectivity is to use the `ping` and `traceroute` commands to confirm the connectivity of different routes on the network. Include testing:

- from AccountingLocal to Internet
- from Internet to AccountingLocal
- from SalesLocal to Internet
- from Internet to SalesLocal
- from AccountingLocal to SalesLocal.

When using the commands on a Windows computer, go to a command line prompt and enter either `ping <IP address>` or `tracert <IP address>`.

When using the commands on a FortiGate unit, go to the CLI and enter either `exec ping <IP address>` or `exec traceroute <IP address>`.

Troubleshooting Tips

When there are problems with connectivity, the following troubleshooting tips will help resolve the issues.

- If a multiple hop test, such as traceroute, is not successful then reduce it to a single hop to simplify the test. Test each link of the path to see which hop is down. If all hops are up, check the FortiGate unit policies to ensure they allow basic traffic to flow as expected.
- If ping does not work, confirm that the FortiGate unit interfaces have Ping enabled and also ensure Ping is enabled in the firewall policies. Otherwise the Ping traffic will be blocked.
- If one protocol does not work but others do work, check the FortiGate unit firewall policies for that one protocol to ensure it is allowed.
- If there are unexplained connectivity problems, check the local computer to ensure it does not have a software firewall running that may be blocking traffic. MS Windows computers have a firewall running by default that can cause problems.

For additional troubleshooting, see “Troubleshooting Virtual Domains” on page 1977.

Troubleshooting Virtual Domains

When you are configuring VDOMs you may run into some issues. This section provides answers to some common issues with VDOMs.

This section includes:

VDOM admin having problems gaining access

With VDOMs configured, administrators have an extra layer of permissions and may have problems accessing their information.

Confirm the admin's VDOM

Each administrator account, other than the super_admin account, is tied to one specific VDOM. That administrator is not able to access any other VDOM. It may be possible they are trying to access the wrong VDOM.

Confirm the VDOM's interfaces

An administrator can only access their VDOM through interfaces that are assigned to that VDOM. If interfaces on that VDOM are disabled or unavailable there will be no method of accessing that VDOM by its local administrator. The super_admin will be required to either bring up the interfaces, fix the interfaces, or move another interface to that VDOM to restore access.

Confirm the VDOMs admin access

As with all FortiGate units, administration access on the VDOM's interfaces must be enabled for that VDOM's administrators to gain access. For example if SSH is not enabled, that is not available to administrators.

To enable admin access, the super_admin will go to the global *System* > *Network* > *Interface* page, and for the interface in question enable the admin access.

FortiGate unit running very slowly

You may experience a number of problems resulting from your FortiGate unit being overloaded. These problems may appear as:

- CPU and memory threshold limits exceeded on a continual basis
- AV failopen happening on a regular basis
- dropped traffic or sessions due to lack of resources

These problems are caused by a lack of system resources. There are a number of possible reasons for this.

Too many VDOMs

If you have configured many VDOMs on your system, past the default ten VDOMs, this could easily be your problem.

Each VDOM you create on your FortiGate unit requires system resources to function - CPU cycles, memory, and disk space. When there are too many VDOMs configured there are not enough resources for operation. This may be a lack of memory in the session table, or no CPU cycles for processing incoming IPS traffic, or even a full disk drive.

Go to *System* > *VDOM* and see the number of configured VDOMs on your system. If you are running 250 or more VDOMs, you must have a FortiGate 5000 chassis. Otherwise you need to reduce the number of VDOMs on your system to fix the problem. Even if you have the proper hardware, you may encounter noticeably slow throughput if you are using advanced features such as UTM or deep content inspection with many configured VDOMs.

One or more VDOMs are consuming all the resources

If you have sufficient hardware to support the number of VDOMs you are running, check the global resources on your FortiGate unit. At a glance it will tell you if you are running out of a particular resource such as sessions, or users. If this is the case, you can then check your VDOMs to see if one particular VDOM is using more than its share of resources. If that is the case you can change the resource settings to allow that VDOM (or those VDOMs) fewer resources and in turn allow the other VDOMs access to those resources.

Too many UTM features in use

If you are running 250 or more VDOMs and have a FortiGate 5000 chassis, it is still possible that you are running too many features for the FortiGate unit to support all those VDOMs. To support 250 or more VDOMs, FortiGate units cannot run advanced UTM features. Instead they are limited to less processor intensive features that do not require stateful inspection.

It is likely that reducing the UTM features in use even with fewer VDOM configuration will greatly improve overall system performance and should be considered as an option.

Finally it is possible that your FortiGate unit configuration is incorrect in some other area, which is using up all your resources. For example, forgetting that you are running a network sniffer on an interface will create significant amounts of traffic that may prevent normal operation.

General VDOM tips and troubleshooting

Besides ping and traceroute, there are additional tools for troubleshooting your VDOM configurations. These include packet sniffing and debugging the packet flow.

Perform a sniffer trace

When troubleshooting networks, it helps to look inside the headers of packets to determine if they are traveling along the route you expect that they are. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your FortiGate unit has NP2 interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP2 interfaces, you should disable offloading on those interfaces.

What can sniffing packets tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the FortiGate unit, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the Fortigate unit is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing, which prevents an IP packet from being forwarded if its Source IP does not either belong to a locally attached subnet (local interface), or be part of the routing between the FortiGate and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`), however this will disable stateful inspection on the FortiGate unit and cause many features to be turned off.

Note If you configure virtual IP addresses on your Fortigate unit, it will use those addresses in preference to the physical IP addresses. You will notice this when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How do you sniff packets

When you are using VDOMs, you must be in a VDOM to access the `diag sniffer` command. At the global level, the command is not available. This is limit the packets only to the ones on your VDOM, and protects the privacy of other VDOM clients.

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose>
   <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as “port1” or “internal”. This can also be “any” to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. “none” indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (‘).
<verbose>	The level of verbosity as one of: **1 -** print header of packets **2 -** print header and data from IP of packets **3 -** print header and data from Ethernet of packets
<count>	The number of packets the sniffer reads before stopping. If you don’t put a number here, the sniffer will run forever unit you stop it with <CTRL C>.

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the port1 interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
```

```
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh
   3177924955 ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh
   1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh
   4225311614 ack 3314279933
```

For a more advanced example of packet sniffing, the following commands will report packets on any interface travelling between a computer with the host name of `PC1` and the computer with the host name of `PC2`. With verbosity 4 and above, the sniffer trace will display the interface names where traffic enters or leaves the FortiGate unit. Remember to stop the sniffer, type `CTRL+C`. Note that `PC1` and `PC2` may be VDOMs.

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2>" 4
```

or

```
FGT# diagnose sniffer packet any "(host <PC1> or host <PC2>) and
   icmp" 4
```

The following sniffer CLI command includes the ARP protocol in the filter which may be useful to troubleshoot a failure in the ARP resolution (for instance PC2 may be down and not responding to the FortiGate ARP requests).

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2> or
   arp" 4
```

Debug the packet flow

Traffic should come in and leave the VDOM. If you have determined that network traffic is not entering and leaving the VDOM as expected, debug the packet flow.

Debugging can only be performed using CLI commands. Debugging the packet flow requires a number of debug commands to be entered as each one configures part of the debug action, with the final command starting the debug.

If your FortiGate unit has NP2 interfaces that are offloading traffic, this will change the packet flow. Before performing the debug on any NP2 interfaces, you should disable offloading on those interfaces.

The following configuration assumes that `PC1` is connected to the internal interface of the FortiGate unit and has an IP address of `10.11.101.200`. `PC1` is the host name of the computer.

To debug the packet flow in the CLI, enter the following commands:

```
FGT# diag debug enable
FGT# diag debug flow filter add <PC1>
FGT# diag debug flow show console enable
FGT# diag debug flow trace start 100
FGT# diag debug enable
```

The `start 100` argument in the above list of commands will limit the output to 100 packets from the flow. This is useful for looking at the flow without flooding your log or your display with too much information.

To stop all other debug activities, enter the command:

```
FGT# diag debug flow trace stop
```

The following is an example of debug flow output for traffic that has no matching Firewall Policy, and is in turn blocked by the FortiGate unit. The denied message indicates the traffic was blocked. Note that even with VDOMs not enabled, vd-root is still shown.

```
id=20085 trace_id=319 func=resolve_ip_tuple_fast line=2825
   msg="vd-root received a packet(proto=6,
   192.168.129.136:2854->192.168.96.153:1863) from port3."

id=20085 trace_id=319 func=resolve_ip_tuple line=2924
   msg="allocate a new session-013004ac"

id=20085 trace_id=319 func=vf_ip4_route_input line=1597
   msg="find a route: gw-192.168.150.129 via port1"

id=20085 trace_id=319 func=fw_forward_handler line=248 msg="

```

Chapter 12 High Availability

This FortiOS Handbook chapter contains the following sections:

Solving the High Availability problem describes the high availability problem and introduces the FortiOS solutions described in this document (FGCP, VRRP, and standalone session synchronization).

An introduction to the FortiGate Clustering Protocol (FGCP) introduces the FGCP clustering protocol and many of its features and terminology.

Configuring and connecting HA clusters describes configuring HA clusters and contains HA clustering configuration examples.

Configuring and connecting virtual clusters describes configuring HA virtual clusters and contains virtual clustering configuration examples.

Configuring and operating FortiGate full mesh HA describes configuring FortiGate Full mesh HA and contains a full mesh HA configuration example.

Operating a cluster describes how to operate a cluster and includes detailed information about how various FortiGate systems operate differently in a cluster.

HA and failover protection describes in detail how FortiGate HA device failover, link failover, and session failover work.

HA and load balancing describes in detail how FortiGate HA active-active load balancing load balances sessions.

HA with third-party products describes how FortiGate units interact with third-party products.

VRRP describes FortiOS support of the Virtual Router Redundancy Protocol (VRRP) and its use for high availability.

TCP session synchronization describes the FortiGate standalone session synchronization feature and its use for high availability.

Solving the High Availability problem

The basic high availability (HA) problem for TCP/IP networks and security gateways is keeping network traffic flowing. Uninterrupted traffic flow is a critical component for online systems and media because critical business processes quickly come to a halt when the network is down.

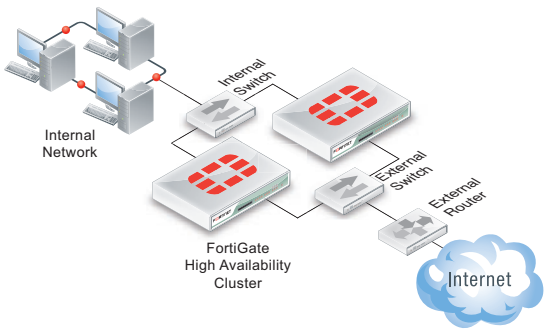
The security gateway is a crucial component of most networks since all traffic passes through it. A standalone network security gateway is a single point of failure that is vulnerable to any number of software or hardware problems that could compromise the device and bring all traffic on the network to a halt.

A common solution to the high availability problem is to eliminate the security gateway as single point of failure by introducing redundancy. With two or more redundant security gateways, if one fails, the remaining one or more gateways keep the traffic flowing. FortiOS provides three redundancy solutions: VRRP, TCP session synchronization, and Fortinet's proprietary FortiGate Cluster Protocol (FGCP) high availability solution.

FCGP HA, TCP session synchronization and VRRP are not compatible. You cannot configure more than one of these high availability methods on the same FortiGate unit.

A strong and flexible High availability solution is required for many mission-critical firewall and UTM applications. Each FortiOS high availability solution can be fine tuned to fit into many different network scenarios.

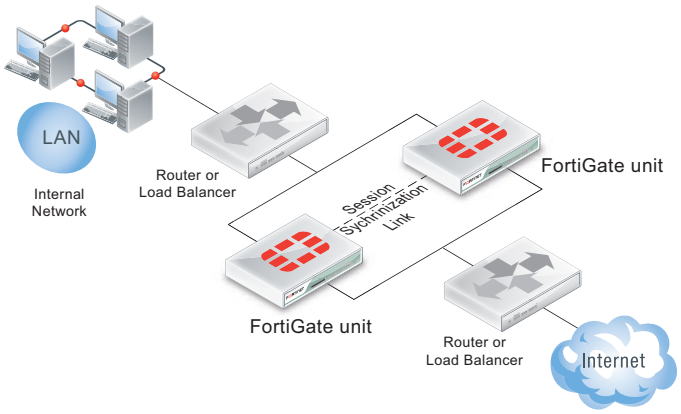
FortiGate Cluster Protocol (FGCP)



FGCP HA provides a solution for two key requirements of critical enterprise networking components: enhanced reliability and increased performance. Enhanced reliability is achieved through device failover protection, link failover protection and remote link failover protection. Increased performance is achieved though active-active HA load balancing. Extended FGCP features include full mesh HA and virtual clustering. You can also fine tune the performance of the FGCP to change how a cluster forms and shares information among cluster units and how the cluster responds to failures. When configured onto your network an FGCP cluster appears to be a single FortiGate unit operating in NAT/Route or Transparent mode. If a failover occurs, the cluster recovers quickly and automatically and also sends administrator notifications so that the problem that caused the failure can be corrected and any failed equipment restored.

The FGCP is compatible with most network environments and most networking equipment. While initial configuration is relatively quick and easy, a large number of tools and configuration options are available to fine tune the cluster for most situations.

TCP session synchronization

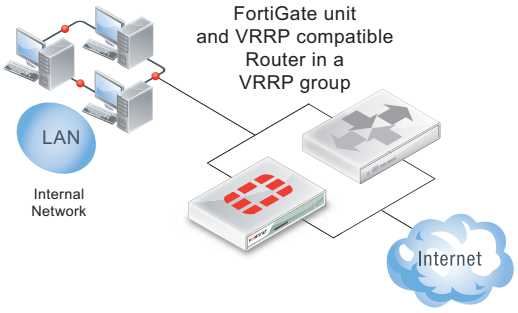


In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two or more FortiGate units can be integrated into the load balancing configuration by enabling TCP session synchronization (also called standalone session synchronization) between them. The external load balancers or routers can distribute TCP sessions among the FortiGate units and TCP session synchronization keeps both FortiGate unit's session tables synchronized.

If one of the FortiGate units fails, session failover occurs and active TCP sessions fail over to the unit that is still operating. This failover occurs without any loss of data. As well, the external routers or load balancers detect the failover and re-distribute all sessions to the unit that is still operating.

Unlike the FCGP, TCP session synchronization does not include configuration synchronization. In fact, the configurations of the two FortiGate units (sometimes called peers) are not identical since in most cases the peers would have different IP addresses. Also unlike the FCGP, load balancing and session failover is done by external routers or load balancers instead of by the FGCP. The FortiGate units just perform session synchronization which supports the session failover.

VRRP



FortiGate units can function as master or backup Virtual Router Redundancy Protocol (VRRP) routers and can be quickly and easily integrated into a network that has already deployed VRRP. A FortiGate unit can be integrated into a VRRP group with any third-party VRRP devices and VRRP can provide redundancy between multiple FortiGate units.

In a VRRP configuration, when a FortiGate unit operating as the master unit fails, a backup unit takes its place and continues processing network traffic. If the backup unit is a FortiGate unit, the network continues to benefit from FortiOS security features. If the backup unit is a router, after a failure traffic will continue to flow, but FortiOS security features will be unavailable until the FortiGate unit is back on line. You can include different FortiGate models in the same VRRP group.

FortiOS supports VRRP between two or more FortiGate units and between FortiGate units and third-party routers that support VRRP. Using VRRP you can assign VRRP routers as master or backup routers. The master router processes traffic and the backup routers monitor the master router and can begin forwarding traffic if the master fails. Similar to the FGCP you can configuration VRRP between multiple FortiGate units to provide redundancy. You can also create a VRRP group with a FortiGate units and any routers that support VRRP.

In a VRRP configuration that consists of one FortiGate unit and one router, normally the FortiGate unit would be the master and all traffic would be processed by the FortiGate unit. If the FortiGate unit fails, all traffic switches to the router. Network connectivity is maintained even though FortiGate security features will be unavailable until the FortiGate unit can is back on line.

An introduction to the FortiGate Clustering Protocol (FGCP)

A FortiGate HA cluster consists of two to four FortiGate units configured for HA operation. Each FortiGate unit in a cluster is called a cluster unit. All cluster units must be the same FortiGate model with the same FortiOS firmware build installed. All cluster units must also have the same hardware configuration (for example, the same AMC modules installed in the same slots, the same number of hard disks and so on) and be running in the same operating mode (NAT/Route mode or Transparent mode).

You can create an FGCP cluster of up to four FortiGate units.

On startup, after configuring the cluster units with the same HA configuration, the cluster units use the FortiGate Clustering Protocol (FGCP) to find other FortiGate units configured for HA operation and to negotiate to create a cluster. During cluster operation, the FGCP shares communication and synchronization information among the cluster units. This communication and synchronization is called the FGCP heartbeat or the HA heartbeat. Often, this is shortened to just heartbeat. For a cluster to form, the cluster units must be able to communicate using their configured heartbeat interfaces.

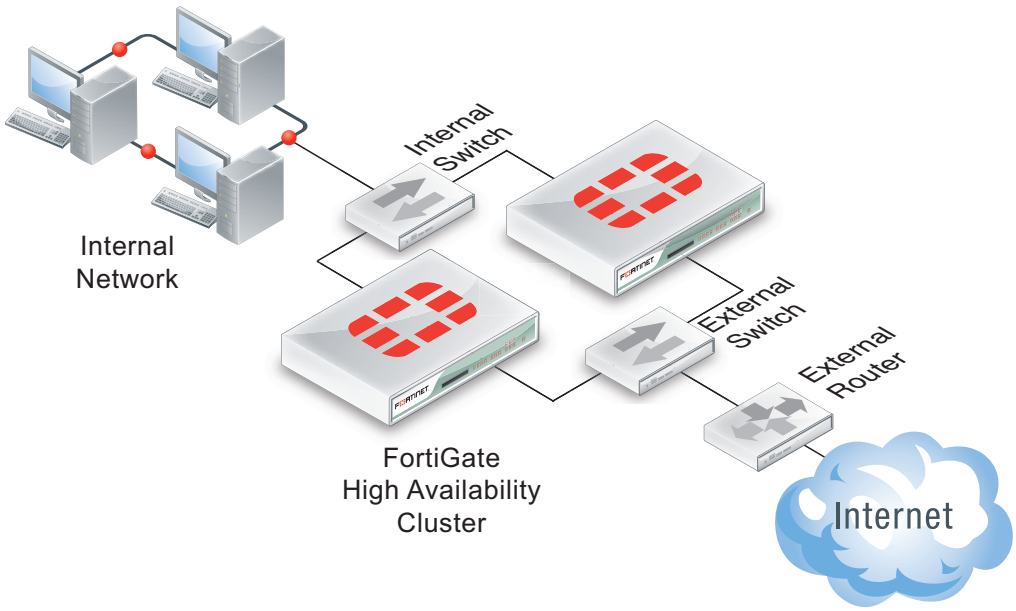
The cluster uses the FGCP to select the primary unit, and to provide device, link and session failover. The FGCP also manages the two HA modes; active-passive (failover HA) and active-active (load balancing HA).

This chapter describes.

About the FGCP

FortiGate HA is implemented by configuring two or more FortiGate units to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate unit, processing network traffic and providing normal security services such as firewalling, Unified Threat Management (UTM) and VPN services.

Figure 193: HA cluster installed between an internal network and the Internet



Inside the cluster the individual FortiGate units are called cluster units. These cluster units share state and configuration information. If one cluster unit fails, the other units in the cluster automatically replace that unit, taking over the work that the failed unit was doing. After the failure, the cluster continues to process network traffic and provide normal FortiGate services with virtually no interruption.

Every FortiGate cluster contains one primary unit (also called the master unit) and one or more subordinate units (also called slave or backup units). The primary unit controls how the cluster operates. The roles that the primary and subordinate units play in the cluster depend on the mode in which the cluster operates. See “Active-passive HA (failover protection)” on page 1998 and “Active-active HA (load balancing and failover protection)” on page 1998.

The ability of an HA cluster to continue providing firewall services after a failure is called failover. FortiGate HA failover means that your network does not have to rely on one FortiGate unit to continue functioning. You can install additional units and form an HA cluster. Other units in the cluster will take over if one of the units fails.

A second HA feature, called load balancing, can be used to increase performance. A cluster of FortiGate units can increase overall network performance by sharing the load of processing network traffic and providing Unified Threat Management (UTM) services. The cluster appears to your network to be a single device, adding increased performance without changing your network configuration.

Virtual clustering extends HA features to provide failover protection and load balancing for a FortiGate operating with virtual domains. A virtual cluster consists of a cluster of two FortiGate units operating with virtual domains. Traffic on different virtual domains can be load balanced between the cluster units. For details about virtual clustering, see "Configuring and connecting virtual clusters" on page 2089.

FortiGate models that support redundant interfaces can be configured to support a clustering configuration called full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster. For details about full mesh HA, see "Configuring and operating FortiGate full mesh HA" on page 2111.

FGCP failover protection

The FGCP provides IP/MAC takeover for failover protection by assigning virtual MAC addresses to the primary cluster unit and then sending gratuitous ARP packets from the primary unit interfaces to reprogram the network.

Failover times can be less than a second under optimal conditions. You can fine tune failover performance for your network by adjusting cluster status checking, routing table update, and wait timers.

An HA cluster fails over if the primary unit experiences a device or link failure. The cluster can detect link failures for connections to the primary unit using port monitoring and for connections between downstream network components using remote IP monitoring. To compensate for a link failover, the cluster maintains active links to keep traffic flowing between high-priority networks. Port and remote IP monitoring can be fine tuned without disrupting cluster operation.

Session Failover

FCGP session failover maintains TCP, SIP and IPsec VPN sessions after a failure. Session failover does not failover UDP, multicast, ICMP, or SSL VPN sessions. Session failover may not be required for all networks because many TCP/IP protocols can resume sessions on their own. Supporting session failover adds extra overhead to cluster operations and can be disabled to improve cluster performance if its not required.

Load Balancing

Active-active HA load balances resource-intensive UTM processing among all cluster units to provide better UTM performance than a standalone FortiGate unit. If network traffic consists of mainly TCP sessions, the FGCP can also load balance all TCP sessions to improve TCP performance in some network configurations. You can use accelerated FortiGate interfaces to also accelerate HA load balancing and HA load balancing schedules can be adjusted to optimize performance for the traffic mix on your network. Weighted load balancing can be used to control the relative amount of sessions processed by each cluster unit.

Virtual Clustering

Virtual clustering is an extension of the FGCP for a cluster of 2 FortiGate units operating with multiple VDOMS enabled. Not only does virtual clustering provide failover protection for a multiple VDOM configuration, but a virtual cluster can load balance traffic between the cluster units. Load balancing with virtual clustering is quite efficient and load balances all traffic (not just UTM and TCP traffic). Its possible to fine tune virtual clustering load balancing in real time to actively optimize load sharing between the cluster units without affecting the smooth operation of the cluster.

Full Mesh HA

High availability improves the reliability of a network by replacing a single point of failure (a singe FortiGate unit) with a cluster that can maintain network traffic if one of the cluster units fails. However, in a cluster configuration single points of failure remain. Full mesh HA removes these single points of failure by allowing you to connect redundant switches to each cluster interface. Full mesh HA is achieved by configuring 802.3ad aggregate or redundant interfaces on the FortiGate unit and connecting redundant switches to these interfaces. Configuration is a relatively simple extension of the normal aggregate/redundant interface and HA configurations.

Cluster Management

FortiOS HA provides a wide range of cluster management features:

- Automatic continuous configuration synchronization. You can get a cluster up and running almost as quickly as a standalone FortiGate unit by performing a few basic steps to configure HA settings and minimal network settings on each cluster unit. When the cluster is operating you can make start configuring FortiGate features such as UTM and IPsec VPN in the same way as for a standalone FortiGate unit. All configuration changes (even complex changes such as switching to multiple VDOM mode or from NAT/Route to Transparent mode) are synchronized among all cluster units.
- Firmware upgrades/downgrades. Upgrading or downgrading cluster firmware is similar to upgrading or downgrading standalone FortiGate firmware. The Firmware is uploaded once to the primary unit and the cluster automatically upgrades or downgrades all cluster units in one operation with minimal or no service interruption.
- Individual cluster unit management. In some cases you may want to manage individual cluster units. You can do so from cluster CLI by navigating to each cluster unit. You can also use the reserved management interface feature to give each cluster unit its own IP address and default route. You can use the reserved management interfaces and IP addresses to connect to the GUI and CLI of each cluster unit and configure an SNMP server to poll each cluster unit.
- Removing and adding cluster units. In one simple step any unit (even the primary unit) can be removed from a cluster and given a new IP address. The cluster keeps operating as it was; the transition happening without interrupting cluster operation. Any unit can also be added to an operating cluster without disrupting network traffic. All you have to do is connect the new unit and change its HA configuration to match the cluster's. The cluster automatically finds and adds the unit and synchronizes its configuration with the cluster.
- Debug and diagnose commands. A full range of debug and diagnose commands can be used to report on HA operation and find and fix problems.
- Logging and reporting. All cluster units can be configured to record all log messages. These message can be stored on the individual cluster units or sent to a FortiAnalyzer unit. You can view all cluster unit log messages by logging into any cluster unit.
- FortiManager support. FortiManager understands FortiOS HA and automatically recognizes when you add a FortiOS cluster to the FortiManager configuration.

Configuring a FortiGate unit for FGCP HA operation

Each FortiGate unit in the cluster must have the same HA configuration. Once the cluster is connected, you can configure it in the same way as you would configure a standalone FortiGate unit. The following procedures set the HA mode to active-passive and sets the HA password to HA_pass.

To configure a FortiGate unit for HA operation - web-based manager

1 Power on the FortiGate unit to be configured.

2 Log into the web-based manager.

3 On the Dashboard *System Information* dashboard widget, beside *Host Name* select *Change*.

4 Enter a new Host Name for this FortiGate unit.

Changing the host name makes it easier to identify individual cluster units when the cluster is operating.

5 Go to *System* > *Config* > *HA* and change the following settings:

Mode	Active-Passive
Group Name	Example_cluster
Password	HA_pass The password must be the same for all FortiGate units in the cluster.

You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

6 Select *OK*.

The FortiGate unit negotiates to establish an HA cluster. When you select *OK* you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all ARP table entries). You may be able to delete the ARP table of your management PC from a command prompt using a command similar to `arp -d`.

7 Power off the FortiGate unit.

8 Repeat this procedure for all of the FortiGate units in the cluster.

Once all of the units are configured, continue with "Connecting a FortiGate HA cluster" on page 1996.

To configure a FortiGate unit for HA operation - CLI

1 Power on the FortiGate unit to be configured.

2 Log into the CLI.

3 Enter the following command to change the FortiGate unit host name.

```
config system global
  set hostname Example1_host
end
```

Changing the host name makes it easier to identify individual cluster units when the cluster is operating.

4 Enter the following command to enable HA:

```
config system ha
  set mode active-passive
  set group-name Example_cluster
  set password HA_pass
end
```

You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

5 Power off the FortiGate unit.

6 Repeat this procedure for all of the FortiGate units in the cluster.

Once all of the units are configured, continue with "Connecting a FortiGate HA cluster".

Connecting a FortiGate HA cluster

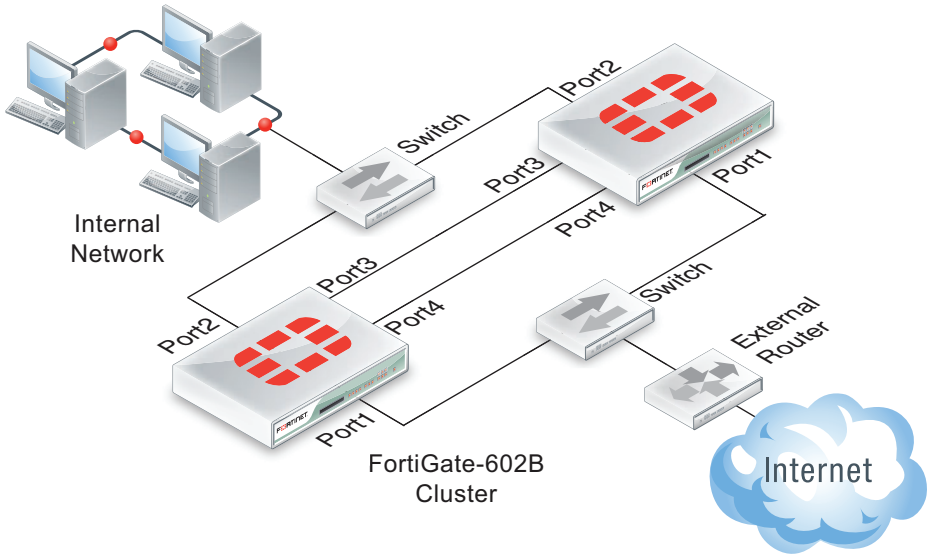
Use the following procedure to connect a cluster. Connect the cluster units to each other and to your network. You must connect all matching interfaces in the cluster to the same switch, then connect these interfaces to their networks using the same switch.

Although you can use hubs, Fortinet recommends using switches for all cluster connections for the best performance.

Connecting an HA cluster to your network temporarily interrupts communications on the network because new physical connections are being made to route traffic through the cluster. Also, starting the cluster interrupts network traffic until the individual cluster units are functioning and the cluster completes negotiation. Cluster negotiation is automatic and normally takes just a few seconds. During system startup and negotiation all network traffic is dropped.

This section describes how to connect the cluster shown in Figure 194 on page 1997 that consists of two FortiGate-620B units to be connected between the Internet and a head office internal network. The port1 interfaces of the FortiGate unit connect the cluster to the Internet and the port2 interfaces connect the cluster to the internal network. The port3 and port4 interfaces are used for redundant HA heartbeat links.

Figure 194: Example cluster connections



To connect a FortiGate HA cluster

1. Connect the port1 interfaces of each cluster unit to a switch connected to the Internet.
2. Connect the port2 interfaces of each cluster unit to a switch connected to the internal network.
3. Connect the port3 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on both of the FortiGate units.

   As the cluster units start, they negotiate to choose the primary unit and the subordinate units. This negotiation occurs with no user intervention and normally just takes a few seconds.

   At least one heartbeat interface should be connected together for the cluster to operate. You can also connect the heartbeat interfaces to a network. If the cluster consists of just two FortiGate units, you can connect the heartbeat interfaces directly using a crossover cable. For more information about heartbeat interfaces, see "HA heartbeat and communication between cluster units" on page 2170.

   You could use one switch to connect all four heartbeat interfaces. However, this is not recommended because if the switch fails both heartbeat interfaces will become disconnected.

   You can now configure the cluster as if it is a single FortiGate unit.

Active-passive and active-active HA

The first decision to make when configuring FortiGate HA is whether to choose active-passive or active-active HA mode. To configure the HA mode, go to *System* > *Config* > *HA* and set Mode to *Active-Passive* or *Active-Active*.

From the CLI enter the following command to set the HA mode to active-passive:

```
config system ha
  set mode a-p
end
```

To form a cluster, all cluster units must be set to the same mode. You can also change the mode after the cluster is up and running. Changing the mode of a functioning cluster causes a slight delay while the cluster renegotiates to operate in the new mode and possibly select a new primary unit.

Active-passive HA (failover protection)

An active-passive (A-P) HA cluster provides hot standby failover protection.
An active-passive cluster consists of a primary unit that processes communication sessions, and one or more subordinate units. The subordinate units are connected to the network and to the primary unit but do not process communication sessions. Instead, the subordinate units run in a standby state. In this standby state, the configuration of the subordinate units is synchronized with the configuration of the primary unit and the subordinate units monitor the status of the primary unit.

Active-passive HA provides transparent device failover among cluster units. If a cluster unit fails, another immediately take its place. See "Device failover" on page 2169.

Active-passive HA also provides transparent link failover among cluster units. If a cluster unit interface fails or is disconnected, this cluster unit updates the link state database and the cluster negotiates and may select a new primary unit. See "Link failover" on page 2194 for more information.

If session failover (also called session pickup) is enabled, active-passive HA provides session failover for some communication sessions. See "Session failover (session pick-up)" on page 2205 for information about session failover and its limitations.

The following example shows how to configure a FortiGate unit for active-passive HA operation. You would enter the exact same commands on every FortiGate unit in the cluster.

```
config system ha
  set mode a-p
  set group-name myname
  set password HApass
end
```

Active-active HA (load balancing and failover protection)

Active-active (A-A) HA load balances resource-intensive UTM processing among all cluster units. UTM processing applies protocol recognition, virus scanning, IPS, web filtering, email filtering, data leak prevention (DLP), application control, and VoIP content scanning and protection to HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, NNTP, SIP, SIMPLE, and SCCP sessions accepted by security policies. By load balancing this resource-intensive UTM processing among all cluster units, an active-active HA cluster may provide better UTM performance than a standalone FortiGate unit. Other features enabled in security policies such as Endpoint security, traffic shaping and authentication (identity-based policies) have no effect active-active load balancing.

All non-UTM sessions are not load balanced and are processed by the primary unit. You can also optionally configure active-active HA to load balance all TCP sessions in addition to UTM sessions. For more information see "Load balancing UTM sessions and TCP sessions" on page 2221.

An active-active HA cluster consists of a primary unit that receives all communication sessions and load balances them among the primary unit and all of the subordinate units. In an active-active cluster the subordinate units are also considered active since they also process UTM sessions.

In all other ways active-active HA operates the same as active-passive HA.

The following example shows how to configure a FortiGate unit for active-active HA operation. You would enter the exact same commands on every FortiGate unit in the cluster.

```
config system ha
  set mode a-a
  set group-name myname
  set password HApass
end
```

Identifying the cluster and cluster units

You can use the cluster group name, group id, and password to identify a cluster and distinguish one cluster from another. If you have more than one cluster on the same network, each cluster must have a different group name, group id, and password.

Group name

Use the group name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units.

The default group name is *FGT-HA*. The group name appears on the FortiGate dashboard of a functioning cluster as the *Cluster Name*.

To change the group name from the web-based manager go to *Config* > *System* > *HA* and change the *Group Name*.

Enter the following CLI command to change the group name to Cluster_name:

```
config system ha
  set group-name Cluster_name
end
```

Password

Use the password to identify the cluster. You should always change the password when configuring a cluster. The password must be the same for all FortiGate units before they can form a cluster. The maximum password length is 19 characters. When the cluster is operating you can change the password, if required. Two clusters on the same network cannot have the same password.

To change the password from the web-based manager go to *Config* > *System* > *HA* and change the *Password*.

Enter the following CLI command to change the group name to ha_pwd:

```
config system ha
  set password ha_pwd
end
```

Group ID

Similar to the group name, the group ID is also used to identify the cluster. In most cases you do not have to change the group ID. However, you should change the group ID if you have more than one cluster on the same network. All members of the HA cluster must have the same group ID. The group ID range is from 0 to 63.

Changing the group ID changes the cluster virtual MAC address. See "Cluster virtual MAC addresses" on page 2177.

Enter the following CLI command to change the group ID to 10:

```
config system ha
  set group-id 10
end
```

Device failover, link failover, and session failover

The FGCP provides transparent device and link failover. You can also enable session pickup to provide session failover. A failover can be caused by a hardware failure, a software failure, or something as simple as a network cable being disconnected. When a failover occurs, the cluster detects and recognizes the failure and takes steps to respond so that the network can continue to operate without interruption. The internal operation of the cluster changes, but network components outside of the cluster notice little or no change.

If a failover occurs, the cluster also records log messages about the event and can be configured to send log messages to a syslog server and to a FortiAnalyzer unit. The cluster can also send SNMP traps and alert email messages. These alerts can notify network administrators of the failover and may contain information that the network administrators can use to find and fix the problem that caused the failure.

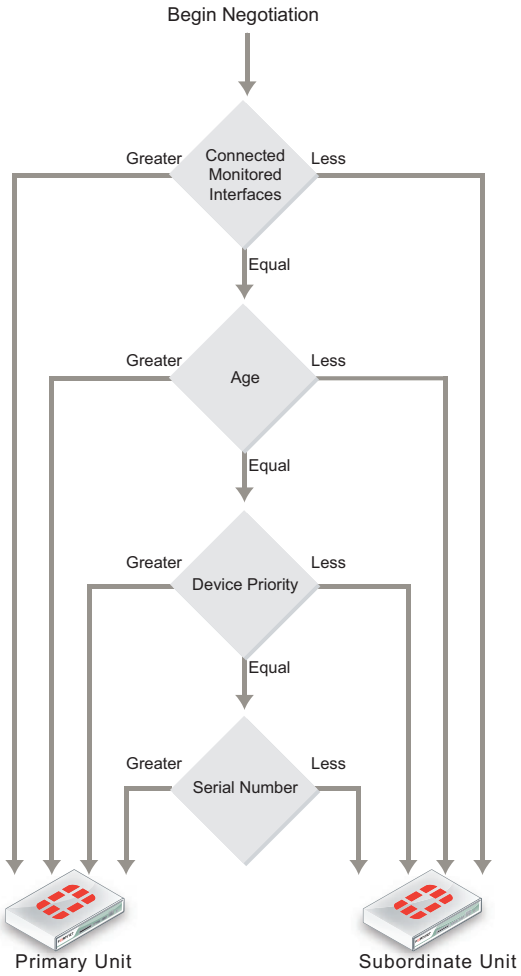
For a complete description of device failover, link failover, and session failover, how clusters support these types of failover, and how FortiGate HA clusters compensate for a failure to maintain network traffic flow see "HA and failover protection" on page 2167.

Primary unit selection

Once FortiGate units recognize that they can form a cluster, the cluster units negotiate to select a primary unit. Primary unit selection occurs automatically based on the criteria shown in Figure 195. After the cluster selects the primary unit, all of the remaining cluster units become subordinate units.

Negotiation and primary unit selection also takes place if a primary unit fails (device failover) or if a monitored interface fails or is disconnected (link failover). During a device or link failover, the cluster renegotiates to select a new primary unit also using the criteria shown in Figure 195.

Figure 195: Selecting the primary unit



For many basic HA configurations primary unit selection simply selects the cluster unit with the highest serial number to become the primary unit. A basic HA configuration involves setting the HA mode to active-passive or active-active and configuring the cluster group name and password. Using this configuration, the cluster unit with the highest serial number becomes the primary unit because primary unit selection disregards connected monitored interfaces (because interface monitoring is not configured), the age of the cluster units would usually always be the same, and all units would have the same device priority.

Using the serial number is a convenient way to differentiate cluster units; so basing primary unit selection on the serial number is predictable and easy to understand and interpret. Also the cluster unit with the highest serial number would usually be the newest FortiGate unit with the most recent hardware version. In many cases you may not need active control over primary unit selection, so basic primary unit selection based on serial number is sufficient.

In some situations you may want control over which cluster unit becomes the primary unit. You can control primary unit selection by setting the device priority of one cluster unit to be higher than the device priority of all other cluster units. If you change one or more device priorities, during negotiation, the cluster unit with the highest device priority becomes the primary unit. As shown in Figure 195 the FGCP selects the primary unit based on device priority before serial number. For more information about how to use device priorities, see "Primary unit selection and device priority" on page 2006.

The only other way that you can influence primary unit selection is by configuring interface monitoring (also called port monitoring). Using interface monitoring you can make sure that cluster units with failed or disconnected monitored interfaces cannot become the primary unit. See "Primary unit selection and monitored interfaces" on page 2002.

Finally, the age of a cluster unit is determined by a number of cluster operating factors. Normally the age of all cluster units is the same so normally age has no effect on primary unit selection. Age does affect primary unit selection after a monitored interface failure. For more information about age, see "Primary unit selection and age" on page 2003.

This section describes:

- Primary unit selection and monitored interfaces
- Primary unit selection and age
- Primary unit selection and device priority
- Primary unit selection and FortiGate unit serial number
- Points to remember about primary unit selection

Primary unit selection and monitored interfaces

If you have configured interface monitoring the cluster unit with the highest number of monitored interfaces that are connected to networks becomes the primary unit. Put another way, the cluster unit with the highest number of failed or disconnected monitored interfaces cannot become the primary unit.

Normally, when a cluster starts up, all monitored interfaces of all cluster units are connected and functioning normally. So monitored interfaces do not usually affect primary unit selection when the cluster first starts.

A cluster always renegotiates when a monitored interface fails or is disconnected (called link failover). A cluster also always renegotiates when a failed or disconnected monitored interface is restored.

If a primary unit monitored interface fails or is disconnected, the cluster renegotiates and if this is the only failed or disconnected monitored interface the cluster selects a new primary unit.

If a subordinate unit monitored interface fails or is disconnected, the cluster also renegotiates but will not necessarily select a new primary unit. However, the subordinate unit with the failed or disconnected monitored interface cannot become the primary unit.

Multiple monitored interfaces can fail or become disconnected on more than one cluster unit. Each time a monitored interface is disconnected or fails, the cluster negotiates to select the cluster unit with the most connected and operating monitored interfaces to become the primary unit. In fact, the intent of the link failover feature is just this, to make sure that the primary unit is always the cluster unit with the most connected and operating monitored interfaces. For information about monitored interfaces and link failover see "Link failover" on page 2194.

Primary unit selection and age

The cluster unit with the highest age value becomes the primary unit. The age of a cluster unit is the amount of time since a monitored interface failed or is disconnected. Age is also reset when a cluster unit starts (boots up). So, when all cluster units start up at the same time, they all have the same age. Age does not affect primary unit selection when all cluster units start up at the same time. Age also takes precedence over priority for primary unit selection.

If a link failure of a monitored interface occurs, the age value for the cluster unit that experiences the link failure is reset. So, the cluster unit that experienced the link failure also has a lower age value than the other cluster units. This reduced age does not effect primary unit selection because the number of link failures takes precedence over the age.

If the failed monitored interface is restored the cluster unit that had the failed monitored interface cannot become the primary unit because its age is still lower than the age of the other cluster units.

In most cases, the way that age is handled by the cluster reduces the number of times the cluster selects a new primary unit, which results in a more stable cluster since selecting a new primary unit has the potential to disrupt traffic.

Cluster age difference margin (grace period)

In any cluster, some of the cluster units may take longer to start up than others. This startup time difference can happen as a result of a number of issues and does not affect the normal operation of the cluster. To make sure that cluster units that start slower can still become primary units, by default the FGCP ignores age differences of up to 5 minutes (300 seconds).

In most cases, during normal operation this age difference margin or grace period helps cluster function as expected. However, the age difference margin can result in some unexpected behavior in some cases:

- During a cluster firmware upgrade with `uninterruptable-upgrade` enabled (the default configuration) the cluster should not select a new primary unit after the firmware of all cluster units has been updated. But since the age difference of the cluster units is most likely less than 300 seconds, age is not used to affect primary unit selection and the cluster may select a new primary unit. See “Upgrading cluster firmware” on page 2152 for more information.
- During failover testing where cluster units are failed over repeatedly the age difference between the cluster units will most likely be less than 5 minutes. During normal operation, if a failover occurs, when the failed unit rejoins the cluster its age will be very different from the age of the still operating cluster units so the cluster will not select a new primary unit. However, if a unit fails and is restored in a very short time the age difference may be less than 5 minutes. As a result the cluster may select a new primary unit during some failover testing scenarios.

Changing the cluster age difference margin

You can change the cluster age difference margin using the following command:

```
config system ha
  set ha-uptime-diff-margin 60
end
```

This command sets the cluster age difference margin to 60 seconds (1 minute). The age difference margin range 1 to 65535 seconds. The default is 300 seconds.

You may want to reduce the margin if during failover testing you don't want to wait the default age difference margin of 5 minutes. You may also want to reduce the margin to allow uninterruptable upgrades to work. See "Upgrading cluster firmware" on page 2152.

You may want to increase the age margin if cluster unit startup time differences are larger than 5 minutes.

Displaying cluster unit age differences

You can use the CLI command `diagnose sys ha dump 1` to display the age difference of the units in a cluster. This command also displays information about a number of HA-related parameters for each cluster unit. You can enter the command from the primary unit CLI or you can enter the command from a subordinate unit after using `execute ha manage` to log into a subordinate unit CLI. The information displayed by the command is relative to the unit that you enter the command from.

For example, for a cluster of two FortiGate-5001SX units with no changes to the default HA configuration except to enable interface monitoring for port5, entering the `diagnose sys ha dump 1` command from the primary unit CLI displays information similar to the following:

```
diagnose sys ha dump 1
            HA information.
vcluster id=1, nventry=2, state=work,
   digest=fe.21.14.b3.e1.8d...
ventry idx=0,id=1,FG50012205400050,prio=128,0,claimed=0,
   override=0,flag=1,time=0,mon=0.
     mondev=port5,50
ventry idx=1,id=1,FG50012204400045,prio=128,0,claimed=0,
   override=0,flag=0,time=194,mon=0.
```

The command displays one `ventry` line for each cluster unit. The first `ventry` in the example contains information for the cluster unit that you are logged into. The other `ventry` lines contain information for the subordinate units (in the example there is only one subordinate unit). The `mondev` entry displays the interface monitoring configuration.

The `time` field is always `0` for the unit that you are logged into. The `time` field for the other cluster unit is the age difference between the unit that you are logged into and the other cluster unit. The age difference is in the form seconds/10.

In the example, the age of the primary unit is 19.4 seconds more than the age of the subordinate unit. The age difference is less than 5 minutes (less than 300 seconds or `time` is less than 3000) so age has no affect on primary unit selection. The cluster selected the unit with the highest serial number to be the primary unit.

If you use `execute ha manage 1` to log into the subordinate unit CLI and enter `diagnose sys ha dump 1` you get results similar to the following:

```
diagnose sys ha dump 1
            HA information.
vcluster id=1, nventry=2, state=standy,
   digest=fe.21.14.b3.e1.8d...
ventry idx=1,id=1,FG50012204400045,prio=128,0,claimed=0,
   override=0,flag=1,time=0,mon=0.
     mondev=port5,50
ventry idx=0,id=1,FG50012205400050,prio=128,0,claimed=0,
   override=0,flag=0,time=-194,mon=0.
```

The `time` for the primary unit is `-194`, indicating that age of the subordinate unit is 19.4 seconds less than the age of the primary unit.

If port5 (the monitored interface) of the primary unit is disconnected, the cluster renegotiates and the former subordinate unit becomes the primary unit. When you log into the new primary unit CLI and enter `diagnose sys ha dump 1` you could get results similar to the following:

```
diagnose sys ha dump 1
            HA information.
vcluster id=1, nventry=2, state=work,
   digest=9e.70.74.a2.5e.4a...
ventry idx=0,id=1,FG50012204400045,prio=128,0,claimed=0,
   override=0,flag=1,time=0,mon=0.
     mondev=port5,50
ventry idx=1,id=1,FG50012205400050,prio=128,-50,claimed=0,
   override=0,flag=0,time=58710,mon=0.
```

The command results show that the age of the new primary unit is 5871.0 seconds more than the age of the new subordinate unit.

If port5 of the former primary unit is reconnected the cluster will not select a new primary unit because the age of the primary unit will still be 5871.0 seconds more than the age of the subordinate unit. When you log into the primary unit CLI and enter `diagnose sys ha dump 1` you get results similar to the following:

```
diagnose sys ha dump 1
            HA information.
vcluster id=1, nventry=2, state=work,
   digest=9e.70.74.a2.5e.4a...
ventry idx=0,id=1,FG50012204400045,prio=128,0,claimed=0,
   override=0,flag=1,time=0,mon=0.
     mondev=port5,50
ventry idx=1,id=1,FG50012205400050,prio=128,0,claimed=0,
   override=0,flag=0,time=58710,mon=0.
```

Resetting the age of all cluster units

In some cases, age differences among cluster units can result in the wrong cluster unit or the wrong virtual cluster becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units when it rejoins the cluster. Since age takes precedence over priority the priority of this cluster unit will not be a factor in primary unit selection.

This problem also affects virtual cluster VDOM partitioning in a similar way. After a reboot of one of the units in a virtual cluster configuration, traffic for all VDOMs could continue to be processed by the cluster unit that did not reboot. This can happen because the age of both virtual clusters on the unit that did not reboot is greater that the age of both virtual clusters on the unit that rebooted.

One way to resolve this issue is to reboot all of the cluster units at the same time so that the age of all of the cluster units is reset. However, rebooting cluster units may interrupt or at least slow down traffic. If you would rather not reboot all of the cluster units you can instead use the following command to reset the ages of all of the cluster units.

```
diagnose sys ha reset-uptime
```

This command resets the age of all cluster units so age is no longer a factor in primary unit selection and device priority is used to select the primary unit.

The `diagnose sys ha reset-uptime` command should only be used as a temporary solution. The command resets the HA age internally and does not affect the up time displayed for cluster units using the `diagnose sys ha dump 1` command or the up time displayed on the Dashboard or cluster members list. To make sure the actual up time for cluster units is the same as the HA age you should reboot the cluster units during a maintenance window.

Primary unit selection and device priority

A cluster unit with the highest device priority becomes the primary unit when the cluster starts up or renegotiates. By default, the device priority for all cluster units is 128. You can change the device priority to control which FortiGate unit becomes the primary unit during cluster negotiation. All other factors that influence primary unit selection either cannot be configured (age and serial number) or are synchronized among all cluster units (interface monitoring). You can set a different device priority for each cluster unit. During negotiation, if all monitored interfaces are connected, and all cluster units enter the cluster at the same time (or have the same age), the cluster with the highest device priority becomes the primary unit.

A higher device priority does not affect primary unit selection for a cluster unit with the most failed monitored interfaces or with an age that is higher than all other cluster units because failed monitored interfaces and age are used to select a primary unit before device priority.

Increasing the device priority of a cluster unit does not always guarantee that this cluster unit will become the primary unit. During cluster operation, an event that may affect primary unit selection may not always result in the cluster renegotiating. For example, when a unit joins a functioning cluster, the cluster will not renegotiate. So if a unit with a higher device priority joins a cluster the new unit becomes a subordinate unit until the cluster renegotiates.

Enabling the `override` HA CLI keyword makes changes in device priority more effective by causing the cluster to negotiate more often to make sure that the primary unit is always the unit with the highest device priority. For more information about `override`, see "HA override" on page 2008.

Controlling primary unit selection by changing the device priority

You set a different device priority for each cluster unit to control the order in which cluster units become the primary unit when the primary unit fails.

To change the device priority from the web-based manager go to *Config* > *System* > *HA* and change the *Device Priority*.

Enter the following CLI command to change the device priority to 200:

```
config system ha
  set priority 200
end
```

The device priority is not synchronized among cluster units. In a functioning cluster you change device priority to change the priority of any unit in the cluster. Whenever you change the device priority of a cluster unit, when the cluster negotiates, the unit with the highest device priority becomes the primary unit.

The following example shows how to change the device priority of a subordinate unit to 255 so that this subordinate unit becomes the primary unit. This example involves connecting to the cluster CLI and using the `execute ha manage 0` command to connect to the highest priority subordinate unit. After you enter the following commands the cluster renegotiates and selects a new primary unit.

```
execute ha manage 1
  config system ha
    set priority 255
  end
```

If you have three units in a cluster you can set the device priorities as shown in Table 113. When the cluster starts up, cluster unit A becomes the primary unit because it has the highest device priority. If unit A fails, unit B becomes the primary unit because unit B has a higher device priority than unit C.

Table 113: Example device priorities for a cluster of three FortiGate units

Cluster unit	Device priority
A	200
B	100
C	50

Normally, when configuring HA you do not have to change the device priority of any of the cluster units. If all cluster units have the same device priority, when the cluster first starts up the FGCP negotiates to select the cluster unit with the highest serial number to be the primary unit.

Clusters also function normally if all units have the same device priority. However, you can use the device priority if you want to control the roles that individual units play in the cluster. For example, if you want the same unit to always become the primary unit, set this unit device priority higher than the device priority of other cluster units. Also, if you want a cluster unit to always become a subordinate unit, set this cluster unit device priority lower than the device priority of other cluster units.

The device priority range is 0 to 255. The default device priority is 128.

If you are configuring a virtual cluster, if you have added virtual domains to both virtual clusters, you can set the device priority that the cluster unit has in virtual cluster 1 and virtual cluster 2. If a FortiGate unit has different device priorities in virtual cluster 1 and virtual cluster 2, the FortiGate unit may be the primary unit in one virtual cluster and the subordinate unit in the other. For more information, see “Virtual clustering and load balancing or VDOM partitioning” on page 2091.

Primary unit selection and FortiGate unit serial number

The cluster unit with the highest serial number is more likely to become the primary unit. When first configuring FortiGate units to be added to a cluster, if you do not change the device priority of any cluster unit, then the cluster unit with the highest serial number always becomes the primary unit.

Age does take precedence over serial number, so if a cluster unit takes longer to join a cluster for some reason (for example if one cluster unit is powered on after the others), that cluster unit will not become the primary unit because the other units have been in the cluster longer.

Device priority and failed monitored interfaces also take precedence over serial number. A higher device priority means a higher priority. So if you set the device priority of one unit higher or if a monitored interface fails, the cluster will not use the FortiGate serial number to select the primary unit.

Points to remember about primary unit selection

Some points to remember about primary unit selection:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored interfaces > Age > Device Priority > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered if a cluster unit fails or if a monitored interface fails.
- If the HA age difference is more than 5 minutes, the cluster unit that is operating longer becomes the primary unit.
- If HA age difference is less than 5 minutes, the device priority and FortiGate serial number selects the cluster unit to become the primary unit.
- Every time a monitored interface fails the HA age of the cluster unit is reset to 0.
- Every time a cluster unit restarts the HA age of the cluster unit is reset to 0.

HA override

The HA `override` CLI keyword is disabled by default. When `override` is disabled a cluster may not renegotiate when an event occurs that affects primary unit selection. For example, when `override` is disabled a cluster will not renegotiate when you change a cluster unit device priority or when you add a new cluster unit to a cluster. This is true even if the unit added to the cluster has a higher device priority than any other unit in the cluster. Also, when `override` is disabled a cluster does not negotiate if the new unit added to the cluster has a failed or disconnected monitored interface.

For a virtual cluster configuration, `override` is enabled by default for both virtual clusters when you enable virtual cluster 2. For more information, see “Virtual clustering and HA override” on page 2090.

In most cases you should keep `override` disabled to reduce how often the cluster negotiates. Frequent negotiations may cause frequent traffic interruptions.

However, if you want to make sure that the same cluster unit always operates as the primary unit and if you are less concerned about frequent cluster negotiation you can enable `override`.

To enable `override`, select a cluster unit to always be the primary unit. Connect to this cluster unit CLI and use the `config system ha` CLI command to enable `override`.

For `override` to be effective, you must also set the device priority highest on the cluster unit with `override` enabled. To increase the device priority, from the CLI use the `config system ha` command and increase the value of the `priority` keyword to a number higher than the default priority of 128.

You can also increase the device priority from the web-based manager by going to *System* > *Config* > *HA*. To increase the device priority of the primary unit select edit for the primary or subordinate unit and set the *Device Priority* to a number higher than 128.

The `override` setting and device priority value are not synchronized to all cluster units.

With `override` enabled, the primary unit with the highest device priority will always become the primary unit. Whenever an event occurs that may affect primary unit selection, the cluster negotiates. For example, when `override` is enabled a cluster renegotiates when you change the device priority of any cluster unit or when you add a new cluster unit to a cluster.

This section also describes:

- Override and primary unit selection
- Controlling primary unit selection using device priority and override
- Points to remember about primary unit selection when override is enabled
- Configuration changes can be lost if override is enabled
- Override and disconnecting a unit from a cluster

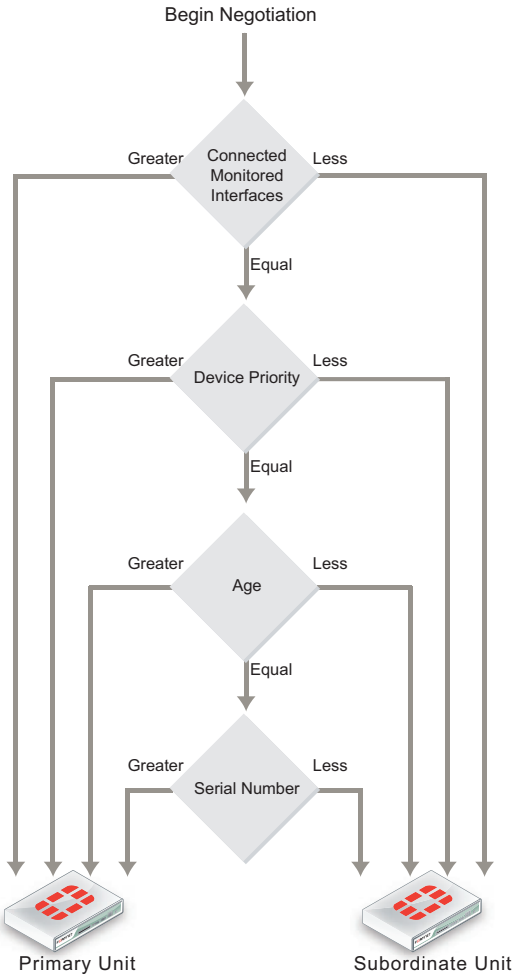
Override and primary unit selection

Enabling `override` changes the order of primary unit selection. As shown in Figure 196 if `override` is enabled, primary unit selection considers device priority before age and serial number. This means that if you set the device priority higher on one cluster unit, with `override` enabled this cluster unit becomes the primary unit even if its age and serial number are lower than other cluster units.

Similar to when `override` is disabled, when `override` is enabled primary unit selection checks for connected monitored interfaces first. So if interface monitoring is enabled, the cluster unit with the most disconnected monitored interfaces cannot become the primary unit, even of the unit has the highest device priority.

If all monitored interfaces are connected (or interface monitoring is not enabled) and the device priority of all cluster units is the same then age and serial number affect primary unit selection.

Figure 196: Selecting the primary unit with override enabled



Controlling primary unit selection using device priority and override

To configure one cluster unit to always become the primary unit you should set its device priority to be higher than the device priorities of the other cluster units and you should enable `override` for this cluster unit.

Using this configuration, when the cluster is operating normally the primary unit is always the unit with `override` enabled and with the highest device priority. If the primary unit fails the cluster renegotiates to select another cluster unit to be the primary unit. If the failed primary unit recovers, starts up again and rejoins the cluster, because `override` is enabled, the cluster renegotiates. Because the restarted primary unit has the highest device priority it once again becomes the primary unit.

In the same situation with `override` disabled, because the age of the failed primary unit is lower than the age of the other cluster units, when the failed primary unit rejoins the cluster it does not become the primary unit. Instead, even though the failed primary unit may have the highest device priority it becomes a subordinate unit because its age is lower than the age of all the other cluster units.

Points to remember about primary unit selection when override is enabled

Some points to remember about primary unit selection when `override` is enabled:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored Interfaces > Device Priority > Age > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered whenever an event occurs which may affect primary unit selection. For example negotiation occurs, when you change the device priority, when you add a new unit to a cluster, if a cluster unit fails, or if a monitored interface fails.
- Device priority is considered before age. Otherwise age is handled the same when `override` is enabled.

Configuration changes can be lost if override is enabled

In some cases, when override is enabled and you make configuration changes to an HA cluster these changes can be lost. For example, consider the following sequence:

1. A cluster of two FortiGate units is operating with `override` enabled.
   - FGT-A: Primary unit with device priority 200 and with `override` enabled
   - FGT-B: Subordinate unit with device priority 100 and with `override` disabled
   - If both units are operating, FGT-A always becomes the primary unit because FGT-A has the highest device priority.
2. FGT-A fails and FGT-B becomes the new primary unit.
3. The administrator makes configuration changes to the cluster.

   The configuration changes are made to FGT-B because FGT-B is operating as the primary unit. These configuration changes are not synchronized to FGT-A because FGT-A is not operating.
4. FGT-A is restored and starts up again.
5. The cluster renegotiates and FGT-A becomes the new primary unit.
6. The cluster recognizes that the configurations of FGT-A and FGT-B are not the same.
7. The configuration of FGT-A is synchronized to FGT-B.

   The configuration is always synchronized from the primary unit to the subordinate units.
8. The cluster is now operating with the same configuration as FGT-A. The configuration changes made to FGT-B have been lost.

The solution

When `override` is enabled, you can prevent configuration changes from being lost by doing the following:

- Verify that all cluster units are operating before making configuration changes (from the web-based manager go to *System* > *Config* > *HA* to view the cluster members list or from the FortiOS CLI enter `get system ha status`).
- Make sure the device priority of the primary unit is set higher than the device priorities of all other cluster units before making configuration changes.
- Disable `override` either permanently or until all configuration changes have been made and synchronized to all cluster units.

Override and disconnecting a unit from a cluster

A similar scenario to that described in "Configuration changes can be lost if override is enabled" may occur when `override` is enabled and you use the Disconnect from Cluster option from the web-based manager or the `execute ha disconnect` command from the CLI to disconnect a cluster unit from a cluster.

Configuration changes made to the cluster can be lost when you reconnect the disconnected unit to the cluster. You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. Otherwise, when the disconnected unit joins the cluster, if `override` is enabled, the cluster renegotiates and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units and any configuration changes made between when the unit was disconnected and reconnected are lost.

FortiGate HA compatibility with PPPoE and DHCP

FortiGate HA is not compatible with PPP protocols such as PPPoE. FortiGate HA is also not compatible with DHCP. If one or more FortiGate unit interfaces is dynamically configured using DHCP or PPPoE you cannot switch to operate in HA mode. Also, you cannot switch to operate in HA mode if one or more FortiGate unit interfaces is configured as a PPTP or L2TP client.

Configuring an interface for DHCP or PPPoE is only supported in NAT/Route mode. So, usually when configuring HA in Transparent mode an interface being configured for DHCP or PPPoE should not affect HA operation. However, in some cases you may not be able to enable HA if you had configured an interface for DHCP or PPPoE before switching to Transparent mode. So, if you are blocked from operating a Transparent mode FortiGate unit in HA and cannot find another reason for the problem, try switching the FortiGate unit back to NAT/Route mode and setting all interface modes to static before switching to Transparent mode and enabling HA. You could also enable HA before switching to Transparent mode.

You can configure a cluster to act as a DHCP server or a DHCP relay agent. In both active-passive and active-active clusters DHCP relay sessions are always handled by the primary unit. It is possible that a DHCP relay session could be interrupted by a failover. If this occurs the DHCP relay session is not resumed after the failover and the DHCP client may have to repeat the DHCP request.

When a cluster is operating as a DHCP server the primary unit responds to all DHCP requests and maintains the DHCP server address lease database. The cluster also dynamically synchronizes the DHCP server address lease database to the subordinate units. If a failover occurs, the new primary unit will have an up-to-date DHCP server address lease database. Synchronizing the DHCP address lease database prevents the new primary unit from responding incorrectly to new DHCP requests after a failover.

Also, it is possible that when FortiGate units first negotiate to form a cluster that a unit that ends up as a subordinate unit in the cluster will have information in its DHCP address lease database that the cluster unit operating as the primary unit does note have. This can happen if a FortiGate unit responds to DHCP requests while operating as a standalone unit and then when the cluster is formed this unit becomes a subordinate unit. Because of this possibility, after a cluster is formed the DHCP address lease databases of all of the cluster units are merged into one database which is then synchronized to all cluster units.

Hard disk configuration and HA

If your cluster units include hard disks, all cluster units must have identical hard disk configurations. This means each cluster unit must have same number of hard disks (including AMC and FortiGate Storage Module (FSM) hard disks) and also means that matching hard disks in each cluster unit must be the same size, have the same hard disk format, and have the same number of partitions.

In most cases the default hard disk configuration of the cluster units will be compatible. However, a hard disk formatted by an older FortiGate firmware version may not be compatible with a hard disk formatted by a more recent firmware version. Problems may also arise if you have used the `execute scsi-dev` command to add or change hard disk protections.

If a cluster unit CLI displays hard disk compatibility messages, you may need to use the `execute scsi-dev delete` command to delete partitions. You can also use the `execute formatlogdisk` command to reformat hard disks. In some cases after deleting all partitions and reformatting the hard disks, you may still see hard disk incompatibility messages. If this happens, contact Fortinet Customer Support for assistance.

HA Best practices

Fortinet suggests the following practices related to high availability:

- Use Active-Active HA to distribute TCP and UTM sessions among multiple cluster units. An active-active cluster may have higher throughput than a standalone FortiGate unit or than an active-passive cluster.
- Use a different host name on each FortiGate unit when configuring an HA cluster. Fewer steps are required to add host names to each cluster unit before configuring HA and forming a cluster.
- Enabling `load-balance-all` can increase device and network load since more traffic is load-balanced. This may be appropriate for use in a deployment using the firewall capabilities of the FortiGate unit and IPS but no other content inspection. See “Load balancing UTM sessions and TCP sessions” on page 2221.
- An advantage of using session pickup is that non-UTM sessions will be picked up by the new primary unit after a failover. The disadvantage is that the cluster generates more heartbeat traffic to support session pickup as a larger portion of the session table must be synchronized. Session pickup should be configured only when required and is not recommended for use with SOHO FortiGate models. Session pickup should only be used if the primary heartbeat link is dedicated (otherwise the additional HA heartbeat traffic could affect network performance). See “Session failover (session pick-up)” on page 2205.
- If you need to enable session pickup, consider enabling session pickup delay to improve performance by reducing the number of sessions that are synchronized. If possible, also consider enabling session synchronization or multiple FortiGate Interfaces. See “Improving session synchronization performance” on page 2205 for more information.
- To avoid unpredictable results, when you connect a switch to multiple redundant or aggregate interfaces in an active-passive cluster you should configure separate redundant or aggregate interfaces on the switch; one for each cluster unit. See “HA MAC addresses and 802.3ad aggregation” on page 2058.

- Use SNMP, syslog, or email alerts to monitor a cluster for failover messages. Alert messages about cluster failovers may help find and diagnose network problems quickly and efficiently. See “Operating a cluster” on page 2127.

Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See “Enabling or disabling HA heartbeat encryption and authentication” on page 2177.
- Configure and connect multiple heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.

Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.
- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See “Remote link failover” on page 2200.

Troubleshooting

The following sections in this document contain troubleshooting information:

- “Troubleshooting HA clusters” on page 2083
- “Troubleshooting virtual clustering” on page 2109
- “Troubleshooting full mesh HA” on page 2125
- “Troubleshooting layer-2 switches” on page 2233

FGCP HA terminology

The following HA-specific terms are used in this document.

Cluster

A group of FortiGate units that act as a single virtual FortiGate unit to maintain connectivity even if one of the FortiGate units in the cluster fails.

Cluster unit

A FortiGate unit operating in a FortiGate HA cluster.

Device failover

Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device. See also "Device failover, link failover, and session failover" on page 2000.

Failover

A FortiGate unit taking over processing network traffic in place of another unit in the cluster that suffered a device failure or a link failure.

Failure

A hardware or software problem that causes a FortiGate unit or a monitored interface to stop processing network traffic.

FGCP

The FortiGate clustering protocol (FGCP) that specifies how the FortiGate units in a cluster communicate to keep the cluster operating.

Full mesh HA

Full mesh HA is a method of removing single points of failure on a network that includes an HA cluster. FortiGate models that support redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA includes redundant connections between all network components. If any single component or any single connection fails, traffic switches to the redundant component or connection.

HA virtual MAC address

When operating in HA mode, all of the interfaces of the primary unit acquire the same HA virtual MAC address. All communications with the cluster must use this MAC address. The HA virtual MAC address is set according to the group ID.

Heartbeat

Also called FGCP heartbeat or HA heartbeat. The heartbeat constantly communicates HA status and synchronization information to make sure that the cluster is operating properly.

Heartbeat device

An ethernet network interface in a cluster that is used by the FGCP for heartbeat communications among cluster units.

Heartbeat failover

If an interface functioning as the heartbeat device fails, the heartbeat is transferred to another interface also configured as an HA heartbeat device.

Hello state

In the hello state a cluster unit has powered on in HA mode, is using HA heartbeat interfaces to send hello packets, and is listening on its heartbeat interfaces for hello packets from other FortiGate units. Hello state may appear in HA log messages.

High availability

The ability that a cluster has to maintain a connection when there is a device or link failure by having another unit in the cluster take over the connection, without any loss of connectivity. To achieve high availability, all FortiGate units in the cluster share session and configuration information.

Interface monitoring

You can configure interface monitoring (also called port monitoring) to monitor FortiGate interfaces to verify that the monitored interfaces are functioning properly and connected to their networks. If a monitored interface fails or is disconnected from its network the interface leaves the cluster and a link failover occurs. For more information about interface monitoring, see “Link failover” on page 2194.

Link failover

Link failover means that if a monitored interface fails, the cluster reorganizes to re-establish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic. See also “Device failover, link failover, and session failover” on page 2000.

Load balancing

Also known as active-active HA. All units in the cluster process network traffic. The FGCP employs a technique called unicast load balancing in which a given interface of all cluster units has the same virtual MAC address. The primary unit is associated with the cluster HA virtual MAC address and cluster IP address. The primary unit is the only cluster unit to receive packets sent to the cluster. The primary unit can process packets itself, or propagate them to subordinate units according to a load balancing schedule.

Monitored interface

An interface that is monitored by a cluster to make sure that it is connected and operating correctly. The cluster monitors the connectivity of this interface for all cluster units. If a monitored interface fails or becomes disconnected from its network, the cluster will compensate.

Primary unit

Also called the primary cluster unit, this cluster unit controls how the cluster operates. The primary unit sends hello packets to all cluster units to synchronize session information, synchronize the cluster configuration, and to synchronize the cluster routing table. The hello packets also confirm for the subordinate units that the primary unit is still functioning.

The primary unit also tracks the status of all subordinate units. When you start a management connection to a cluster, you connect to the primary unit.

In an active-passive cluster, the primary unit processes all network traffic. If a subordinate unit fails, the primary unit updates the cluster configuration database.

In an active-active cluster, the primary unit receives all network traffic and re-directs this traffic to subordinate units. If a subordinate unit fails, the primary unit updates the cluster status and redistributes load balanced traffic to other subordinate units in the cluster.

The FortiGate firmware uses the term master to refer to the primary unit.

Session failover

Session failover means that a cluster maintains active network sessions after a device or link failover. FortiGate HA does not support session failover by default. To enable session failover you must change the HA configuration to select Enable Session Pick-up. See also “Device failover, link failover, and session failover” on page 2000.

Session pickup

If you enable session pickup for a cluster, if the primary unit fails or a subordinate unit in an active-active cluster fails, all communication sessions with the cluster are maintained or picked up by the cluster after the cluster negotiates to select a new primary unit.

If session pickup is not a requirement of your HA installation, you can disable this option to save processing resources and reduce the network bandwidth used by HA session synchronization. In many cases interrupted sessions will resume on their own after a failover even if session pickup is not enabled. You can also enable session pickup delay to reduce the number of sessions that are synchronized by session pickup.

Standby state

A subordinate unit in an active-passive HA cluster operates in the standby state. In a virtual cluster, a subordinate virtual domain also operates in the standby state. The standby state is actually a hot-standby state because the subordinate unit or subordinate virtual domain is not processing traffic but is monitoring the primary unit session table to take the place of the primary unit or primary virtual domain if a failure occurs.

In an active-active cluster all cluster units operate in a work state.

When standby state appears in HA log messages this usually means that a cluster unit has become a subordinate unit in an active-passive cluster or that a virtual domain has become a subordinate virtual domain.

State synchronization

The part of the FGCP that maintains connections after failover.

Subordinate unit

Also called the subordinate cluster unit, each cluster contains one or more cluster units that are not functioning as the primary unit. Subordinate units are always waiting to become the primary unit. If a subordinate unit does not receive hello packets from the primary unit, it attempts to become the primary unit.

In an active-active cluster, subordinate units keep track of cluster connections, keep their configurations and routing tables synchronized with the primary unit, and process network traffic assigned to them by the primary unit. In an active-passive cluster, subordinate units do not process network traffic. However, active-passive subordinate units do keep track of cluster connections and do keep their configurations and routing tables synchronized with the primary unit.

The FortiGate firmware uses the terms slave and subsidiary unit to refer to a subordinate unit.

Virtual clustering

Virtual clustering is an extension of the FGCP for FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Work state

The primary unit in an active-passive HA cluster, a primary virtual domain in a virtual cluster, and all cluster units in an active-active cluster operate in the work state. A cluster unit operating in the work state processes traffic, monitors the status of the other cluster units, and tracks the session table of the cluster.

When work state appears in HA log messages this usually means that a cluster unit has become the primary unit or that a virtual domain has become a primary virtual domain.

HA web-based manager options

Go to *System* > *Config* > *HA* to change HA options.

You can configure HA options for a FortiGate unit with virtual domains (VDOMs) enabled by logging into the web-based manager as the global admin administrator and going to *System* > *Config* > *HA*.

If already operating in HA mode, go to *System* > *Config* > *HA to* display the cluster members list (see “Cluster members list” on page 2147).

Go to *System* > *Config* > *HA* and select *View HA Statistics* to view statistics about cluster operation. See “Viewing HA statistics” on page 2150.

If your cluster uses virtual domains, you are configuring HA virtual clustering. Most virtual cluster HA options are the same as normal HA options. However, virtual clusters include VDOM partitioning options. Other differences between configuration options for regular HA and for virtual clustering HA are described below and see “Configuring and connecting virtual clusters” on page 2089.

HA is not compatible with PPP protocols such as PPPoE. HA is also not compatible with DHCP. If one or more FortiGate interfaces is dynamically configured using DHCP or PPPoE, you cannot switch to operate in HA mode. You also cannot switch to operate in HA mode if one or more FortiGate interfaces is configured as a PPTP or L2TP client or if the FortiGate unit is configured for standalone session synchronization.

Mode	Select an HA mode for the cluster or return the FortiGate unit in the cluster to standalone mode. When configuring a cluster, you must set all members of the HA cluster to the same HA mode. You can select *Standalone* (to disable HA), *Active-Passive*, or *Active-Active*. If virtual domains are enabled you can select *Active-Passive* or *Standalone*.
Device Priority	Optionally set the device priority of the cluster FortiGate unit. Each FortiGate unit in a cluster can have a different device priority. During HA negotiation, the FortiGate unit with the highest device priority usually becomes the primary unit. See “Primary unit selection” on page 2000. In a virtual cluster configuration, each cluster FortiGate unit can have two different device priorities, one for each virtual cluster. During HA negotiation, the FortiGate unit with the highest device priority in a virtual cluster becomes the primary FortiGate unit for that virtual cluster. Changes to the device priority are not synchronized. You can accept the default device priority when first configuring a cluster. When the cluster is operating you can change the device priority for different cluster units as required.
Group Name	Enter a name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units. When the cluster is operating you can change the group name, if required.
Password	Enter a password to identify the cluster. The maximum password length is 15 characters. The password must be the same for all cluster FortiGate units before the cluster FortiGate units can form a cluster. The default is no password. When the cluster is operating, you can add a password, if required. Two clusters on the same network must have different passwords.
Enable Session pickup	Select to enable session pickup so that if the primary unit fails, sessions are picked up by the cluster unit that becomes the new primary unit. You must enable session pickup for session failover protection. If you do not require session failover protection, leaving session pickup disabled may reduce HA CPU usage and reduce HA heartbeat network bandwidth usage. Session pickup is disabled by default. You can accept the default setting for session pickup and later choose to enable session pickup after the cluster is operating. See “Session failover (session pick-up)” on page 2205.

Port Monitor	Select to enable or disable monitoring FortiGate interfaces to verify the monitored interfaces are functioning properly and are connected to their networks. See “Link failover” on page 2194. If a monitored interface fails or is disconnected from its network, the interface leaves the cluster and a link failover occurs. The link failover causes the cluster to reroute the traffic being processed by that interface to the same interface of another cluster FortiGate unit that still has a connection to the network. This other cluster FortiGate unit becomes the new primary unit. Port monitoring (also called interface monitoring) is disabled by default. Leave port monitoring disabled until the cluster is operating and then only enable port monitoring for connected interfaces. You can monitor up to 16 interfaces. This limit only applies to FortiGate units with more than 16 physical interfaces.
Heartbeat Interface	Select to enable or disable HA heartbeat communication for each interface in the cluster and set the heartbeat interface priority. The heartbeat interface with the highest priority processes all heartbeat traffic. If two or more heartbeat interfaces have the same priority, the heartbeat interface with the lowest hash map order value processes all heartbeat traffic. The web-based manager lists interfaces in alphanumeric order: • port1 • port2 through 9 • port10 Hash map order sorts interfaces in the following order: • port1 • port10 • port2 through port9 The default heartbeat interface configuration is different for each unit. This default configuration usually sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration or change it as required. The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0. You must select at least one heartbeat interface. If heartbeat communication is interrupted, the cluster stops processing traffic. See “HA heartbeat and communication between cluster units” on page 2170. You can select up to 8 heartbeat interfaces. This limit only applies to units with more than 8 physical interfaces.
VDOM partitioning	If you are configuring virtual clustering, you can set the virtual domains to be in virtual cluster 1 and the virtual domains to be in virtual cluster 2. The root virtual domain must always be in virtual cluster 1. See “Configuring and connecting virtual clusters” on page 2089.

Configuring and connecting HA clusters

This chapter contains general procedures and descriptions as well as detailed configuration examples that describe how to configure FortiGate HA clusters.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameters.

This chapter contains the following sections:

About the procedures in this chapter

The procedures in this chapter describe some of many possible sequences of steps for configuring HA clustering. As you become more experienced with FortiOS HA you may choose to use a different sequence of configuration steps.

For simplicity, many of these procedures assume that you are starting with new FortiGate units set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

Example: NAT/Route mode active-passive HA configuration

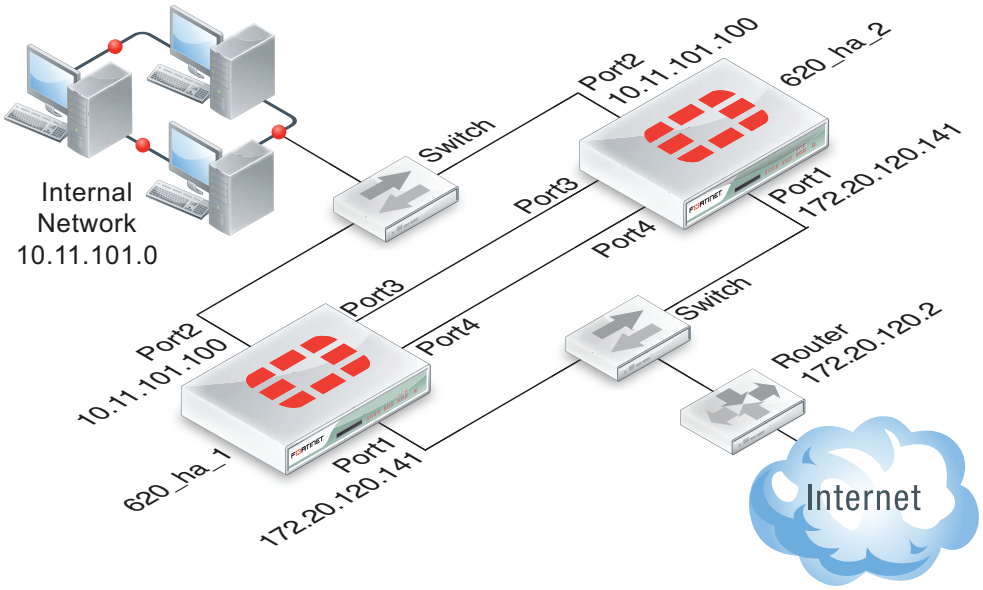
This section describes a simple HA network topology that includes an HA cluster of two FortiGate-620B units in NAT/Route mode installed between an internal network and the Internet.

- Configuring a NAT/Route mode active-passive cluster of two FortiGate-620B units - CLI

Example NAT/Route mode HA network topology

Figure 197 shows a typical FortiGate-620B HA cluster consisting of two FortiGate-620B units (620_ha_1 and 620_ha_2) connected to the same internal (port2) and external (port1) networks.

Figure 197: Example NAT/Route mode HA network topology



Port3 and port4 are the default FortiGate-620B heartbeat interfaces. Because the cluster consists of two FortiGate units, you can make the connections between the heartbeat interfaces using crossover cables. You could also use switches and regular ethernet cables.

General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Configure the FortiGate units for HA operation.
   - Optionally change each unit's host name.
   - Configure HA.
2. Connect the cluster to the network.
3. Confirm that the cluster units are operating as a cluster and add basic configuration settings to the cluster.
   - View cluster status from the web-based manager or CLI.
   - Add a password for the admin administrative account.
   - Change the IP addresses and netmasks of the internal and external interfaces.
   - Add a default route.

Configuring a NAT/Route mode active-passive cluster of two FortiGate-620B units - web-based manager

Use the following procedures to configure two FortiGate-620B units for NAT/Route HA operation using the FortiGate web-based manager. These procedures assume you are starting with two FortiGate-620B units with factory default settings.

Give each cluster unit a unique host name to make the individual units easier to identify when they are part of a functioning cluster. The default FortiGate unit host name is the FortiGate serial number. You may want to change this host name to something more meaningful for your network.

To configure the first FortiGate-620B unit (host name 620_ha_1)

1. Power on the first FortiGate unit.
2. On your management computer with an Ethernet connection, set the static IP address to 192.168.1.2 and the netmask to 255.255.255.0.
3. On a management computer, start a web browser and browse to the address https://192.168.1.99 (remember to include the “s” in https://).

   The FortiGate login is displayed.
4. Type *admin* in the *Name* field and select *Login*.

   The FortiGate dashboard is displayed.
5. On the *System Information* dashboard widget beside *Host Name*, select *Change*.
6. Enter a new Host Name for this FortiGate unit.

New Name	620_ha_1

7. Select OK.
8. Go to *System* > *Config* > *HA* and change the following settings:

Mode	Active-Passive
Group Name	example1.com
Password	HA_pass_1

This is the minimum recommended configuration for an active-active HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each unit in the cluster.

9 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`MAC`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

10 Power off the first FortiGate unit (620_ha_1).

To configure the second FortiGate-620B unit (host name 620_ha_2)

1 Power on the second FortiGate unit.

2 On a management computer, start a web browser and browse to the address https://192.168.1.99 (remember to include the “s” in https://).

The FortiGate login is displayed.

3 Type *admin* in the *Name* field and select *Login*.

The FortiGate dashboard is displayed.

4 On the *System Information* dashboard widget, beside *Host Name* select *Change*.

5 Enter a new Host Name for this FortiGate unit.

New Name	620_ha_2

6 Select OK.

7 Go to *System* > *Config* > *HA* and change the following settings:

Mode	Active-Passive
Group Name	example1.com
Password	HA_pass_1

8 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

9 Power off the second FortiGate unit.

To connect the cluster to the network

1 Connect the port1 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

2 Connect the port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

3 Connect the port3 interfaces of 620_ha_1 and 620_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4 Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

Once the cluster is operating, because configuration changes are synchronized to all cluster units, configuring the cluster is the same as configuring an individual FortiGate unit. You could have performed the following configuration steps separately on each FortiGate unit before you connected them to form a cluster.

1 Start Internet Explorer and browse to the address https://192.168.1.99 (remember to include the “s” in https://).

The FortiGate Login is displayed.

2 Type `admin` in the *Name* field and select Login.

The FortiGate dashboard is displayed.

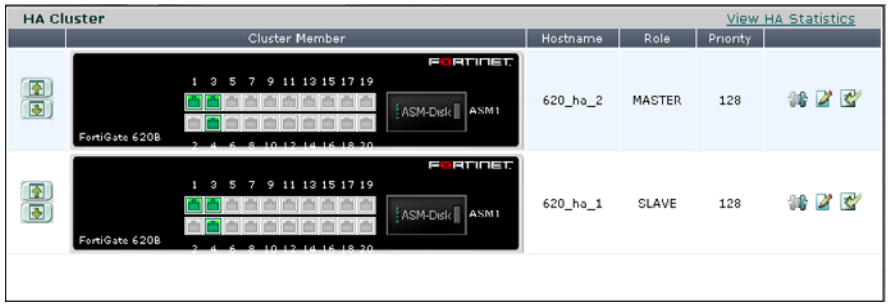
The System Information dashboard widget shows the *Cluster Name* (example1.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

Figure 198: Sample FortiGate-620B System Information dashboard widget

3 Go to *System* > *Config* > *HA* to view the cluster members list.

The list shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

Figure 199: Sample FortiGate-620B cluster members list



To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See "Troubleshooting HA clusters" on page 2083 to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to configure the cluster to connect to its network. The following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1. Log into the cluster web-based manager.
2. Go to *System* > *Admin* > *Administrators*.
3. For *admin*, select the *Change Password* icon
4. Enter and confirm a new password.
5. Select OK.
6. Go to *System* > *Network* > *Interface*.
7. Edit the *port2* interface and change *IP/Netmask* to 10.11.101.100/24.
8. Select OK.

After changing the IP address of the port1 interface you may have to change the IP address of your management computer and then reconnect to the port1 interface using the 172.20.120.141 IP address.

9. Edit the *port1* interface and change *IP/Netmask* to 172.20.120.141/24.
10. Select OK.
11. Go to *Router* > *Static*.
12. Change the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	port1
Distance	10

13. Select OK.

Configuring a NAT/Route mode active-passive cluster of two FortiGate-620B units - CLI

Use the following procedures to configure two FortiGate-620B units for NAT/Route HA operation using the FortiGate CLI. These procedures assume you are starting with two FortiGate-620B units with factory default settings.

To configure the first FortiGate-620B unit (host name 620_ha_1)

1. Power on the FortiGate unit.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal (or any terminal emulation program), enter a name for the connection, and select OK.

4 Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select OK.

5 Select the following port settings and select OK.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6 Press Enter to connect to the FortiGate CLI.

The FortiGate unit CLI login prompt appears.

If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate unit and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.

7 Type `admin` and press Enter twice.

8 Change the host name for this FortiGate unit.

```
config system global
  set hostname 620_ha_1
end
```

9 Configure HA settings.

```
config system ha
  set mode a-p
  set group-name example1.com
  set password HA_pass_1
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`

- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`MAC`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

10 Display the HA configuration (optional).

```
get system ha
  group-id              : 0
  group-name            : example1.com
  mode                  : a-p
  password              : *
  hbdev                 : "port3" 50 "port4" 50
  session-sync-dev      :
  route-ttl             : 10
  route-wait            : 0
  route-hold            : 10
  sync-config           : enable
  encryption            : disable
  authentication        : disable
  hb-interval           : 2
  hb-lost-threshold     : 6
  helo-holddown         : 20
  arps                  : 5
  arps-interval         : 8
  session-pickup        : disable
  link-failed-signal    : disable
  uninterruptable-upgrade: enable
  ha-mgmt-status        : disable
  ha-eth-type           : 8890
  hc-eth-type           : 8891
```

```
l2ep-eth-type       : 8893
subsecond           : disable
vcluster2           : disable
vcluster-id         : 1
override            : disable
priority            : 128
monitor             :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom                : "root"
```

11 Power off the FortiGate unit.

To configure the second FortiGate-620B unit (host name 620_ha_2)

1 Power on the FortiGate unit.

2 Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.

3 Start HyperTerminal, enter a name for the connection, and select OK.

4 Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select OK.

5 Select the following port settings and select OK.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6 Press Enter to connect to the FortiGate CLI.

The FortiGate unit CLI login prompt appears.

7 Type `admin` and press Enter twice.

8 Change the host name for this FortiGate unit.

```
config system global
  set hostname 620_ha_2
end
```

9 Configure HA settings.

```
config system ha
  set mode a-p
  set group-name example1.com
  set password HA_pass_1
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

10 Display the HA configuration (optional).

```
get system ha
  group-id              : 0
  group-name            : example1.com
  mode                  : a-p
  password              : *
  hbdev                 : "port3" 50 "port4" 50
  session-sync-dev      :
  route-ttl             : 10
  route-wait            : 0
  route-hold            : 10
  sync-config           : enable
  encryption            : disable
  authentication        : disable
  hb-interval           : 2
  hb-lost-threshold     : 6
  helo-holddown         : 20
  arps                  : 5
  arps-interval         : 8
  session-pickup        : disable
  link-failed-signal    : disable
  uninterruptable-upgrade: enable
  ha-mgmt-status        : disable
  ha-eth-type           : 8890
  hc-eth-type           : 8891
  l2ep-eth-type         : 8893
  subsecond             : disable
  vcluster2             : disable
  vcluster-id           : 1
  override              : disable
  priority              : 128
  monitor               :
  pingserver-monitor-interface:
  pingserver-failover-threshold: 0
  pingserver-flip-timeout: 60
  vdom                  : "root"
```

11 Power off the FortiGate unit.

To connect the cluster to the network

1 Connect the port1 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

2 Connect the port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

3 Connect the port3 interfaces of 620_ha_1 and 620_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4 Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1 Determine which cluster unit is the primary unit.

- Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
- Enter the command `get system status`.

  If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step 2.

  If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect the null-modem cable to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode and you should review your HA configuration.

2 Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
  Model: 620
  Mode: a-a
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:128 620_ha_2          FG600B3908600825 0
  Slave :128 620_ha_1          FG600B3908600705 1
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See "Troubleshooting HA clusters" on page 2083 to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to add some basic settings to the cluster so that it can connect to the network.

1 Log into the primary unit CLI.

2 Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <password_str>
end
```

3 Configure the port1 and port2 interfaces.

```
config system interface
  edit port1
    set ip 172.20.120.141/24
  next
  edit port2
    set ip 10.11.101.100/24
end
```

4 Add a default route.

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device port1
end
```

Example: Transparent mode active-active HA configuration

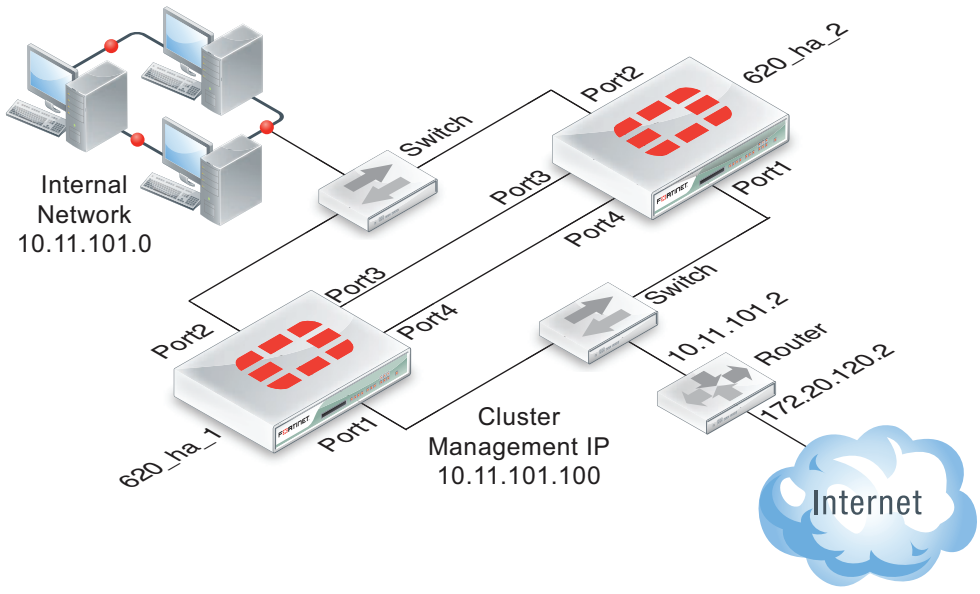
This section describes a simple HA network topology that includes an HA cluster of two FortiGate-620B units installed between an internal network and the Internet and running in Transparent mode.

- Example Transparent mode HA network topology
- General configuration steps

Example Transparent mode HA network topology

Figure 200 shows a Transparent mode FortiGate-620B HA cluster consisting of two FortiGate-620B units (620_ha_1 and 620_ha_2) installed between the Internet and internal network. The topology includes a router that performs NAT between the internal network and the Internet. The cluster management IP address is 10.11.101.100.

Figure 200: Transparent mode HA network topology



Port3 and port4 are the default FortiGate-620B heartbeat interfaces. Because the cluster consists of two FortiGate units, you can make the connections between the heartbeat interfaces using crossover cables. You could also use switches and regular ethernet cables.

General configuration steps

This section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

In this example, the configuration steps are identical to the NAT/Route mode configuration steps until the cluster is operating. When the cluster is operating, you can switch to Transparent mode and add basic configuration settings to cluster.

General configuration steps

1. Configure the FortiGate units for HA operation.
   - Optionally change each unit's host name.
   - Configure HA.
2. Connect the cluster to the network.
3. Confirm that the cluster units are operating as a cluster.
4. Switch the cluster to Transparent mode and add basic configuration settings to the cluster.
   - Switch to Transparent mode, add the management IP address and a default route.
   - Add a password for the admin administrative account.
   - View cluster status from the web-based manager or CLI.

Configuring a Transparent mode active-active cluster of two FortiGate-620B units - web-based manager

Use the following procedures to configure the FortiGate-620B units for HA operation using the FortiGate web-based manager. These procedures assume you are starting with two FortiGate-620B units with factory default settings.

Waiting until you have established the cluster to switch to Transparent mode means fewer configuration steps because you can switch the mode of the cluster in one step.

To configure the first FortiGate-620B unit (host name 620_ha_1)

1. Power on the first FortiGate unit.
2. Set the IP address of a management computer with an Ethernet connection to the static IP address 192.168.1.2 and a netmask of 255.255.255.0.
3. On a management computer, start a web browser and browse to the address https://192.168.1.99 (remember to include the "s" in https://).

   The FortiGate login is displayed.
4. Type *admin* in the *Name* field and select *Login*.

   The FortiGate dashboard is displayed.
5. On the *System Information* dashboard widget, beside *Host Name* select *Change*.

6 Enter a new Host Name for this FortiGate unit.

New Name	620_ha_1

7 Select OK.

8 Go to *System* > *Config* > *HA* and change the following settings:

Mode	Active-Active
Group Name	example2.com
Password	HA_pass_2

This is the minimum recommended configuration for an active-active HA cluster. You can configure other HA options at this point, but if you wait until the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

9 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`MAC`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

10 Power off the first FortiGate unit.

To configure the second FortiGate-620B unit (host name 620_ha_2)

1 Power on second FortiGate unit.

2 On a management computer, start Internet Explorer and browse to the address https://192.168.1.99 (remember to include the “s” in https://).

The FortiGate login is displayed.

3 Type *admin* in the *Name* field and select *Login*.

The FortiGate dashboard is displayed.

4 On the *System Information* dashboard widget, beside *Host Name* select *Change*.

5 Enter a new Host Name for this FortiGate unit.

New Name	620_ha_2

6 Select OK.

7 Go to *System* > *Config* > *HA* and change the following settings:

Mode	Active-Active
Group Name	example2.com
Password	HA_pass_2

8 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

9 Power off the second FortiGate unit.

To connect the cluster to the network

1 Connect the port1 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

2 Connect the port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

3 Connect the port3 interfaces of 620_ha_1 and 620_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4 Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To switch the cluster to Transparent mode

Switching from NAT/Route to Transparent mode involves adding the Transparent mode management IP address and default route.

Since configuration changes are synchronized to all cluster units, switching the cluster to operate in Transparent mode once the cluster is operating is the same as switching an individual FortiGate unit to Transparent mode. You could have performed the following configuration steps separately on each FortiGate unit before you connected them to form a cluster.

1. Start a web browser and browse to the address `https://192.168.1.99` (remember to include the “s” in `https://`).

   The FortiGate Login is displayed.
2. Type admin in the Name field and select Login.
3. Under System Information, beside *Operation Mode* select *Change*.
4. Set Operation Mode to Transparent.
5. Configure basic Transparent mode settings.

Operation Mode	Transparent
Management IP/Mask	10.11.101.100/24
Default Gateway	10.11.101.2

6. Select Apply.

   The cluster switches to operating in Transparent mode. The virtual MAC addresses assigned to the cluster interfaces do not change.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

Once the cluster is operating, because configuration changes are synchronized to all cluster units, configuring the cluster is the same as configuring an individual FortiGate unit. You could have performed the following configuration steps separately on each FortiGate unit before you connected them to form a cluster.

1. Start Internet Explorer and browse to the address https://10.11.101.100 (remember to include the “s” in https://).

   The FortiGate Login is displayed.
2. Type admin in the Name field and select Login.

   The FortiGate dashboard is displayed.

   The System Information dashboard widget shows the *Cluster Name* (example2.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.
3. Go to *System* > *Config* > *HA* to view the cluster members list.

   The list shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See "Troubleshooting HA clusters" on page 2083 to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to configure the cluster. Note that the following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1 Log into the cluster web-based manager.
2 Go to *System* > *Admin* > *Administrators*.
3 For *admin*, select the *Change Password* icon
4 Enter and confirm a new password.
5 Select OK.

You added a default gateway when you switched to Transparent mode so you don't need to add a default route as part of the basic configuration of the cluster at this point.

Configuring a Transparent mode active-active cluster of two FortiGate-620B units - CLI

Use the following procedures to configure the FortiGate-620B units for Transparent mode HA operation using the FortiGate CLI.

To configure each FortiGate unit for HA operation

1 Power on the FortiGate unit.
2 Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3 Start HyperTerminal, enter a name for the connection, and select OK.
4 Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select OK.
5 Select the following port settings and select OK.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6 Press Enter to connect to the FortiGate CLI.

The FortiGate unit CLI login prompt appears.If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate unit and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.

7 Type `admin` and press Enter twice.
8 Change the host name for this FortiGate unit. For example:

```
config system global
```

```
  set hostname 620_ha_1
end
```

9 Configure HA settings.

```
config system ha
  set mode a-a
  set group-name example2.com
  set password HA_pass_2
end
```

This is the minimum recommended configuration for an active-active HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`MAC`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

10 Display the HA configuration (optional).

```
get system ha
  group-id              : 0
```

```
group-name          : example2.com
mode                : a-a
password            : *
hbdev               : "port3" 50 "port4" 50
session-sync-dev    :
route-ttl           : 10

vdom                : "root"
```

11 Power off the FortiGate unit.

To configure the second FortiGate-620B unit (host name 620_ha_2)

1 Power on the FortiGate unit.

2 Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.

3 Start HyperTerminal, enter a name for the connection, and select OK.

4 Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select OK.

5 Select the following port settings and select OK.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6 Press Enter to connect to the FortiGate CLI.

The FortiGate unit CLI login prompt appears.If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate unit and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.

7 Type `admin` and press Enter twice.

8 Change the host name for this FortiGate unit.

```
config system global
  set hostname 620_ha_2
end
```

9 Configure HA settings.

```
config system ha
  set mode a-a
  set group-name example2.com
  set password HA_pass_2
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

10 Display the HA configuration (optional).

```
get system ha
  group-id              : 0
  group-name            : example2.com
  mode                  : a-a
  password              : *
  hbdev                 : "port3" 50 "port4" 50
  session-sync-dev      :
  route-ttl             : 10
  route-wait            : 0
  route-hold            : 10
  sync-config           : enable
  encryption            : disable
  authentication        : disable
  hb-interval           : 2
  hb-lost-threshold     : 6
  helo-holddown         : 20
  arps                  : 5
  arps-interval         : 8
  session-pickup        : disable
  link-failed-signal    : disable
  uninterruptable-upgrade: enable
  ha-mgmt-status        : disable
  ha-eth-type           : 8890
  hc-eth-type           : 8891
  l2ep-eth-type         : 8893
  subsecond             : disable
  vcluster2             : disable
```

```
vcluster-id          : 1
override             : disable
priority             : 128
monitor              :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom                 : "root"
```

11 Power off the FortiGate unit.

To connect the cluster to the network

1 Connect the port1 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

2 Connect the port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

3 Connect the port3 interfaces of 620_ha_1 and 620_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4 Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To connect to the cluster CLI and switch the cluster to Transparent mode

1 Determine which cluster unit is the primary unit.

- Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
- Enter the command `get system status`.

  If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step 2.

  If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode. See "Troubleshooting the initial cluster configuration" on page 2084.

2 Change to transparent mode.

```
config system settings
  set opmode transparent
  set manageip 192.168.20.3/24
  set gateway 192.168.20.1
```

```
end
```

The cluster switches to Transparent Mode, and your administration session is disconnected.

You can now connect to the cluster CLI using SSH to connect to the cluster internal interface using the management IP address (192.168.20.3).

To view cluster status

Use the following steps to view cluster status from the CLI.

1 Determine which cluster unit is the primary unit.

- Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
- Enter the command `get system status`.

  If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step 2.

  If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect the null-modem cable to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode and you should review your HA configuration.

2 Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
  Model: 620
  Mode: a-p
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:128 620_ha_2          FG600B3908600825 0
  Slave :128 620_ha_1          FG600B3908600705 1
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See “Troubleshooting HA clusters” on page 2083 to troubleshoot the cluster.

To add a password for the admin administrative account

1 Add a password for the admin administrative account.

```
config system admin
  edit admin
```

```
    set password <psswrd>
end
```

Example: advanced Transparent mode active-active HA configuration

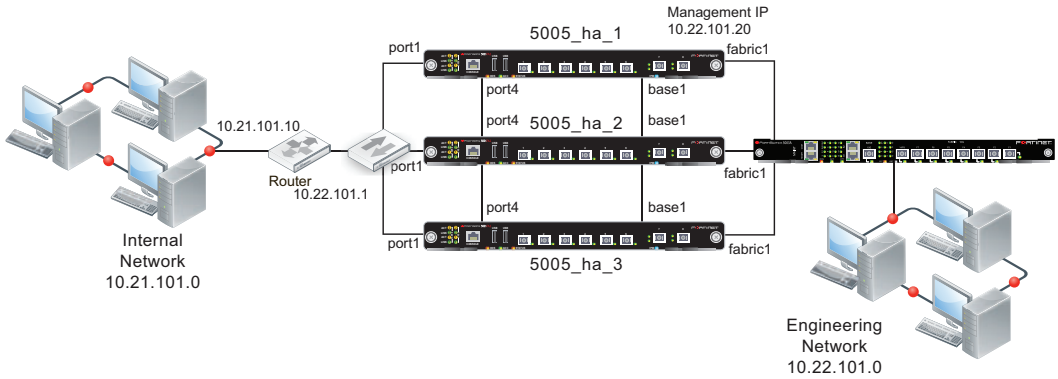
This section describes a more complex HA network topology that includes an HA cluster of three FortiGate-5002FA2 units running in Transparent mode and installed between an internal network and an engineering network.

- Example Transparent mode HA network topology
- General configuration steps

Example Transparent mode HA network topology

Figure 201 shows a Transparent mode FortiGate-5005FA2 HA cluster consisting of three FortiGate-5005FA2 units (5005_ha_1, 5005_ha_2, and 5005_ha_3) installed in a FortiGate-5000 series chassis with one FortiSwitch-5003A board. The cluster applies virus scanning to traffic passing between an engineering network and an internal network. The topology includes a router that performs NAT between the internal network and the engineering network. The cluster is connected to the engineering network with an management IP address of 10.22.101.20. This IP address is on the engineering network subnet.

Figure 201: Transparent mode HA network topology



By default fabric1 and fabric2 are the FortiGate-5005FA2 heartbeat interfaces. This example changes the heartbeat configuration to use the base1 and port4 interfaces for the heartbeat. The base1 connection is handled using the base backplane channel switched by the FortiSwitch-5003A board. The port4 connection is handled by connecting the port4 interfaces together using a switch.

The cluster connects to the engineering network using fabric1. The FortiSwitch-5003A board provides switching for the fabric1 interfaces and the fabric1 connection to the engineering network.

Configuring a Transparent mode active-active cluster of three FortiGate-5005FA2 units - web-based manager

These procedures assume you are starting with three FortiGate-5005FA2 units with factory default settings but not installed in chassis slots and a FortiSwitch-5003A board installed in chassis slot 1. The chassis is powered on. This configuration works for a FortiGate-5050 chassis or for a FortiGate-5140 chassis. No configuration changes to the FortiSwitch-5003A board are required.

To configure the FortiGate-5005FA2 units

1 Power on the first FortiGate unit by inserting it into chassis slot 5.

2 Connect port1 to the network and log into the web-based manager.

3 On the *System Information* dashboard widget, beside *Host Name* select *Change*.

4 Enter a new Host Name for this FortiGate unit.

New Name	5005_ha_1

5 Select OK.

6 Go to *System* > *Network* > *Interface* and select *Show backplane interfaces*.

7 Make sure the administrative status and link status is for base1 and fabric1.

You can edit the interface to set the administrative status to up. The link status will be up if the administrative status is up and the FortiGate-5005FA2 board can connect to the FortiSwitch-5003A board.

8 Go to *System* > *Config* > *HA* and change the following settings:

Mode	Active-Active	
Group Name	example3.com	
Password	HA_pass_3	
Heartbeat Interface		
	Enable	**Priority**
base1	Select	50
fabric1	Clear check box	0
fabric2	Clear check box	0
port4	Select	50

9 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-5005FA2 interfaces change to the following virtual MAC addresses:

- base1 interface virtual MAC: `00-09-0f-09-00-00`
- base2 interface virtual MAC: `00-09-0f-09-00-01`
- fabric1 interface virtual MAC: `00-09-0f-09-00-02`
- fabric2 interface virtual MAC: `00-09-0f-09-00-03`
- port1 interface virtual MAC: `00-09-0f-09-00-04`
- port2 interface virtual MAC: `00-09-0f-09-00-05`
- port3 interface virtual MAC: `00-09-0f-09-00-06`
- port4 interface virtual MAC: `00-09-0f-09-00-07`
- port5 interface virtual MAC: `00-09-0f-09-00-08`
- port6 interface virtual MAC: `00-09-0f-09-00-09`
- port7 interface virtual MAC: `00-09-0f-09-00-0a`
- port8 interface virtual MAC: `00-09-0f-09-00-0b`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
Current_HWaddr      00:09:0f:09:00:04
Permanent_HWaddr    00:09:0f:71:0a:dc
.
.
.
```

10 Power off the first FortiGate unit.

11 Repeat these steps for the second and third FortiGate units, with the following difference.

Set the second FortiGate unit host name to:

New Name	5005_ha_2

Set the third FortiGate unit host name to:

New Name	5005_ha_3

As you insert and configure each FortiGate unit, they will negotiate and join the cluster using the base1 interface for HA heartbeat communication.

To connect the cluster to the network

1 Connect the port1 interfaces of the cluster to a switch that can connect to the router and the internal network.

2 Connect the port4 interfaces of the cluster units together using a switch.

These interfaces become the backup heartbeat interface.

3 Connect one of the FortiSwitch-5003A front panel fabric interfaces (for example, F3) to the engineering network.

To switch the cluster to operate in Transparent mode

Switching from NAT/Route to Transparent mode also involves adding the Transparent mode management IP address and default route.

1 Log into the web-based manager.

2 Under System Information, beside *Operation Mode* select *Change*.

3 Set *Operation Mode* to *Transparent*.

4 Configure basic Transparent mode settings.

Operation Mode	Transparent
Management IP/Mask	10.22.101.20/24
Default Gateway	10.22.101.1

5 Select Apply.

The cluster switches to operating in Transparent mode. The virtual MAC addresses assigned to the cluster interfaces do not change. You must login again using the new TP address.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1 View the system dashboard.

The System Information dashboard widget shows the *Cluster Name* (example3.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

2 Go to *System* > *Config* > *HA* to view the cluster members list.

The list shows three cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See "Troubleshooting HA clusters" on page 2083 to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to configure the cluster. The following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1 Log into the cluster web-based manager.

2 Go to *System* > *Admin* > *Administrators*.

3 For *admin*, select the *Change Password* icon
4 Enter and confirm a new password.
5 Select OK.

The default route was changed when you switched to Transparent mode.

Configuring a Transparent mode active-active cluster of three FortiGate-5005FA2 units - CLI

Use the following procedures to configure the three FortiGate-5005FA2 units for Transparent mode HA operation using the FortiGate CLI.

To configure the FortiGate-5005FA2 units

1 Power on the first FortiGate unit by inserting it into chassis slot 5.
2 Connect port1 to the network and log into the CLI.

You can also use a console connection.

3 Change the host name for this FortiGate unit. For example:

```
config system global
  set hostname 5005_ha_1
end
```

4 Enable showing backplane interfaces.

```
config system global
  set show-backplane-intf enable
end
```

5 Make sure the administrative status and link status is up for base1 and fabric1.

Enter `get system interface` to view the status of these interfaces.

You can use the following commands to set the administrative status to up for these interfaces.

```
config system interface
  edit base1
    set status up
  next
  edit fabricq
    set status up
end
```

6 Configure HA settings.

```
config system ha
  set mode a-a
  set group-name example3.com
  set password HA_pass_3
  set hbdev base1 50 port4 50
end
```

This is the minimum recommended configuration for an active-active HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- base1 interface virtual MAC: `00-09-0f-09-00-00`
- base2 interface virtual MAC: `00-09-0f-09-00-01`
- fabric1 interface virtual MAC: `00-09-0f-09-00-02`
- fabric2 interface virtual MAC: `00-09-0f-09-00-03`
- port1 interface virtual MAC: `00-09-0f-09-00-04`
- port2 interface virtual MAC: `00-09-0f-09-00-05`
- port3 interface virtual MAC: `00-09-0f-09-00-06`
- port4 interface virtual MAC: `00-09-0f-09-00-07`
- port5 interface virtual MAC: `00-09-0f-09-00-08`
- port6 interface virtual MAC: `00-09-0f-09-00-09`
- port7 interface virtual MAC: `00-09-0f-09-00-0a`
- port8 interface virtual MAC: `00-09-0f-09-00-0b`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
Current_HWaddr      00:09:0f:09:00:04
Permanent_HWaddr    00:09:0f:71:0a:dc
.
.
.
```

7 Display the HA configuration (optional).

```
get system ha
group-id              : 0
group-name            : example3.com
mode                  : a-a
password              : *
hbdev                 : "base1" 50 "port4" 50
session-sync-dev      :
route-ttl             : 10
route-wait            : 0
route-hold            : 10
sync-config           : enable
encryption            : disable
authentication        : disable
```

```
  hb-interval          : 2
  hb-lost-threshold    : 20
  helo-holddown        : 20
  arps                 : 5
  arps-interval        : 8
  session-pickup       : disable
  link-failed-signal   : disable
  uninterruptable-upgrade: enable
  ha-mgmt-status       : disable
  ha-eth-type          : 8890
  hc-eth-type          : 8891
  l2ep-eth-type        : 8893
  subsecond            : disable
  vcluster2            : disable
  vcluster-id          : 1
  override             : disable
  priority             : 128
  schedule             : round-robin
  monitor              :
  pingserver-monitor-interface:
  pingserver-failover-threshold: 0
  pingserver-flip-timeout: 60
  vdom                 : "root"
  load-balance-all     : disable
```

8 Repeat these steps for the second and third FortiGate units.

Set the second FortiGate unit host name to:

```
config system global
  set hostname 5005_ha_2
end
```

Set the third FortiGate unit host name to:

```
config system global
  set hostname 5005_ha_3
end
```

As you insert and configure each FortiGate unit they will negotiate and join the cluster using the base1 interface for HA heartbeat communication.

To connect the cluster to the network

1 Connect the port1 interfaces of the cluster to a switch that can connect to the router and the internal network.

2 Connect the port4 interfaces of the cluster units together using a switch.

These interfaces become the backup heartbeat interface.

3 Connect one of the FortiSwitch-5003A front panel fabric interfaces (for example, F3) to the engineering network.

To switch the cluster to Transparent mode

1 Log into the cluster CLI.

2 Change to Transparent mode.

```
config system settings
  set opmode transparent
  set manageip 10.22.101.20/24
```

```
  set gateway 10.22.101.1
end
```

The cluster switches to Transparent Mode.

You can now connect to the cluster CLI using SSH to connect to the cluster internal interface using the management IP address (10.22.101.20).

To view cluster status

Use the following steps to view cluster status from the CLI.

1 Log into the CLI.

2 To verify the HA status of the cluster unit that you logged into, enter the CLI command `get system status`. Look for the following information in the command output.

`Current HA mode: a-a, master`	The cluster units are operating as a cluster and you have connected to the primary unit.
`Current HA mode: a-a, backup`	The cluster units are operating as a cluster and you have connected to a subordinate unit.
`Current HA mode: standalone`	The cluster unit is not operating in HA mode

3 Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
  Model: 5005
  Mode: a-a
  Group: 0
  Debug: 0
  ses_pickup: disable
  load_balance: disable
  schedule: round robin
  Master:128 5005_ha_1        FG5A253E07600124 0
  Slave :128 5005_ha_2        FG5A253E06500088 1
  Slave :128 5005_ha_3        FG5A253E06500099 2
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG5A253E07600124
  Slave :1 FG5A253E06500088
  Slave :2 FG5A253E06500099
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See “Troubleshooting HA clusters” on page 2083 to troubleshoot the cluster.

To add a password for the admin administrative account

1 Add a password for the admin administrative account.

```
config system admin
  edit admin
    set password <psswrd>
```

```
end
```

Example: converting a standalone FortiGate unit to a cluster

You can convert an already configured and installed FortiGate unit into a cluster by configuring this FortiGate unit to be a primary unit and then adding subordinate units.

General configuration steps:

- Configure the original FortiGate unit for HA operation.
- Set the HA Device Priority of the original FortiGate unit to 255 to make sure that this FortiGate unit becomes the primary unit after cluster negotiation and synchronization.
- Back up the configuration of the original FortiGate unit.
- Configure one or more new FortiGate units with the same HA configuration as the original FortiGate unit with one exception. Keep the Unit Priority at the default setting, which is 128.
- Connect the FortiGate units to form a cluster and connect the cluster to your network.

When you power on all of the FortiGate units in the cluster, the original FortiGate unit becomes the primary unit. Its configuration is synchronized to all of the subordinate units. The entire cluster now operates with the original FortiGate unit configuration. No further configuration changes are required.

The new FortiGate units must:

- Have the same hardware configuration as the original FortiGate unit. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the original FortiGate unit.
- Be set to the same operating mode (NAT or Transparent) as the original FortiGate unit.
- Be operating in single VDOM mode.

In addition to one or more new FortiGate units, you need sufficient switches to connect all of the FortiGate interfaces in the cluster. Generally you will need one switch per interface, as it will have to connect that same interface on all cluster units. That is, all port1 interfaces use the port1 switch, port2 interfaces use the port2 switch, and so on. Intelligent switches that can be partitioned can reduce your switch requirements.

Converting a FortiGate unit to a primary unit and adding in the subordinate unit or units results in a brief service interruption as you disconnect and reconnect FortiGate interfaces and as the cluster negotiates. Therefore, conversion should only be done during off peak hours.

To configure the original FortiGate unit for HA operation

1 Connect to the FortiGate unit web-based manager.

2 Go to *System* > *Config* > *HA*.

3 Configure the FortiGate unit for HA operation.

Mode	Active-Active
Device Priority	255
Group Name	example4.com
Password	HA_pass_4

You can make other HA configuration changes after the cluster is operating.

4 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177).

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

5 Configure the new FortiGate units with the same HA configuration as the original FortiGate unit. The one exception is to keep the device priorities of the new FortiGate units at 128 to ensure the original FortiGate unit will become the primary unit in the new cluster.

Mode	Active-Active
Device Priority	128
Group Name	example4.com
Password	HA_pass_4

6 Configure the other FortiGate units to the same operation mode as the original FortiGate unit.

There is no need to make any other configuration changes (including network configuration changes) to the other FortiGate units.

7 Optionally power off all of the cluster units.

If you don't power off all of the units they may not negotiate to form a cluster when they are connected together.

8 Connect the cluster to your network.

For example, for a configuration similar to the FortiGate-620B cluster configuration described in this chapter, see "To connect the cluster to the network" on page 2025.

9 Power on all of the cluster units.

As the units start they change their MAC addresses and then negotiate to choose the primary unit and the subordinate units. This negotiation occurs with no user intervention and normally takes less than a minute.

The original the FortiGate unit becomes the primary unit because the device priority of the original FortiGate unit is higher than the device priority of the other FortiGate units. The configuration of the original FortiGate unit is synchronized to all the cluster units. As a result, the cluster is quickly up and running and configured for your network. No further configuration changes are required.

Example: adding a new unit to an operating cluster

This procedure describes how to add a new FortiGate unit to a functioning cluster. Adding a new unit to a cluster does not interrupt the operation of the cluster unless you have to change how the cluster is connected to the network to accommodate the new cluster unit.

You can use this procedure to add as many units as required to the cluster.

To add a new unit to a functioning cluster

1 Install the same firmware build on the new cluster unit as is running on the cluster.

2 Configure the new cluster unit for HA operation with the same HA configuration as the other units in the cluster.

3 If the cluster is running in Transparent mode, change the operating mode of the new cluster unit to Transparent mode.

4 Connect the new cluster unit to the cluster.

For example, for a configuration similar to the FortiGate-620B cluster configuration described in this chapter, see "To connect the cluster to the network" on page 2025.

5 Power on the new cluster unit.

When the unit starts it negotiates to join the cluster. After it joins the cluster, the cluster synchronizes the new unit configuration with the configuration of the primary unit.

You can add a new unit to a functioning cluster at any time. The new cluster unit must:

- Have the same hardware configuration as the cluster units. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the cluster.
- Be set to the same operating mode (NAT or Transparent) as the cluster.
- Be operating in single VDOM mode.

Example: replacing a failed cluster unit

This procedure describes how to remove a failed cluster unit from a cluster and add a new one to replace it. You can also use this procedure to remove a failed unit from a cluster, repair it and add it back to the cluster. Replacing a failed does not interrupt the operation of the cluster unless you have to change how the cluster is connected to the network to accommodate the replacement unit.

You can use this procedure to replace more than one cluster unit.

To replace a failed cluster unit

1 Disconnect the failed unit from the cluster and the network.

If you maintain other connections between the network and the still functioning cluster unit or units and between remaining cluster units network traffic will continue to be processed.

2 Repair the failed cluster unit, or obtain a replacement unit with the exact same hardware configuration as the failed cluster unit.

3 Install the same firmware build on the repaired or replacement unit as is running on the cluster.

4 Configure the repaired or replacement unit for HA operation with the same HA configuration as the cluster.

5 If the cluster is running in Transparent mode, change the operating mode of the repaired or replacement cluster unit to Transparent mode.

6 Connect the repaired or replacement cluster unit to the cluster.

For example, for a configuration similar to the FortiGate-620B cluster configuration described in this chapter, see "To connect the cluster to the network" on page 2025.

7 Power on the repaired or replacement cluster unit.

When the unit starts it negotiates to join the cluster. After it joins the cluster, the cluster synchronizes the repaired or replacement unit configuration with the configuration of the primary unit.

You can add a repaired or replacement unit to a functioning cluster at any time. The repaired or replacement cluster unit must:

- Have the same hardware configuration as the cluster units. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the cluster.
- Be set to the same operating mode (NAT or Transparent) as the cluster.
- Be operating in single VDOM mode.

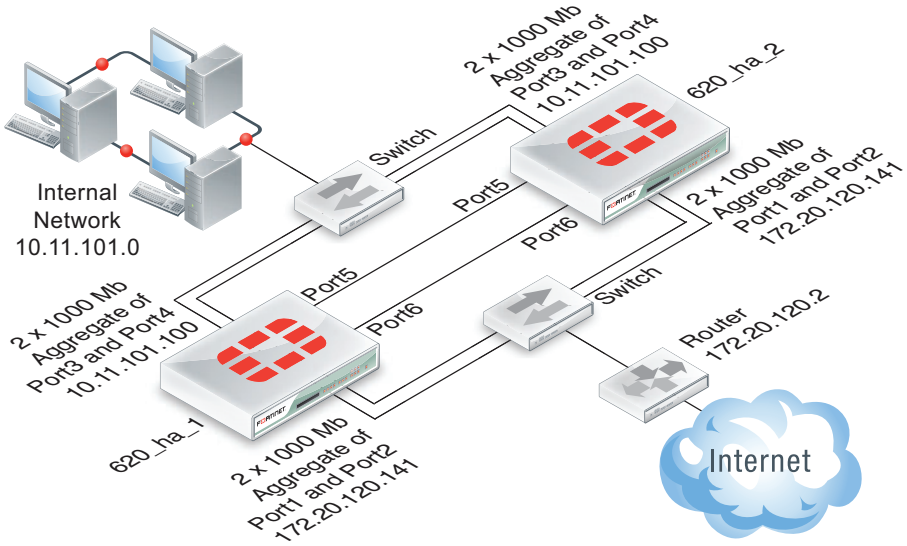
Example: HA and 802.3ad aggregated interfaces

On FortiGate models that support it you can use 802.3ad link aggregation to combine two or more interfaces into a single aggregated interface. 802.3ad Link Aggregation and it's management protocol, Link Aggregation Control Protocol (LACP) are a method for combining multiple physical links into a single logical link.This increases both potential throughput and network resiliency. Using LACP, traffic is distributed among the physical interfaces in the link, potentially resulting in increased performance.

This example describes how to configure an HA cluster consisting of two FortiGate-620B units with two aggregated 1000 Mb connections to the Internet using port1 and port2 and two aggregated 1000 Mb connections to the internal network using port3 and port4. The aggregated interfaces are also configured as HA monitored interfaces.

Each of the aggregate links connects to a different switch. Each switch is configured for link aggregation (2x1000Mb).

Figure 202: Example cluster with aggregate interfaces



HA interface monitoring, link failover, and 802.3ad aggregation

When monitoring the aggregated interface, HA interface monitoring treats the aggregated link as a single interface and does not monitor the individual physical interfaces in the link. HA interface monitoring registers the link to have failed only if all the physical interfaces in the link have failed. If only some of the physical interfaces in the link fail or become disconnected, HA considers the link to be operating normally.

HA MAC addresses and 802.3ad aggregation

If a configuration uses the Link Aggregate Control Protocol (LACP) (either passive or active), LACP is negotiated over all of the interfaces in any link. For a standalone FortiGate unit, the FortiGate LACP implementation uses the MAC address of the first interface in the link to uniquely identify that link. For example, a link consisting of port1 and port2 interfaces would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. An aggregate interface in a cluster acquires the virtual MAC address that would have been acquired by the first interface in the aggregate.

Link aggregation, HA failover performance, and HA mode

To operate an active-active or active-passive cluster with aggregated interfaces and for best performance of a cluster with aggregated interfaces, the switches used to connect the cluster unit aggregated interfaces together should support configuring multiple Link Aggregation (LAG) groups.

For example, the cluster shown in Figure 202 should be configured into two LAG groups on the external switch: one for the port1 and port2 aggregated interface of 620_ha_1 and a second one for the port1 and port2 aggregate interface of 620_ha_2. You should also be able to do the same on the internal switch for the port3 and port4 aggregated interfaces of each cluster unit.

As a result, the subordinate unit aggregated interfaces would participate in LACP negotiation while the cluster is operating. In an active-active mode cluster, packets could be redirected to the subordinate unit interfaces. As well, in active-active or active-passive mode, after a failover the subordinate unit can become a primary unit without having to perform LACP negotiation before it can process traffic. Performing LACP negotiation causes a minor failover delay.

However if you cannot configure multiple LAG groups on the switches, due to the primary and subordinate unit interfaces having the same MAC address, the switch will put all of the interfaces into the same LAG group which would disrupt the functioning of the cluster. To prevent this from happening, you must change the FortiGate aggregated interface configuration to prevent subordinate units from participating in LACP negotiation.

For example, use the following command to prevent subordinate units from participating in LACP negotiation with an aggregate interface named Port1_Port2:

```
config system interface
  edit Port1_Port2
    set lacp-ha-slave disable
  end
```

As a result of this setting, subordinate unit aggregated interfaces cannot accept packets. This means that you cannot operate the cluster in active-active mode because in active-active mode the subordinate units must be able to receive and process packets. Also, failover may take longer because after a failover the subordinate unit has to perform LACP negotiation before being able to process network traffic.

Also, it may also be necessary to configure the switch to use Passive or even Static mode for LACP to prevent the switch from sending packets to the subordinate unit interfaces, which won't be able to process them.

Finally, in some cases depending on the LACP configuration of the switches, you may experience delayed failover if the FortiGate LACP configuration is not compatible with the switch LACP configuration. For example, in some cases setting the FortiGate LACP mode to static reduces the failover delay because the FortiGate unit does not perform LACP negotiation. However there is a potential problem with this configuration because static LACP does not send periodic LAC Protocol Data Unit (LACPDU) packets to test the connections. So a non-physical failure (for example, if a device is not responding because its too busy) may not be detected and packets could be lost or delayed.

General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Configure the FortiGate units for HA operation.
   - Change each unit's host name.
   - Configure HA.
2. Connect the cluster to the network.
3. View cluster status.
4. Add basic configuration settings and configure the aggregated interfaces.
   - Add a password for the admin administrative account.
   - Add the aggregated interfaces.
   - Disable `lacp-ha-slave` so that the subordinate unit does not send LACP packets.
   - Add a default route.

   You could also configure aggregated interfaces in each FortiGate unit before the units form a cluster.
5. Configure HA port monitoring for the aggregated interfaces.

Configuring active-passive HA cluster that includes aggregated interfaces - web-based manager

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

To configure the FortiGate-620B units for HA operation

1. Power on the first FortiGate-620B unit and log into the web-based manager.
2. On the *System Information* dashboard widget, beside *Host Name* select *Change*.
3. Enter a new Host Name for this FortiGate unit.

New Name	620_ha_1

4. Select OK.

5 Go to *System* > *Config* > *HA* and change the following settings.

Mode	Active-Passive	
Group Name	example5.com	
Password	HA_pass_5	
Heartbeat Interface		
	Enable	**Priority**
port5	Select	50
port6	Select	50

Since port3 and port4 will be used for a aggregated interface, you must change the HA heartbeat configuration to not use those interfaces.

6 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7 Power off the first FortiGate unit.

8 Repeat these steps for the second FortiGate unit.

Set the second FortiGate unit host name to:

New Name	620_ha_2

To connect the cluster to the network

1 Connect the port1 and port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

Configure the switch so that the port1 and port2 of 620_ha_1 make up an aggregated interface and port1 and port2 of 620_ha_2 make up a second aggregated interface.

2 Connect the port3 and port4 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

Configure the switch so that the port3 and port4 of 620_ha_1 make up an aggregated interface and port3 and port4 of 620_ha_2 make up another aggregated interface.

3 Connect the port5 interfaces of 620_ha_1 and 620_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4 Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5 Power on the cluster units.

The units negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete, the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1 View the system dashboard.

The System Information dashboard widget shows the *Cluster Name* (example5.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

2 Go to *System* > *Config* > *HA* to view the cluster members list.

The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See "Troubleshooting HA clusters" on page 2083 to troubleshoot the cluster.

To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings.

1 Log into the cluster web-based manager.

2 Go to *System* > *Admin* > *Administrators*.

3 For *admin*, select the *Change Password* icon.

4 Enter and confirm a new password.

5 Select OK.

6 Go to *Router* > *Static* and temporarily delete the default route.

You cannot add an interface to a aggregated interface if any settings (such as the default route) are configured for it.

7 Go to *System* > *Network* > *Interface* and select *Create New* to add the aggregate interface to connect to the Internet.

8 Set *Type* to *802.3ad Aggregate* and configure the aggregate interface to be connected to the Internet:

Name	Port1_Port2
Physical Interface Members	
Selected Interfaces	port1, port2
IP/Netmask	172.20.120.141/24

9 Select OK.

10 Select *Create New* to add the aggregate interface to connect to the internal network.

11 Set *Type* to *802.3ad Aggregate* and configure the aggregate interface to be connected to the Internet:

Name	Port3_Port4
Physical Interface Members	
Selected Interfaces	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

12 Select OK.

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

13 Connect to the CLI and enter the following command to disable sending LACP packets from the subordinate unit:

```
config system interface
  edit Port1_Port2
    set lacp-ha-slave disable
  next
  edit Port3_Port4
    set lacp-ha-slave disable
end
```

14 Go to *Router* > *Static*.

15 Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

16 Select OK.

To configure HA port monitoring for the aggregate interfaces

1 Go to *System* > *Config* > *HA*.

2 In the cluster members list, edit the primary unit.

3 Configure the following port monitoring for the aggregate interfaces:

	Port Monitor
Port1_Port2	Select
Port3_Port4	Select

4 Select OK.

Configuring active-passive HA cluster that includes aggregate interfaces - CLI

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

To configure the FortiGate-620B units for HA operation

1 Power on the first FortiGate-620B unit and log into the CLI.

2 Change the host name for this FortiGate unit:

```
config system global
  set hostname 620_ha_1
end
```

3 Configure HA settings.

```
config system ha
  set mode a-p
  set group-name example5.com
  set password HA_pass_5
  set hbdev port5 50 port6 50
```

```
end
```

Since port3 and port4 will be used for an aggregated interface, you must change the HA heartbeat configuration.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4 Display the HA configuration (optional).

```
get system ha
group-id              : 0
group-name            : example5.com
mode                  : a-p
password              : *
hbdev                 : "port5" 50 "port6" 50
session-sync-dev      :
route-ttl             : 10
route-wait            : 0
route-hold            : 10
sync-config           : enable
encryption            : disable
authentication        : disable
hb-interval           : 2
hb-lost-threshold     : 20
helo-holddown         : 20

subsecond             : disable
vcluster2             : disable
vcluster-id           : 1
override              : disable
priority              : 128
monitor               :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom                  : "root"
```

5 Repeat these steps for the other FortiGate unit.

Set the other FortiGate unit host name to:

```
config system global
  set hostname 620_ha_2
end
```

To connect the cluster to the network

1 Connect the port1 and port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

Configure the switch so that the port1 and port2 of 620_ha_1 make up an aggregated interface and port1 and port2 of 620_ha_2 make up another aggregated interface.

2 Connect the port3 and port4 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

Configure the switch so that the port3 and port4 of 620_ha_1 make up an interfaced and port3 and port4 of 620_ha_2 make up another aggregated interface.

3 Connect the port5 interfaces of 620_ha_1 and 620_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4 Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1 Log into the CLI.

2 Enter `get system status` to verify the HA status of the cluster unit that you logged into.Look for the following information in the command output.

`Current HA mode: a-a, master`	The cluster units are operating as a cluster and you have connected to the primary unit.
`Current HA mode: a-a, backup`	The cluster units are operating as a cluster and you have connected to a subordinate unit.
`Current HA mode: standalone`	The cluster unit is not operating in HA mode

3 Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
  Model: 620
  Mode: a-a
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:128 620_ha_2          FG600B3908600825 0
  Slave :128 620_ha_1          FG600B3908600705 1
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See “Troubleshooting HA clusters” on page 2083 to troubleshoot the cluster.

To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings and the aggregate interfaces.

1 Add a password for the admin administrative account.

```
config system admin
```

```
  edit admin
    set password <psswrd>
end
```

2 Temporarily delete the default route.

You cannot add an interface to an aggregate interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```
config router static
  delete 1
end
```

3 Add the aggregate interfaces:

```
config system interface
  edit Port1_Port2
    set type aggregate
    set lacp-ha-slave disable
    set member port1 port2
    set ip 172.20.120.141/24
    set vdom root
  next
  edit Port3_Port4
    set type aggregate
    set lacp-ha-slave disable
    set member port3 port4
    set ip 10.11.101.100/24
    set vdom root
```

```
end
```

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

4 Add the default route.

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device Port1_Port2
end
```

To configure HA port monitoring for the aggregate interfaces

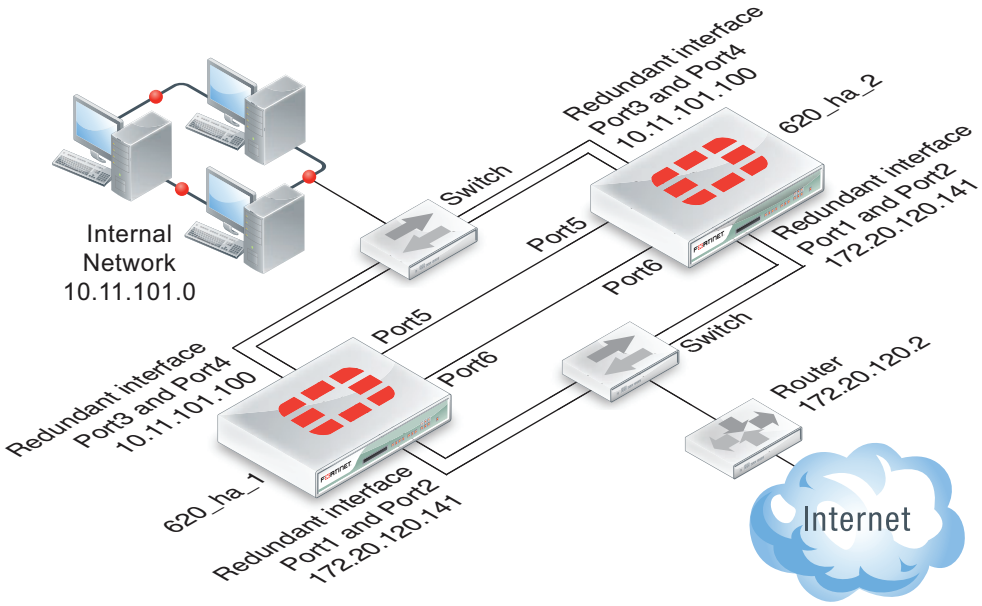
1 Configure HA port monitoring for the aggregate interfaces.

```
config system ha
  set monitor Port1_Port2 Port3_Port4
end
```

Example: HA and redundant interfaces

On FortiGate models that support it you can combine two or more interfaces into a single redundant interface. A redundant interface consists of two or more physical interfaces. Traffic is processed by the first physical interface in the redundant interface. If that physical interface fails, traffic fails over to the next physical interface. Redundant interfaces don't have the benefit of improved performance that aggregate interfaces can have, but they do provide failover if a physical interface fails or is disconnected.

Figure 203: Example cluster with a redundant interfaces



This example describes how to configure an HA cluster consisting of two FortiGate-620B units with a a redundant interface connection to the Internet and to an internal network. The connection to the Internet uses port1 and port2. The connection to the internal network uses port3 and port4. The HA heartbeat uses port5 and port6.

The redundant interfaces are also configured as HA monitored interfaces.

HA interface monitoring, link failover, and redundant interfaces

HA interface monitoring monitors the redundant interface as a single interface and does not monitor the individual physical interfaces in the redundant interface. HA interface monitoring registers the redundant interface to have failed only if all the physical interfaces in the redundant interface have failed. If only some of the physical interfaces in the redundant interface fail or become disconnected, HA considers the redundant interface to be operating normally.

HA MAC addresses and redundant interfaces

For a standalone FortiGate unit a redundant interface has the MAC address of the first physical interface added to the redundant interface configuration. A redundant interface consisting of port1 and port2 would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. A redundant interface in a cluster acquires the virtual MAC address that would have been acquired by the first physical interface added to the redundant interface configuration.

Connecting multiple redundant interfaces to one switch while operating in active-passive HA mode

HA assigns the same virtual MAC addresses to the subordinate unit interfaces as are assigned to the corresponding primary unit interfaces. Consider a cluster of two FortiGate units operating in active-passive mode with a redundant interface consisting of port1 and port2. You can connect multiple redundant interfaces to the same switch if you configure the switch so that it defines multiple separate redundant interfaces and puts the redundant interfaces of each cluster unit into separate redundant interfaces. In this configuration, each cluster unit forms a separate redundant interface with the switch.

However, if the switch is configured with a single four-port redundant interface configuration, because the same MAC addresses are being used by both cluster units, the switch adds all four interfaces (port1 and port2 from the primary unit and port1 and port2 from the subordinate unit) to the same redundant interface.

To avoid unpredictable results, when you connect a switch to multiple redundant interfaces in an active-passive cluster you should configure separate redundant interfaces on the switch; one for each cluster unit.

Connecting multiple redundant interfaces to one switch while operating in active-active HA mode

In an active-active cluster, all cluster units send and receive packets. To operate a cluster with redundant interfaces in active-active mode, with multiple redundant interfaces connected to the same switch, you must separate the redundant interfaces of each cluster unit into different redundant interfaces on the connecting switch.

General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Configure the FortiGate units for HA operation.
   - Change each unit's host name.
   - Configure HA.
2. Connect the cluster to the network.
3. View cluster status.
4. Add basic configuration settings and configure the redundant interfaces.
   - Add a password for the admin administrative account.
   - Add the redundant interfaces.
   - Add a default route.

   You could also configure redundant interfaces in each FortiGate unit before they form a cluster.
5. Configure HA port monitoring for the redundant interfaces.

Configuring active-passive HA cluster that includes redundant interfaces - web-based manager

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

To configure the FortiGate-620B units for HA operation

1 Power on the first FortiGate-620B unit and log into the web-based manager.

2 On the *System Information* dashboard widget, beside *Host Name* select *Change*.

3 Enter a new Host Name for this FortiGate unit.

New Name	620_ha_1

4 Select OK.

5 Go to *System* > *Config* > *HA* and change the following settings.

Mode	Active-Passive	
Group Name	example6.com	
Password	HA_pass_6	
Heartbeat Interface		
	Enable	**Priority**
port5	Select	50
port6	Select	50

Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

6 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7 Power off the first FortiGate unit.

8 Repeat these steps for the second FortiGate unit.

Set the second FortiGate unit host name to:

New Name	620_ha_2

To connect the cluster to the network

1 Connect the port1 and port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

Configure the switch so that the port1 and port2 of 620_ha_1 make up a redundant interface and port1 and port2 of 620_ha_2 make up another redundant interface.

2 Connect the port3 and port4 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

Configure the switch so that the port3 and port4 of 620_ha_1 make up a redundant interface and port3 and port4 of 620_ha_2 make up another redundant interface.

3 Connect the port5 interfaces of 620_ha_1 and 620_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4 Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1 View the system dashboard.

The System Information dashboard widget shows the *Cluster Name* (example5.com) and the host names and serial numbers of the *Cluster Members*. The Unit Operation widget shows multiple cluster units.

2 Go to *System* > *Config* > *HA* to view the cluster members list.

The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See "Troubleshooting HA clusters" on page 2083 to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1 Log into the cluster web-based manager.

2 Go to *System* > *Admin* > *Administrators*.

3 For *admin*, select the *Change Password* icon

4 Enter and confirm a new password.

5 Select OK.

6 Go to *Router* > *Static* and temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.

7 Go to *System* > *Network* > *Interface* and select *Create New* to add the redundant interface to connect to the Internet.

8 Set *Type* to *Redundant Interface* and configure the redundant interface to be connected to the Internet:

Name	Port1_Port2
Physical Interface Members	
Selected Interfaces	port1, port2
IP/Netmask	172.20.120.141/24

9 Select OK.

10 Select *Create New* to add the redundant interface to connect to the internal network.

11 Set *Type* to *Redundant Interface* and configure the redundant interface to be connected to the Internet:

Name	Port3_Port4
Physical Interface Members	
Selected Interfaces	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

12 Select OK.

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

13 Go to *Router* > *Static*.

14 Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

15 Select OK.

To configure HA port monitoring for the redundant interfaces

1 Go to *System* > *Config* > *HA*.

2 In the cluster members list, edit the primary unit.

3 Configure the following port monitoring for the redundant interfaces:

	Port Monitor
Port1_Port2	Select
Port3_Port4	Select

4 Select OK.

Configuring active-passive HA cluster that includes redundant interfaces - CLI

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

To configure the FortiGate-620B units for HA operation

1 Power on the first FortiGate-620B unit and log into the CLI.

2 Change the host name for this FortiGate unit:

```
config system global
  set hostname 620_ha_1
end
```

3 Configure HA settings.

```
config system ha
  set mode a-p
  set group-name example6.com
  set password HA_pass_6
  set hbdev port5 50 port6 50
```

```
end
```

Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4 Display the HA configuration (optional).

```
get system ha
group-id              : 0
group-name            : example6.com
mode                  : a-p
password              : *
hbdev                 : "port5" 50 "port6" 50
session-sync-dev      :
route-ttl             : 10
route-wait            : 0
route-hold            : 10
sync-config           : enable
encryption            : disable
authentication        : disable
hb-interval           : 2
hb-lost-threshold     : 20
helo-holddown         : 20
arps                  : 5
arps-interval         : 8
session-pickup        : disable
link-failed-signal    : disable
uninterruptable-upgrade: enable
ha-mgmt-status        : disable
ha-eth-type           : 8890
hc-eth-type           : 8891
l2ep-eth-type         : 8893
subsecond             : disable
vcluster2             : disable
vcluster-id           : 1
override              : disable
priority              : 128
monitor               :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom                  : "root"
```

5 Repeat these steps for the other FortiGate unit.

Set the other FortiGate unit host name to:

```
config system global
  set hostname 620_ha_2
end
```

To connect the cluster to the network

1 Connect the port1 and port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

Configure the switch so that the port1 and port2 of 620_ha_1 make up a redundant interface and port1 and port2 of 620_ha_2 make up another redundant interface.

2 Connect the port3 and port4 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

Configure the switch so that the port3 and port4 of 620_ha_1 make up a redundant interface and port3 and port4 of 620_ha_2 make up another redundant interface.

3 Connect the port5 interfaces of 620_ha_1 and 620_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

4 Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

5 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1 Log into the CLI.

2 Enter `get system status` to verify the HA status of the cluster unit that you logged into.Look for the following information in the command output.

`Current HA mode: a-a, master`	The cluster units are operating as a cluster and you have connected to the primary unit.
`Current HA mode: a-a, backup`	The cluster units are operating as a cluster and you have connected to a subordinate unit.
`Current HA mode: standalone`	The cluster unit is not operating in HA mode

3 Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
  Model: 620
  Mode: a-a
  Group: 0
  Debug: 0
  ses_pickup: disable
  Master:128 620_ha_2          FG600B3908600825 0
  Slave :128 620_ha_1          FG600B3908600705 1
  number of vcluster: 1
  vcluster 1: work 169.254.0.1
  Master:0 FG600B3908600825
  Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See “Troubleshooting HA clusters” on page 2083 to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings and the redundant interfaces.

1 Add a password for the admin administrative account.

```
config system admin
```

```
  edit admin
    set password <psswrd>
end
```

2 Temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```
config router static
  delete 1
end
```

3 Add the redundant interfaces:

```
config system interface
  edit Port1_Port2
    set type redundant
    set member port1 port2
    set ip 172.20.120.141/24
    set vdom root
  next
  edit Port3_Port4
    set type redundant
    set member port3 port4
    set ip 10.11.101.100/24
    set vdom root
```

```
end
```

The virtual MAC addresses of the FortiGate-620B interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

4 Add the default route.

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device Port1_Port2
end
```

To configure HA port monitoring for the redundant interfaces

1 Configure HA port monitoring for the redundant interfaces.

```
config system ha
  set monitor Port1_Port2 Port3_Port4
end
```

Troubleshooting HA clusters

This section describes some HA clustering troubleshooting techniques.

Before you set up a cluster

Before you set up a cluster ask yourself the following questions about the FortiGate units that you are planning to use to create a cluster.

1. Do all the FortiGate units have the same hardware configuration? Including the same hard disk configuration and the same AMC cards installed in the same slots?
2. Do all FortiGate units have the same firmware build?
3. Are all FortiGate units set to the same operating mode (NAT or Transparent)?
4. Are all the FortiGate units operating in single VDOM mode?
5. If the FortiGate units are operating in multiple VDOM mode do they all have the same VDOM configuration?

In some cases you may be able to form a cluster if different FortiGate units have different firmware builds, different VDOM configurations, and are in different operating modes. However, if you encounter problems they may be resolved by installing the same firmware build on each unit, and give them the same VDOM configuration and operating mode.

Troubleshooting the initial cluster configuration

This section describes how to check a cluster when it first starts up to make sure that it is configured and operating correctly. This section assumes you have already configured your HA cluster.

To verify that a cluster can process traffic and react to a failure

1. Add a basic security policy configuration and send network traffic through the cluster to confirm connectivity.

   For example, if the cluster is installed between the Internet and an internal network, set up a basic internal to external security policy that accepts all traffic. Then from a PC on the internal network, browse to a website on the Internet or ping a server on the Internet to confirm connectivity.
2. From your management PC, set ping to continuously ping the cluster, and then start a large download, or in some other way establish ongoing traffic through the cluster.
3. While traffic is going through the cluster, disconnect the power from one of the cluster units.

   You could also shut down or restart a cluster unit.

   Traffic should continue with minimal interruption.
4. Start up the cluster unit that you disconnected.

   The unit should re-join the cluster with little or no affect on traffic.
5. Disconnect a cable for one of the HA heartbeat interfaces.

   The cluster should keep functioning, using the other HA heartbeat interface.
6. If you have port monitoring enabled, disconnect a network cable from a monitored interface.

   Traffic should continue with minimal interruption.

To verify the cluster configuration - web-based manager

1. Log into the cluster web-based manager.
2. Check the system dashboard to verify that the System Information widget displays all of the cluster units.

3 Check the cluster member graphic to verify that the correct cluster unit interfaces are connected.

4 Go to *System* > *Config* > *HA* and verify that all of the cluster units are displayed on the cluster members list.

5 From the cluster members list, edit the primary unit (master) and verify the cluster configuration is as expected.

To troubleshoot the cluster configuration - web-based manager

1 Connect to each cluster unit web-based manager and verify that the HA configurations are the same.

To connect to each web-based manager, you may need to disconnect some units from the network to connect to the other if the units have the same IP address.

2 If the configurations are the same, try re-entering the cluster *Password* on each cluster unit in case you made an error typing the password when configuring one of the cluster units.

3 Check that the correct interfaces of each cluster unit are connected.

Check the cables and interface LEDs.

Use the Unit Operation dashboard widget, system network interface list, or cluster members list to verify that each interface that should be connected actually is connected.

If Link is down re-verify the physical connection. Try replacing network cables or switches as required.

To verify the cluster configuration - CLI

1 Log into each cluster unit CLI.

You can use the console connection if you need to avoid the problem of units having the same IP address.

2 Enter the command `get system status`.

Look for the following information in the command output.

`Current HA mode: a-a, master`	The cluster units are operating as a cluster and you have connected to the primary unit.
`Current HA mode: a-a, backup`	The cluster units are operating as a cluster and you have connected to a subordinate unit.
`Current HA mode: standalone`	The cluster unit is not operating in HA mode

3 Verify that the `get system ha status` command displays all of the cluster units.

4 Enter the `get system ha` command to verify that the HA configuration is correct and the same for each cluster unit.

To troubleshoot the cluster configuration - CLI

1 Try using the following command to re-enter the cluster password on each cluster unit in case you made an error typing the password when configuring one of the cluster units.

```
config system ha
  set password <password>
end
```

2 Check that the correct interfaces of each cluster unit are connected.

Check the cables and interface LEDs.

Use `get hardware nic <interface_name>` command to confirm that each interface is connected. If the interface is connected the command output should contain a `Link: up` entry similar to the following:

```
get hardware nic port1
.
.
.
Link: up
.
.
.
```

If Link is down, re-verify the physical connection. Try replacing network cables or switches as required.

More troubleshooting information

Much of the information in this HA guide can be useful for troubleshooting HA clusters. Here are some links to sections with more information.

- If sessions are lost after a failover you may need to change route-ttl to keep synchronized routes active longer. See "Change how long routes stay in a cluster unit routing table" on page 2192.
- To control which cluster unit becomes the primary unit, you can change the device priority and enable override. See "Controlling primary unit selection using device priority and override" on page 2010.
- Changes made to a cluster can be lost if override is enabled. See "Configuration changes can be lost if override is enabled" on page 2011.
- In some cases, age differences among cluster units result in the wrong cluster unit becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units. You can resolve this problem by resetting the age of one or more cluster units. See "Resetting the age of all cluster units" on page 2005. You can also adjust how sensitive the cluster is to age differences. This can be useful if large age differences cause problems. See "Cluster age difference margin (grace period)" on page 2003 and "Changing the cluster age difference margin" on page 2003
- If one of the cluster units needs to be serviced or removed from the cluster for other reasons, you can do so without affecting the operation of the cluster. See "Disconnecting a cluster unit from a cluster" on page 2164.
- The web-based manager and CLI will not allow you to configure HA if:
  - You have configured a FortiGate interface to get its IP address using DHCP or PPPoE. See "FortiGate HA compatibility with PPPoE and DHCP" on page 2012.
  - You have enabled VRRP. See "VRRP" on page 2237.
  - You have enabled TCP session synchronization. See "TCP session synchronization" on page 2243.

- Some third-party network equipment may prevent HA heartbeat communication, resulting in a failure of the cluster or the creation of a split brain scenario. For example, some switches use packets with the same Ethertype as HA heartbeat packets use for internal functions and when used for HA heartbeat communication the switch generates CRC errors and the packets are not forwarded. See "Heartbeat packet Ethertypes" on page 2174.
- Very busy clusters may not be able to send HA heartbeat packets quickly enough, also resulting in a split brain scenario. You may be able to resolve this problem by modifying HA heartbeat timing. See "Modifying heartbeat timing" on page 2175.
- Very busy clusters may suffer performance reductions if session pickup is enabled. If possible you can disable this feature to improve performance. If you require session pickup for your cluster, several options are available for improving session pickup performance. See "Improving session synchronization performance" on page 2205.
- If it takes longer than expected for a cluster to failover you can try changing how the primary unit sends gratuitous ARP packets. See "Changing how the primary unit sends gratuitous ARP packets after a failover" on page 2178.
- You can also improve failover times by configuring the cluster for subsecond failover. See "Subsecond failover" on page 2200 and "Failover performance" on page 2214.
- When you first put a FortiGate unit in HA mode you may loose connectivity to the unit. This occurs because HA changes the MAC addresses of all FortiGate unit interfaces, including the one that you are connecting to. The cluster MAC addresses also change if you change the some HA settings such as the cluster group ID. The connection will be restored in a short time as your network and PC updates to the new MAC address. To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.
- Since HA changes all cluster unit MAC addresses, if your network uses MAC address filtering you may have to make configuration changes to account for the HA MAC addresses.
- A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID. See "Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain" on page 2182.
- The cluster CLI displays `slave is not in sync` messages if there is a synchronization problem between the primary unit and one or more subordinate units. See "How to diagnose HA out of sync messages" on page 2189.
- If you have configured dynamic routing and the new primary unit takes too long to update its routing table after a failover you can configure graceful restart and also optimize how routing updates are synchronized. See "Configuring graceful restart for dynamic routing failover" on page 2191 and "Controlling how the FGCP synchronizes routing updates" on page 2192.

- Some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur after a link failover if the switch does not detect the failure and does not clear its MAC forwarding table. See "Updating MAC forwarding tables when a link failover occurs" on page 2198.
- If a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails you can enable remote link failover to maintain communication. See "Remote link failover" on page 2200.
- If you find that some cluster units are not running the same firmware build you can reinstall the correct firmware build on the cluster to upgrade all cluster units to the same firmware build. See "Synchronizing the firmware build running on a new cluster unit" on page 2153.

Configuring and connecting virtual clusters

This chapter provides an introduction to virtual clustering and also contains general procedures and configuration examples that describe how to configure FortiGate HA virtual clustering.

This chapter contains the following sections:

Virtual clustering overview

Virtual clustering is an extension of the FGCP for a cluster of 2 FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Figure shows an example virtual cluster configuration consisting of two FortiGate-620B units. The virtual cluster has two virtual domains, root and Eng_vdm.

The root virtual domain includes the port1 and port2 interfaces. The Eng_vdm virtual domain includes the port5 and port6 interfaces. The port3 and port4 interfaces (not shown in the diagram) are the HA heartbeat interfaces.

FortiGate virtual clustering is limited to a cluster of 2 FortiGate units with multiple VDOMs enabled. If you want to create a cluster of more than 2 FortiGate units operating with multiple VDOMS you could consider other solutions that either do not include multiple VDOMs in one cluster or employ a feature such as standalone session synchronization. See “TCP session synchronization” on page 2243.

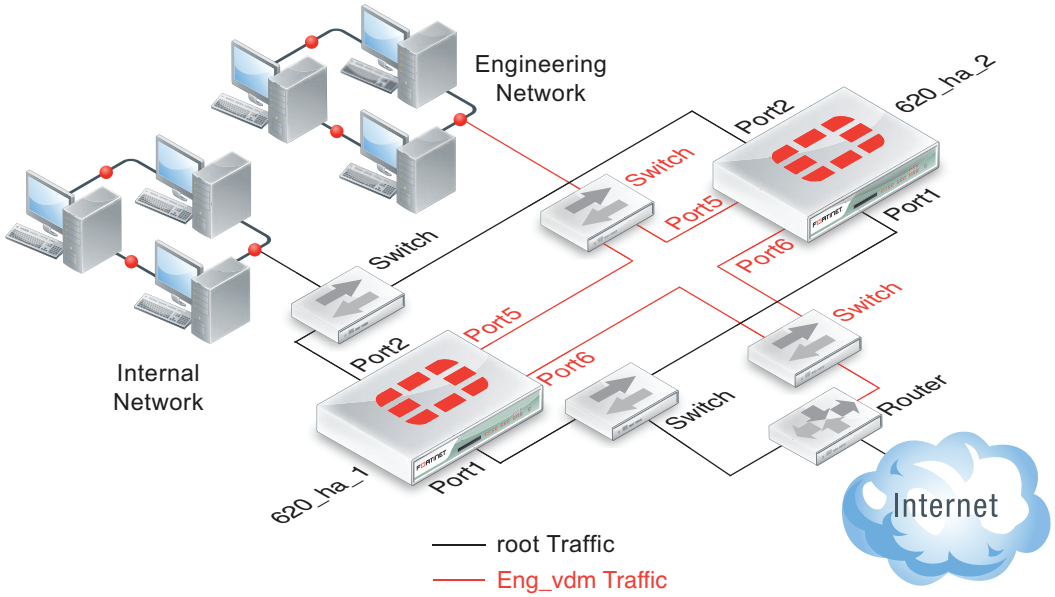
Virtual clustering and failover protection

Virtual clustering operates on a cluster of two (and only two) FortiGate units with VDOMs enabled. Each VDOM creates a cluster between instances of the VDOMs on the two FortiGate units in the virtual cluster. All traffic to and from the VDOM stays within the VDOM and is processed by the VDOM. One cluster unit is the primary unit for each VDOM and one cluster unit is the subordinate unit for each VDOM. The primary unit processes all traffic for the VDOM. The subordinate unit does not process traffic for the VDOM. If a cluster unit fails, all traffic fails over to the cluster unit that is still operating.

Virtual clustering and heartbeat interfaces

The HA heartbeat provides the same HA services in a virtual clustering configuration as in a standard HA configuration. One set of HA heartbeat interfaces provides HA heartbeat services for all of the VDOMs in the cluster. You do not have to add a heartbeat interface for each VDOM.

Figure 204: Example virtual cluster of two FortiGate-620B units



Virtual clustering and HA override

For a virtual cluster configuration, override is enabled by default for both virtual clusters when you:

- Enable VDOM partionning from the web-based manager by moving virtual domains to virtual cluster 2
- Enter `set vcluster2 enable` from the CLI `config system ha` command to enable virtual cluster 2.

Usually you would enable virtual cluster 2 and expect one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. For this distribution to occur override must be enabled for both virtual clusters. Otherwise you will need to restart the cluster to force it to renegotiate.

If override is enabled the cluster may renegotiate too often.You can choose to disable override at any time. If you decide to disable override, for best results, you should disable it for both cluster units.

For more information about HA override see “HA override” on page 2008.

Virtual clustering and load balancing or VDOM partitioning

There are two ways to configure load balancing for virtual clustering. The first is to set the HA mode to active-active. The second is to configure VDOM partitioning. For virtual clustering, setting the HA Mode to active-active has the same result as active-active HA for a cluster without virtual domains. The primary unit receives all sessions and load balances them among the cluster units according to the load balancing schedule. All cluster units process traffic for all virtual domains.

In a VDOM partitioning virtual clustering configuration, the HA mode is set to active-passive. Even though virtual clustering operates in active-passive mode you can configure a form of load balancing by using VDOM partitioning to distribute traffic between both cluster units. To configure VDOM partitioning you set one cluster unit as the primary unit for some virtual domains and you set the other cluster unit as the primary unit for other virtual domains. All traffic for a virtual domain is processed by the primary unit for that virtual domain. You can control the distribution of traffic between the cluster units by adjusting which cluster unit is the primary unit for each virtual domain.

For example, you could have 4 VDOMs, two of which have a high traffic volume and two of which have a low traffic volume. You can configure each cluster unit to be the primary unit for one of the high volume VDOMs and one of the low volume VDOMs. As a result each cluster unit will be processing traffic for a high volume VDOM and a low volume VDOM, resulting in an even distribution of traffic between the cluster units. You can adjust the distribution at any time. For example, if a low volume VDOM becomes a high volume VDOM you can move it from one cluster unit to another until the best balance is achieved.

From the web-based manager you configure VDOM partitioning by setting the HA mode to active-passive and distributing virtual domains between Virtual Cluster 1 and Virtual Cluster 2. You can also configure different device priorities, port monitoring, and remote link failover, for Virtual Cluster 1 and Virtual Cluster 2.

From the CLI you configure VDOM partitioning by setting the HA mode to `a-p`. Then you configure device priority, port monitoring, and remote link failover and specify the VDOMs to include in virtual cluster 1. You do the same for virtual cluster 2 by entering the `config secondary-vcluster` command.

Failover protection does not change. If one cluster unit fails, all sessions are processed by the remaining cluster unit. No traffic interruption occurs for the virtual domains for which the still functioning cluster unit was the primary unit. Traffic may be interrupted temporarily for virtual domains for which the failed unit was the primary unit while processing fails over to the still functioning cluster unit.

If the failed cluster unit restarts and rejoins the virtual cluster, VDOM partitioning load balancing is restored.

Configuring HA for virtual clustering

If your cluster uses VDOMs, you are configuring virtual clustering. Most virtual cluster HA options are the same as normal HA options. However, virtual clusters include VDOM partitioning options. Other differences between configuration options for regular HA and for virtual clustering HA are described below.

To configure HA options for a cluster with VDOMs enabled:

- Log into the global web-based manager and go to *System* > *Config* > *HA*.
- From the CLI, log into the Global Configuration:

The following example shows how to configure active-active virtual clustering:

```
config global
  config system ha
    set mode a-a
    set group-name vexample1.com
    set password vHA_pass_1
  end
end
```

The following example shows how to configure active-passive virtual clustering:

```
config global
  config system ha
    set mode a-p
    set group-name vexample1.com
    set password vHA_pass_1
  end
end
```

The following example shows how to configure VDOM partitioning for virtual clustering. In the example, the FortiGate unit is configured with three VDOMs (domain_1, domain_2, and domain_3) in addition to the root VDOM. The example shows how to set up a basic HA configuration that sets the device priority of virtual cluster 1 to 200. The example also shows how to enable `vcluster2`, how to set the device priority of virtual cluster 2 to 100 and how to add the virtual domains `domain_2` and `domain_3` to virtual cluster 2.

When you enable multiple VDOMs, `vcluster2` is enabled by default. Even so the command to enable `vcluster2` is included in this example in case for some reason it has been disabled. When `vcluster2` is enabled, `override` is also enabled.

The result of this configuration would be that the cluster unit that you are logged into becomes the primary unit for virtual cluster 1. This cluster unit processes all traffic for the root and domain_1 virtual domains.

```
config global
  config system ha
    set mode a-p
    set group-name vexample1.com
    set password vHA_pass_1
    set priority 200
    set vcluster2 enable
    config secondary-vcluster
      set vdom domain_2 domain_3
      set priority 100
    end
  end
end
```

The following example shows how to use the `execute ha manage` command to change the device priorities for virtual cluster 1 and virtual cluster 2 for the other unit in the cluster. The commands set the device priority of virtual cluster 1 to 100 and virtual cluster 2 to 200.

The result of this configuration would be that the other cluster unit becomes the primary unit for virtual cluster 2. This other cluster unit would process all traffic for the domain_2 and domain_3 virtual domains.

```
config global
  execute ha manage 1
    config system ha
      set priority 100
```

```
        set vcluster2 enable
          config secondary-vcluster
            set priority 200
          end
        end
      end
    end
```

Example: virtual clustering with two VDOMs and VDOM partitioning

This section describes how to configure the example virtual clustering configuration shown in Figure 205. This configuration includes two virtual domains, root and Eng_vdm and includes VDOM partitioning that sends all root VDOM traffic to 620_ha_1 and all Eng_vdom VDOM traffic to 620_ha_2. The traffic from the internal network and the engineering network is distributed between the two FortiGate units in the virtual cluster. If one of the cluster units fails, the remaining unit will process traffic for both VDOMs.

The procedures in this example describe some of many possible sequences of steps for configuring virtual clustering. For simplicity many of these procedures assume that you are starting with new FortiGate units set to the factory default configuration. However, this is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

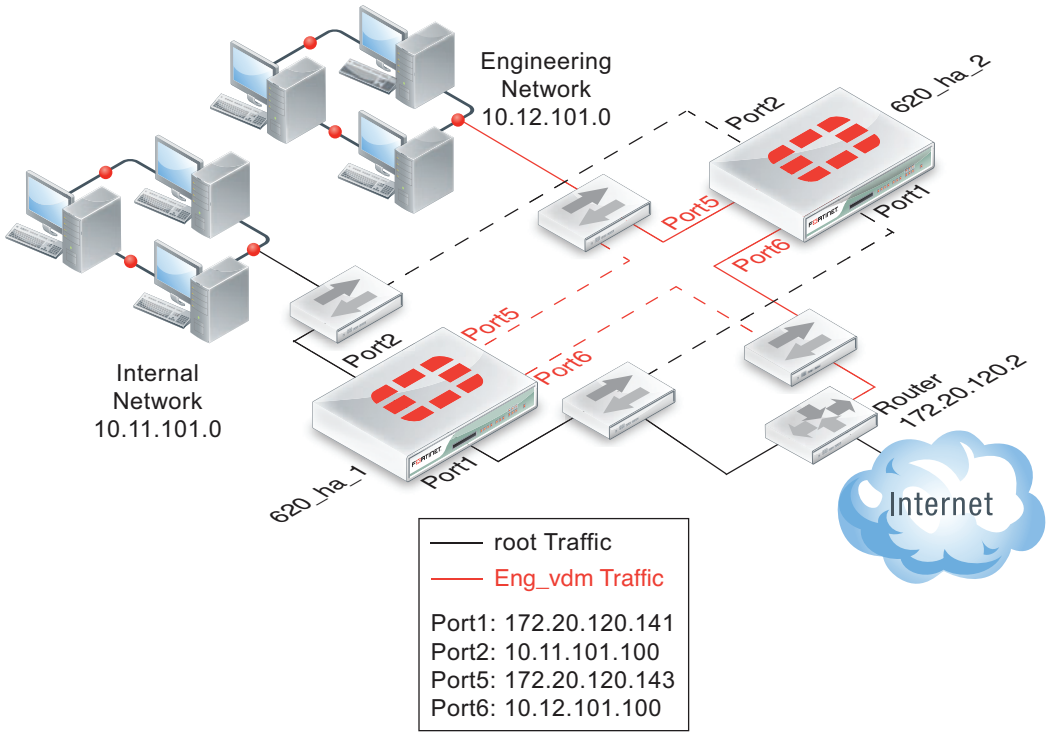
Example virtual clustering network topology

Figure 205 shows a typical FortiGate-620B HA virtual cluster consisting of two FortiGate-620B units (620_ha_1 and 620_ha_2) connected to and internal network, an engineering network and the Internet. To simplify the diagram the heartbeat connections are not shown.

The traffic from the internal network is processed by the root VDOM, which includes the port1 and port2 interfaces. The traffic from the engineering network is processed by the Eng_vdm VDOM, which includes the port5 and port6 interfaces. VDOM partitioning is configured so that all traffic from the internal network is processed by 620_ha_1 and all traffic from the engineering network is processed by 620_ha_2.

This virtual cluster uses the default FortiGate-620B heartbeat interfaces (port3 and port4).

Figure 205: Example virtual cluster of two FortiGate-620B units showing VDOM partitioning



General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate-620B units are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1 Configure the FortiGate units for HA operation.
   - Optionally change each unit's host name.
   - Configure HA.

2 Connect the cluster to the network.

3 Configure VDOM settings for the cluster:
   - Enable multiple VDOMs.
   - Add the Eng_vdm VDOM.
   - Add port5 and port6 to the Eng_vdom.

4 Configure VDOM partitioning.

5 Confirm that the cluster units are operating as a virtual cluster and add basic configuration settings to the cluster.
   - View cluster status from the web-based manager or CLI.
   - Add a password for the admin administrative account.
   - Change the IP addresses and netmasks of the port1, port2, port5, and port6 interfaces.
   - Add a default routes to each VDOM.

Configuring virtual clustering with two VDOMs and VDOM partitioning - web-based manager

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

To configure the FortiGate-620B units for HA operation

1 Power on the first FortiGate-620B unit and log into the web-based manager.

2 On the *System Information* dashboard widget, beside *Host Name* select *Change*.

3 Enter a new Host Name for this FortiGate unit.

New Name	620_ha_1

4 Select OK.

5 Go to *System* > *Config* > *HA* and change the following settings.

Mode	Active-Passive
Group Name	vexample2.com
Password	vHA_pass_2

6 Select OK.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7 Power off the first FortiGate unit.

8 Repeat these steps for the second FortiGate unit.

Set the second FortiGate unit host name to:

New Name	620_ha_2

To connect the cluster to the network

1 Connect the port1 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

2 Connect the port5 interfaces of 620_ha_1 and 620_ha_2 to switch connected to the Internet.

You could use the same switch for the port1 and port5 interfaces.

3 Connect the port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

4 Connect the port6 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the engineering network.

5 Connect the port3 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

6 Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

7 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete you can continue.

To configure VDOM settings for the cluster

1 Log into the web-based manager.

2 On the *System Information* dashboard widget, beside *Virtual Domain* select *Enable*.

3 Select OK and then log back into the web-based manager.

4 Go to *System* > *VDOM* and select *Create New* to add a new VDOM.

Name	Eng_vdm

5 Go to *System* > *Network* > *Interface*.

6 Edit the *port5* interface, add it to the Eng_vdm VDOM and configure other interface settings:

Alias	Engineering_external
Virtual Domain	Eng_vdm
IP/Netmask	172.20.120.143/24

7 Select OK.

8 Edit the *port6* interface, add it to the Eng_vdm VDOM and configure other interface settings:

Alias	Engineering_internal
Virtual Domain	Eng_vdm

IP/Netmask	10.120.101.100/24
Administrative Access	HTTPS, PING, SSH

9 Select OK.

To add a default route to each VDOM

1 Go to System > VDOM and Enter the root VDOM.
2 Go to *Router* > *Static*.
3 Change the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	port1
Distance	10

4 Select *Global*.
5 Go to System > VDOM and Enter the Eng_vdm VDOM.
6 Go to *Router* > *Static*.
7 Change the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	port5
Distance	10

To configure VDOM partitioning

1 Go to *System* > *Config* > *HA*.
The cluster members shows two cluster units in Virtual Cluster 1.
2 Edit the cluster unit with the *Role* of *MASTER*.
3 Change *VDOM partitioning* to move the *Eng_vdm* to the *Virtual Cluster 2* list.
4 Select OK.

5 Change the Virtual Cluster 1 and Virtual Cluster 2 device priorities for each cluster unit to the following:

	Device Priority	
Host Name	**Virtual Cluster 1**	**Virtual Cluster 2**
620_ha_1	200	100
620_ha_2	100	200

You can do this by editing the HA configurations of each cluster unit in the cluster members list and changing device priorities.

Since the device priority of Virtual Cluster 1 is highest for 620_ha_1 and since the root VDOM is in Virtual Cluster 1, all traffic for the root VDOM is processed by 620_ha_1.

Since the device priority of Virtual Cluster 2 is highest for 620_ha_2 and since the Eng_vdm VDOM is in Virtual Cluster 2, all traffic for the Eng_vdm VDOM is processed by 620_ha_2.

To view cluster status and verify the VDOM partitioning configuration

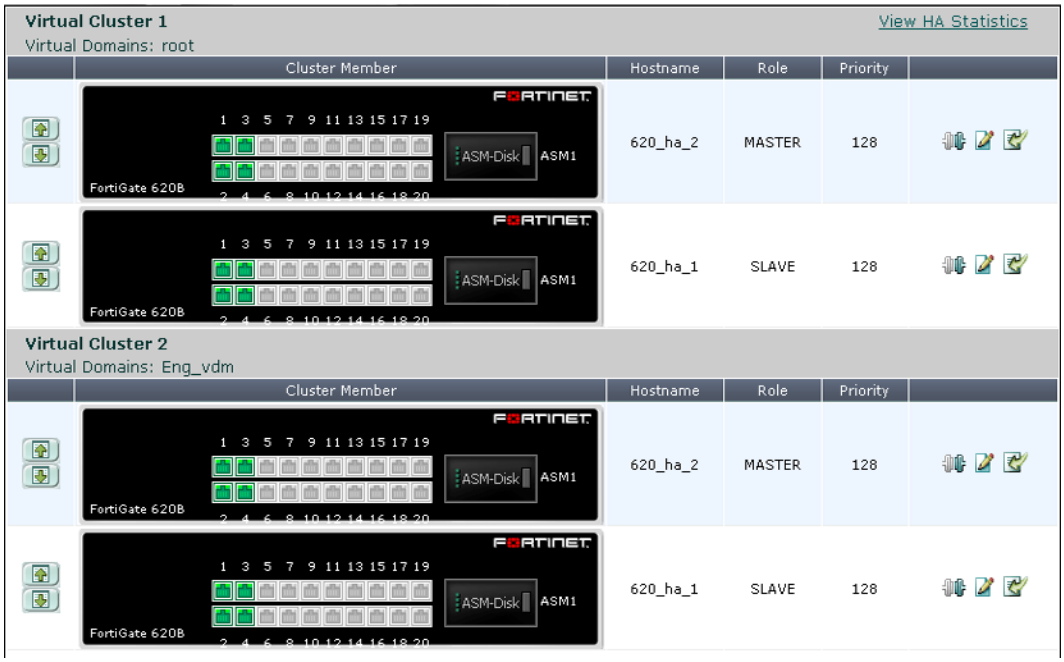
1 Log into the web-based manager.

2 Go to *System* > *Config* > *HA*.

The cluster members list should show the following:

- Virtual Cluster 1 contains the root VDOM.
- 620_ha_1 is the primary unit (master) for Virtual Cluster 1.
- Virtual Cluster 2 contains the Eng_vdm VDOM.
- 620_ha_2 is the primary unit (master) for Virtual Cluster 2.

Figure 206: Example virtual clustering cluster members list



To test the VDOM partitioning configuration

You can do the following to confirm that traffic for the root VDOM is processed by 620_ha_1 and traffic for the Eng_vdm is processed by 620_ha_2.

1 Log into the web-based manager by connecting to port2 using IP address 10.11.101.100.

   You will log into 610_ha_1 because port2 is in the root VDOM and all traffic for this VDOM is processed by 610_ha_1. You can confirm that you have logged into 610_ha_1 by checking the HTML title displayed by your web browser. The title will include the 610_ha_1 host name. Also on the System Information dashboard widget displays the serial number of the 610_ha_1 FortiGate unit.

2 Log into the web-based manager by connecting to port6 using IP address 10.12.101.100.

   You will log into 610_ha_2 because port6 is in the Eng_vdm VDOM and all traffic for this VDOM is processed by 610_ha_2.

3 Add security policies to the root virtual domain that allows communication from the internal network to the Internet and connect to the Internet from the internal network.

4 Log into the web-based manager and go to *Config* > *System* > *HA* and select *View HA Statistics*.

   The statistics display shows more active sessions, total packets, network utilization, and total bytes for the 620_ha_1 unit.

5 Add security policies to the Eng_vdm virtual domain that allow communication from the engineering network to the Internet and connect to the Internet from the engineering network.

6 Log into the web-based manager and go to *Config* > *System* > *HA* and select *View HA Statistics*.

   The statistics display shows more active sessions, total packets, network utilization, and total bytes for the 620_ha_2 unit.

Configuring virtual clustering with two VDOMs and VDOM partitioning - CLI

These procedures assume you are starting with two FortiGate-620B units with factory default settings.

To configure the FortiGate-620B units for HA operation

1 Power on the first FortiGate-620B unit and log into the CLI.

2 Change the host name for this FortiGate unit:

```
config system global
  set hostname 620_ha_1
end
```

3 Configure HA settings.

```
config system ha
  set mode a-p
  set group-name vexample2.com
  set password vHA_pass_2
```

```
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 2177). The MAC addresses of the FortiGate-620B interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4 Display the HA configuration (optional).

```
get system ha
```

```
group-id              : 0
group-name            : vexample2.com
mode                  : a-p
password              : *
hbdev                 : "port3" 50 "port4" 50
session-sync-dev      :
route-ttl             : 10
route-wait            : 0
route-hold            : 10
sync-config           : enable
encryption            : disable
authentication        : disable
hb-interval           : 2
hb-lost-threshold     : 20
helo-holddown         : 20
arps                  : 5
arps-interval         : 8
session-pickup        : disable
link-failed-signal    : disable
uninterruptable-upgrade: enable
ha-mgmt-status        : disable
ha-eth-type           : 8890
hc-eth-type           : 8891
l2ep-eth-type         : 8893
subsecond             : disable
vcluster2             : disable
vcluster-id           : 1
override              : disable
priority              : 128
monitor               :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-flip-timeout: 60
vdom                  : "root"
```

5 Power off the first FortiGate unit.

6 Repeat these steps for the second FortiGate unit.

Set the other FortiGate unit host name to:

```
config system global
  set hostname 620_ha_2
end
```

To connect the cluster to the network

1 Connect the port1 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the Internet.

2 Connect the port5 interfaces of 620_ha_1 and 620_ha_2 to switch connected to the Internet.

You could use the same switch for port1 and port5.

3 Connect the port2 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the internal network.

4 Connect the port6 interfaces of 620_ha_1 and 620_ha_2 to a switch connected to the engineering network.

5 Connect the port3 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

6 Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.

7 Power on the cluster units.

The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

When negotiation is complete you can continue.

To configure VDOM settings for the cluster

1 Log into the CLI.

2 Enter the following command to enable multiple VDOMs for the cluster.

```
config system global
  set vdom-admin enable
end
```

3 Log back into the CLI.

4 Enter the following command to add the Eng_vdm VDOM:

```
config vdom
  edit Eng_vdm
end
```

5 Edit the port5 interface, add it to the Eng_vdm VDOM and configure other interface settings:

```
config global
  config system interface
    edit port5
      set vdom Eng_vdm
      set alias Engineering_external
      set ip 172.20.12.143/24
    next
    edit port6
      set vdom Eng_vdm
      set alias Engineering_internal
      set ip 10.120.101.100/24
    end
end
```

To add a default route to each VDOM

1 Enter the following command to add default routes to the root and Eng_vdm VDOMs.

```
config vdom
  edit root
    config router static
      edit 1
        set dst 0.0.0.0/0.0.0.0
        set gateway 172.20.120.2
        set device port1
      end
  next
  edit Eng_vdm
    config router static
      edit 1
```

```
        set dst 0.0.0.0/0.0.0.0
        set gateway 172.20.120.2
        set device port5
      end
end
```

To configure VDOM partitioning

1 Enter the `get system ha status` command to view cluster unit status:

For example, from the 620_ha_2 cluster unit CLI:

```
config global
  get system ha status
    Model: 620
    Mode: a-p
    Group: 0
    Debug: 0
    ses_pickup: disable
    Master:128 620_ha_2         FG600B3908600825 0
    Slave :128 620_ha_1         FG600B3908600705 1
    number of vcluster: 1
    vcluster 1: work 169.254.0.1
    Master:0 FG600B3908600825
    Slave :1 FG600B3908600705
```

This command output shows that VDOM partitioning has not been configured because only virtual cluster 1 is shown. The command output also shows that the 620_ha_2 is the primary unit for the cluster and for virtual cluster 1 because this cluster unit has the highest serial number

2 Enter the following commands to configure VDOM partitioning:

```
config global
  config system ha
    set vcluster2 enable
      config secondary-vcluster
        set vdom Eng_vdm
      end
  end
end
```

3 Enter the `get system ha status` command to view cluster unit status:

For example, from the 620_ha_2 cluster unit CLI:

```
config global
  get system ha status
    Model: 620
    Mode: a-p
    Group: 0
    Debug: 0
    ses_pickup: disable
    Master:128 620_ha_2         FG600B3908600825 0
    Slave :128 620_ha_1         FG600B3908600705 1
    number of vcluster: 2
    vcluster 1: work 169.254.0.1
    Master:0 FG600B3908600825
    Slave :1 FG600B3908600705
    vcluster 2: work 169.254.0.1
```

```
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

This command output shows VDOM partitioning has been configured because both virtual cluster 1 and virtual cluster 2 are visible. However the configuration is not complete because 620_ha_2 is the primary unit for both virtual clusters. The command output shows this because under both vcluster entries the `Master` entry shows `FG600B3908600825`, which is the serial number of 620_ha_2. As a result of this configuration, 620_ha_2 processes traffic for both VDOMs and 620_ha_1 does not process any traffic.

4 Change the Virtual Cluster 1 and Virtual Cluster 2 device priorities for each cluster unit so that 620_ha_1 processes virtual cluster 1 traffic and 620_ha_2 processes virtual cluster 2 traffic.
